## **Introduction**

In September 2005, the tenth annual International Conference on Finance and Banking, *Future of Banking after the Year 2000 in the World and in the Czech Republic*, took place at the School of Business Administration, Silesian University, in Karviná. Every year it focuses on a specific development in the banking and financial sector. This year, mainly because of the 15<sup>th</sup> anniversary of the School of Business Administration, and 10<sup>th</sup> anniversary of the conference itself, the theme was unspecified and all papers focused on financial and banking topics were considered for presentation. The conference hosted 209 participants from 35 countries and 5 continents.

The conference was introduced, as in the past years, by invited keynote speakers, who were very reputable and respected figures in the finance field. The first speaker was Jan Frait, member of the Bank Board of the Czech National Bank with the paper “Prices and Asset Monetary Policy”. The second speech was delivered by Reint Gropp, deputy head of Division European Central Bank (ECB). He explained the importance of financial research at the ECB. The next presenter was Iikka Korhonen from the Institute for Economies in Transition, Bank of Finland. He described contemporary development of the current euro area and solving the future eastern enlargement of it. The last was Jan Juchelka, head of the Executive Committee, National Property Fund with the topic “Is it time to Abolish Transformation Institutions?” All presentations very nicely covered a broad range of contemporary finance issues. The plenary session was followed by panel discussion. Participants discussed various topics related to the prior presentations (central bank research, privatisation, Maastricht criteria, etc.).

In the afternoon and the following day, the meeting of registered participants was divided into several sections: Banking, Banking and Financial Risks Management, Financial Systems and Markets, Central Banking and Monetary Policy, Public Finance, Rating and Audit, International Finance, Corporate and SME's Financing, Empirical Analyses of Financial Markets, Insurance, Business Administration, Equity and Options Markets, International Economy and Finance, Banking Services and Payment Systems, Public Finance and Anti Money Laundering, Audit and Accounting, Collective Investment and Financial Consultancy, European Union and Regional Policy. Most of over 200 participants, including foreign guests, presented their papers. After every paper very interesting and meaningful ideas surfaced in the discussion. There was a supportive and friendly environment in all sections.

The majority of the papers presented at the Conference are included in these Proceedings. They are also published on the University website and can be found at [www.opf.slu.cz/pb2000/proceedings2005.pdf](http://www.opf.slu.cz/pb2000/proceedings2005.pdf). The differing views of the participants are reflected by the various topics covered. Presentation of ideas and views were the main contribution of the conference, which included not only the practical application of the subject but also directed scientific activities of universities both in the Czech Republic and abroad. That is why the conference is known as a regular meeting place of banking experts as well as academic and scientific specialists.

For the seventh year in a row, graduates of the School of Business Administration of Silesian University took part in the conference. The School of Business Administration was founded in 1990, and today has more than 2000 students in attendance. Most of the graduates who majored in Finance, or Banking, or Corporate Finance work primarily in the finance sector. Some of them are employed in well-known banking, leasing, insurance, audit, and

other financial firms and institutions, as well as in non-financial companies. It was a great pleasure to have the opportunity to welcome again our graduate, Jan Juchelka, as our guest speaker this year. He was a guest speaker at the conference four years ago. As a chairman of the National Property Fund of the Czech Republic, he is one of the most well-known graduates of the School of Business Administration in the Czech Republic and abroad.

We expect the next conference to be held in two years, during October 2007. All of this year participants, as well as participants of the previous nine conferences, are invited to come again. We will do our best to arrange a friendly and warm environment for you. We believe all participants bring new ideas and methods, which will move forward research and practice in finance and banking.

## **Abstract**

*Banks and other financial institutions are a unique set of business firms whose assets and liabilities, regulatory restrictions, economic functions and operation make them an important subject of research. Banks' performance monitoring, analysis and control deserve special attention in respect to their operation and performance results from the viewpoint of different audiences, such as investors/owners, regulators, customers, and management. This article presents some historical notes on the development of the Estonian banking system and the capital structure of banks. Different versions of financial ratio analysis are applied for bank performance analysis using financial statement items as initial data sources. The use of a modified version of DuPont financial ratio analysis, and using econometric models are discussed. Empirical results of the Estonian commercial banking system performance analysis are also presented.*

**Keywords:** *entrepreneurship, bank performance, DuPont analysis, econometric models*

## 1. Introduction: Theoretical Background and Overview of Related Literature

Problems concerning the soundness of the banking and financial systems has become more important in all countries over the recent years. The financial sector, and especially the banking system, is vulnerable to systemic crises, which has led to the creation of costly safety nets as depositor insurance schemes with the well-known moral hazard problem. It is argued that there is increasing evidence that banks are “black boxes” due to the weak transparency and banks’ unwillingness to disclose information (Hyytinen and Takalo, 2002 and 2003). To measure banks’ creditworthiness and risk exposures is a complicated issue and it is not easy to interpret banks’ accounting data. Kaminsky and Reinhart (1999, p. 476) argued that “Indicators of business failures and non-performing loans are also usually available only at low frequencies, if at all; the latter are also made less informative by banks’ desire to hide their problems for as long as possible.” This means that it is necessary to use all available financial information from the official financial statements of banks as fully and comprehensively as possible for making financial analysis of banks’ performance.

The contemporary banking crises can be classified mostly as “growth crises”, which are characterized by economic deregulation and liberalization, removal of cross-border restrictions on capital flows, and increased competition in the financial sector. Based on a newly constructed cross-country database of financial liberalization, Abiad and Mody (2003) examined the experience of 35 countries over the period 1973–1996 to analyze underlying causes of financial sector reforms. They found that liberalization is a combination of discrete changes in response to economic and political “shocks”, reinforced by a self-sustaining dynamics (they called it “learning”). They draw five specific conclusions about what produce changes (reform):

- Countries whose financial sectors are fully repressed (unliberalized) are the ones with the strongest tendency to maintain their policy stance and hence remain closed and highly regulated. But, initial reforms cause changes that make further reforms necessary.
- Regional diffusion effects appear to be important – the further a country’s stage of liberalization is from that of the regional leader, the greater is the pressure to liberalize.
- Shocks to the economic environment (a new government; decline in US interest rates) play an important role in weakening the *status quo* and making reforms possible.

- Crises do trigger action, but not always is the direction of reform – balance of payments crises raise the likelihood of reform; banking crises have the opposite effect.
- Among variables representing ideology and structure, only trade openness appears related to the pace of reform. Not important: presidential or parliamentary regimes, right- or left-wing governments, and the legal system prove not to be influential either.

It is evident that to study results of financial sector reform and restructuring, a profound performance analysis is needed. The traditional financial ratio analysis is mainly used for bank performance analysis. We can find different versions of this approach from various textbooks about banking and financial institutions. Different versions of DuPont financial ratio analysis (see Cole, 1973) seem to be more promising for banks' and other financial institutions' performance analysis (see, for example, Dietrich, 1996). The focus of financial analysis for the management of any bank (or the banking sector as a whole) should be on the efficiency of performance of the bank measured from the viewpoint of investors/owners' income maximization. More widely, all stakeholders have to be interested in the performance of the bank. The concept of a "stakeholder monitor" is useful in designing performance analysis of any bank. This concept was developed by David Llewellyn (see Llewellyn, 2002; Llewellyn and Mayes, 2003). We agree with the suggestion that "Stakeholders, as the name implies, have something in stake in the relative success or failure of the firm. Those who participate in the process of observing the behavior of the firm and forming judgements in the light of it can be described as "monitors". Such monitors may have access to both market and private information. Combining these ideas, "Stakeholder monitors" are all those agents who have an interest in the outcome of the monitoring process" (Llewellyn and Mayes, 2003, p. 11). The incomplete list of "stakeholder monitors" includes: supervisory agencies, rating agencies, market traders, shareholders, board of directors, debt-holders, depositors, managers, borrowers, employees.

In carrying out bank performance analysis, it is important to emphasize that banks differ in their corporate governance from firms in other, less regulated industries. These differences, in turn, present their own challenges for bank managers, regulators, depositors, investors, and other stakeholders. "Bank managers live in a more complex environment than their peers in industry due to bank regulations. In addition to the demands placed on them by shareholders, regulators have strong incentives to influence managerial action, and this may be in conflict with shareholder demands" (Harm, 2002, p. 5). Governance is a set of mechanisms with which the

providers of capital and other stakeholders are defending their interests against the firm. The firm is run by managers, and this is a point where conflicts of interests start. Harm (op. cit., pp. 109–128) presents also an excellent survey of recent literature (both theoretical and empirical).

Macey and O’Hara (2003) argue that bank officers and directors should be held to broader (if not higher) set of standards than their counterparts in less regulated non-financial firms, and banks pose special corporate governance problems. Kose and Qian (2003) consider another important theme in the corporate governance of banks – the effect of the incentive features built into the compensation schemes of bank managers. Adams and Mehran (2003) focus also on the differences between the corporate governance of banks and manufacturing firms and support the theory that governance structures are industry-specific. In general, the components of firm’s governance structure are determined by various factors, which all will influence also performance analysis aims and techniques: the nature and structure of firm’s assets and liabilities (leverage, share of financial assets, business risk, cash-flow patterns), firm size, industry, regulations, etc.

For performance analysis mainly various measures of rates of return are used. We fully agree with the opinion that “Relying too heavily on just a few indicators of bank profitability can be misleading. While ROA, ROE, and interest margin (and non-interest expenses) to gross income remain the key measures, they should ideally be supplemented by the analysis of other operating ratios” (Sundararajan et al., 2002, p. 20). In this article, we present one of the possible approaches to such financial analysis using the modified version of DuPont analysis (see Cole, 1973), which is similar to Dietrich’s (1996) approach (see also Vensel, 2001). We have selected the following years for empirical analysis of the Estonian banking system performance:

1994 – the first year of macroeconomic stabilization after the currency reform in June 2002 and after resolution of the first banking crisis in Estonia;  
1997 – extraordinarily optimistic year, the first unsuccessful attempts of Estonian banks to expand into Russian and Baltic countries’ markets, “bubble” of the Tallinn Stock Exchange;  
2000 – the second phase of macroeconomic stabilization and resolution of the second banking crisis in Estonia;  
2001–2002 – last years before accession to the EU.

The most important recent developments in the Estonian banking system are presented in the next section (some historical notes; banking crises and banks’ rehabilitation; structural developments). Then, a modified methodology of DuPont financial ratio analysis and empirical results of the

Estonian banking system performance are discussed. The paper ends with some concluding remarks.

## **2. Development of the Estonian Banking System**

The first commercial bank (Tartu Commercial Bank) on the territory of the former Soviet Union was established in Estonia in 1988. This bank went bankrupt and was liquidated in 1992–1993. As there was a great demand for banking services by the emerging private sector, the maximum number of commercial banks operating simultaneously in the small Estonian banking market was 42 in 1992. Some of them were liquidated during the banking crises in 1992–1994 and in 1998–1999, and some of them were merged into larger commercial banks. In 1998, a wave of mergers and restructuring took place in the Estonian banking sector. After the completion of these mergers, Scandinavian banks started to show greater interest in the Estonian banking market. As a result, *Swedbank* acquired 56% of *Hansapank* and *Skandinaviska Enskilda Banken* (SEB) acquired 32% of the Union Bank of Estonia. We may conclude that the Estonian banking sector became healthier when Swedish banks and other Nordic investors joined the circle of bank owners, improving the future outlook of the banking system. So when during the first banking crisis in 1992–1994, Estonia had to resolve the problems by itself, then during the second banking crisis in 1998–1999, foreign banks also helped and supported to get over the crises.

Estonia has experienced two serious banking crises during the about 12-years period of its banking sector development and restructuring, the first crisis in 1992–1994 and the second in 1998–1999. The first banking crisis occurred during the hard period when drastic economic restructuring was started and when production output was reducing dramatically and the country underwent a period of hyperinflation. The characteristic feature of the first banking crisis in Estonia was that it was caused by internal reasons and it was overcome with Estonia's own resources and management skills. The main causes of this banking crisis were severe problems in the whole economy, poor bank management and lack of professional skills, weak supervision both from the side of the central bank and owners. The depositors' losses in the banking crisis were large, the money supply decreased, many loans were depreciated, and the trustworthiness of the banking system fell significantly.

Looking back, it is possible to establish some signs of the banking crisis in 1998–1999:

- (1) Estonian banks took extraordinarily high financial risks through investment companies and their subsidiary companies to get large profits via speculating in securities market – rapid fall in prices on the share market in autumn 1997 reduced significantly banks' profits and at the end of 1997 and in 1998 almost all banks operated at losses;
- (2) Banks held a very high negative level of gap (interest rate sensitive liabilities exceeded significantly rate-sensitive assets) for earning excessive profits in the environment where interest rates steadily decreased during the previous years and they were not able to adjust to changed environment with increasing interest rates from the second half-year of 1997;
- (3) Commercial banks absorbed heavily into non-banking business – for example, the later bankrupted Land Bank of Estonia owned seven subordinate establishments and related companies, which dealt with leasing and investing, and with anything else but banking (hotels, processing agricultural products, broadcasting etc.); also other banks were absorbed in risky non-banking business;
- (4) The decision to expand to the Eastern market (Russia and other Baltic States), where the interest rates and possible profitability seemed to be higher, was also too risky and premature, especially in the framework of the Russian crisis in 1998;
- (5) There were various disputes and conflicts of interests between the owners and management, which led to wrong (mismanagement) decisions. Good examples should be the Land Bank of Estonia and the Estonian Investment Bank – for example, the shareholders of the Investment Bank intended to sell the bank to the German Schleswig-Holstein Bank in autumn 1997, but the top executives threatened to hand in a collective resignation and so the bank was sold to them;
- (6) Sometimes there were inadvisable relations between the bank management and political powers, and corresponding political pressure – a typical “political” bank was the Land Bank of Estonia where almost all financial risks were ignored and later the Government lost its deposits in the bank amounting to more than 800 million Estonian kroons, EEK (more than 50 million euros).

The authors are of the opinion that the currency board arrangement helped to resolve banking crises rapidly and mostly effectively without very large rehabilitation costs in Estonia. The main instruments for anticipating banking crises are tightening of prudential requirements and strengthening of banking supervision. Recent changes in the operational framework for monetary policy and banks' prudential ratios in Estonia were aimed at

enhancing financial stability and increasing the liquidity buffers of the financial system. In short-term, the priority focused on restoring foreign investors' confidence in Estonian economic viability.

We may argue that the currency board arrangement practically did not help banks that were in trouble because its resources are intended for guaranteeing the local currency and the central bank is not acting as the lender of the last resort. The currency board is not able to avoid banking crises and cannot guarantee a “soft landing” and rehabilitation of banks in trouble. At the same time, the currency board arrangement supported and strengthened the discipline and responsibility of the main actors – banks, the central bank, depositors, and the Government. A stable currency and presence of respective financial safety net compensated for the absence of classical lender-of-last resort facility and ensured the development of a generally reliable banking sector.

*Source: Estonian Bank*

The structure of the Estonian banking sector has changed fundamentally during the last years. Today, the banking system is highly concentrated and two Swedish-owned banks dominate in the market. The consolidation process continued throughout the second banking crisis in 1998–1999 and resulted in fundamental bank reorganizations. We can notice all three worldwide trends in the financial consolidation process also in the Estonian market: domestic consolidation, foreign entry and cross-border consolidation, and the formation of financial conglomerates and bank assurances. The ownership structure of Estonian banks is presented in Table 1. The dependence of the Estonian banking system on the developments in

international financial markets and on foreign investors' preferences has deepened from year to year. In the course of the restructuring process, foreign banks increased their share in equity capital from 10.3% in 1996 to 79% at the end of 2002. The total share of non-resident owners had risen to 86.7% by the end of 2002.

### 3. DuPont Financial Ratio Analysis

The starting point of bank performance analysis is to calculate the book rate of return on equity,  $ROE$

$$ROE = \frac{\text{Earnings After Taxes, } EAT}{\text{Book Value of Equity, } BVE} \quad (1)$$

which consists of three components:

- pull-through,  $U$

$$U = \frac{\text{Earnings After Taxes, } EAT}{\text{Earnings Before Taxes, } EBT} \quad (2)$$

- financial leverage,  $LEV$

$$LEV = \frac{\text{Total Assets, } TA}{\text{Book Value of Equity, } BVE} \quad (3)$$

- return on total assets,  $ROA$

$$ROA = \frac{\text{Earnings Before Taxes, } EBT}{\text{Total Assets, } TA} \quad (4)$$

These financial ratios form the multiple factor system

$$ROE = \frac{EAT}{EBT} \times \frac{TA}{BVE} \times \frac{EBT}{TA} = \frac{EAT}{BVE} \quad (5)$$

Changes in  $ROA$  are usually the cause of the most important changes in banks' performance and need a more detailed analysis. The other financial ratios such as components of  $ROE$ , pull-through ( $U$ ) and financial leverage ( $LEV$ ), reflect tax treatment and capitalization rate, and they usually change less.  $ROA$  may be divided into the following components:

- bank burden,  $B$

$$B = \frac{\text{Net Non - Interest Revenue, } NNIR}{\text{Total Assets, } TA} = \frac{NIR - NIE}{TA} \quad (6)$$

where  $NIR$  - non-interest revenue;

*NIE* - non-interest expense;

- earning assets ratio, *EAR*

$$EAR = \frac{\text{Earning Assets, } EA}{\text{Total Assets, } TA} \quad (7)$$

- net interest margin, *NIM*

$$NIM = \frac{\text{Net Interest Revenue, } NIR}{\text{Earning Assets, } EA} = \frac{IR - IE}{EA} \quad (8)$$

where *IR* - interest revenue;

*IE* - interest expense,

Financial ratios (6-8) form a factor system

$$ROA = \frac{NNIR}{TA} + \frac{EA}{TA} \times \frac{NIR}{EA} = \frac{NNIR + NIR}{TA} = \frac{EBT}{TA} \quad (9)$$

For a more detailed analysis, *NIM* may be divided into the following three components:

- return on earning assets, *REA*

$$REA = \frac{\text{Interest Revenue, } IR}{\text{Earning Assets, } EA} \quad (10)$$

- cost of liabilities, *COL*

$$COL = \frac{\text{Interest Expense, } IE}{\text{Liabilities, } L} \quad (11)$$

- liabilities to earning assets ratio, *LEA*

$$LEA = \frac{\text{Liabilities, } L}{\text{Earning Assets, } EA} \quad (12)$$

which form the factor system

$$NIM = \frac{IR}{EA} - \frac{IE}{L} \times \frac{L}{EA} = \frac{IR - IE}{EA} = \frac{NIR}{EA} \quad (13)$$

Initial financial information for Estonian banking sector performance analysis (1994–2002) is presented in Table 2 on the basis aggregated consolidated financial statements published by the Bank of Estonia.

## 4. Econometric Modelling

As far as we know, nobody has earlier used the existing information about banks to construct production function type econometric models treating banking as a separate sector of a country (Aarma and Vainu, 2003). One can ask what is the production or product of a bank? In our opinion the product of the bank is the amount of the services, the volume of which can be measured by the total income of the bank what is the measure of the amount of production.

We selected the total income of the banks ( $y$ ) as the output variable (dependent variable) and used profit earning assets ( $x_1$ ), equity ( $x_2$ ), liabilities ( $x_3$ ) and fixed assets ( $x_4$ ) as factors (independent variables). The time series were treated as consisting of three components:

$$y(t) = f(t) + h(t) + e_t \quad (14)$$

where  $y(t)$  – the actual time series;  
 $f(t)$  – the linear trend in the time series;  
 $h(t)$  – the harmonious component in the time series;  
 $e_t$  – residuals.

The harmonious component is determined as Fourier's series:

$$h(t) = a_0 + \sum_{j=1}^k (a_j \cos \alpha + b_j \sin \alpha), \quad \alpha = j \frac{t2\pi}{T} \quad (15)$$

where  $j$  – the number of harmonious component,  
 $t$  – time,  
 $T$  – length of the time series (the number of periods).

We chose the power function as the type of the model.

$$y = ax^\alpha z^\beta, \quad \alpha + \beta = 1. \quad (16)$$

To estimate the parameters  $a$ ,  $\alpha$  and  $\beta$  with the method of least squares it was first necessary to find logarithms of the primary data. Then, according to the rules of analyzing time series, we checked the existence of trend and harmonious component in the time series of the logarithms of the selected parameters and got next results.

*Trendlines:*

$$\ln y = 6,2067 + 0,0398t \quad (17)$$

$$\ln x_1 = 9,25 + 0,0612t \quad (18)$$

$$\ln x_2 = 7,0659 + 0,0738t \quad (19)$$

$$\ln x_3 = 9,4373 + 0,0542t \quad (20)$$

$$\ln x_4 = 7,0913 + 0,3206 \ln t \quad (21)$$

*Harmonious components:*

$$u \ln y = \ln y - f(t) = -0,1006 \cos \alpha - 0,0134 \sin \alpha - 0,0421 \cos 2\alpha + 0,0994 \sin 2\alpha - 0,0787 \cos 3\alpha - 0,0696 \sin 3\alpha \quad (22)$$

$$u \ln x_1 = -0,1749 \cos \alpha + 0,0583 \sin \alpha - 0,0850 \cos 2\alpha - 0,0992 \sin 2\alpha \quad (23)$$

$$u \ln x_2 = -0,3193 \cos \alpha + 0,0691 \sin \alpha + 0,0326 \cos 2\alpha - 0,1142 \sin 2\alpha \quad (24)$$

$$u \ln x_3 = -0,1743 \cos \alpha + 0,0514 \sin \alpha - 0,0749 \cos 2\alpha - 0,0861 \sin 2\alpha \quad (25)$$

$$u \ln x_4 = -0,2073 \cos \alpha + 0,0453 \sin \alpha \quad (26)$$

We treated all possible combinations of the factors and obtained only the one model that proved to be statistically significant:

$$\ln y = -2,2884 + 0,0074t - 0,1288 \ln t + 0,087 \cos \alpha - 0,0092 \sin \alpha + 0,0027 \cos 2\alpha + 0,1009 \sin 2\alpha - 0,0787 \cos 3\alpha - 0,0696 \sin 3\alpha + 0,5984 \ln x_3 + 0,4016 \ln x_4 ,$$

what gives finally the next result:

$$y = 0,1014 x_3^{0,5984} x_4^{0,4016} t^{-0,1288} \exp \begin{bmatrix} 0,0074t + 0,087 \cos \alpha - 0,0092 \sin \alpha + \\ + 0,0027 \cos 2\alpha + 0,1009 \sin 2\alpha - \\ - 0,0787 \cos 3\alpha - 0,0696 \sin 3\alpha \end{bmatrix} .(27)$$

## 5. Conclusion

The development of the Estonian banking sector is described by a quite rapid nominal growth of total assets, loan portfolios, net income and other quantitative financial indicators. The capitalization of Estonian banks improved, and the share of non-residents in the share capital increased significantly.

Some most important empirical results of the use of the DuPont financial ratio analysis for the Estonian commercial banking system (1997–2003) are as follows (see Table 3):

- The book rate of return on equity (ROE) decreased during the analyzed period from 31,73% in 1997 to 19,26% in 2003. We can also mention very high volatility of profitability ratios (both ROE and ROA) during the analyzed period. Banks' financial leverage ratio (LEV) decreased substantially due to the central bank's new equity requirements, which forced banks to raise equity or to merge.
- The average return on earning assets (REA) has fallen substantially over the recent years due to the overall falling of interest rates in the Estonian banking market. REA has fallen much faster than average cost of liabilities (COL), i.e. the interest spread decreased considerably over the analyzed period. This change reflects the sharpened competition between banks themselves and with other financial institutions, as for example insurance and investment funds.
- It is possible to treat and analyse a bank as an enterprise. Model (14) shows that the most important factors in development of Estonian banking system have been liabilities (what is the loan resource) and fixed assets.

## **Abstract**

*The aim of the paper is to identify the main effects of foreign banks' entry on the stability and performance of banks in the Central and Eastern European Countries. The FDI theory applied to banking sector is used to distinguish between competition and spillover effects of foreign banks' entry on the behavior of the domestic banking sector. Bank level accounting data from 10 CEE countries is used in empirical analysis. Arellano-Bond dynamic panel data estimation technique used in the regressions. In addition, a summary of a survey based questionnaire conducted in four CEE countries is presented for the qualitative analysis. The results are that foreign banks' entry is likely to reduce the profitability of local banks through the increasing level of competition and foreign banks' entry contributes to the stability of local banking sector in short run.*

**Keywords:** *Bank performance; banking sector stability; foreign bank's entry; transition countries*

## **1. Introduction**

The internationalization process of firms has been intensively studied since the 1960s. Due to the increase in international capital flows, foreign direct investments and international trade at that time, active development of international banking also began. In the transition countries, international banks have operated only since the beginning of the 1990s, after a significant liberalization of the financial market and elimination of entry barriers. At present foreign banks already have more than 60 per cent of the market in the CEE countries.

Growing foreign ownership in the banking sector raises several interesting questions about the entry process of foreign banks into transition economies. There are no generally accepted theories to explain the internationalization process of banks in the transition economies and its implications. The main reason for this gap in the literature is that foreign bank entry into emerging market has been actual only with the “third wave” of international banks’ activities during the second half of 1990s (Herrero and Simón 2003, p. 3).

The aim of the paper is to identify the effect of foreign banks’ entry on bank performance and stability in the CEE countries.

The reminder of the paper is structured as following: in the second section, the recent foreign bank entry literature is discussed. The effect of foreign banks entry on the performance of banks is discussed in section three. The volatility of credit supply and effect of foreign banks entry on the quality of loan portfolio of local banks is analyzed in section four. In section five the results of questionnaire based survey are presented. Conclusions of the paper are summarized in section six.

## **2. Theoretical aspects of foreign banks’ entry effects**

The first argumentation that greater international financial competition should improve the credit supply is based on the financial liberalization (FL) framework. McKinnon (1973) and Shaw (1973) proposed that there is excess of credit demand in less developed countries and elimination of entry restriction would make it possible for multinational banks to satisfy the excess of credit demand.

Theorists who discuss the impact of FDI underscore the importance of inter-industry and intra-industry spillover effects. The extent of intra-industry spillover effects of FDI on technology transfer depend on a particular local firm’s own ability to innovate and imitate (Glass and Saggi, 1998; Petit and

Sanna-Randaccio 2000). Technology diffusion with FDI is rather a complicated topic. Teece (1977) pointed out several channels for technology run to domestic firms, namely labor flow from foreign to domestic firms, imitation and liberalization (removal of entry barriers to foreign firms).

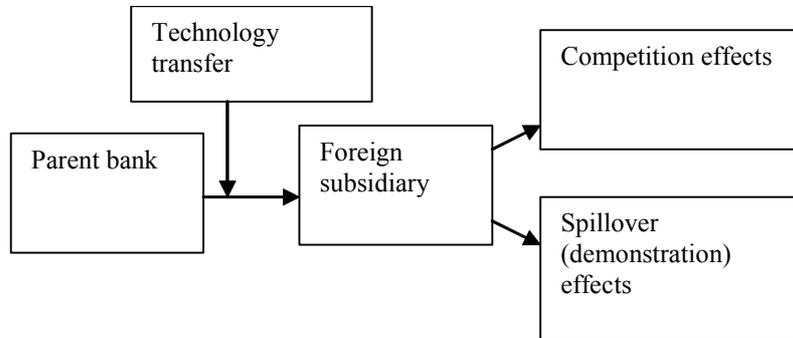

It is also suggested that spill-over effects of foreign entry depend on how much the domestic and foreign banking market differ by their levels of development. This phenomenon is known as the “technology gap hypothesis” which suggests that the spillover effects from FDI to domestic firms will occur only if the technology gap is not overly large and if the country has a minimum required level of human capital (Borensztein *et al* 1998; Kokko 1994; Konings, 1999). An overly large technology gap between the foreign enterprise and domestic firm will lead to the dominance of competition effects. Aitken and Harrison (1999) showed that the productivity of domestic firms was negatively affected by FDI in Venezuela, where the competition effect slightly dominated. The reason was that foreign firms were “market stealers” who forced the domestic firms to produce less, which lead to an increase in the average cost.

Besides the quantity of knowledge transfer, it is important to consider the level of quality of the knowledge transfer. Glass and Saggi (1998) found in their general equilibrium model that host countries with a higher technology gap receive lower technological quality with FDI. The capability to imitate and accept technology transfer is known as “absorptive capacity”. Countries that are able to imitate more and have a more intensive level of local research and development (R&D) receive more high-quality technological FDI. Therefore their conclusion about policy is that host countries should enhance the imitation by supporting local R&D to receive high-quality FDI. Glass and Saggi (1998) found on the example of the oligopoly model that if a host firm (country) has a lower technological level than the source firm (country), then there are at least two rationales for attracting FDI: higher profits of the host firm or a wage premium benefiting workers.

The application of FDI literature into banking sector would mean that the transfer of know-how from parent bank to a subsidiary has both competition and spillover effects on host banking sector (see Figure 1). Foreign subsidiary that operates more effectively due to more modern banking technology taken over from mother banks forces other. There could also be spillover effects – domestic banks can learn from foreign banks. Thus the competition effect can work in two ways: either domestic banks have high absorptive capacity and become more effective (catch-up effect), or if the technology gap is too high then domestic banks are unable to compete with foreign banks and foreign banks will just easily increase their market

shares (market-stealing effect). The technology transfer and local firms' reaction to foreign banks' entry therefore depend on the development of the financial sector.

**Figure 1. Effect of technology transfer on the local banking sector.**

*Source: Compiled by the author.*

A most comprehensive empirical survey about foreign banks entry was carried out by Claessens *et al* (2001) who investigated the relationship between foreign banks entry and the performance of the domestic banking sector in 80 countries. They used panel estimations with 7,900 bank observations for 1988–1995. The main result of the study was that foreign banks tend to have higher profits than domestic banks in the developing countries, while in developed countries foreign banks are less profitable than domestic banks. Their results also indicated that higher foreign bank presence is related with lower profitability, costs and margins of domestic banks.

Hermes and Lensink (2003) developed further the model used by Claessens *et al* (2001). They used bank-level accounting data from 990 banks in 48 countries for the period 1990-1996. Threshold estimations were used to study how foreign banks entry effects are related, in a short term, with the economic development of the countries involved. The results indicate that at a lower level of economic development, foreign banks entry is associated with higher costs and margins for domestic banks. At a higher level of economic development, on the other hand, foreign banks entry has a less significant effect on domestic banks' profitability. This result adds some support to the technology gap hypothesis.

Zajc (2004) analysed foreign banks entry effects on domestic banks in the Czech Republic, Estonia, Hungary, Poland, Slovakia and Slovenia for the period 1995–2000. His results are somewhat different from those presented

by Claessens *et al* (2001). He found that foreign banks entry is associated with lower non-interest income but increases overhead expenses.

Mathieson and Roldos (2001) pointed out two related issues: whether the presence of foreign banks makes systemic banking crises more or less likely to occur, and whether there is a tendency for foreign banks to “cut and run” during the crises periods. In general, it has been suggested that foreign banks can provide a more stable source of credit because branches and subsidiaries of large international banks can draw on their parent (which typically hold more diversified portfolios) for additional funding. Large international banks are likely to have better access to global financial markets and the entry of foreign banks can improve the overall stability of the host country’s banking system (stronger prudential supervision; better disclosure, accounting and reporting practice, etc.).

Bonin and Ábel (2000: 8) addressed that foreign bank entry is a double-edged sword as it is welfare enhancing for the host country’s banking sector as a whole but often threatening to the market position of already weak domestic banks as foreign banks cream skim by taking away good clients.

Cárdenas *et al* (2002) suggest that along with better services and management techniques, there can be also some adverse effects of foreign control. Foreign subsidiaries are often centrally controlled and are supposed to focus only on local market and cut majority of international activities. This can be harmful for stability during a shock in local market as the subsidiary’s asset portfolio is concentrated into local market.

One of the important issues of foreign banks’ entry is a possible reduction of credit in host country. For example Weller (2000) found that foreign bank entry led to reduction of credit supply by Polish domestic banks. Clarke *et al* (2004) concluded that the privatization and foreign bank entry are not negatively associated with the credit supply in Argentina, at least not in long term.

### **3. Effect of foreign bank entry on bank performance in the CEE countries**

#### ***3.1 Data and methodology***

In the current paper I use both bank-level and macro-level data to investigate the relationship between foreign banks entry and banks’ performance. A foreign bank is defined as foreign if it is at least 50 percent foreign owned, i.e. more than 50 percent of its share capital is owned by foreign residents. The study covers the 1995–2001 data of 10 countries:

Bulgaria, Croatia, the Czech Republic, Estonia, Hungary Latvia, Lithuania, Poland, Slovakia and Slovenia. The annual data is used in the following subgroups: bank-level accounting data, foreign banks entry data, the country's specific variables and the banking market development data. A detailed description of all variables used in the analysis is given in Appendix 1.

Bank-level accounting data was obtained from the Bankscope database; panel data for 319 banks during 1995–2001 was used. An important difference between the current and previous studies is that both foreign and domestic banks are included into the sample. Several balance sheet variables and profit statement variables are used. First, I use two variables measuring the income of banks: net interest margin (NIM) and non-interest income to total assets (OOITA). Second, a bank's profitability is characterised by the ratio of its before-tax profits to total assets (PTPTA). Third, a bank's costs are measured by two variables: overhead costs to total assets (OHTA) and loan loss provisions to total assets (LLPTA). These variables are calculated on the basis of the bank's income statement and balance sheet. The following internationally comparable accounting identity is used:

$$PTPTA = NIM + OOITA - OHTA - LLPTA \quad (1)$$

The bank-specific exogenous variables are as follows: short-term and long-term deposits and other funding to total assets (CSTFTA), equity ratio to total assets (ETA), and non-earning assets to total assets (NEATA).

I use two different foreign entry variables: the share of foreign banks' assets in the total banking market assets (FSA), and the ratio of foreign banks to the total number of banks (FBSN). Since Bankscope covers about 90% of the banks on the market and the precise ownership structure of a bank is described only in the last reporting period, it is not possible to calculate foreign ownership by aggregating the data of the reporting banks, because of the danger to either overestimate or underestimate the proportion of foreign ownership on the market. The possibility to overestimate foreign ownership comes from the fact that foreign banks are more active internationally and also provide data more actively to Bankscope. The possibility to underestimate foreign ownership in some countries is also quite high because Bankscope does not cover branches of foreign banks, and therefore the countries where the main foreign bank entry mode has been branching tend to significantly underestimate foreign ownership on the market. The problem of data is more relevant for small countries like Estonia, Latvia and Lithuania, where the number of banks is small, and the absence of even two or three banks from the database may significantly affect foreign ownership data. To overcome these problems, different sources of data was used. Foreign banks'

share in the total assets (FSA) data was drawn from Bankscope and national central banks, while foreign banks' share in the total number of banks (FBSN) was obtained from the EBRD Transition Report 2003.

The development of the banking sector is characterised by the ratio of domestic private credit to the GDP (DCGDP). This is a widely used measure of banking sector development, used also by Hermes and Lensink (2003). Another banking-market-specific variable used is the concentration index, calculated as the ratio of three biggest banks' assets to total banking market assets in the given country (CONC). Market concentration data is obtained from the database provided by the website of Asly Demirgüç-Kunt from Worldbank. The DCGDP data is from the EBRD Transition report 2002.

Three country-specific variables are included. Similarly to Claessens *et al* (2001), Hermes and Lensink (2003), and Zajc (2004) real GDP growth (GDPG), GDP per capita (INCOME, in logarithm) and inflation rate (CPI) are included as indicators of macroeconomic development. All country variables were obtained from the EBRD Transition Report 2002. The sample is unbalanced because of lack of data for some banks in some periods. The number of observations varies between 884 and 1041.

Next the short-term relationship between foreign banks entry and bank performance is tested empirically. The analysis starts with the empirical model which is similar to that used by Claessens *et al* (2001):

$$\Delta I_{ijt} = \alpha_0 + \beta_j \Delta FS_{jt} + \delta_{ij} \Delta B_{ijt} + \gamma_j \Delta X_{jt} + \varepsilon_{ijt} \quad (2)$$

where  $I_{ijt}$  is a vector of dependent variables for bank  $i$  in country  $j$  at time  $t$ ,  $FS_{jt}$  is a measure of foreign bank penetration in country  $j$  at time  $t$ ,  $B_{ijt}$  is a set of bank-specific variables for bank  $i$  in country  $j$  at time  $t$ .  $B_{ijt}$  is included into the equation as a set of control variables.  $X_{jt}$  is a vector of country variables in country  $j$  at time  $t$ .

Then the initial empirical model characterised by equation 2 is developed further, adding banking market development variables and an interactive term of foreign banks entry and banking market development; the same methodology was also used by Hermes and Lensink (2003). The model involving banking sector development and interactive term is as follows:

$$\Delta I_{ijt} = \alpha_0 + \beta_j \Delta FS_{jt} + \gamma_j \Delta FS_{jt} \times DCGDP_{jt} + \delta_{ij} \Delta B_{ijt} + \phi_j BMD_{jt} + \varepsilon_j \Delta X_{jt} + \varepsilon_{ijt} \quad (3)$$

$DCGDP_{jt}$  is a proxy for banking market development in country  $j$  at time  $t$ ,  $FS \times DCGDP$  is a variable that has been created by interacting the foreign banks entry variable with the banking market development variable. The interactive term is included to test whether foreign entry effects in a particular country depend on the level of development of that country's

banking market. It can be expected that foreign banks entry has a more relevant impact in the early stage of internationalisation and to be lower when the banking market in the target country is well-developed. It may even be the case that the sign of the coefficient of  $FS$  changes from negative to positive or vice versa. The banking market development variables are expected to have a negative effect on the cost and income of a bank.

Finally, an interactive term of foreign banks entry and bank market share is included into the equation. Banks with different market shares may react differently to foreign banks entry. I suggest that smaller banks react more actively, because they are more flexible to changes in market conditions and have to adjust themselves more readily in order to be competitive. The model is as follows:

$$\Delta I_{ijt} = \alpha_0 + \beta_j \Delta FS_{jt} + \gamma_j \Delta FS_{jt} \times MSHARE_{jt} + \delta_{ij} \Delta B_{ijt} + \varphi_j BMD_{jt} + \varepsilon_j \Delta X_{jt} + \varepsilon_{ijt} \quad (4)$$

where  $FS \times MSHARE$  is a variable that has been created by interacting the foreign banks entry variable with the banking market development variable.

### 3.2 Estimation results and discussion

Two variables are used to measure foreign banks' presence: the number of foreign banks as the share of the total number of banks (FBSN) and foreign banks' share in the total assets of the banking market (FSA). An interactive terms with private credit to the GDP (DCGDP) and the bank market share (MSHARE) are also included. Five bank performance measures (ALINT (interest income on interest earning assets), PTPTA, OOITA, OHTA and LLPTA) are the main dependent variables. Stata SE 8 is used for estimations.

Compared with Claessens *et al* (2001), who used a fixed effects model, the methodology for estimating regression coefficients is somewhat different. The Arellano-Bond linear, dynamic panel data estimation technique is implemented which enables to use a lagged term of dependent variable as exogenous variable, and instrumental variables (Arellano and Bond, 1991) to reduce the endogeneity problem and get more consistent estimates. To reduce the heteroskedasticity that is often the problem in micro level panels, robust standard errors are reported (see Stata, 2003). Robust standard errors are higher and therefore relationships are statistically less significant.

It is a general assumption that foreign banks entry at time  $t$  is exogenous, i.e. FBSN or FSA do not depend on bank-specific variables at time  $t$  (Zajc, 2004). In practice, foreign banks entry may be associated with timing, thus a bank enters the market in year  $t$  because of the market

conditions in period  $t$ . It may be the case that foreign banks are entering by acquisition at time  $t$  because of the crisis period of a single bank or the whole banking market in order to acquire banks at a low price. It can be argued that this makes foreign banks entry partly endogenous. The endogeneity problem here is not very strong, because in most cases the bank's name changes after the merger, and the bank that was acquired, for example, because of negative profit and low price, drops out from period  $t$  estimation as all variables are in first differences. Nevertheless, some endogeneity may remain, because sometimes foreign banks consider the average performance of the whole market in period  $t$  when making entry decisions.

To reduce possible endogeneity problems in estimations, it is suggested that levels of lag operators can be used (Stata, 2003). Levels of lag operators of foreign bank entry variables (1 period lag of FBSN and FSA) are included as instrument variables.

An important difference between this study and previous works is that I analyse foreign banks entry effects on both foreign and domestic banks' performance. The first differences of variables ensure that the observations of a foreign bank entering the market at time  $t$  are not included. Yearly time dummies (1996–2001) are included into the estimations, while regression coefficients of time dummies are not reported. Arellano-Bond estimations include also tests of autocorrelations AR(1) and AR(2) that are not reported. Autocorrelation was not significantly present in the regressions except for ALINT.

The estimation results with FBSN as the foreign banks entry variable are given in Table 1.

Foreign banks entry variable FBSN has a statistically significant and negative effect on banks' average interest rate on earning assets and loan loss provisions (LLPTA). The author tested the foreign banks entry effect also on the banks' net interest margin, but found no statistically significant relations. Therefore ALINT was used to analyse the effect on interest revenues. It seems that foreign banks entry has a significant effect only on interest income of interest earning assets and not on interest expenses. Hermes and Lensink (2003) found a positive and significant effect of FBSN on non-interest income, whereas Zajc (2004) found similar results. A negative relationship with profitability measures indicates that foreign banks entry enhances the level of competition in the banking sector.

A negative relationship between FBSN and LLPTA shows that foreign banks entry leads to more strict lending policies of the local banks. FBSN is not statistically associated with profits, overhead costs and non-interest income of banks. The banking market concentration index was

excluded from the regression equations because of no significant effect on any dependent variables.

FSA has a somewhat different effect on bank performance. The estimation results in Table 2 show that FSA has a negative effect on the average loan interest rate and a positive effect on loan loss provisions. FSA reflects the relative size of foreign banks versus domestic banks.

The estimation results indicate that if entering foreign banks are comparatively larger than the local banks, then due to the increasing competition on the loan market, the banks offer better loan conditions to firms and this could result in increasing loan losses. From other explanatory variables, MSHARE is negatively associated with overhead costs and non-interest income and positively associated with profits. The results indicate that bigger banks are able to achieve some economies of scale.

The estimation results with interactive term with foreign ownership (FBSN) and banking sector development are given in Table 3. The results

indicate that the development of the banking sector has some effect on short-term foreign banks entry effects. As concluded above, foreign banks entry is generally associated with decreasing interest incomes. Estimations with interactive term FBSN\*DCGDP show that in more developed banking markets this fall in interest revenues is lower, because interest rates are already more converged with developed markets.

FSA\*DCGDP has a significant effect on average loan interest rates, pre-tax profits and non-interest incomes. Foreign banks entry reduces the profitability of the local banks, but in more developed markets this fall is lower because the entering bank does not have such a high competitive advantage as in less developed countries.

The development of the banking market has also some effect on banks' overhead costs. The results indicate that in countries with a lower level of financial sector development, foreign entry is more related with higher overhead costs, but for countries with a higher level of financial sector development, foreign entry causes less and less extra costs for banks because the banking system is already developed and fewer additional investments are needed to upgrade the banking equipment.

The results show that foreign banks entry reduces non-interest incomes of the local banks, but the coefficient may turn positive in more developed markets, where competition is more intense. One reason for the limited role of the banking sector development on foreign entry effects can be the homogenous sample of countries.

Generally, lags of difference of dependent variables do not have statistically significant coefficients. From among other explanatory variables, the ratio of bank equity to total assets is positively correlated with bank profits.

Next, the interactive term with foreign banks entry variable and a bank's market share is introduced. It can be expected that small banks react to foreign banks entry somewhat differently from big banks. Obviously, banks having a bigger market share react less to foreign banks entry. This can be so because firstly, they are too big to react so quickly and secondly, banks with high market shares may care less about foreign entry, because it affects them less than small banks.

The estimation results in Table 5 show that the role of the bank's market share in foreign entry effects is very limited. The interactive term  $FBSN * MSHARE$  has a statistically significant negative effect on non-interest income and loan loss provisions. Bigger banks tend to have lower loss provisions, indicating that they have comparably more creditworthy clients and/or a better credit risk policy. No significant coefficients for  $FSA * MSHARE$  was found, therefore those results are not reported.

A summary of results and comparison with other studies is given in Table 6. The results are consistent with earlier studies, having, however, some differences. It can be generalised that foreign banks entry is negatively correlated with the income variables (ALINT, PTPTA and OOITA) and foreign banks entry is also negatively associated with loan loss provisions. Overhead costs are positively correlated with FBSN, but the increase is less important for countries with higher DCGDP, therefore the results support the technology gap hypothesis. Hermes and Lensink (2002, 2003) and Zajc (2004) have also found positive and significant effects of foreign banks entry on overhead costs. In most studies, foreign banks entry is negatively correlated with non-interest income; Hermes and Lensink (2003) found positive and significant correlation between foreign banks entry and non-interest income.

## 4. Effect of foreign bank entry on the stability of banks in the CEE countries

### 4.1 The stability of credit growth

One of the main issues of banking market development in transition countries is the level of financial intermediation and the credit to private sector. Despite the rapid growth of banking markets in transition countries, the level of the financial intermediation remains relatively low, compared with Euro area, where the average bank credit to private sector to GDP ratio is about 150% (ECB 2002).

To analyse, whether foreign banks have more stable credit supply growth in the CEE countries, the mean values and standard deviations of the credit growth in each country were calculated. The credit growth is calculated based on bank level data from Bankscope database. Bank market shares are used as weights to calculate the average credit supply growth. The standard deviation of credit growth of foreign and domestic banks in 1995 to 2003 is given in Figure 2. The volatility of credit growth among foreign and domestic banks has been quite equal. The average standard deviation of the credit supply growth in the CEE countries for domestic banks is 0.15 and 0.14 for foreign banks respectively. Nevertheless Figure 2 shows that in majority of the CEE countries the volatility of credit supply is lower than in domestic banks.

**Figure 2. The standard deviation of credit growth in the CEE countries.**

*Source: Bankscope 2005, author's calculations*

The conclusion from this section is that foreign banks have contributed to the stability of credit supply in the CEE countries during crises, although the differences of credit supply volatility are not very big and

further studies are required to get deeper understanding of about the effects of foreign banks entry on the credit market stability.

#### ***4.2 Effect of foreign entry on the quality of loan portfolios***

As the analysis showed in section 3, more detailed analysis of foreign banks' entry effect on loan losses of local banks is required, as the results were not stable. Therefore the regressions are recalculated. In the final version of regressions, the only significant bank level independent variable in the regressions is bank market share,  $D(\text{MSHARE})$ . The accounting variables did not have statistically significant effect on the dependent variable  $D(\text{LLPTA})$ . This result indicates, that accounting variables do not reflect the credit risk of a bank.

The estimation results in column A (Table 7) indicate that foreign bank entry in terms of number of foreign banks on the market has negative effect on banks' loan loss provisions to total assets. This result is similar to Weller (2000), who showed that in presence of foreign banks' entry, local banks may reduce credit by more strict credit conditions to firms because of comparatively weak financial situation and fear of bankruptcy. The negative relationship between foreign bank entry and banks loan loss provisions can be also interpreted as a positive effect of foreign bank entry on banking market stability.

In column B, the regression results with combination of foreign entry and bank market share ( $D(\text{FBSN}*\text{MSHARE})$ ) is introduced. The regression estimation shows that banks with higher market share have less loan loss provisions to total assets and react less on foreign bank entry. This can be concluded from column B, where the regression coefficient for ( $D(\text{FBSN}*\text{MSHARE})$ ) is positive but the regression coefficients for  $D(\text{FBSN})$  and for  $D(\text{MSHARE})$  are negative.

Foreign bank entry variable  $D(\text{FSA})$  does not have statistically significant effect on banks loan loss provisions in the regressions. The results are reported in column C. The results in column D show that generally domestic banks react similarly to foreign entry as does the full sample. The most significant difference is that the regression coefficient of  $\text{MSHARE}$  in column D is  $-0.449$ , while it is  $-0.11$  in the regression presented in column A. This result indicates that for domestic banks their market share (also size) is an important factor of loan losses. Bigger domestic banks have lower loan loss provisions, i.e. their loan portfolio quality is higher.

**Table 7 Effect of foreign banks' entry on loan loss provisions of banks**

Variable	D(LLPTA) (A)	D(LLPTA) (B)	D(LLPTA) (C)	D(LLPTA) (D)

*Notes: t – statistics are in parentheses; \* – significant at 10% level, \*\* – significant at 5% level, \*\*\* – significant at 1% level.*

*Source: authors' calculations.*

The regression coefficient for D(DCGDP) is positive in all regressions, indicating, that higher private sector credit is associated with higher loan loss provisions to total assets of banks. The interpretation of this result can be twofold. If we take DCGDP as the indicator of banking market development, like in Hermes and Lensink (2003), then the interpretation would be that are higher average loan loss provisions to total assets of banks in countries with higher banking market development. Another interpretation is that in transitions countries with higher private sector dept to GDP, there are higher average loan loss provisions to total assets of banks.

The result show that banking market concentration D(CONC) is positively associated with banks loan loss provisions to total assets. The economic intuition behind this result is that if there is a high concentration on the market, then there some big banks and other banks are comparatively small and smaller banks have less diversified credit portfolio and higher share of loan loss provisions. Another interpretation for transition countries, where major banks are foreign owned could be, that big foreign banks “cream skim”, focusing on bigger less risky firms and leaving more risky credit projects to smaller domestic banks.

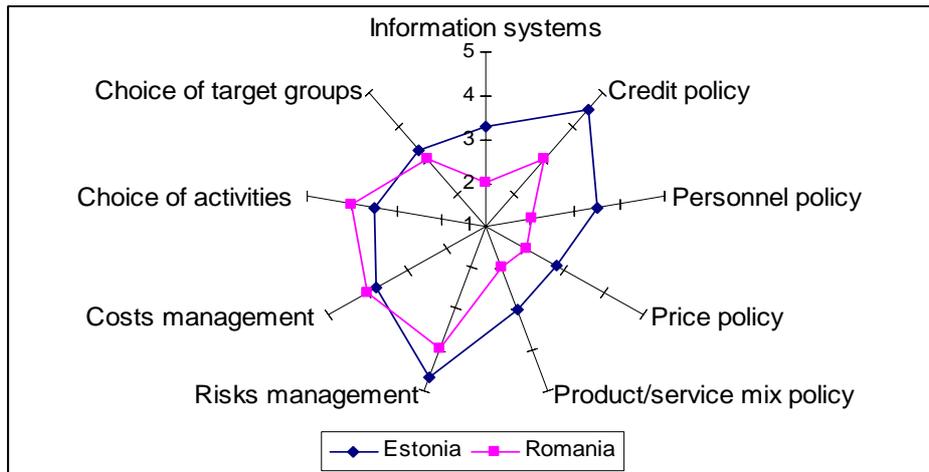

The general conclusion of this section is that foreign bank entry tends to be negatively associated with banks loan loss provisions, indicating that foreign bank entry is contributing to banking market stability of transition countries.

## **5 Results of the survey**

In order to analyze the effect of foreign banks' entry into the CEE countries a survey was carried out. A special questionnaire was designed to study various aspects of banks' internationalization in the CEE countries using the experience and lessons of previous analogous studies (see Konopielko (1999); Kraft and Galac (2000); Pomerleano and Vojta (2001)). A survey of foreign and domestic banks was carried out in 2001–2002 in Estonia, Lithuania, Poland, and Romania; some comparative data were available also from an analogous Croatian (CR) study (Kraft and Galac, 2000).

The transfer of various know-how from foreign banks has been important, especially for foreign-owned banks' management (see Figure 3). The transferred know-how about interest rates, solvency and credit risks management techniques was evaluated by respondents most highly (over 4.0 points by Estonian foreign banks' respondents). Liquidity risk management techniques, information systems, credit policy and personnel policy transfer from foreign banks was also evaluated quite highly by Estonian domestic banks. On the other hand, the average grades given by the responding Polish domestic banks were somewhat different: the transfers of information systems and banking services/products mix policy were considered as the most important know-how transfers from foreign banks (4.3 and 4.2 grades, respectively). This difference between Estonia and Poland can be explained by the technology gap argument. Electronic banking and up-to-date computer technology are considered to be at a much higher level in Estonia than in the other CEE countries and therefore additional know-how transfer from mother banks has not been so relevant. It is even argued that the Estonian e-banking system is more advanced than the corresponding systems in many developed EU countries.

**Figure 3 Evaluations of the adoption of mother bank's policies and systems**

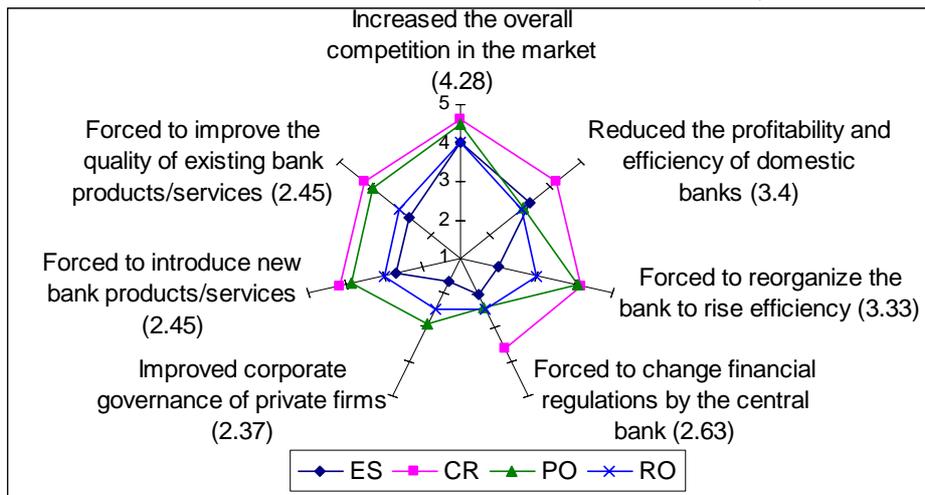

*Source: author's figure*

The impact of foreign banks' entry into the observed CEE banking markets (as evaluated by the responding domestic banks) is presented in Figure 4.

The results show that foreign banks' entry significantly intensified the overall competition in the banking market (average grade 4.0 points in Estonia and Romania, 4.5 in Poland), reducing the domestic banks' profitability and efficiency of operation. All other impacts were evaluated by Estonian respondents as unimportant, among them, surprisingly, even corporate governance of private firms (average grade only 1.7 points).

**Figure 4 Impact of foreign banks' entry into the host country's market (ES – Estonia, CR – Croatia, PO – Poland, RO – Romania)**

Source: author's figure.

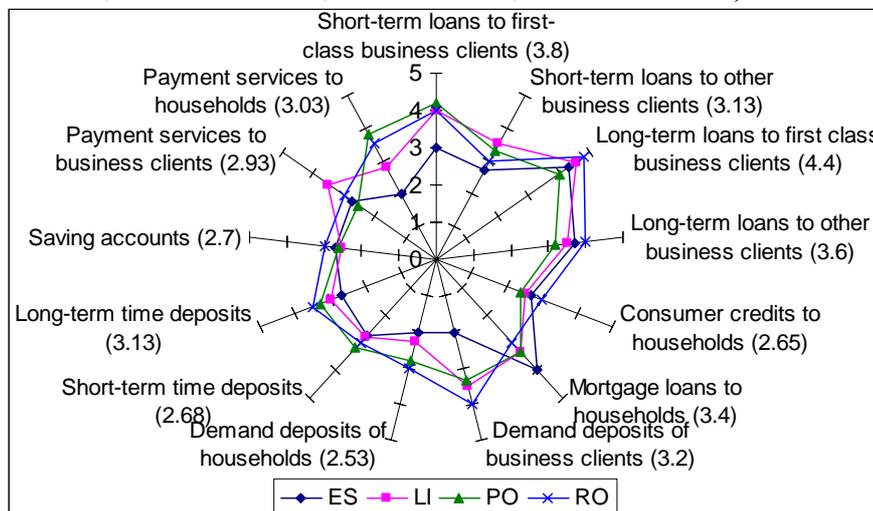

Polish respondents were of the opinion that foreign banks' entry significantly forced banks to reorganize their internal structure in order to raise efficiency (4.1 points), as well as to introduce new banking services/products and improve the quality of the existing banking products and services (both 3.9 points). It is quite interesting that the Croatian respondents evaluated the impact of foreign banks' entry into the Croatian banking market more highly than the respondents from other countries.

It is interesting to note that the average effects of foreign banks' entry were clearly different in different countries. It can be seen in Figure 4 that the importance of different impacts of foreign entry in descending order is as follows: Croatia, Poland, Romania and finally Estonia. Seemingly, the general effect of foreign banks depends on market-specific factors. The Estonian banking market is comparatively more highly developed and so the overall effect of foreign banks has been evaluated to be lower. Therefore, the technology gap hypothesis seems to hold.

The responding domestic banks' evaluations about the degree of competitive pressure resulting from foreign banks' entry are given in Figure 5. Quite clearly, here long-term loans to first-class business clients (average grade 4.4 points) dominated among the other market segments. Mortgage loans to households (average grade 4.0 points) were mentioned as the most important market segments on the Estonian banking market that were influenced by the pressure from foreign banks. The Lithuanian, Polish and Romanian respondents' evaluations were somewhat different: short-term

loans to first-class business clients were mentioned as the more important competitive market segment (average grades respectively 4.0, 4.2 and 4.0 points). The Romanian respondents ranked highly also long-term loans to other business clients and demand deposits of business clients.

**Figure 5 The degree of competitive pressure from foreign banks (ES – Estonia, LI – Lithuania, PO – Poland, RO – Romania)**

Source: author's figure.

## 6 Conclusions

This paper tries to shed light to some aspects of foreign banks entry in the CEE countries. The author suggests that foreign banks' entry can have both competition and spillover effect on domestic banking sector in the CEE countries.

The negative competition effects of foreign banks' entry were weaker in those countries whose banking market was more advanced, indicating that the technology gap hypothesis holds in the CEE banking markets. The entry of foreign banks was positively correlated with the quality of loan portfolios of local banks. This result indicates that there is a positive competition effect of foreign banks' entry also on the stability of domestic banks. Additionally, there were some positive spillover effects of know-how transfer to local banks. The survey results indicate that the main technology spillover from foreign to domestic banks has been in the field of risk management. Therefore there is also a positive spillover effect on the stability of domestic banks. The general conclusion of the paper is that foreign banks entry is

likely to have positive effect to transition banking markets by increasing competition and stability of the banking sector.

## Appendix 1

### List of variables used in the analysis

Variable	Source	Description
FBSN	Central banks, EBRD	Number of foreign banks as percentage of all banks in a given country and year
FSA	BankScope	Share of foreign banks' assets in total banking market assets in a given country and year
FD	BankScope, bank web sites	Dummy variable with value 1 if bank is foreign-owned and 0 for domestic bank
NIM	BankScope	Net interest income (interest income minus interest expense) over total assets
ALINT	BankScope	Interest income to interest earning assets
PTPTA	BankScope	Before tax profit over total assets
OOITA	BankScope	Non-interest income over total assets
OHTA	BankScope	Total operating expenses (all but interest expenses) over total assets
LLPTA	BankScope	Loan loss provisions over total assets
ETA	BankScope	Equity over total assets
NEATA	BankScope	Non-interest earning assets over total assets
CSTFTA	BankScope	Short- and long-term deposits, and other non-deposit short-term funding over total assets
MSHARE	BankScope	Bank assets to total banking market assets in a given year
GGDP	EBRD	Real GDP annual growth rate
INCOME	EBRD	GDP per capita in US dollars
CPI	EBRD	Annual CPI change
MMR	IFS	End of year money market interest rate
DCGDP	IFS	Private credit to the GDP in a given country and year

*Note: all variables are in percentages except GDP per capita (in US dollars (th.), 1995 prices)*

## Abstract

*Foreign banks' presence in Central and Eastern Europe has reached a level way above other emerging and EU markets. What is the long-term impact of this special situation on economic growth and stability? Through which channels do foreign banks influence a host country's economy? What are the lessons for other regions? The purpose of this paper is (1) to discuss the challenges that the banking industry in CEE countries was faced with through the massive entry of foreign banks; (2) to describe how this industry has developed under the conditions of increased foreign ownership; (3) to delineate the impact on GDP growth. We find that via direct (price, volume and institutional) and indirect channels (e.g. signalling), foreign banks can contribute positively to financial sector development and economic growth if they follow a prudent, long-term regional strategy.*

**Keywords:** *financial liberalization; foreign banks; financial development; economic growth*

## 1. Introduction

During the 1990s, one of the most striking structural changes in the financial systems in Central and Eastern Europe (CEE)<sup>2</sup> has been the growing presence of foreign banks. Their entry into the financial structures of these countries significantly altered the business potential in the banking sector, shaped its environment and the development of the aggregate financial system. Beyond the short-term, direct implications: what is the long-term outcome of massive foreign bank entry onto economic growth and stability? Did foreign bank entry accelerate economic development and growth in CEE countries, and if so, how? Given that more than half of the total number of banks in the CEE region are foreign owned now, exceeding the level in comparable emerging markets, the role foreign banks play in CEE countries and their importance for the economic and financial development of these countries is an important issue both for domestic development and beyond.

The aim of this paper is to discuss various channels of influence of foreign bank entry onto the host country financial sector and whether or not this special situation favours economic growth. We begin with a brief characteristic of the banking market of CEE countries, dominated by foreign banks – foreign banks concentration, services offered, their efficiency. Then we analyse the effects that foreign banks have on the development of the financial sector of these countries – starting with the stability, efficiency and improved competition that they provide in the banking sector, and also their influence on domestic banks behaviour and performance. Next we examine if there is any relationship between financial development (affected positively by foreign financial intermediation) and economic development and growth. At the end we present the results of two studies analysing the financing of small and medium enterprises and the role of foreign banks by serving the private and public sector. We conclude that foreign banks with a long-term orientation towards the region contribute positively to economic development of their CEE host countries both directly and indirectly. They directly promote efficiency in the financial sector and provide more stable sources of credit. Together with technology transfer and improved corporate governance, this spills over into attracting further foreign direct and portfolio investment and jointly leads to improved economic growth.

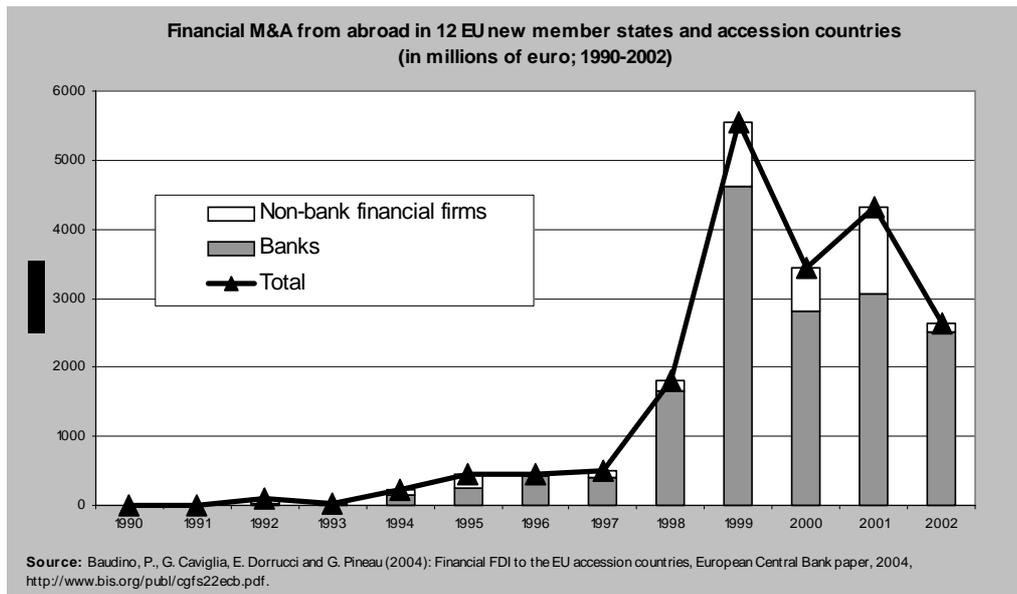

---

<sup>2</sup> As foreign bank presence only recently gained in importance in South-Eastern Europe, we focus on the New EU Member States and EU Accession Countries from CEE in the following.

## 2. Foreign banks in CEE

Foreign banks have been active in CEE countries since the early 1990s when many of these countries implemented financial liberalisation policies and eliminated entry barriers allowing foreign banks to set up subsidiaries or to privatise domestic banks. In recent years, progress has been particularly significant in restructuring and consolidating the banking sector. All this has led to a rapid increase of foreign ownership in the banking industry in the second half of the 1990s (Roldos, 2001).

**Figure 1 Financial M&A from abroad in 12 EU new member states and accession countries (in millions of euro; 1990-2002)**

Source: Haiss/Steiner/Eller, 2005

As CEE countries differ in their economic and banking market development, foreign banks entered these countries to different degrees. Hasan and Marton (2003) mention Hungary as a leader in inviting foreign banking institutions during the late 1980s and that within a short period of time the foreign banking sector has become a dominant force in the industry as well as in the economy.

### 2.1 Concentration of foreign banks in CEE markets

Today foreign banks account for more than half of the total number of banks in CEE, and hold more than two thirds of total bank assets (Uiboupin, 2004, 7) and at least three out of the top five banks are foreign-owned

(Baudino/Caviglia/Corrucci/Pineau, 2004, 19). Still, foreign bank presence in these countries is considerably higher than in the old member countries of the European Union. With the exception of Slovenia and Latvia, the banking sector in the New EU Member States (NMS) and the EU Candidate Countries (Croatia, Bulgaria, and Romania) is dominated by foreign banks. In the Czech Republic, Slovakia, Estonia, Lithuania, Croatia and Bulgaria, foreign banks own more than 80 per cent of the banking market. Although the CEE banking market is relatively small with total assets of some EUR 350 billion in absolute terms (by comparison, total assets of banks operating in Austria were some EUR 605 billion at the end of 2003), it is nevertheless a growth market. As Breyer (2004) argues, this above-average growth potential and the higher interest margins than in Western Europe have led Western European banks to invest heavily in the CEE banking sector. In addition to higher economic growth, the low degree of bank intermediation (about a third relative to its Western European equivalent) suggests continuing strong growth potential for banks in CEE in the coming years (Breyer, 2004).

Foreign involvement, though important, is not evenly spread across the CEE region. According to Bonin, Hasan and Wachtel (2005, 32), the foreign share in bank assets in CEE countries in 2000 ranged from highs of 97.4% in Estonia and 84.1% in Croatia to a low of 15.6% in Slovenia. Slovenia has the least amount of foreign participation but the highest relative measures of financial depth, deposit collection, and bank lending (Bonin 2004, 143). In Slovakia and Romania, 42.7% and 46.7% of assets are in banks having majority foreign ownership and in the other CEE countries more than half of the assets are in banks having majority foreign ownership (Bonin/Hasan/Wachtel, 2005, 32). At the same time there is a very small involvement of foreign banks in CIS countries, and especially in Russia (Svetlov, 2002).

Baudino, Caviglia, Corrucci and Pineau (2004, 25) examine the concentration and involvement of EU banking groups in CEE. They find that large Austrian banks are very active in the Eastern expansion - due to several reasons, including the strategic interest of Austria vis-à-vis the so-called Visegrad countries (Czech Republic, Hungary, Poland and Slovakia) and other neighbouring markets. Austrian banks have been among the first participants in the privatisation of the CEE banks and their involvement goes beyond being a by-product of Austria's strong trade relations with many of the New EU Member States. Proximity and early-mover-advantages may play a major role in this regional market approach. Further north, the largest Swedish and Finnish banks found the ground for natural expansion in the Baltic countries. Greek banks concentrated on South-Eastern Europe (SEE), Italian banks followed an active international strategy towards the whole

Central and Eastern Europe (Baudino/Caviglia/Corrucci/Pineau, 2004, 25), with a high degree of involvement also in neighbouring markets. A significant number of foreign banks active in CEE markets hail from Europe's smaller markets, where the prospects for domestic growth are limited. This applies to the three Austrian players (Erste Bank, Bank Austria Creditanstalt and Raiffeisen Zentralbank), the two Benelux players (KBC and ING) and Portugal's Banca Comercial Portuguesa (European Banker, 2004).

## ***2.2 Services offered by foreign banks in CEE***

In CEE countries due to the small size of the respective financial markets, foreign banks seem to have a preference for developing retail banking rather than wholesale activity. In 2001 retail (32%) and commercial banking (34%) were the most developed business lines (Baudino/Caviglia/Corrucci/Pineau, 2004, 30). Conversely, corporate finance, trading and asset management accounts for altogether, only 28% (9.8%, 11.2% and 7% respectively) of the overall business and other banking activities like agency services and retail brokerage are hardly being developed. However, there are significant differences across countries. Wholesale versus retail banking appears to be more balanced in the Czech Republic (21% and 31 %, respectively) and Poland (14% and 25%, respectively), whereas in most of the remaining countries the small size of the domestic money and capital markets contributes to limiting importance of the wholesale activity. Business such as asset management tends to be conducted at the parent company level, owing to economies of scale, predominance of crossover investment on dedicated investment and need to concentrate expertise in units with strong awareness of global trends (Baudino/Caviglia/Corrucci/Pineau, 2004, 31). Foreign banks offer also a range of new products known as Western style consumer goods – consumer credit products, including personal loans, mortgages, store cards, credit cards, auto and retail finance (European Banker, 2004).

## ***2.3 Foreign banks efficiency***

Foreign banks benefit from their involvement in CEE markets, generally enjoying higher levels of growth and profitability than they do in their home markets (European Banker, 2004). Goldberg (2003, 3) argues that foreign banks appear to be more efficient than their domestic counterparts, whether privately or government owned. Bonin, Hasan and Wachtel (2005, 51-52) add that foreign banks are more cost-efficient and also provide better service so that domestic banks are forced to become more efficient and to improve their service as well after foreign entry. Sabi (1996, 179) analysed the performance of foreign and domestic banks in Hungary. They conclude

that compared to domestic banks, foreign banks are more profitable, not exposed to a greater liquidity or credit risk, providing less money for consumer loans, and hesitant to provide long term loans for development purposes (Sabi, 1996, 179). These conclusions may be applied to other transition countries as well. Drawing also on Hungary, Hasan and Marton (2003) conclude that the higher the foreign involvement in bank ownership the lower is the inefficiency. Banks with at least 75% and with 50-75% foreign involvement are the most efficient group. Banks with less than 50% foreign ownership fared substantially lower relative to the groups with over 50% foreign ownership and the group with banks up to 25% foreign involvement is relatively less efficient among the foreign-based groups. So massive-scale foreign involvement seems to be better than low-key-approaches.

### **3. Foreign banks in CEE: Micro/Macro issues**

#### ***3.1 Foreign banks role in the banking industry of CEE countries***

Foreign banks fulfil an important role for the financial stability in CEE countries and effect considerably the development of the banking market and even the overall economic development in these countries. Roldos (2001, 8) considers that foreign bank entry is generally seen as improving the efficiency and stability of local banking system. Foreign banks promote efficiency of the domestic banking sectors. In most cases banks that extend their operations abroad are among the most efficient in their own country, and when such banks start to operate in CEE, they are bound to outperform domestic banks. They improve the quality, pricing, and availability of financial services and are often seen as improving the allocation of credit since they have more sophisticated systems for evaluating and pricing credit risks. As a consequence, those domestic banks that manage to remain active are under pressure to increase their efficiency, thus leading to improved efficiency of the domestic banking system (Baudino/Caviglia/Corrucci/Pineau, 2004, 46).

Uiboupin (2004, 9) argues that the entry of large international banks improve the stability of the host country's banking system because they have better access to global financial markets. Foreign banks' presence helps to achieve even overall financial stability in host countries. Host countries may benefit immediately from foreign entry, if the foreign bank recapitalises a struggling local institution and, in the process, also provides needed balance of payments financing. The better capitalisation and wider diversification of foreign banks, along with the access of local operations to parent funding,

may reduce the sensitivity of the host country banking system to local business cycles and changing financial market conditions. In stress situations, foreign-owned institutions can also provide an alternative location for deposits that does not involve capital outflows (BIS, 2004). The entry of foreign banks can also affect the banking system concentration. In some cases, large foreign banks acquire a significant share of local bank assets by purchasing a local state bank that was being privatized or by acquisition of a large private bank that was in need of recapitalization. The entry of such banks would in turn create pressures on local banks to merge to remain competitive both by capturing economies of scale in back office operations and by being viewed by depositors as offering the same degree of safety and soundness as large foreign banks (Roldos, 2001, 15).

Besides improving financial sector efficiency, foreign banks can provide a more stable source of credit and thus make the banking system more robust to shocks. In times of financial stress local operations of foreign banks are likely to have recourse to additional funding and capital from their head-offices. Roldos (2001, 11) provides an example with Hungary, where head-offices quickly injected capital, when the brokerage subsidiaries of foreign banks suffered large losses in the aftermath of the Russian crisis. While domestic banks contracted their credit and deposits during crisis periods, foreign banks did not show such a procyclical behaviour and thus contributed to a more stable development of bank credit in CEE (De Haas/Van Lelyveld, 2003).

Foreign banks also introduce stronger competition to the local banking market. They exert in some way competitive pressures and demonstration effects on local institutions, often inducing them to reassess business practices, including local lending practices. The result can be better risk management, more competitive pricing, and in general a more efficient allocation of credit in the financial sector as a whole (BIS, 2004). As it is relatively easy for foreign banks to introduce new banking technology and financial innovations, it can be said that host countries benefit from this technology transfers and innovations in products and processes that is commonly associated with foreign bank entry (BIS, 2004). Uiboupin (2004, 10) finds that foreign banks play important role in the improvement of the financial system's infrastructure in the host country – through transfer of good banking practice and know-how, accounting, transparency, financial regulation, supervision and supervisory skills.

The presence of foreign banks may increase the amount of funding available to domestic projects by facilitating capital inflows, diversifying the capital and funding basis and thus attracting foreign direct investments (Uiboupin, 2004, 10). Foreign banks entry may help deepen the inter-bank

market and attract business from customers that would otherwise have gone to foreign banks in other countries. In this way they stimulate the development of the financial markets in the host countries (Uiboupin, 2004, 10). Lensink and De Haan (2002, 214) argue that foreign bank presence may also lead to improvements of bank regulation and supervision, since these banks may demand improved systems of regulation and supervision from the regulatory authorities in the recipient countries. This may then contribute to improving the quality of banking operations of domestic banks. Foreign banks can help encourage consolidation of the banking system, because they have knowledge and experience of other financial activities: insurance, brokerage and portfolio management services (Uiboupin, 2004, 10). These banks may reach and introduce economies of scale and scope beyond the reach of purely local institutions. Cross-border financial conglomerates also induce regional cooperation by the respective financial market supervisors.

Besides all the benefits and positive effects foreign banks have on the local financial market and the overall economic development of the host country, the growing involvement of foreign banks – especially if these are not committed to long-term-regional involvement - gives rise to some concerns. If foreign owners are merely interested in short-term profits from selling non-banking subsidiaries (“asset stripping” as was the case of IPB in the Czech Republic) instead of prudently running a commercial bank, they cause harm to economic growth. The further away their home market is, the easier it is for them to leave.

When integration transforms a domestic institution such that key decision-making and control functions – including strategic planning and risk management – are shifted to the parent, this may backfire onto economic development at large as well. A purely local focus of major banks may reduce the information available to host country supervisors and monetary authorities, and it may interfere with the access of authorities to key firm decision-makers. The reduction in information could become an issue, especially when parent institutions make subsequent strategic changes that significantly affect host country financial markets (BIS, 2004). De Haas and Van Lelyveld (2002, 6) mention that foreign banks may only provide credit to the large and multinational firms, leaving the bad corporate credit risks as well as the retail market and the related payment services to domestic banks. They state also that in some way foreign banks may weaken the position of the less-sophisticated domestic banking system. Domestic banks that are not able to cope with the increased competitive pressures may fail and lead to periods of severe financial instability. Another point that the authors considered is related to the credit supply of foreign banks. If for instance the economic environment in their home countries deteriorates, foreign banks

may lower the credit supply in the host country (De Haas/Van Lelyveld, 2002, 6).

### ***3.2 Foreign banks influence on domestic banks behaviour and performance***

Foreign banks have a strong influence on domestic banks performance and behaviour. Lensink and Hermes (2004) argue that foreign banks may stimulate domestic banks to reduce costs, increase efficiency and increase the diversity of financial services through competition. Domestic banks are pressured to improve the quality of their services in order to retain their market shares. Increased competition may lead to lower interest rate margins and profits (Lensink/Hermes, 2004, 555). In contrary, as result of the increased competition domestic banks react with higher overhead costs because they want to retain their image. This can cause reduced profitability (Uiboupin, 2004, 13), but as already mentioned also improve efficiency and functioning of domestic banks (Lensink/Hermes, 2004, 555).

Foreign bank entry also results in spill-over effects. If foreign banks introduce new financial services, this may stimulate domestic banks to also develop such new services, improving the efficiency of financial intermediation of the domestic financial system (Lensink and Hermes, 2004, 555-556). Foreign banks may also introduce modern and more efficient banking techniques that are new to domestic banks and that might be copied by them. Additionally, foreign banks may help to improve management of domestic banks, especially if foreign banks directly participate in the management of a domestic bank, for example in the case of a joint-venture or a take-over. Foreign banks may demand improved systems of regulation and supervision from the regulatory authorities that will result in improved quality of banking operations. Finally, foreign bank entry may contribute to a reduced influence of the government and influential business and political elites on the domestic financial sector, which may reduce the importance of directed credit policies. All these spill-over effects may contribute to more efficient domestic banking practices, which may help to reduce costs.

Foreign banks may increase the quality of human capital in the domestic banking system in a number of ways. If foreign banks import high skilled bank managers to work in their foreign branches, local employees may learn from the practices of the foreign bank managers. Moreover, foreign banks may invest in training of local employees. Increasing the quality of available human capital for the domestic banking system may again contribute to more efficient domestic banking practices (Lensink/Hermes, 2004, 556).

The effects of foreign bank entry on the performance of domestic banks may depend on the banking market development (Uiboupin, 2004, 15) or even on the level of economic development of the given country, as Lensink and Hermes (2004) stated. At least in the short-term, at lower levels of economic development foreign bank entry leads to increased costs, and perhaps also increased margins of domestic banks. At higher levels of economic development the effects may be less clear: foreign bank entry either has no effects or costs and margins of domestic banks fall. The effect of foreign bank entry on profits of domestic banks at lower levels of development is ambiguous. At higher levels of development profits will decline due to higher competitive pressure (Lensink/Hermes, 2004, 558).

The way domestic banks react to foreign banks entry may depend on their market share as well. Bigger banks probably react less to foreign entry, because they are either too big to react quickly to market conditions, or foreign banks entry is less important to them than to smaller banks. Small banks react to foreign banks entry somewhat differently from big banks (Uiboupin, 2004, 15).

There are a lot of studies carried out to analyse the effects that foreign banks entry have on the performance of domestic banks, on their efficiency and profitability. A most comprehensive empirical survey was carried out by Claessens (2001) who investigated the relationship between foreign banks entry and the performance of the domestic banking sector in 80 countries. They used panel estimations with 7,900 bank observations for the period 1988–1995. The main result is that foreign banks tend to have higher interest margins, profitability, and tax payments than domestic banks in developing countries, while the opposite is true in developed countries. Higher foreign bank presence is related to lower profitability and margins of domestic banks. According to Claessens (2001), foreign bank entry may improve the functioning of national banking markets, with positive welfare implications for banking customers in the long run, and the number of entrants matters rather than their market share. This indicates that the impact of foreign bank entry on local bank competition felt immediately upon entry rather than after they have gained substantial market share (Claessens/Demirgüç-Kunt/Huizinga, 2001).

Hermes and Lensink (2003) developed further the model used by Claessens (2001) using data from 990 banks in 48 countries for the period 1990-1996. The results indicate that at a lower level of economic development, foreign banks entry is associated with higher costs and margins for domestic banks. At a higher level of economic development, on the other hand, foreign banks entry has a less significant effect on domestic banks' profitability." (Uiboupin, 2004, 11). Zajc (2002) analysed foreign banks

entry effects on domestic banks in the Czech Republic, Estonia, Hungary, Poland, Slovakia and Slovenia for the period 1995–2000. His results are somewhat different from those presented by Claessens (2001). He found that foreign banks entry is associated with lower non-interest income but increases overhead expenses (Uiboupin, 2004, 12).

### ***3.3 Foreign banks and economic growth***

Among the many factors examined in the literature as possible determinants of economic growth, the financial sector has recently gained growing attention in this respect. The consensus view is that financial development is associated with superior economic performance: countries with better-developed financial systems have higher levels of per capita real GDP and tend to grow faster. As many empirical studies conclude that foreign banks play an influential role in stimulating financial development, the issue arises to what extent these are spurring economic growth. As they have the incentive, the know-how and expertise to drive financial sector development, they mobilize savings and allocate and redistribute capital for investment. If domestic financial institutions do not perform these functions properly, foreign banks' role in the economy becomes essential. This central notion is developed further in the following.

#### **3.3.1 Financial development and economic growth**

Levine (1996b) argues that the country's level of financial development plays an important role in determining the rate of economic growth as financial development crucially affects the speed and pattern of economic development. He states that there is a positive relationship between financial development and economic growth. The level of financial development will affect growth by altering the economy's saving rate and by influencing the efficiency with which economies allocate resources. Beck, Levine and Loayza (2000) further add that accounting reforms that strengthen creditor rights, contract enforcement, and accounting practices can further boost financial intermediary development and thereby induce a rapid acceleration in economic growth.

#### **3.3.2 Financial sector and economic growth**

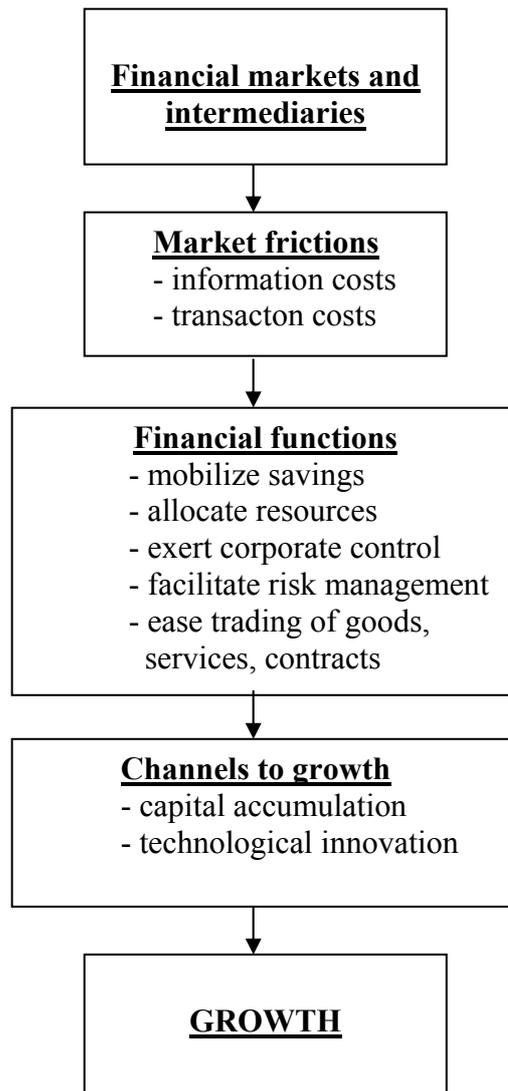

Financial systems are a fundamental feature of the process of economic development and there is strong positive link between the functioning of the financial system and long-run economic growth. Many theoretical and empirical studies prove that a strong financial sector promotes economic growth. Schumpeter (1934) stressed the role of the banking sector

as a financier of productive investments and thus as an accelerator of economic growth. Pagano (1993) suggests three ways in which the development of financial sector might affect economic growth - it can increase the productivity of investments, it reduces transaction costs and thus increases the share of savings, and third the financial sector development can either promote or decline savings. Greenwood and Jovanovic (1990), Levine (1991), Bencivenga and Smith (1991) and Saint-Paul (1992) have all also developed theoretical models to prove that efficient financial markets improve the quality of investments and enhance economic growth (Koivu, 2002, 9). According to Wachtel (2003) the depth of the financial sector and a greater provision of financial services are associated with economic growth (Haiss/Steiner/Eller, 2005, 4-5).

Levine (1996b) argues that financial systems reduce information and transaction costs and influence saving rates, investment decisions, technological innovation, and long-run growth rates. He finds a positive relationship between growth and the quality of the functions provided by the financial system that will be mentioned further down. Countries with larger financial sectors relative to GDP and countries where banks play a larger role relative to the central bank in allocating credit have higher levels of real per capita income and grow faster (Levine, 1996b). As Koivu (2002, 7) shows, CEE countries with developed banking sectors have smaller interest margins and higher economic growth than countries struggling with banking sector reform.

Levine (1996b, 55) states that the financial system is shaped by non-financial developments as well. Legal systems, political changes, national institutions, changes in Telecommunications, computers, non-financial sector policies, institutions, and economic growth itself influence the quality of financial services and the structure of the financial system. Changes in economic activity can influence financial systems as well. According to Levine (1996a) all financial systems provide basic financial services that are crucial for economic activity and long-run economic growth. These services may affect growth through two channels: by increasing the rate of physical capital accumulation or by improving the efficiency with which economies combine capital and labour in production. Specifically, the financial system facilitates transactions, eases risk management, mobilizes saving, allocates savings, and monitors the behaviour of managers after funding projects. Countries with financial systems that are better at providing and performing these financial services are more economically developed and grow at a faster pace than those with less developed financial services (Levine, 1996a).

The following figure, provided by Levine (1996b) can also explain how financial system stimulates capital formation and enhances economic efficiency:

*Source: Levine, 1996b*

Particular market frictions – transaction and information costs - motivate the emergence of financial markets and intermediaries that provide basic financial functions (Levine, 1996b, 6). These financial functions affect economic growth through each of the following channels – capital accumulation and technological innovation. Levine (1996a) concludes that if the financial system stimulates capital formation and enhances economic efficiency, foreign banks may then have an important role in economic

development. Foreign banks that improve the provision of growth-enhancing financial services will promote economic development.

Koivu (2002) examined the link between efficiency and size of the banking sector and economic growth, using panel data from 25 transition countries during the period 1993-2000. She used two variables to measure the level of financial sector development – the interest rate margin (the margin between lending and deposit interest rates) and the amount of bank credit allocated to the private sector. The results show that the interest rate margin is significantly and negatively related to economic growth and the amount of bank credit does not accelerate economic growth. Its value is even negatively related to economic growth and the causality between the growth of credit and real GDP growth is unclear. The main reasons behind this result could be the numerous banking crises the transition countries have experienced and the soft budget constraints that are still prevalent in many transition countries. The findings of this study also support the view that the presence of an efficient banking sector accelerated economic growth in transition economies (Koivu, 2002).

### 3.3.3 Transmission channels from foreign banks to economic growth

Berger (2004) find that larger market shares for foreign banks are associated with better economic performance in terms of faster GDP growth, and higher bank lending to GDP ratios (BIS, 2004, 12). In this respect, Haiss, Steiner and Eller (2005) identified four transmission channels how foreign banks (or more specifically, financial sector foreign direct investment, FSFDI) spur economic growth. They distinguish between price effects (i.e. shrinking interest margins that translate into lower cost of capital for companies), volume effects (more stable, larger credit flows), institutional effects (e.g. well-capitalized banks with sophisticated risk assessment systems have a broader array of investments) and spillover effects.

**Table 1 Financial Sector FDI (FSFDI) - Growth Transmission Channels**

<b>Intermediation/price:</b>	FSFDI ↑	spread ↓	cost of capital ↓	investment ↑	GDP ↑
<b>Intermediation/volume:</b>	FSFDI ↑	credit availability ↑	investment ↑	investment ↑	GDP ↑
<b>Institution building &amp; corporate governance:</b>	FSFDI ↑	bad loans ↓	credit availability ↑	investment ↑	GDP ↑
<b>Signal effects:</b>	FSFDI ↑	FDI & PFI ↑		investment ↑	GDP ↑

*Source: Haiss/Steiner/Eller, 2005*

Increased competition, credit technology transfer that improve productivity and efficiency, and improved risk assessment (that we already mentioned as positive effects from foreign banks involvement) bring down spreads and make financing investments cheaper, thus stimulating investment and economic growth. Foreign banks inject fresh money in the financial sector of host countries and generally stabilize lending. Better risk assessment allows financing of higher risk/return-projects and broader product range allows diversified company finance. All this increases the availability of credit that again means more capital for investment and economic growth. The third transmission channel implies that international accounting standards and better management techniques will reduce bad loans, so that there is more room for “good loans”. Foreign bank entry may attract further foreign direct investment and portfolio foreign by productive and other services sector companies (e.g. large banks will attract their customers - big companies to follow them in new markets). Foreign banks can increase economic growth by raising the increasing capital inflows (Levine, 1996a). Foreign banks can also facilitate capital market growth by helping local companies raise money via stock or bond issuance and will also facilitate the access to international capital markets so that this will again stimulate and accelerate economic growth (Haiss/Steiner/Eller, 2005). Foreign bank presence can also influence economic growth in more indirect ways.

### ***3.4 Foreign banks and Small and Medium Enterprises***

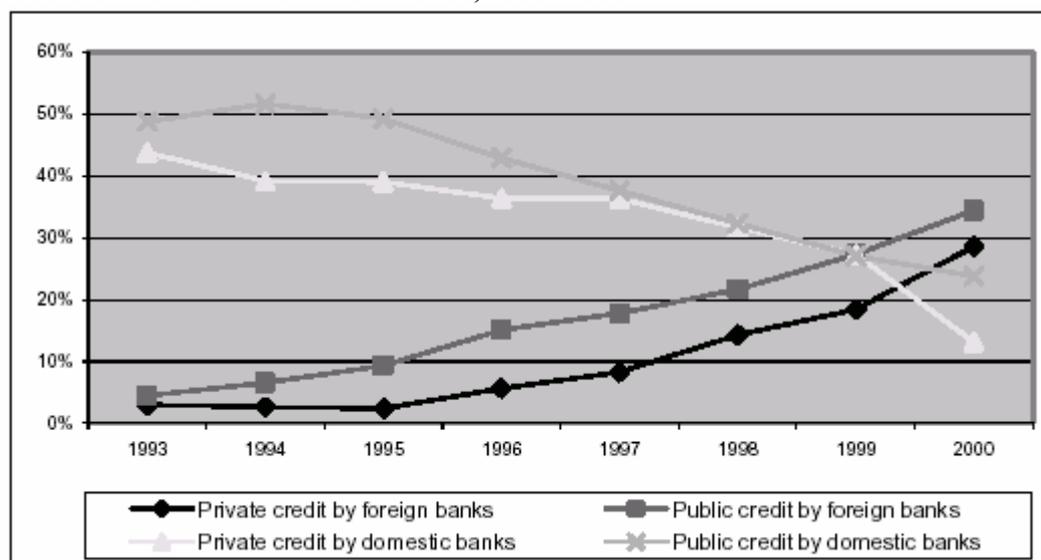

As small and medium sized enterprises (SME) represent around 90 percent of the total firms in the transition countries, they play a major role in their economies. The access to credit is crucial for their survival and as they are significant sources of innovation, their financing contributes significantly to economic development and growth (Cárdenas/Graf/O’Dogherty, 2004, 7). However, De Haas and Naaborg (2005) argue that foreign banks initially focused almost exclusively on multinationals and the largest local corporations or even on serving multinational corporations from their home country, rather neglecting SMEs. The reason for that could be that foreign banks that acquired large regional banks in CEE “inherited” a portfolio focused on large corporate customers or, in the case of former savings banks, retail banking. Other banks entered CEE mainly through greenfield investments with the goal of serving multinational customers. For both types of banks, small business finance remained unimportant during the first half of the 1990s. However, when the transition process advanced, foreign banks started to lend more to SME. This was a consequence from the increased competition in the market for large corporate customers, eroding interest

margins and fees and stimulated foreign banks to start serving SMEs and retail clients as well. Another reason for increasing the lending to SME was that foreign banks improved their ability to efficiently screen and monitor smaller firms (De Haas/Naaborg, 2005).

### 3.5 Foreign banks serving the public and private sector

Besides SMEs, the public sector plays a shrinking, though important role in CEE economies. Naaborg, Scholtens, De Haan, Bol and De Haas (2003) analysed the role played by foreign banks in extending credit to both the private and public sector in comparison with domestic banks over the 1993-2000 period for selected CEE countries (Croatia, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland and Slovenia). Apparently, foreign banks replaced domestic banks as creditors. In 1993, domestic banks were the primary source of credit for the public and the private sector, while in 2000 foreign banks dominate both markets. Although foreign banks increased their lending to both public and private sector, credit to the private sector is still relatively low and public credit of foreign as well as of domestic banks exceeds private credit (Naaborg/Scholtens/De Haan/Bol/De Haas, 2003).

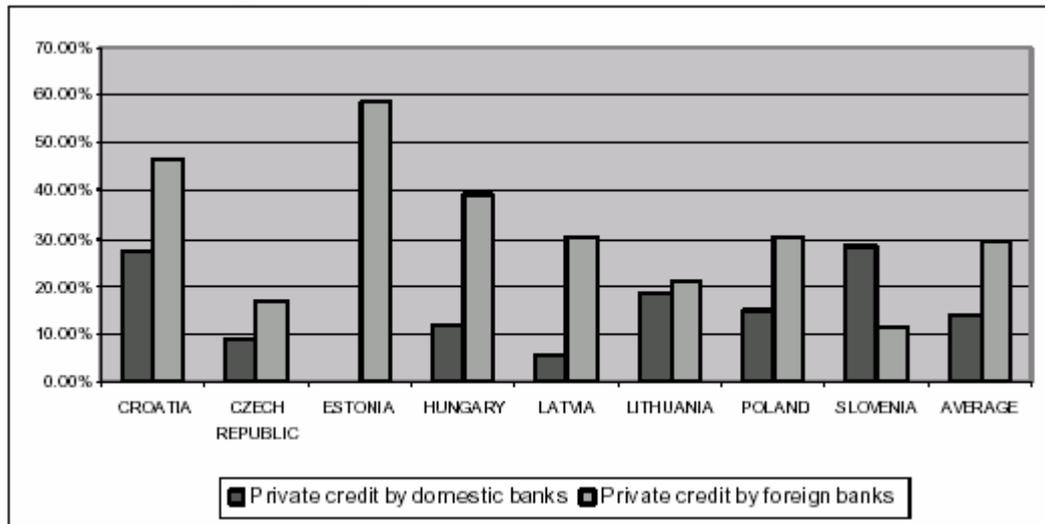

**Figure 2 Credit supply of domestic and foreign banks as share (%) of total bank credit in CEE countries, 1993-2000**

Source: Naaborg/Scholtens/De Haan/Bol/De Haas (2003)

Comparing the fraction of private credit provided by both foreign and domestic banks in some CEE countries, in all countries, except for Slovenia, foreign banks appear to be more involved with lending to the private sector than domestic banks. Still, there are substantial differences among the CEE countries as to the relative importance of private lending by foreign banks. The most extreme case is Estonia, where domestic banks hardly provide credit to the private sector (Naaborg/Scholten/De Haan/Bol/De Haas, 2003).

**Figure 3 Credit to the private sector as share of total bank credit: domestic vs. foreign banks, 2000**

Source: Naaborg/Scholten/De Haan/Bol/De Haas (2003)

As Haiss, Steiner and Eller (2005) conclude credit supply to different target-groups – public and private borrowers, has various impacts on economic development. For example, lending to the public sector may be important to reduce budget deficits and thus promote economic stability whereas credit to the private sector is necessary to further support private investment and thus leading to economic growth. Credit to the private sector is very important for economic development but remains relatively low in CEE. Credit to the public sector may be growth enhancing as well (Haiss/Steiner/Eller, 2005, 5). But growing credit-supply is not enough to guarantee a positive impact on investments because as Mehl and Winkler (2003) stress fast credit growth can also be a warning signal indicating a potential financial crisis.

## 4. Conclusion

The financial systems in CEE countries have experienced a lot of structural changes over the past decade - the increased entry of foreign banks is one of the most impressive and crucial of them. Their involvement has created new challenges for the financial sector in CEE countries and their successful operations have contributed to a lot of positive changes and further development of the financial markets in these countries. Today foreign banks have a strong presence in CEE – they own more than 70 per cent of banking assets in the region and have become major players in the financial systems of these countries. They fulfil an important role for the financial stability there and contribute not only to the development of the financial markets, in particular the banking markets, but also to the overall economic development of these countries.

We conclude that foreign banks promote efficiency in local banking systems. They improve the financial stability of the host country in the way that they provide stable source of credit and thus making the financial sector more stable in time of crises. Foreign banks help also to improve quality, pricing and availability of financial services - directly as providers of these services and indirectly through increased competition. Their presence intensifies competition in the domestic banking markets that results again in improved efficiency and quality of financial infrastructures. Foreign banks may stimulate better regulation and supervision and thus contributing to improved quality of banking operations of domestic banks, and may even attract foreign direct investments. Host countries can benefit from technology transfer, better banking practices and know-how, innovations in products and processes that foreign banks implement. All these spill-over effects contribute to more efficient domestic banking practices, which, in turn, may accelerate economic development and enhance economic growth in these countries.

Well developed financial sector affects economic growth in the way that it increases investments, reduces transaction costs, stimulates capital formation, alters the saving rate and thus promoting or declining savings, and enhances economic efficiency. We argue that if this consensus that financial development and efficient financial sector influence economic growth holds true, prudent foreign banks with long-term regional commitment doing just that will also contribute to economic growth. Both direct channels (price, volume and institutional) as well as indirect channels (e.g. signalling) were identified through which foreign banks contribute to economic growth and stability. More empirical research is necessary to verify these channels.

## **Abstract**

*Banks in financial systems, specially in thin one, like as the financial system in Bosnia and Herzegovina (BH), have an important role in financial intermediation between creditors and debtors, implementation of monetary policy and improvement and growth of financial market (money market). Financial system of Bosnia and Herzegovina is “bank dominated” system, which means that in financial system dominated banks (credit institution). For that reason it is an important that financial regulation and supervision conduct in order to enhance a stability promotion and a soundness of the financial sector. Bosnia and Herzegovina is the country, which has a complex social order. Dayton Peace Agreement from 1995, has been organized this country in two entities and in one district. In Bosnia and Herzegovina regulation and supervision of banks has been implemented by the Banking Agencies from two entities, the one in the Federation of Bosnia and Herzegovina (FBiH) and the other in the Republic of Srpska (RS). They conduct financial regulation and supervision in the name of the entities and they are independent in the conduct of financial supervision on territory of their entities. Because of current situation it's vary important to improve organizational structure of bank's regulation and supervision and make good quality system of regulation and supervision unique for complete banking system which is the base of the BH financial system.*

**Keywords:** bank, regulation, separate entities regulation, reform, new organizational structure;

## 1. Introduction

Banks in financial systems, specially in thin one, like as the financial system in Bosnia and Herzegovina (BH), have an important role in financial intermediation between creditors and debtors, implementation of monetary policy and improvement and growth of financial market (money market). Financial system of Bosnia and Herzegovina is “bank dominated”. In table 1 we will show number of banks and assets of banking system through last five years in Bosnia and Herzegovina.

**Table 1 Number of banks and assets of banks in Bosnia and Herzegovina**

	<b>2000</b>	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2004</b>
<i>Number of banks</i>	55	48	40	37	33
<i>Assets (in millions EUR)</i>	2187,2	2858,9	3253,8	3942,6	4820,4
<i>Assets of banks in GDP</i>	31,7%	41,4%	47,4%	57,2%	71,8%

Source: Author's calculation.

Because of special nature of banking and banking contracts, regulators have imposed numerous restrictions on their products and geographic activities. Failure to provide these services or breakdown in their efficient provision can be costly to both ultimate source (household) and users (firms) of saving.

---

<sup>1</sup> Bosnia and Herzegovina have two public pension funds on entities level and soon we expected to start reform of that system.

For that reason it is very important to create and continually improve good bank's system of regulation. Financial regulation and supervision is conducted in order: to enhance a stability promotion and a soundness of the financial sector, reduce risks in the financial system to enhance transparency of the financial sector and contribute to the prevention of abuse of the financial sector for criminal purposes.

Banks demand deposits, but depositors, as bank's creditors must have confidence that their money is in safe hands. Banks left to their in free banking market will not produce their financial products and services in an efficient manner and the lowest possible cost. Reasons that justify regulation and supervision of bank are: moral hazard, asymmetric information, competition, and monopoly.

Moral hazard is the name given to one kind of risk, which presents possibility that one party in a contract can change their behaviour to the detriment of the other party once the contract, has been concluded. In banking system moral hazard is the risk that banks will engage in activities that are undesirable (immoral) for lenders (depositors).<sup>2</sup>

Problems or the biggest cost which one person can has in process of ensured informations, which need for make business decision, we call asymmetric information. For that reason depositors can't evaluate soundness and security other banks in banking system, as they can evaluate economics effects in make business with that banks.

If a bank or group of banks has monopoly position in that case they can use theirs monopoly position for making monopoly profits on banking market. For that is important that banks have to comply with financial rules and supervisory requirements. Bank's regulation must give answers on next questions:

1. Who is responsible for bank's regulation?
2. Which are relevant source of lows regulation?
3. What are aims of regulation system?
4. Is system of bank's regulation sound and stabile?
5. Is system of bank's regulation effective?
6. Are there problems in system of regulation and how to solved it?

Answers to those questions can give the mark for organizational structure's quality, capability and possibility that system realizes aims of regulation. There are numerous aims in system of regulation, but we will give only the most important of them:

---

<sup>2</sup> Mishkin, S. F. The Economics of Money, Banking and Financial Markets, 7th ed., Person Addison-Wesley, Boston, USA, 2004, pp. 181

1. safety of banking system
2. soundness and competitive of banking system
3. consumer protection
4. economic efficiency
5. market structure and competition
6. credit allocation
7. monetary control.

Banking system is sound and safety if banks, which represent parts of banking system, are sounded and safety. In front of bank's supervisors, there is a need for supervision and control size of bank's risks exposure. Supervision is oriented in this case on control procedures for managing of bank's risks and an internal control. Specially, it is important to make clear is one bank able to manage with its risks.

Second goal is a consumer protection, which is an active part in bank's credit business as in deposits business and business with transactions accounts. Regulators must give possibilities to formulate and implement laws about consumer protections from bank's credit discrimination through insuring equal credit possibilities to all consumers, abolished inappropriate credit's costs (different kind of provisions) or interest rate in negotiate in credit business or taking deposits and services electronic fund transfers.

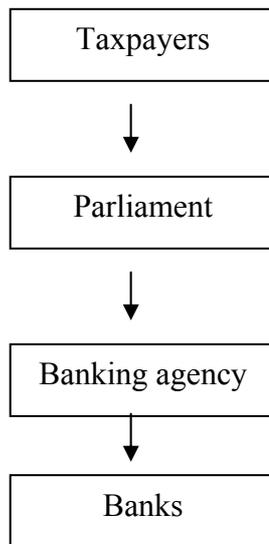

Bank's technical efficiency means giving services with a small possible costs looking in the term of social funds, which are used, in giving services. For banks, we can say that they have allocation efficiency when they form prices for their products on the level of their marginal costs.<sup>3</sup>

Regulation of banks must take in account conflicts aims in banking business, bank's safety and soundness on the one side and efficiency of banking system on the other. We can say how regulation's aim minimizes banks' exposure to the risks in their business (unsystematic risk). Also for regulators are important isolating banks failures to avoid a domino effect within the system (systematic risk). Regularly, country's Parliament represents legal representative of tax's payers (their citizens), supervise bank's regulators which now supervise banks in insurance deposits system. From this fact we can derivate principal – agent model of bank's supervision, which we can shows in figure 1.

---

<sup>3</sup> Miler, R. L., Van Hoose, D.D. Modern Money and Banking, Mate, Zagreb, 1997, pp. 229

**Figure 1 Principal – agent model of bank’s supervision**

*Source: Sinkey, J. Commercial Bank Financial Management, Prentice Hall, New Jersey, 2002. pp. 560*

From figure 1 is clear that voters or taxpayers citizens elect Parliament, which makes banking laws, confirms and supervise regulators and deposit insurers. Regulators and deposit insurers than regulate, supervise, insure, and examine depository institutions.

## **2. Banking system in Bosnia and Herzegovina – their characteristics**

Banking system of Bosnia and Herzegovina present Central Bank of Bosnia and Herzegovina, entities banking agencies and commercial banks, which have been existed in two separate banking, sector, Federation of Bosnia and Herzegovina and Republic of Srpska. In this part of the paper we will say something about characteristics of banking system and rule of CBBH in that banking system.

In Bosnia and Herzegovina operate 33 banks. From that number 75% are in foreign private ownership. Banks of Bosnia and Herzegovina like as banks in other transitional countries pass through fazes of banking crises, capitalization and privatisation. Process of globalisation increases performances of banks. In first place we think on diversification of banking

products and services, involved new media as Internet in delivery system of banks and increasing quality of bank's services.

**Table 3 Balance sheet of banking system of Bosnia and Herzegovina at the end of 2004. (000 Euro)**

Assets		Liabilities	
Money assets	1.702.750	Deposits	3.544.669
Securities	13.067	Loans from other banks	1.707
Placements in other banks	56.515	Loans payable	464.063
Loans - net	2.676.021	Other liabilities	201.235
Premises and other assets	210.692	Capital	566.523
Other assets	119.152		

*Source: Authors calculation.*

Major position in banks' liability are deposits, while in banks' assets dominant credits. Share of investment in total value of bank's balance sheet is small. That situation is result of undeveloped money market and existed orthodox currency board. Today commercial banks are one of creators of money as important component of money supply process. For that reason it is important regulate and supervise banks.

### ***2.1 Role of Central Bank of Bosnia and Herzegovina***

Parliament of Bosnia and Herzegovina 1997 established central bank of Bosnia and Herzegovina (CBBH). With aim to formulating and implementing monetary policy CBBH don't have possibility to manage with monetary policy instruments in relation to other central banks. Reason for that position of CBBH is pure (orthodox) currency board system. A currency board is a monetary institution that issues notes and coins fully backed by a foreign "reserve" currency and fully convertible into the reserve currency at a fixed rate and on demand. The reserve currency is a convertible foreign currency or a commodity chosen for its expected stability. The country that issues the reserve currency is called the reserve country. Table 3 lists differences between currency board and a typical central bank.

**Table 3 Differences between typical currency board and central bank**

<b>Typical currency board</b>	<b>Typical central bank</b>
Usually supplies notes and coins only	Supplies notes, coins, and deposits
Fixed exchange rate with reserve currency	Pegged or floating exchange rate
Foreign reserves of 100 per cent	Variable foreign reserves
Full convertibility	Limited convertibility
Rule-bound monetary policy	Discretionary monetary policy
Not a lender of last resort	Lender of last resort
Does not regulate commercial banks	Often regulates commercial banks
Transparent	Opaque
Protected from political pressure	Politicised
High credibility	Low credibility
Earns seigniorage only from interest	Earns seigniorage from interest and inflation
Cannot create inflation	Can create inflation
Cannot finance spending by domestic government	Can finance spending by domestic government
Requires no "preconditions" for monetary reform	Requires "preconditions" for monetary reform
Rapid monetary reform	Slow monetary reform

*Source: Hanke, S., Schuler, K., Currency Board for Developing Countries – A Handbook, Institute for Contemporary Studies, San Francisco, USA, 1994, Access from <http://www.users.erols.com/kurrency/icegrev.html>*

For our analyse of bank regulation it is clear that CBBH don't have possibility to regulate and supervise their banking and financial system.

### **2.1.1 Mission and goals of Central bank of Bosnia and Herzegovina**

The main goals and tasks of the Central Bank are defined by the Law and in accordance with the General Peace Agreement in Bosnia and Herzegovina. Central Bank of Bosnia and Herzegovina maintains monetary stability by issuing domestic currency according to the Currency Board arrangement with full coverage in freely convertible foreign exchange funds under fixed

exchange rate 1 KM: 0,51129 euro. CBBH have must achieve the stability of domestic currency. The basic tasks of CBBH are:<sup>4</sup>

1. formulate, adopt, and control the monetary policy of Bosnia and Herzegovina
2. hold and manage the official foreign exchange reserves of the central bank in a safe and profitable way
3. support and maintains appropriate payment and settlement systems
4. co-ordinate the activities of the BH Entity Banking Agencies which are in charge of bank licensing and supervision.

### **3. Organisational structure of bank's regulation system in Bosnia and Herzegovina**

Bosnia and Herzegovina is the country, which has a complex social order. Dayton Peace Agreement from 1995. has been organized this country in two entities and in one district. In Bosnia and Herzegovina regulation and supervision of banks has been implemented by the Banking Agencies from two entities, the one in the Federation of Bosnia and Herzegovina (FBiH) and the other in the Republic of Srpska (RS).<sup>5</sup> They conduct financial regulation and supervision in the name of the entities and they are independent in the conduct of financial supervision (figure 1). The main tasks of entities agencies, determined by the Law, are:

1. issuing licenses for establishment and performance of banks,
2. issuing licenses for changes of the organizational structure of banks,
3. issuing approvals for appointment of their managing staff,
4. issuing licenses for performing internal payment system,
5. collecting, processing and recording data submitted to agency by banks in accordance with the regulations,
6. supervising banking operations and undertaking appropriate measures in accordance with the Law on Banks, the Law on the Banking Agency and regulations,

---

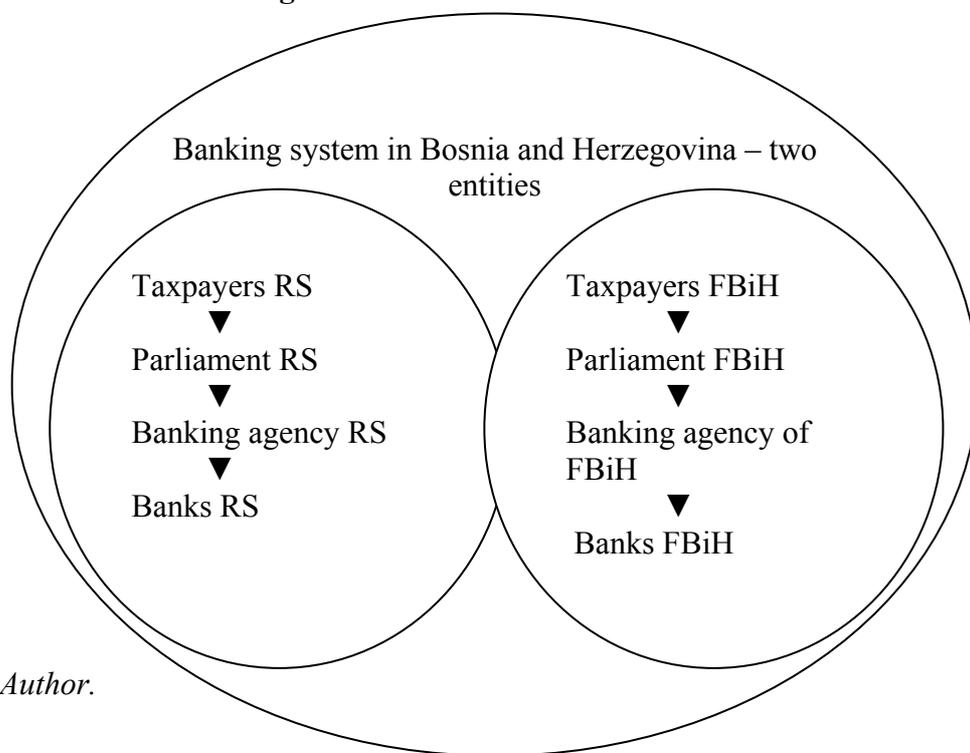

<sup>4</sup> Law of Central Bank of Bosnia and Herzegovina, The Official Gazette, No. 1., 1997.

<sup>5</sup> Law in the Banking Agency of the Federation of Bosnia and Herzegovina, the Official Gazette No. 9/96, 27/98, 20/00 and 45/00; The Law on Banking Agency of Republic Srpska, the Official Gazette of Republic Srpska No. 10/98, 16/00, 18/01, 71/02, 18/03, and 39/03.

7. initiating, managing and supervising the procedure of provisional administration, liquidation, bankruptcy, and rehabilitation of banks,
8. revoking banking licenses in accordance with the Law,
9. issuing decisions regulating banks work,
10. performing evaluation of conditions and issuing approvals to banks regarding new issues of shares, etc.

Practically Bosnia and Herzegovina has got a dual and a separate system of banking regulation and supervision on entities level. It is possible, that in this situation, two separate and independent agencies can bring different roles for the regulation and procedures in bank's supervision.

**Figure 2 Dual principal – agent model of regulation and supervision in Bosnia and Herzegovina**

*Source: Author.*

Bosnia and Herzegovina today has got two valid bank's law<sup>6</sup> and also two supervision's procedures.<sup>7</sup> Impossibility to provide the regulation an

---

<sup>6</sup> Low on Banks, the FBH Official Gazette No. 39/98, 32/00; Low on RS Banks, the Official Gazette of RS No. 44/03.

bank's supervision through all territory of the state is the biggest problems because the entity's agencies has been charged to make it only on their own territory. Banking system in Bosnia and Herzegovina is the single system (political impact on work in the entities agencies, majority of large banks are doing business over the entire territory of country through networks of branches, the degree of the foreign ownership in the BH banking system is extremely high and it is necessary for BH to continue the adoption of the international standards in the supervision domain).

So, how to regulate banks which make business through all the territory of state? The Central bank of Bosnia and Herzegovina doesn't have an impact on the regulation and supervision of banks in the country because of the existed currency board in the monetary system. How to find than a solution for these problems in system of regulation and supervision?

#### **4. Organizational structures of regulation systems in the world**

For this purpose we shall make comparison between both the characteristics of the BH regulation system and the characteristics of the systems in other countries. Selected countries are countries with currency boards and countries with central banks. In the United States, the Federal Reserve makes regulation and supervision, but the Office of the Comptroller of the Currency (OCC), the FDIC, and an individual state banking departments also supervise banks. In Germany, the Bundesbank collects and processes banking information, even though the Federal Banking Supervisory Office (FBSO) is the primary regulator, and private accounting firms are responsible for most of the on-site supervision. In Japan, the Ministry of Finance is the chief regulator, but it alternates on-site inspections with the Bank of Japan. It is clear that in different models of organize structures exist in bank's regulation and supervision and financial systems. In the United Kingdom operate Financial Services Authority, which supervised all financial institution in the country. Estonia has the same system like the United Kingdom in supervision but regulating of banks is role of Central bank of Estonia. Only, the National Bank of Lithuania regulates and supervises banks in its country.

---

<sup>7</sup> Decision on Minimum Standards for Bank's Capital Management, Decision on Minimum Standards for Bank's Credit Risk Management and Assets Classification, Decision on Minimum Standards for Bank's Risk Concentration Management, Decision on Minimum Standards for Documenting Bank's Lending Activities Criteria for Internal Bank rating by the Banking Agency of entities agencies, Instruction for Preparation of Bank's Balance Sheets and Supporting Forms etc.

According to table 4 we can see how in selected countries there are also different organizational structures of bank's regulation systems. Function of regulation and supervision make central banks, independent banking agency under central bank hand, or we can talk about combination of these two structures.

In some countries there are centralize regulation's systems which supervise all financial activities (England, Estonia). There are two independent banking agencies in Bosnia and Herzegovina which present inappropriate supervision's organizational structure in consideration on the fact that these two agencies can make regulation and supervision only on it's territory – territory of entities in which agencies have it's location.

In continuous attempting countries of region to come closely European Union they faced with need of permanent adaptation to "acquis communautaire" EU in banking regulation and supervision. European Central Bank with euro system systematically supervises structural and cyclical changes in euro era/banking system of EU and the other financial sectors. Aim of these activities is:

1. protection financial system
2. increasing sensitivity on possible socks in financial sector.

**Table 4 Comparison characteristics of regulation system Bosnia and Herzegovina and systems of regulation selected countries**

Countries	Croatia	England	Estonia	Lithuania	Hong Kong	Bosnia and Herzegovina
Regulators/Supervisors	Croatian National Bank  Sector for regulation and supervise	Financial Services Authority  Independent nongovernmental body	Financial Supervision Authority  Finantsinspektsioon  Independent nongovernmental body it operate in coordination with central bank	Central bank of Republic Lithuania	Hong Kong Monetary Authority	1. Banking Agency of Federation Bosnia and Herzegovina FBA,  2. Banking Agency of Republic Srpska ABRS
Institutions under supervision	banks	Credit institutions – banks, insurance companies, investment company, financial markets, pension fund.	Credit institutions – banks, insurance companies, investment company, financial markets, pension fund.	Credit institutions – banks, other legal entities and subsidiary foreign credit institutions which operate on license issued at central bank	authorized institutions: licensed banks, restricted license banks, deposit-taking companies	FBA supervise commercial banks in Federation Bosnia and Herzegovina,  ABRS supervise commercial banks in Republic Srpska
Issuing licenses for establishment and performance of banks	yes	yes	no	yes	yes	yes
Regulation and supervision	yes	yes	yes	yes	yes	yes
Cooperation with other supervisors	yes	yes	yes	yes	yes	yes

## **5. Possible new organizational structures of banks' regulation system in Bosnia and Herzegovina**

Bosnia and Herzegovina must reorganize the banks' regulation and supervision system. There are two possible solutions:

1. establish unique Banking Agency on state level for regulation and supervision of all banks in Bosnia and Herzegovina which will be coordinated with Central bank of Bosnia and Herzegovina (umbrella system) or
2. function of regulation of banks remove from the entities banking agencies to the Central bank of Bosnia and Herzegovina, on that way the process of regulation and supervision of banks in Bosnia and Herzegovina will be closer to practice in other transitional countries and European Union.

The financial system of Bosnia and Herzegovina is so thin and isn't realistic to expect establishing unique supervision on all financial institutions in the financial system but it's important to make good quality system of regulation and supervision on banking system which is the base of the BH financial system.

Advantages of integrated model of regulation banking system on all territory of Bosnia and Herzegovina are:

1. possibility of regulation and supervision banks on all territory of Bosnia and Herzegovina
2. economies of scale
3. economies of scope (one database, unique roles and procedures for all banking system)
4. increase supervisory accountability.

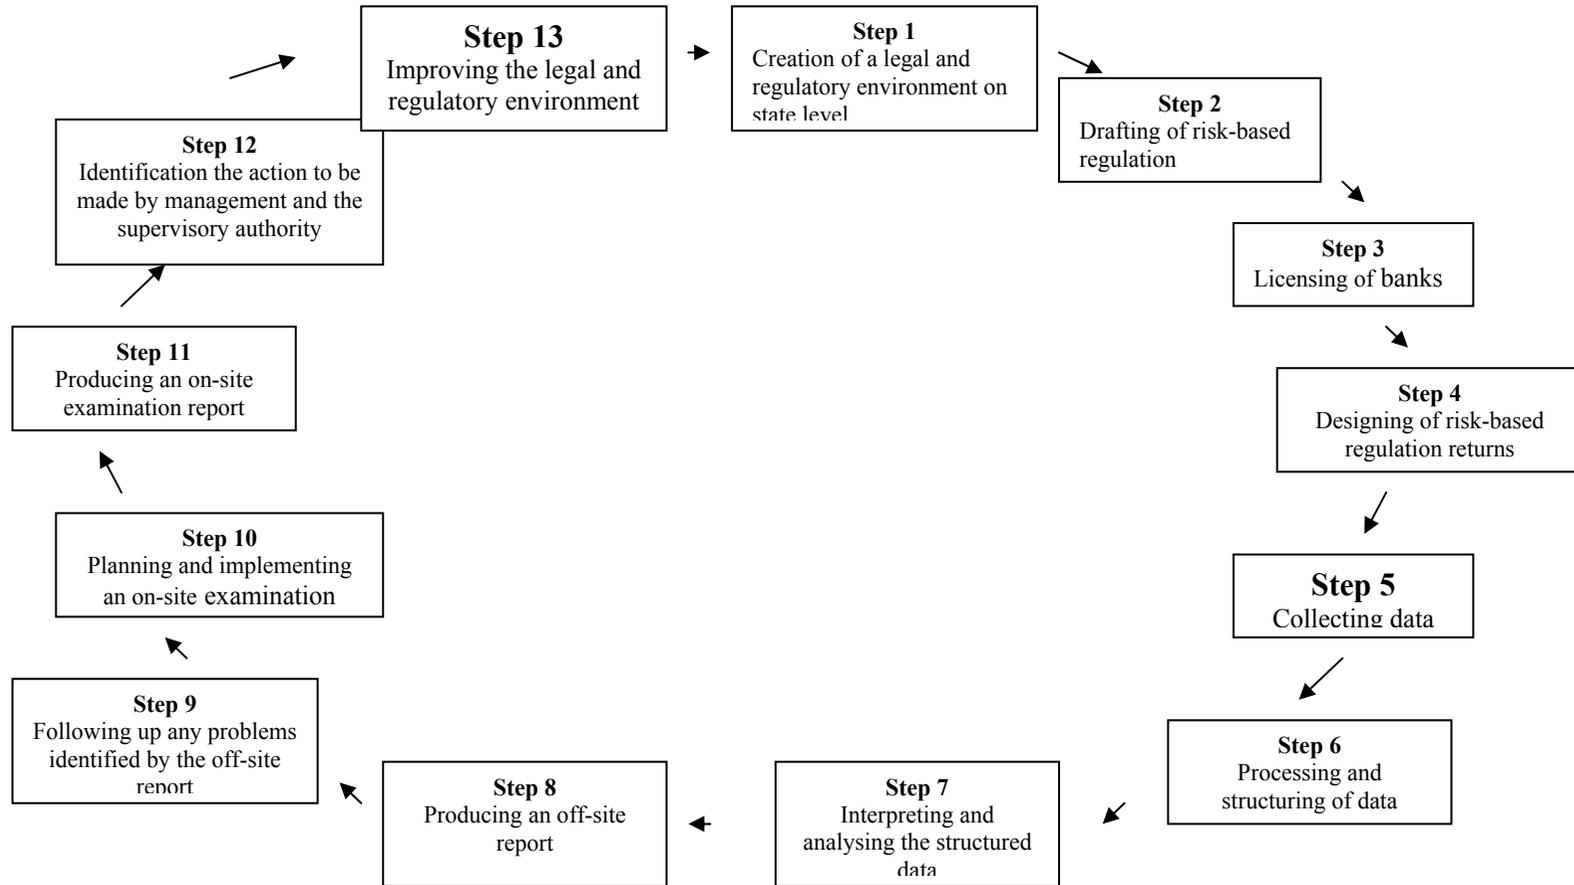

Typical problems in establishing new organizational model of bank's regulation and supervision are:

1. legal constraints – entities governments must change legislations for each banking sector in Bosnia and Herzegovina (bank's laws, laws of banking agencies) which regulate banking
2. departures of experienced personnel – reallocation of personnel and define new roles
3. create integrate IT system, network for new model
4. demoralization of staff of the merged entities
5. identification of strategy plan, mission and aims in new organizational model
6. budgetary problems.

For those showed models of possible organizational forms in regulation and supervision system Bosnia and Herzegovina must have political consent between political parties of two BH entities.

Unique system of regulation and supervision for banks and their branches and affiliates on territory of Bosnia and Herzegovina without barriers on entities level demand unique stage whereby the results of one stage serve as inputs of the next. The final aim of this process is safe, sound, and properly functioning financial intermediation. Figure 3. summarizes the stages of regulation and supervision process.

**Figure 3 The stages of unique bank' supervision and regulation in Bosnia and Herzegovina**

*Source: adopted from Greuning, H., Brajović, S., Analyzing and Managing Banking Risk, The World Bank, Washington, USA, pp. 300*

## 6. Conclusion

Banking industry a recent years in Bosnia and Herzegovina has experienced change. Banks have much more flexibility on the service, which they offer. Many banks offer new services to their clients, banks expanded across the country by opening new branches or making acquisition in an attempt to use their resources efficiently. Those changes in the banking industry of Bosnia and Herzegovina are normal trends for the banks in the world.

But on the other side in Bosnia and Herzegovina the system of banks' regulation and supervision isn't appropriate. In Bosnia and Herzegovina there has been existed two separate and independent entities banking agency while don't exist a regulator for complete banking system on all territory of Bosnia and Herzegovina. Existing organizational structure of bank' regulation and supervision make problems as: two separate regulation systems, two different banking laws, two different supervision procedures and etc. All these problems force authorities to make reorganization of banks' regulation and supervision system.

There are two possible solutions: establish unique Banking Agency on state level for regulation and supervision of all banks in Bosnia and Herzegovina which will be coordinated with Central bank of Bosnia and Herzegovina (umbrella system) or function of regulation of banks remove from the entities banking agencies to the Central bank of Bosnia and Herzegovina. Both models for their implementation need change in legislations, IT systems and solution of problem in financing new organization structures. Political consent of major political parties in Bosnia and Herzegovina is also important.

## **Abstract**

*The aim of this paper is to define the main differences in the balance sheet structure of failed banks and operating banks in the Czech Republic. The analysis was provided on data from balance sheets and profit and loss statements that were published in the bank's annual reports since 1995. Only universal commercial banks in the Czech Republic are the subjects of conducted research. The selected banks are divided into two groups – failed banks and operating banks. The analysis is aimed at financial relations of the banks with other banks (characterized by two balance's items: receivables from banks and liabilities to banks). In the next step the analysis focuses on financial relations of the banks to clients (characterized by two balance's items: receivables from clients and liabilities to clients). The main differences in a structure of assets and structure of liabilities are defined and graphically interpreted in this paper. The recommendations concerning the balance sheet structure of the analyzed banks are the main result of provided research.*

**Keywords:** bank, assets, liabilities

## 1. Introduction

The monitoring of our banks' economical situation was increased when the Czech Republic joined the common market of the European Union. Billions Czech crowns flow through our banking sector. Many banks were in financial lost and huge sums of non quality receivables were taken to the Czech consolidation agency in spite of this fact. Why? We can find the answers in the banks' economical figures.

## 2. The steps of analysis

The analysis was based on data from balance sheets and profit and loss statements which were published in the bank's annual reports since 1995. Only universal commercial banks in the Czech Republic are the subjects of conducted research. We are not considering the subsidiaries of foreign banks and the specialized institutions: the mortgage banks and the Českomoravská záruční a rozvojová banka, Česká exportní banka and the former Konsolidační banka. Only universal commercial banks, which are significantly focused on the offer of all types of commercial and investment products, are subject of our interest. We do not take into consideration the specialized banks which have a little different object of activity, the purpose of existence and the gain of the financial resources.

Another step was distribution of the banks into two groups - failed banks (the banks which bankrupted in the period 1995 – 2004) and operating banks (the banks which are still running). We considered following total number of banks, number of operating and failed banks in the individual years of analysis.

**Table 1 The number of banks considered in the analysis**

	1995	1996	1997	1998	1999	2000	2001	2002
Operating	16	17	19	19	18	17	15	15
Failed	20	8	7	5	4	2	0	0
Total	36	25	26	24	22	19	15	15

*Source: Author's calculation based on the facts from the Bank supervision of CNB*

We recalculated the data included in balance sheet on the percentage values for every bank in the next step. The percentage value shows the share each balance sheet item on the assets and on the liabilities. We calculated the arithmetic average for both groups operating and failed banks for each year considered in the analysis from percentage values. We have data from failed

banks until 2000. The licenses of the Plzeňská banka and the Union banka were taken away in 2003 but the balance sheet data are not public accessible in 2001 and 2002. We operate with these calculated data in this paper.

### **3. Presentation of results**

We show the most substantial differences between failed banks and operating banks during analyzed years at first. It is especially about the business with banks and non financial clients. It is valid for following text where we consider the average values for operating banks and the average values for failed banks in each year.

#### ***3.1 The relation to other banks***

The most substantial differences in the balance sheet structure between operating and failed banks are shown in the items which express the relation to other banks in the banking sector. It is about the receivables from banks in assets and about the liabilities to banks in liabilities.

The difference between average operating bank and average failed banks fluctuates in individual years in the interval 10 – 30 % in case of the share of receivables from banks on assets. The lower difference is shown in the last analysis years. The difference is even more in interval 20 – 35 % in case of the share of liabilities to banks. Here it is valid that this difference is raising during analyzed years.

It is valid that operating banks used as the source of financing the deposit from other banks in bigger scale. In other words some banks deposited their free financial sources to these operating banks. The higher trustworthiness of these banks on the interbank market can be the reason of it. And it is valid that the operating banks deposited a bigger amount of their free financial sources at the small risk rate to other banks than failed banks at the same time. So their behavior was more cautious.

We show the development of the proportion by the liabilities to banks in detail. The values of this indicator for operating banks are influenced by a big measure by the foreign banks values. Approximately the half of them had their sources made by more than 50 % by liabilities to banks till the year 1998 and the rest of the banks from this group usually did not drop under the 30 % boundary in values of this indicator. The change in banks' behavior has come since the year 1999.

The banks started to rid their deposits from other banks and tried to invest their free financial sources into the more profitable instruments. The

result is that the proportion between liabilities to banks and liabilities is under 20 % by majority of banks from this subgroup of operating banks till the end of the year 2002.

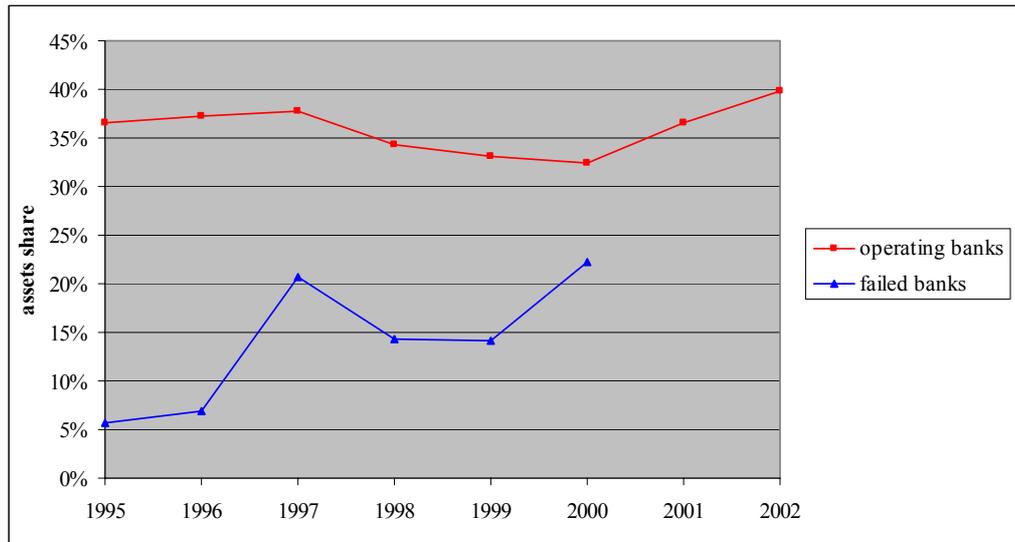

This proportion fluctuated by big banks till the year 1999 (by KB - except one year - usually slightly above 20 %, by CSOB about 30 % and by ČS between 8,5 and 12,5 % - the saving tradition of this institution was shown there). Since the year 2000 we can see the same trend as by the previous subgroup of international banks in the process the proportion decreasing of the liabilities to the banks to the liabilities. One of the most important reasons for it was the decrease of the interest rate. Till the end of the year 2002 these banks hold the deposit from other banks in the level of 5 – 8 % of the liabilities.

In the group of failed banks is clear the trend of decreasing the proportion of the liabilities to the banks thereby how this group bank gradually comes near to bankruptcy. This trend is confirm by the biggest bank from this group – IPB, whose value of the indicator dropped from 29,3 % in the year 1995 to 8,2 % in the year 1999, and further The Union banka (from 22,4 to 5,7 % in the year 2000). The special case is the Plzeňská banka which in last four years did not have any liabilities to the banks this means its indicator was 0 %. The majority of these banks from this group were moving around the average value as mentioned in the graph. The exceptions when the banks had more significant proportion were following: Česká banka and Realitbanka in the year 1995 (54,7 % and 42 %), Zemská bank in the year 1996 (69,9 %) and Pragobanka in the year 1996 and 1997 (25 % and 23,7 %).

From above mentioned it is clear that the bankrupting banks are less engaged in the interbank market. The cause can be that on the interbank market the banks' troubles can be seen usually much earlier than the public is informed and for other banks are these banks aiming to the bankruptcy less trustworthy than other banks.

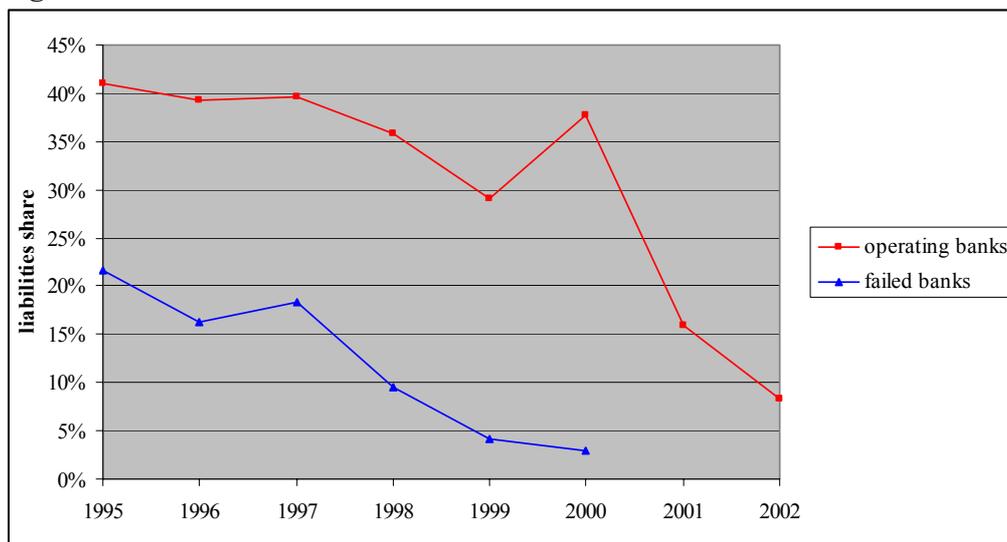

The average values for both these items for given groups of banks are shown in the following graphs.

**Figure 1 Receivables from banks**

Source: Author's calculation

**Figure 2 Liabilities to banks**

Source: Author's calculation

### **3.2 The relationship to the clients**

In this view is shown the more significant difference especially by the liabilities to the clients – this is the clients' deposits by banks. The significant differences between the properly operating and the failed bank in the interval

17 – 35 % are demonstrated till the year 1998. We can explain this by important fact that until this year almost all small banks bankrupted. These banks attracted their clients on the high deposit interest rate. In the year 1999 we have in our analyses just four failed banks, where the Haná Banka had restricted its banking activity and this indicator was just 0,01 %. The indicator for the Plzeňská banka was moving lower than by the properly operating banks and the rest of two failed banks also confirmed their addiction to the clients' deposits (the proportion on the liabilities by the IPB was 68,8 % and by the Union banka was 74,3 %).

On the example of properly operating banks was clearly displayed the trend of the moderate decrease the deposit's proportion on the banks liabilities around 35 % at the first four years and than again the change in the trend and the value of this indicator grew significantly to 60 % in the year 2002. It is valid that some banks achieve up to 70 % of value and the average is put down by banks which put the attention in bigger amount than other banks to the investment banking. In this group the biggest proportion show big Czech banks which traditionally collected the deposits from the petty savers. The lower values are caused by the international banks which did not promise high deposit interest rate as the failed banks.

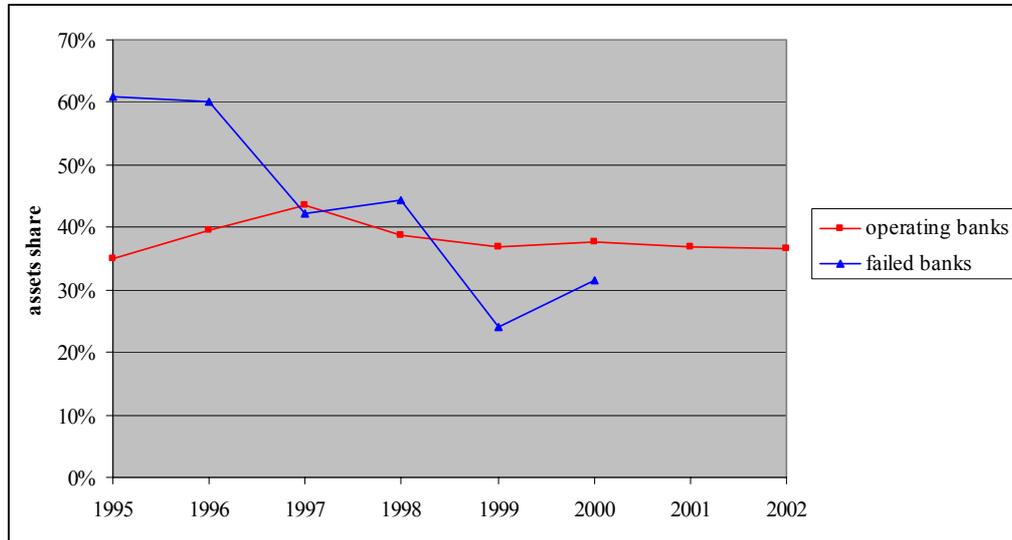

By the receivables from clients is the situation not so simple. During the first two years (1995 -1996) the clients' liabilities by failed banks formed the more significant proportion on the assets than by the properly operating banks. It was again given by a broader being of smaller banks which have to earn to pay the promised higher deposit interest rate by higher and more danger grand of liabilities which was finally fateful for these banks. In the years 1997 – 1998 are the values for both groups in facts similar and in another two years there are lower than by operating banks. This value is very much influenced by existing only four banks near bankruptcy in 1997-98 and only two banks near bankruptcy in the next period, very low amount of given or we can better say not given amount of the liabilities, the liabilities from the Banka Haná (0 % proportion on the liabilities) and the Plzeňská banka (2 %, like 1,6 % proportion on the liabilities). The rest of the failed banks had this indicator higher (IPB around 46 % and the Union banka around 60 % in both years).

As it was mentioned above, it is clear, that the failed banks got involved into the business with non financial clients. Partly they comprised for them the relative higher source of finance than for the operating banks, which searched for the finance at the beginning years of the analysis on the non banking market. In the last years they get more and more involved into the retail banking service, from which flows small individual yield but it is multiplied by the high amount of clients. From the perspective of the

receivables from the clients can be seen, except that the explained exceptions, the relatively higher amount of given liabilities to the liabilities by the failed banks than by the operating banks. The cause was especially the necessity to gain the sufficient finance to pay the promised interest deposit rate.

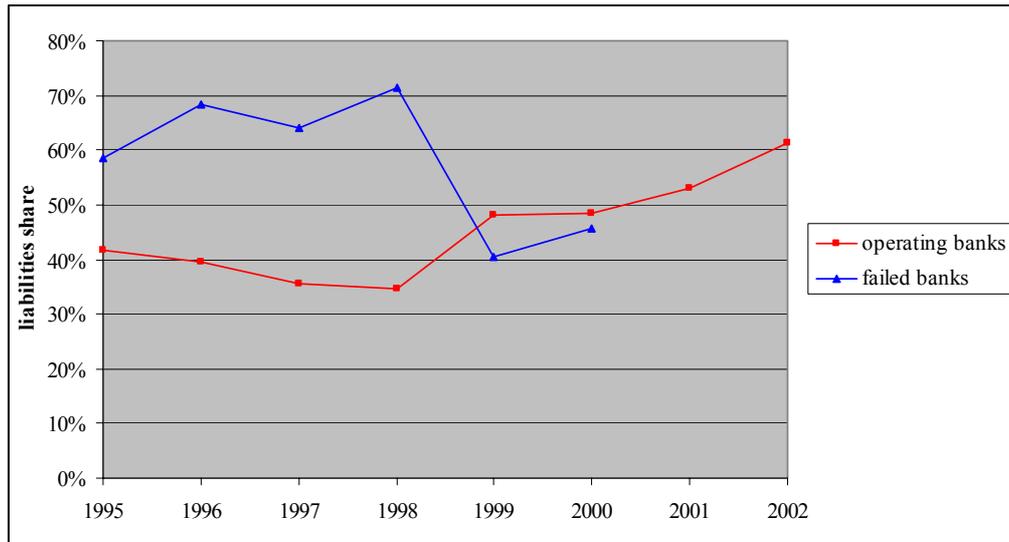

As a summary there are shown the characterized values in following graphs.

**Figure 3 Receivables from clients**

*Source: Author's calculation*

**Figure 4 Liabilities to clients**

*Source: Author's calculation*

### **3.3 Other differences**

Now we will show briefly other differences between the operating and failed banks. The first difference is the proportion size of the registered capital, which is one of the significant component of the own capital in the liabilities.

By operating banks is the course simple. The average value of this proportion is still around 4 % boundary, while by the failed banks it is more above 10 % boundary and in the last two years even around 45 %. These values are influenced by a small amount of failed banks again and the extreme high values by the Plzeňská banka (82 %) and the Haná banka (106 %), which sign their very low productivity.

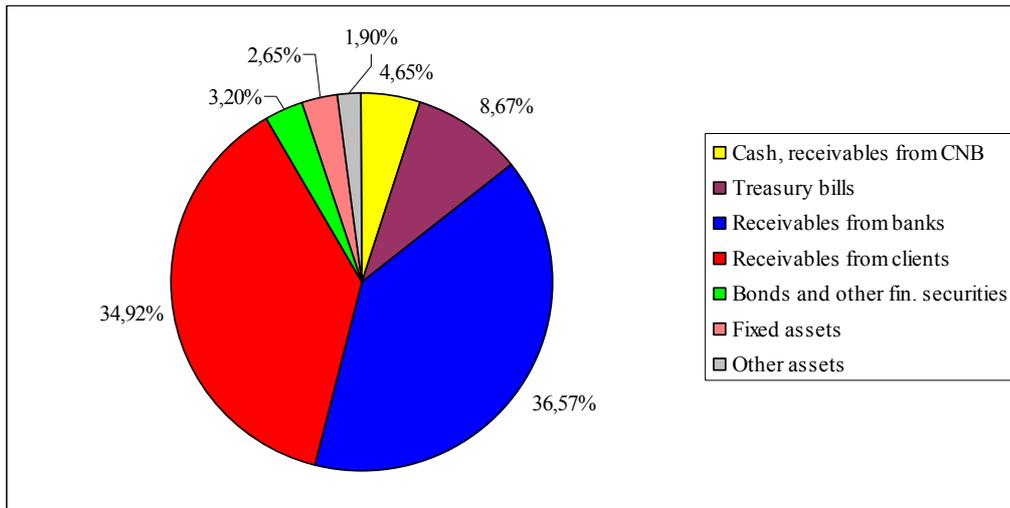

About the differences in this indicator we can say that the failed banks show in average this proportion higher, which present a higher security at the first view but on the other hand the own capital is more expensive than the foreign capital. For sure we have to mention that all banks had to fulfill the safety policy of the Czech National Bank (CNB) and this is the capital adequacy (this means the minimum proportion of own and another specified capital to the risk assets).

The final statement of above mentioned differences is the profit proportion to the liabilities, which is by the failed banks in the years 1995 – 1998 significantly lower than by operating banks and in the first three years it even assumed the minus values. In the last two analyzed years the values for

operating and failed banks evened due to moderate consolidation of the failed banks and due to the fact that the big amount of problematic banks went to bankrupt already.

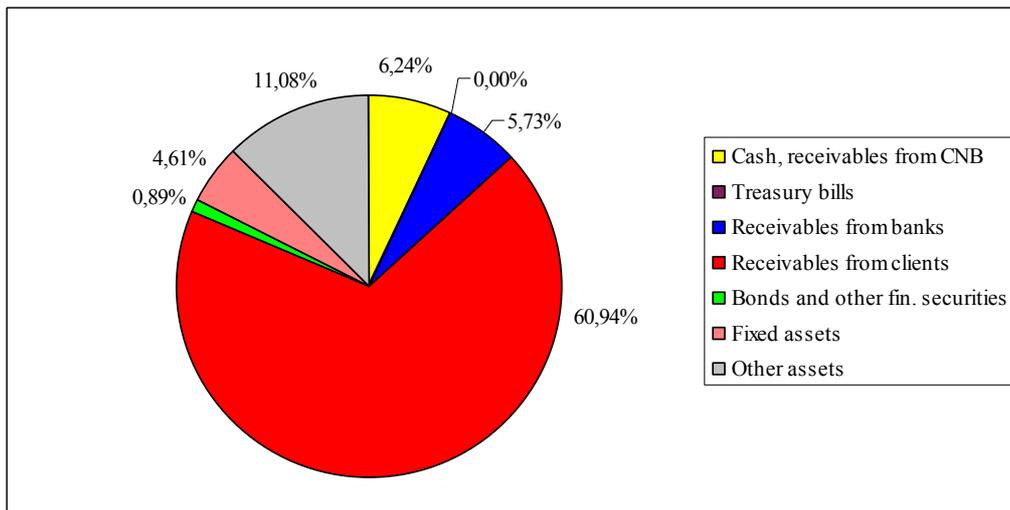

For clearness there are shown the graphs which are showing the structure of balance sheets of the failed and the ordinary operating banks in the year 1995. This year was chosen as an example from this reason, that in this year we have available the highest amount of facts about failed banks. The following graphs confirm clearly the conclusions made above. More to these facts, there is a higher danger by the failed banks which did not buy the short and long term state securities. On the site of the liabilities we mention that by the failed bank the proportion on the earnings to the liabilities goes to the minus value, this is minus 2,47 %.

*Source: Author's calculation*

**Figure 7 Liabilities structure of operating banks**

*Source: Author's calculation*

**Figure 8 Liabilities structure of failed banks**

*Source: Author's calculation*

## **4. Conclusion**

We proved that during last years there were significant differences in the balance sheet structure between the failed and the operating banks. These differences are shown based on the average values that is why it is not possible by every individual indicator especially not for individual bank to conclude, whether the bank in short period will go bankrupt or not. The values for every bank are influenced by their strategic goals; this is for example according to the retail or investment bank's specification. Anyway we can consider the future development of individual bank based on the long term comparison of the balance sheet structure and all its main items partly in the time and partly with some comparable bank or the group of banks.

## **Abstract**

*The aim of this paper is to introduce the bank stability model based on discriminant analysis. The model is devised on the basis of financial indicators analysis of selected banking institutions based in the Czech Republic in the period from 1995 until 2003. The banks were divided into two groups – the group of operating banks and the group of bankrupted banks. This division was done according to the real development of the Czech banking sector based on data provided by the Czech National Bank. All banks providing services in the Czech Republic in the period of 1995- 2003 were analyzed in the model except for building societies (due to their different activities compared to commercial banks) and foreign bank's subsidiaries (strongly influenced by their foreign owners). Data for calculation of financial indicators was taken from bank's financial statements, i.e. from the balance sheet and profit and loss statement. Following financial indicators were used for the bank stability model: rentability to average level of assets, equity / liabilities, interest margin, profit/ margin, equity total /assets.*

**Keywords:** *bank, stability, financial indicators, discriminant analysis*

## 1. Introduction

The banking sector significantly influences economic subjects and its stability is therefore crucial for each economy. The Czech banking sector has seen a sharp development from velvet revolution since 1989. For example, big banks funded manager's leveraged buy-outs and accepted company shares, usually over-priced, as collateral for their loans. In related note, small banks were sometimes founded for financing allied companies or even for financing bank's managers. For these reasons, connection among Czech banks and enterprises was becoming stronger and stronger. Consequently, if a company went bust as a result of acting bank managers, banks posted lower recovery rates from the loans because of value-less collaterals in their portfolios.

Clearly, such conditions did not support company's restructuralization and resulted in losses in bank's books. Therefore plenty of banks went under in the Czech Republic in 1990's and hence the stability of the banking sector was destabilized and the trust of customers in banks dropped (for example collapses of Agrobanka, Union Banka, IPB etc.). It is indisputable that the stabilized banking sector has been built in the Czech Republic in a relatively short period. Despite some pitfalls, the progress towards a higher stability has been made mainly due to new IT technologies, higher-qualified stuff and know-how brought by foreign investors.

The article deals with creating a bank stability model based on the discriminatory analysis made on data obtained by the development of Czech banking sector in the period 1995-2003.<sup>1</sup>

## 2. The Selection of the Financial Indicators

The bank sector has seen fast development in the Czech Republic since 1989. During this development some banks, for various reasons, finished their activity and some of them are working nowadays. Therefore we can suppose that the unstable banks will show different values of financial indicators than the stable (healthy) ones.

The bank is stable if:

- it respects the rule of cautious banks entrepreneurships determined by the CNB;

---

<sup>1</sup>The Altman criteria for Czech banks cannot be used under original conditions, because these criteria were used for the U.S. environment that differs from the Czech one.

- it has not received any financial or other help nor from the state nor the Czech National Bank;
- the value of relevant financial indicators will be moving around the values of the group of stable banks.

The bank is unstable if:

- it was forced to finish its activity for reasons such as taking of the license or forced control or a bank which received any help from the state;
- the value of relevant financial indicators will be moving around the values of the group of the mean value unstable banks.

### ***2.1 Determination of Financial Indicators for Definition the Bank Stability Model***

When creating the bank stability model, it was necessary to choose the suitable financial indicators that are different for values of the stable and unstable banks and are uncorrelated at the same time. Using financial indicators varies both in the Czech (see Babouček [1] or Ziegler [23]) and the foreign literature (Golin [9]). Since data comes from the Czech banking sector, financial indicators have been chosen regarding the Czech market features, the Czech accounting standards and information disclosure of the Czech banks.

According to data availability in the Czech banking sector, the financial indicators were chosen.

First of all, we have chosen 9 financial indicators representing all groups of financial indicators.

For rentability analysis following indicators were used:

- return on average level of assets (ROAA);
- return on average level of equity (ROAE);
- interest margin;
- profit margin.

For assets and capital following indicators were taken:

- equity/liabilities;
- equity/total asset.

For loans and claims following indicators were used:

- provisions/total loans.

For liquidity following indicators were considered:

- liquid assets/total total assets;
- liquid assets/ short-term liabilities.

Regarding data availability the financial indicators for the stable banks in the period 1995 – 2003 and the financial indicators for the unstable banks in 1995 – 2000 (in 2001 and 2002 there were no banks without license or under forced administration). The Table 1 shows the number of both stable and unstable banks between 1995 and 2003. All banks providing services in the Czech Republic in the period of 1995 and 2003 were analyzed in the bank stability model except for building societies (due to their different activities compared to commercial banks) and foreign bank's subsidiaries (strongly influenced by their foreign owners).

**Table 1 The Development of Stable and Unstable Banks in the Period 1995 – 2003**

Year	1995	1996	1997	1998	1999	2000	2001	2002	2003
<i>Number of stable banks</i>	12	13	15	17	16	16	17	17	23
<i>Number of unstable banks</i>	23	11	10	8	7	5	0	0	0
<i>Banks together</i>	<b>35</b>	<b>24</b>	<b>25</b>	<b>25</b>	<b>23</b>	<b>21</b>	<b>17</b>	<b>17</b>	<b>23</b>

*Source: www.cnb.cz*

The financial indicators were calculated for every bank in given years. Based on these calculations the median for each financial indicator was computed in each year, separately for stable and unstable banks (see Table 2 and Table 3) This statistic indicator was chosen because of its using by rating agencies such as Moody's and Standard & Poor when evaluating bank performance (for instance ROAA, the indicator of bad loans volume etc.). The values of these indicators were calculated for last three years and then compared with the median of the classification group.

The main criteria for creating the model of bank stability were the uncorrelated indicators and simultaneously values of the indicators are different for the group of "stable banks" and the group of "unstable banks" (verified by a graph showing time series of the financial indicators).

Based on the abovementioned criteria the following indicators were selected:

- return on to average level of assets (ROAA);

- equity/liabilities;
- interest margin;
- profit margin;
- equity/total assets ratio.

**Table 2 The Financial Indicators for the Stable Banks in the Period 1995 – 2003 (median, in %)**

	1995	1996	1997	1998	1999	2000	2001	2002	2003
ROAA	0,69	0,79	0,52	0,33	0,02	0,13	0,58	0,66	1,60
Equity/Liabilities	18,35	18,41	37,10	34,93	19,92	8,35	18,31	11,26	20,68
Profit margin	5,07	8,18	4,80	2,84	0,23	8,24	6,71	12,31	21,56
Interest margin	3,54	2,89	2,00	2,52	3,47	5,31	2,34	1,97	4,05
Equity/Total assets	8,65	8,42	9,30	10,35	8,30	5,83	7,18	6,72	2,05

*Source: own calculation*

**Table 3 The Values of Selected Financial Indicators for the Unstable Banks in the Period 1995 – 2000 (median, in %)**

	1995	1996	1997	1998	1999	2000
ROAA	-2,02	-1,30	-0,91	-0,35	0,00	0,13
Equity/Liabilities	9,76	11,28	8,73	7,30	8,62	8,35

Equity/Total assets	5,66	7,39	5,50	4,91	6,41	5,83

*Source: own calculation*

### 3. The Creation of the Bank Stability Model

When applying the discriminant analysis, we calculate values  $D_1, \dots, D_k$  for the random quantity  $X$ . The investigated element belongs to the group that has the biggest value from values of  $D_j$ . Values  $\mu_j$  and are usually unknown but we have used their estimates. The probability  $p_j$  is usually chosen as proportionally to the range of the  $j$ -group, if these ranges are unknown, one can choose  $p_j = 1/k$ . [8].

### 3.1 The Creation of the Model

Firstly, for creating of the bank stability model it was necessary to calculate values as follows:

- values of medians ( $\tilde{x}_i$ ) and variances ( $\mu_j$ ) for all indicators for the stable banks in the period 1995 – 2003 (Table 2 and Table 4);
- values of medians and variances for all indicators for the unstable banks in the period 1995 – 2000 (Table 3 and Table 5).

**Table 4 Median and Variance for the Stable Banks in the Period of 1995 - 2003**

	$\tilde{x}_1$	$\mu_1$
<i>ROAA</i>	0,0048563	0,0000056
<i>Equity/Liabilities</i>	0,2189823	0,0072530
<i>Profit margin</i>	0,0548787	0,0011690
<i>Interest margin</i>	0,0271371	0,0000327
<i>Equity/total assets</i>	0,0819767	0,0001461

*Source: own calculation*

**Table 5 Median and Variance for Unstable Banks in the Period of 1995 – 2000**

	$\tilde{x}_2$	$\mu_2$
<i>ROAA</i>	-0,0078	0,0001
<i>Equity/Liabilities</i>	0,0883	0,0001
<i>Profit margin</i>	-0,0405	0,0025
<i>Interest margin</i>	0,0469	0,0000
<i>Equity/total assets</i>	0,0589	0,0001

*Source: own calculation*

The following Tables (Table 7 and Table 8) show the covariance matrix for all financial indicators for both stable and unstable banks. The covariance was counted always for two financial indicators (Table 6).

**Table 6 The Covariance of Financial Indicators**

	<i>Covariance</i>
<i>ROAA/VkZ</i>	ROAA Equity/Laibilities
<i>ROAA/profitR</i>	ROAA Profit margin
<i>ROAA/interestR</i>	ROAA Interest margin
<i>ROAA/VkA</i>	ROAA Equity/total assets
<i>VkZ/profitR</i>	Equity/Laibilities to profid margin
<i>VkZ/interestR</i>	Equity/Laibilities to interest margin
<i>VkZ/interestR</i>	Equity/Laibilities to interest margin
<i>profitR/interestR</i>	Profit margin to interest margin
<i>profitR/VkA</i>	Profit margin to equity/total assets
<i>interestR/VkZ</i>	Interest margin to equity/laibilities

When providing the discriminant analysis, we have to compute also the inverse covariance matrix for both stable and unstable banks.

**Table 11 The Inverse Matrix for the Stable Banks**

Source: own calculation

Then we calculated determinant of the inverse covariance matrix  $D_j$ . The value of  $D_j$  for a particular bank is calculated as follows:

$$D_1 = -0,5 \cdot \ln[\det(\sum_1)] - 0,5 \cdot (\tilde{x} - \mu_1)' \cdot \sum_1^{-1} \cdot (\tilde{x} - \mu_1) + \ln p_1 \quad (1)$$

The size  $D_2$  for a particular bank equal:

$$D_2 = -0,5 \cdot \ln[\det(\sum_2)] - 0,5 \cdot (\tilde{x} - \mu_2)' \cdot \sum_2^{-1} \cdot (\tilde{x} - \mu_2) + \ln p_2 \quad (2)$$

The final result is to set up a model that enables forecasting the classification of a particular bank to the concrete group of banks (either into the first group of the stable banks or into the second group of the unstable banks) based on provided calculations. A particular bank will belong to the group of either stable or unstable banks on dependence of the value of  $D_j$  (the bank will be placed to the group where it reaches the bigger value of  $D_j$ ).

The original intention of the model of bank stability was to create so called “a grey zone” or the situation when it will be not possible to rank the chosen bank neither to the group of the stable banks nor unstable banks. Considering that banks are divided only into two groups in the model when applying the discriminatory analysis, no grey zone is used here.

In case that the relevant average variance was subtracted from the median of the financial indicator (valid in the Cartesian product) for the group of stable banks and unstable banks, it would lead to a creation of two intervals (for the group of stable or unstable banks). The interval would rise in both cases, in the process that inside of these intervals would be the median of the relevant groups of banks. Under condition that the intersection of these intervals would be disjunctive, it would mean that there are different values for the groups of stable and unstable banks. In case that the intersection of these intervals would not be disjunctive, i.e. the intersection exists, it would create an area where the group of stable banks has the same values as the group of the unstable banks.

In the intersection’s interval one cannot determine whether a bank comes of the group of stable or unstable banks. This intersection would be possible to mark as a grey zone, i.e. is the situation when it was not possible to decide into which groups the chosen bank belongs to.

In the calculation of discriminant analysis it is necessary to determine the size of  $p_j$ . In this case is not the number of  $p_j$  the same as the number of stable and unstable banks in the observed period (see Table 1) for the reason that the measurement of big banks (ČS, KB a ČSOB) was divided into the groups of both stable and unstable banks. The reasoning for such division was the fact that all three banks have received the state support and an entry of a foreign owner. Therefore these banks were ranked as the unstable banks until the year of 2000 and since 2001 they belong to the stable banks.

**Table 13 The Number of the Stable and Unstable Banks Used in the Discriminant Analysis Calculation**

### **3.2 The Verification of the Model**

The bank stability model was verified through 38 banks based in the Czech Republic. It was necessary to exclude the chosen bank from the observe group for verification. Hence the new covariance inverse and transposed matrix was created for every of 38 relevant banks. Furthermore, the number of measurement  $p_j$  for every bank was adjusted.

#### **3.2.1 The Identification of Observed Banks**

The verification of the suggested model was carried out for 38 banks. 41 measurements were provided because big banks (ČS, KB, ČSOB) were divided into two time intervals until the year 2000 and since the year 2001.

#### **3.2.2 The Verification of Results by Monitoring Bank of the Model**

The result of the model was verified in such manner that for every bank the values of the testing criterion  $D_1$  a  $D_2$  were found.

Consequently, the bank was classified into the group of either stable or unstable banks according to the value of testing criterion  $D_j$ . Seventeen banks were classified as stable banks and 24 banks as unstable.

Data from the CNB were used for verification of the bank stability model. The CNB presents in the publication “The Bank Supervision 2003” the following overview of the Czech banking sector:

- banks with the valid bank's license;
- banks in the forced administration;
- banks in liquidation;
- banks in bankruptcy proceeding;
- banks as stock companies without the bank license;
- banks in bankruptcy without liquidation;
- banks in bankruptcy with liquidation.

Based on obtained results the comparison between the results from the researched model and the real development of the Czech bank sector was provided.

### ***3.3 The Evaluation the Bank Stability Model***

As it comes from our research, the results from the proposed model completely correspond to the real development of the Czech banking sector. The model has classified 17 banks to the group of stable banks and 21 banks to the group of unstable banks. When comparing with real data, this classification fully matches with the real development of the Czech banking sector (see Table 14).

**Table 14 The Comparison of the Bank Stability Model with the Real Development of the Czech Banking Sector**

<i>Bank group</i>	<i>Total number of banks in group</i>	
	<b>Bank stability model</b>	<b>Real bank development</b>
<i>Stable banks</i>	17	17
<i>Unstable banks</i>	21	21

*Source: own calculation, www.cnb.cz*

Based on results outlined above one can claim that the bank stability model is able to predict if the chosen bank belongs either to the group of the stable or to the group of the unstable banks. Since data used in the model is public available, the model can be used by any economical subject for its decision process when choosing a bank for its financial transactions.

## 4. Conclusion

The proposed bank stability model was verified on the selected banks doing business in the Czech Republic in the period 1995 – 2003. However, the verification could not be done on all the banks doing business in the Czech Republic in this period of time. The reason was data unavailability for an analysis of all needed financial indicators.

The bank stability model was created on the basis of the discriminant analysis. The discriminant analysis includes five financial indicators that help to classify a bank either into the group of the stable banks or unstable banks. The model was drawn up by using 211 measurements, thereof 145 measurements were connected to the stable banks and 66 measurements were connected to the unstable banks. The classification of a bank to the stable or unstable group fully corresponded to the facts published by the Czech National Bank.

The choice of the financial indicators was influenced by data availability. The original intention included 11 financial indicators for providing the discriminant analysis. However, we had to decrease the number of financial indicators because of an uncorrelation of financial indicators requirement. Therefore the number of indicators was cut from 11 to 5 indicators. The choice of these five financial indicators was also supported with the results of the financial analysis and through a graph describing time series of these financial indicators.

The verification of the model shows the practical usage for evaluation of the bank stability. The results verification was done for 41 banks in total, thereof 24 banks were clarified as the stable banks and 17 banks as the unstable banks. The used classification fully matches with the real development of the Czech banking sector.

## **Abstract**

*A bank's activities produce banking information. It consists of outwards-directed (outside) information and internally used (inside) information. The information sent outside to banking regulation institutions and general public according to the law differs substantially from the information used internally by the banks. Various information users, such as shareholders, owners, competitors, government, etc. use some kind of banking information. The bank information for the public consisting of monthly balance sheets and quarterly income statements is analysed. The type and quality of the information requested by different information users and possibilities of finding the requested information from the above-mentioned data sheets are discussed. The paper presents a possible classification of banking information analysis and gives, as an example, methods for one of the variants of analysis.*

**Keywords:** *banking information, banking consumers, banking analysis*

## 1. Introduction

In the Republic of Estonia all companies have given up salary payments in cash. Monthly salaries are transferred to a bank by the employer and from there the money may be withdrawn either by visiting the bank office (and paying a fee for the operation) or via ATM (currently in some banks still free of charge). Increasingly more students and retired persons are using ATMs.

The primary interest of all bank clients is that their money be safe. Only after this has been achieved, people think of making a bit more money by changing their ordinary accounts into time deposits. The fear of losing one's money derives from the recent time when quite a number of banks closed their doors all of a sudden. These closings were unexpected because on previous days the bank had performed all operations without obstacles and therefore nobody could predict that the next day the doors would be closed and the customers would lose their money. Although we may blame the depositors of not dividing their risk (as a proverb warns, one should not keep all eggs in one basket), it would mean being wise only afterwards and it will not bring back the lost savings. Having lost your money once, you'll be more careful while choosing your bank next time. It is a rule with exceptions. Nevertheless, there are cases when a person has experienced three bankruptcies of his/her chosen home bank in sequence. Quite often one failure has been enough to teach a lesson. All these bankruptcies have heavily damaged the image of the banking system among Estonians.

The banks try to create an image of credibility. They erect fancy office buildings and their employees are trained to communicate in a trustworthy way with customers etc. All this belongs to external credibility. It is quite easy to mislead customers with external credibility, but all risks will be wide open once internal credibility is involved. Internal credibility is based on information spread by the bank to the external environment and the results of the analysis of this information. As any other company a bank creates information in the course of its activities. This information can be divided into outside information and information that has to remain between the walls of the bank, i.e. the so-called inside information.

While the external image could help cover the crisis up for some time, the internal image would eventually drag all problems out anyway. By an internal image we mean the result-linked information presented by the bank that allows it to analyse the real situation. Both more experienced and less experienced clients have developed a rather critical attitude towards the Estonian banking system. In addition to an image that banks try to create of themselves through mass media, people have become interested in the real

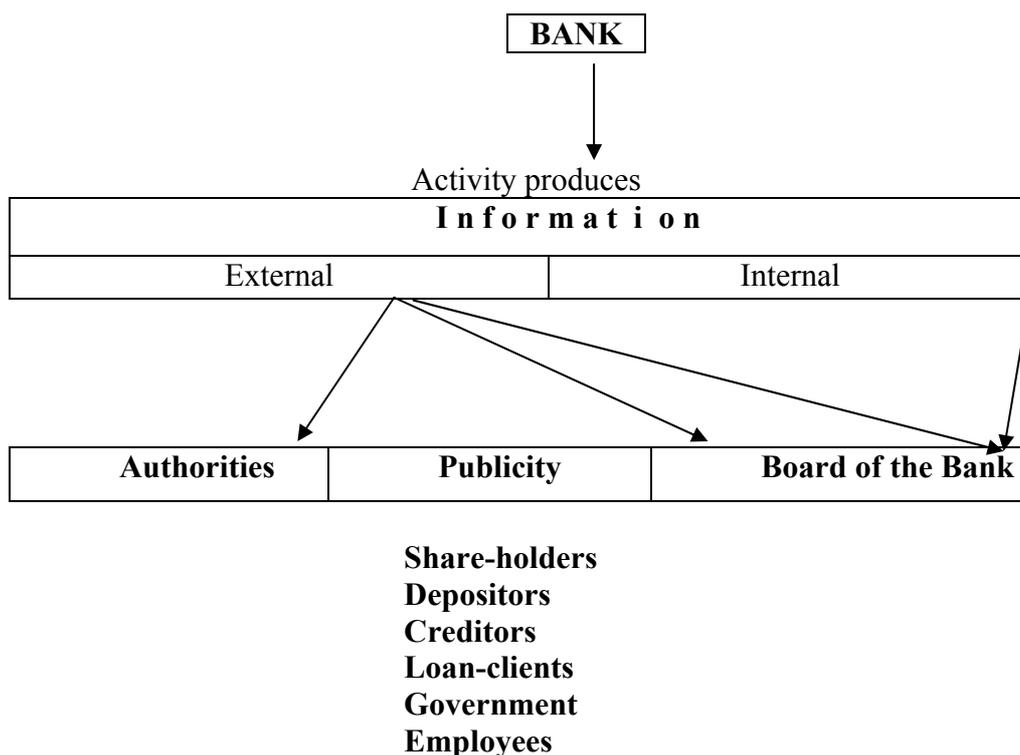

results of the banks. Figures have a unique quality of reflecting mercilessly every bank's health. Having the confirmation of an internationally recognized auditing company the reports gain more trust. The only thing a client has to do then is to read the reports. Unfortunately there are still quite a number of clients unable to understand the reports and to draw conclusions on their basis. Yet there is an obvious need for such a skill.

Discussions with the respondents showed that though everybody would choose a trustworthy bank, they would still describe it only "as a bank that would not end up with bankruptcy". All the banks that have gone bankrupt have never made a public announcement about it before. As a result of bankruptcy hundreds and thousands of people have lost their money and this has made them extremely critical about the banking sector.

## 2. Different interest-groups of bank clients

Information targeted outside (external information) is used by many institutions and interest groups. Figure 1 gives an overview of them.

**Figure 1. Consumers of the Information produced by the Banks**

*Authorities* need information on banks in order to design the government's financial policy. This information is necessary for *investors*, both individuals and institutions, for two purposes. Firstly, in order to decide whether to sell their shares or, on the contrary, to buy more of them. Secondly, to predict a bank's ability to pay dividends.

*Depositors* are interested in the bank's ability to pay interests and make payments in time.

*Creditors* are interested in the information about the bank's ability to return loans in time, whilst potential *borrowers* are interested in the information about the conditions of borrowing.

*Government agencies* need information in order to run national economy and gather statistics.

*Bank employees* need information in order to evaluate the state of their employer and to be sure that salaries will be paid.

The *public* also needs information. The word "public" includes other members of the community who may be considered as potential customers and competitors.

There are one more institution and a group of people that should be mentioned here. The institution is the Stock Exchange, to which external information has to be passed first, if a bank has been listed at the stock exchange. Information is not passed to the stock exchange on a regular basis; it is passed once it has been born. The group of people are researchers, who have not been mentioned yet. They use only regular information sources and their analysis goes far beyond simple reading of data.

### **3. Different interest-groups need different information**

Next, let us have a look at the information that is essential for evaluating a bank's reliability by different clients.

*Regulative institutions* (primarily the Banking Supervision Department) control a bank's reliability through its ability to observe necessary regulations (minimum share capital and equity requirements; capital adequacy, liquidity, reserve, and maximum risk requirements). If the annual report shows that all these regulations have been observed, the bank is reliable. Profitability is not important here.

*Government agencies* (mostly the Department of Statistics) need information purely for statistical purposes. Neither profit nor the

observance of the regulations are of their interest. Small depositors are interested in the interest rate.

In addition to reliability *investors* are also concerned about profitability. The term “investors” includes core investors, long-term shareholders as well as speculators. In the annual report they are interested in the bank’s performance, and based on that they either sell their shares or buy some more.

*Competitors* and *researchers* need more specific information. The published information is insufficient for them, as they have to analyse the balance sheet and income statement very thoroughly.

The most precious good of every bank is its reliability. Knowing the recent history of Estonian banking (Fleming, Chu and Bakker 1997; Vensel 1997; Aarma and Vensel 1998; Sõrg 1999) it is not difficult to explain why the bank customers regard reliability as the most important criterion in their selection of the bank (Aarma 2001). The cornerstone of reliability is openness. This means that everyone who needs or wishes information on the bank’s activities has to have access to it.

Besides reliability, earning a profit and its sufficient size are preconditions for a normal operation and growth of each bank. Information on profit is provided by the profit statement published quarterly. All groups who consume information provided by the bank are interested in the bank’s reliability but its profit-making capacity does not concern some of them. This is illustrated by Table 1.

**Table 1 Groups that care (do not care) about the reliability and profitability of the bank**

<i>Group of bank information consumers</i>	<i>Reliability</i>	<i>Profitability of the bank</i>
<i>Regulatory organs</i>	Yes	No
<i>Government institutions</i>	Yes	Yes
<i>Depositors</i>	Yes	Yes/No
<i>Borrowers</i>	Yes	Yes/No
<i>Investors</i>	Yes	Yes
<i>Bank employees</i>	Yes	Yes
<i>Bank management</i>	Yes	Yes

Source: Aarma 2001

The reliability of a bank is also understood differently by each group of information consumers. Regulatory organs and government institutions understand bank reliability as the correspondence of its performance indicators to the set standards. For depositors reliability is in the first place its cash position. If the bank is liquid its deposit holders will have no obstacles to withdrawing their money at any time they wish. For borrowers the bank is reliable if it is capable of lending money. No specific relationships can be found between the rate of interest on loans and bank reliability. Investors consider the bank reliable if they can be sure that the money they have invested will produce for them as high profits as possible (either in the form of dividends or rising price of shares). Bank employees and management are primarily interested in the fact that the bank is reliable and that the reliability increases continuously. The welfare of both these groups depends directly on the reliability of their bank.

As to profit-making capacity, the situation is somewhat different. There are interest groups who do not care at all whether the bank makes or profit or not. First of all it is the regulatory organs that are not interested in the bank's capacity to make a profit. Depositors and borrowers do not care much about it either. The investors and the bank's own employees, on the contrary, are vitally interested in whether the bank makes or profit or not. The government is likewise interested in the bank's profit as it collects taxes on the profit.

It was mentioned above that the most important reports of a bank are its balance sheet and profit statement. Still, to be quite exact, it should be said that it is the audited annual report that is the most important. The balance sheet and profit statement are its major components. As the balance sheet and profit statement presented in the annual report are the only audited ones of the balance sheets and profit statements published during a year, the most authentic overview of the bank could be obtained if we analysed only the balance sheets and profit statements in the annual reports. However, this would be insufficient as the time series with a time interval of one year would be too short. Therefore, the time series has to be lengthened and to do so the time interval will be shortened to embrace three months. The use of an even shorter time interval (for example one month) is hindered by the fact that the profit statement is presented once in a quarter.

Thus, by losing some trustworthiness of data (the quarterly balance sheets and profit statements are not audited and may be changed later) we can get a sufficiently long time series to make conclusions.

There does not exist any classification of banking information accepted unanimously by all authors involved in banking analysis. Each

author approaches the analysis from their own aspect. The classification of analysis presented in Table 2 is also a subjective vision of the author and is a combination of approaches of several other authors (Koch 1995; Panova 1996; Batrakova 1998, Aarma 2001, Vensel 2001, ).

**Table 2 Classification of banking information analysis**

*Source: The author's vision*

#### **4. Selection of the methods of analysis depends on the bank client's interest and needs**

As already mentioned above, the bank clients' primary interest is that their money be safe. This means that the bank at which they keep their money should be credible. Estonian legislation is in this respect of great help to bank clients. Namely, the Deposit Backing Act from 1st October 1998 guarantees 90% of small depositors' accounts. When the Act was passed the upper limit of the guaranteed deposit was EEK 20 000 and the level of self-

responsibility was 10%. By the beginning of 2005 the guaranteed amount had been raised to EEK 200 00 and by the end of 2007 it has to be EUR 20 000.

Bank clients who either do not wish or are not able to analyse the information published by the bank may use the ratings prepared by others. There are a large number of methods for rating banks and they differ from each other significantly.

The most trustworthy ratings are naturally the ones published by large international rating companies such as Moody's Investors Service, there is no sense in discussing their methods, as they require from the banks such information that is normally not available to the general public. Such rating methods are CAMEL, CAEL, UBSS, FIMS etc.

Those bank clients who prefer to make their own decisions about the credibility of the bank on the basis of the information published by the bank have at their disposal a number of analyses (see Table 2).

The methods listed in the table differ from one another in complexity. Several research papers have been published concerning the most complex analysis methods. For example, the matrix approach (Aarma and Vensel 1999), comparative analysis (Aarma and Vensel, 2000), DuPont Financial Ratio Analysis (Aarma 2001), econometric modelling (Aarma and Vainu 2003) have been discussed.

In the present paper a simple analysis method is treated. This method is one possibility of rating banks. A Moscow economist G. Panova (Панова, 1996) may be considered the author of this method. The method evaluates the potential chances of the bank on the market. The rating is calculated on the basis of six ratios:

1. coefficient of the credibility ( $K_1$ )  
book value equity (BE) / earning assets (EA) (1)
2. coefficient of current liquidity ( $K_2$ )  
liquid assets (LA) / demand deposits (DD) (2)
3. coefficient of risk ( $K_3$ )  
liabilities (L) / (EA) (3)
4. coefficient of liquidity ( $K_4$ )

$$(LA + \text{protected capital}) / (L) \quad (4)$$

Under protected capital we refer to the bank's capital assets minus intangible assets plus capital investments and precious metals

$$5. \quad \begin{array}{l} \text{coefficient of protected capital (K}_5\text{)} \\ \text{protected capital} / (\text{BE}) \end{array} \quad (5)$$

$$6. \quad \begin{array}{l} \text{coefficient of profit capitalization (K}_6\text{)} \\ \text{BE} / \text{share capital (SC)} \end{array} \quad (6)$$

If the coefficients of a bank calculated upon the relevant data of the bank are as follows:

$$K_1 = 1; K_2 = 1; K_3 = 3; K_4 = 1; K_5 = 1; K_6 = 3.$$

then the bank's balance can be described as optimal. All these ratios can be divided into two categories, one showing credibility and the other liquidity. The first group includes  $K_1$ ,  $K_3$ ,  $K_5$  and  $K_6$  and the other  $K_2$  and  $K_4$ . In order to get an overall formula for calculating a bank's credibility, all coefficients are to be put on an equal scale by dividing  $K_3$  and  $K_6$  by 3. However, as every coefficients has a different impact on the bank's performance, they also have to be weighed with a proportional influence factor. The proportional factor on performance of the first group is 70% and the other 30%. Coefficient  $K_1$ , which is of greatest interest to the depositors, has also the greatest weight – 45%,  $K_2$ , showing to bank's ability to satisfy the needs of demand account owners at any time, has a proportional weight of 20%.  $K_5$ , characterizing the protection level of a bank against inflation, and  $K_6$ , showing the level of profit capitalization, have both a proportional weight of 5%. The low importance of  $K_5$ , is due to the fact that buildings and land, which make up the bulk of this coefficient, are periodically revalued. Other coefficients have the following weights:  $K_3$  – 10% and  $K_4$  – 15%.

Thus, the credibility of a bank can be calculates using the following formula:

$$N = \frac{K_1}{1} 45 + \frac{K_2}{1} 20 + \frac{K_3}{3} 10 + \frac{K_4}{1} 15 + \frac{K_5}{1} 5 + \frac{K_6}{3} 5 \quad (7)$$

The banks are ranked according to the credibility rating calculated with this formula. It has to be reminded that every rating is nothing more than

a subjective opinion of experts. Besides, all methods of calculating ratings offer only some assistance in making the decision. The decision has to be made by the owner of the money.

## 5. Conclusions

1. Different client groups have different expectations of the bank. A deposit account holder is interested in the bank's ability to pay interests and make the payments in time. He is not interested in the profitability of the bank. All bank clients can be grouped based on their expectations of the bank: either its reliability or profitability, or both.

2. Different client groups have different needs for information. A deposit account holder needs information about interest rates and bank charges; a shareholder is interested in the bank's profit, as it directly influences the share price. Competitors need the most specified information.

3. Different methods of analysis produce different types of information. The balance sheet and the income statement include various data. Depending on the depth of analysis the used method becomes more complicated and the result more specified.

4. Panova's rating method enables to rank the banks analysed in the order of credibility using a rather limited amount of information and it is not time-consuming.

## **Abstract**

*Banking in Estonia has teenager phase. Estonia has experienced two serious banking crises during the about 15-year period of its banking sector development and restructuring, the first crisis in 1992-1994 and the second in 1998-1999. Countries that have undergone financial crises are often looking to stabilize their banks with the help of international investors, often by allowing multinational banks operations to quickly expand their operations. Foreign investment came primarily from Finland and Sweden. In the research, authors are analyzing reasons, how can influence of strong participation of strategic investor from matured economy be related to the efficiency of commercial banks in Estonia in first period (before 1999) and later, when all key players were connected to some Scandinavian commercial bank. Change of efficiency is analyzed through comparison of key measures before and after involvement of strategic investor, in relation with changed regulative environment of Estonia. In more stabilized economic situation, the comparative advantage of involvement of strategic investor has less influence on efficiency and it is analyzed on the basis of Estonian commercial banks reports from 1999-2004.*

**Keywords:** *banking; efficiency; international investor*

## 1. Introduction

Banks are a unique set of business firms which assets and liabilities, regulatory restrictions, economic functions and operations establish them as an important subject for the study, particularly in the conditions of emerging financial sectors in CEECs. There is a growing interest in the impact of foreign banking on the financial system and the economic development of emerging and transition countries (Naaborg 2004)

A sound banking system is built on profitable and adequately capitalized banks. Modern bankers pay a great deal of attention to the message that is revealed by ratio analysis. Banks usually manage profitability by trying to beat market averages and keep profits steady and predictable; which in turn attracts investors. Ratios are therefore extremely useful tools, but as with other analytical methods, they must be used with judgment and caution, since they alone do not provide complete answers about the bottom line performance of banks. In the short run, many tricks can be used to make bank ratios look good in relation to industry standards. An assessment of the operations and management of a bank should therefore be performed to provide a check on profitability ratios.

Ratios are a basic tool for financial analysts and are essential to examine the effectiveness of a bank's risk management process. They are normally the initial points that provide clues for further analysis. Changes in ratios over time offer a dynamic view of bank performance. Graphs are powerful tools for analyzing trends and structures. They facilitate comparison of performance and structures over time, and show trend lines and changes in significant aspects of bank operations and performance.

The structure of the Estonian banking sector has changed fundamentally during the last years. Today, the banking system is highly concentrated and two Swedish-owned banks dominate in the market (see also table of this paper). The consolidation process continued throughout the second banking crisis in 1998-1999 resulting in fundamental bank reorganizations. We can notice all three worldwide trends in the financial consolidation process also in the Estonian market: domestic consolidation, foreign entry and cross-border consolidation, and the formation of financial conglomerates and bank assurances.

In this research, authors outline how can influence of strong participation of strategic investor from matured economy be related to the efficiency of commercial banks in Estonia in first period (before 1999) and later, when all key players were connected to some Scandinavian commercial bank. Change of efficiency is analyzed through comparison of key measures

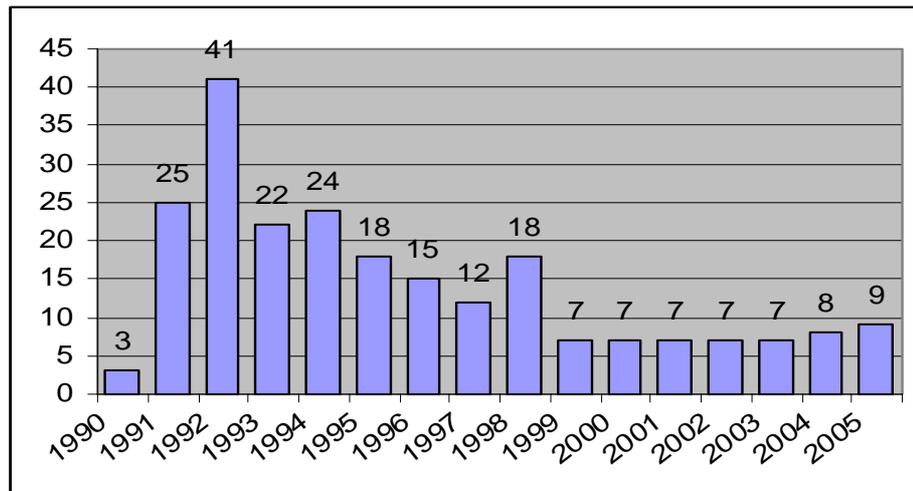

before and after involvement of strategic investor, in relation with changed regulative environment of Estonia.

## **2. Banking in Estonia**

Banking in Estonia has teenager phase (the period is 15 years). Initially Estonia has selected and introduced in life a model of a universal banking that allows banks to participate in other financial activities including operating leasing, insurance, and brokerage firms. The history of the Estonian banking was rooted in 1990s (after acquiring the independence). In most central and eastern European countries (CEECs) and the Baltics, the monobank structure was abolished in the late 1980s. CIS countries introduced a more competitive system in the early 1990s. With the elimination of monobank systems, most countries experienced a rapid expansion of the banking sector with the entry of a large number of new banks and corresponding declines in state ownership in the sector. Foreign banks entered the field in many CEECs and the Baltics in the second half of the 1990s.

At that time, the commercial banks were either new entities established by domestic industry or privatized branches of the former Soviet banks. The stages of development of banking system a little differ from other transition economies. The liberalization and decentralization of the economy accompanied by lax monetary and fiscal policies contributed to overly fast growth in both the volume of credit and the number of banks. Given extremely low barriers to entry the number of banks increased dramatically in the beginning of 1990's. New banks appeared one by one (there were 42 banks), who's careless activity led to the events that shocked all banking system (the moratoriums were declared to many banks) (see figure 1).

**Figure 1. Number of banks in Estonia**

Source: Bank of Estonia

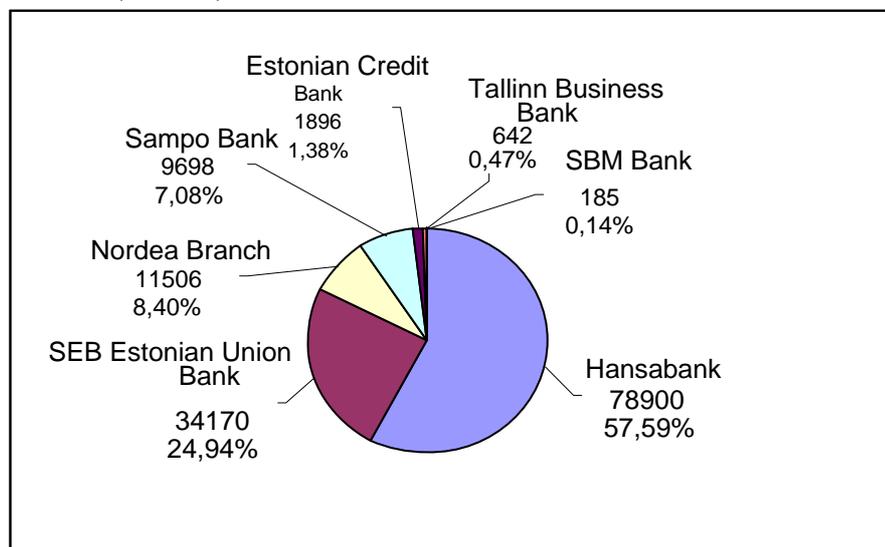

Rapid increases in stocks of non-performing loans led to banking crises in many transition countries during the 1990s. In fact, transition made banking sectors vulnerable in several respects. Many crises arose out of insolvencies in state-owned or formerly state-owned banks caused by bad loans inherited from the Soviet era. Moreover, transition cut enterprise profitability in certain sectors, reduced the ability of companies to service their loans. Estonia has experienced two serious banking crises during the about 15-year period of its banking sector development and restructuring, the first crisis in 1992-1994 and the second in 1998-1999 (Sõrg, M. and Vensel, V.). As a result, problems of banks and the insolvency of eight smaller banks seriously undermined the overall credibility of the Estonian banking sector. The operating environment for banks deteriorated in conjunction with severe output contractions in the early part of transition. Finally, regulatory frameworks and supervisory structures for the banking system in most transition countries were inadequate (EBRD 1998, Tang et al. 2000).

These events in Estonia lead to foreign investment. Countries that have undergone financial crises are often looking to stabilize their banks with the help of international investors, often by allowing multinational banks operations to quickly expand their operations. Foreign investment came primarily from Finland and Sweden, countries with long historical and cultural ties to Estonia. In time the banking system gradually improved, the process of licensing and banks mergers led to a few banks for the moment.

Generally speaking, the events of the late 1990 had a positive effect on banking in Estonia. Banks started to pay more attention to risk analysis and diversification spread; a shift from speculative to cautious action took place. This resulted in the extremely cautious domestic credit policy practiced by the banks and the growth of their foreign assets. Banks' customers who had also learned a lesson from the banking crisis, when choosing a bank did it with greater care now. The keen competition between the banks forced them to be more attentive to their client's needs, which, in turn, fostered the restoration of the trust in the banking system. The 1998 became the year of so-called *second-wave* restructuring in the banking sector. Increased competition resulted in several major mergers as well as the exit of weaker and inefficient institutions from the market.

Today, the banking sector has consolidated and there are mainly Scandinavian banks as strategic investors in Estonian commercial banks. The Estonian banking system is dominated by two foreign controlled banking groups: Hansabank and Union Bank (see figure 2). Together the two banks control around 85 per cent of the Estonian banking sector. In all, six licensed credit institutions and three branches of credit institutions licensed in a EU Member state were operating on the Estonian banking market on 1 October 2005; 63 foreign credit institutions had submitted applications for providing cross-border banking services and five credit institutions had a representative office in Estonia.

**Figure 2. The Balance sheet and market share by commercial banks in Estonia (mln.kr), 31.12.2004**

Source: Estonian Banking Association

Estonia is a small country. Through foreign investments it was able to create a sound banking sector. The ownership structure of Estonian banks is presented in Table 1. Together banks with foreign capital control around 97 per cent of the Estonian banking sector. In addition to capital, the foreign banks brought their credibility. The share of large Swedish banks in the Estonian banking market guarantees confidence in the financial sector here. It is interesting that the owner of Hansabank – Swedbank is a leader in Estonia and the fourth big bank in Sweden. SEB is the second in Estonia and at home. However, Nordea is the largest financial enterprise in the Nordic region, but has the third place in Estonia.

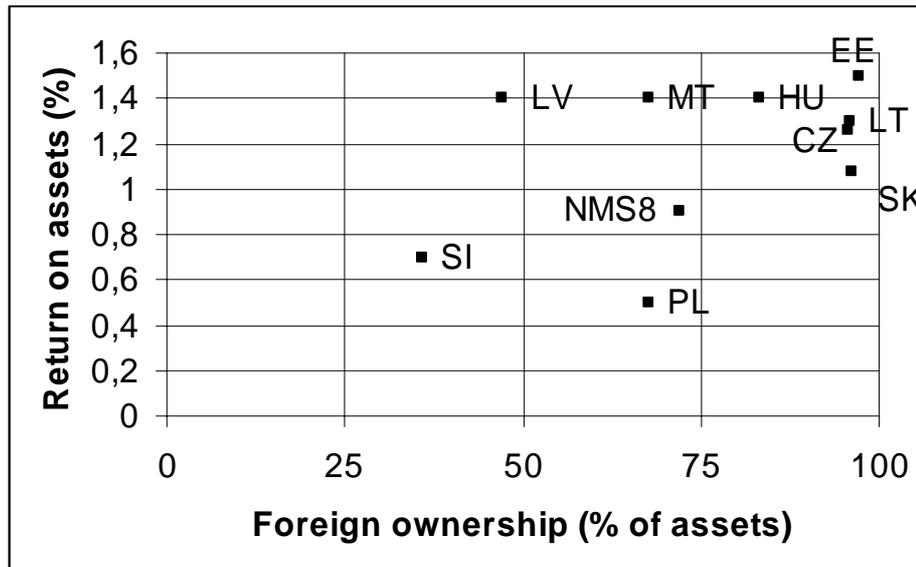

**Table 1. Estonian commercial banks and their owners, 2005**

<i>Group</i>	<i>Large banks</i>	<i>Medium-sized banks</i>	<i>Small banks</i>
<i>Banks</i>	Hansabank (Swedish Swedbank)	Sampo Bank (Finland's leading bank)	Tallinn Business Bank (Estonian residents)
	SEB Estonian Union Bank (Swedish Skandinaviska Enskilda Banken)	Nordea Bank Finland PLC Estonian branch	Estonian Credit Bank (Russian owner)
			SBM Bank (from the end of 2004 Greek and Swedish owners)
			Parex Bank (from the end of 2004) (Latvia owners)
		HVB~Bank (German HypoVereinsbank AG).	

*Source: Bank of Estonia*

Foreign presence is very large in most New Member States. On average, more than 70% of bank assets are foreign-owned. Foreign presence is notably high in Estonia. Correlation between foreign ownership and ROA in New Member States is 0,78 (ECB 2005).

**Figure 3. Foreign ownership and banking sector performance in 2003**

*Source: European Central Bank, 2005*

However, most empirical evidence seems to point toward a positive association between foreign ownership and banking sector performance in transition countries. This is also borne out by the evidence in Figure 3 for the banking sectors of the NMSs. The chart suggests a positive relation between foreign ownership and ROA for the year 2003. It should be acknowledged, however, that banks' performance may vary substantially within the different NMSs, depending not only on ownership, but also on the specialisation and strategy of the individual banks. Foreign presence is very large in most NMSs, mainly in the form of subsidiaries of foreign banks. On average, 72% of bank assets are foreign-owned. In general, NMS banks have a limited presence abroad which more often occurs via branches in neighbouring regions, but some banks also have equity participations in foreign banks. The market structure of NMS banking sectors is generally characterised by relatively high concentration. On average, the largest five banks hold 72% of total banking sector assets in the NMSs. Given the high concentration in most of the NMSs, potential concerns may arise as regards the degree of competition (16).

Foreign ownership is beneficial for the banking systems of (former) transition countries since it involves a transfer of technology and human capital which increases the operational capacity of local banks. In particular, foreign ownership is widely believed to have contributed to an improvement of the risk profile, reputation and risk management of local banks and hence to financial stability in NMSs and a convergence with western standards.

As most new Member States followed similar development paths during the transition period, most NMS banking sectors share common structural characteristics. Despite an upward trend in many countries, the level of financial intermediation is still low in the former transition NMSs, compared with the EU-15 countries. In terms of financial structure, the NMSs rely more heavily on bank finance than on direct market finance, as is the case in most EU-15 countries. The structure of the banking systems is dominated by commercial banks, with an around 90% share of total banking sector assets. In some countries there are also a significant number of small cooperative banks.

### **3. Evaluating Banks' Performance in Estonia**

Banks performance monitoring, analysis and control need special analysis of their operating and activities results from the viewpoint of different audiences, like investors (owners), regulators, customers (clients), and management themselves.

Foreign banks entry into transition economies is very topical and widely discussed subject in the recent literature, because the banking sector has a strong effect on whole economy. As stated above, the Baltic banking has changed dramatically since the new economic and legal framework was introduced in the early 1990s. Estonian has very liberal economic policy and the share of the foreign capital in Estonian banking is 97%. At the same time, the Estonian banking market is highly concentrated and all largest are controlled by foreign capital. They say that „Swedish use of Estonian banking system“. Consolidation was followed by an inflow of foreign capital from Scandinavia.

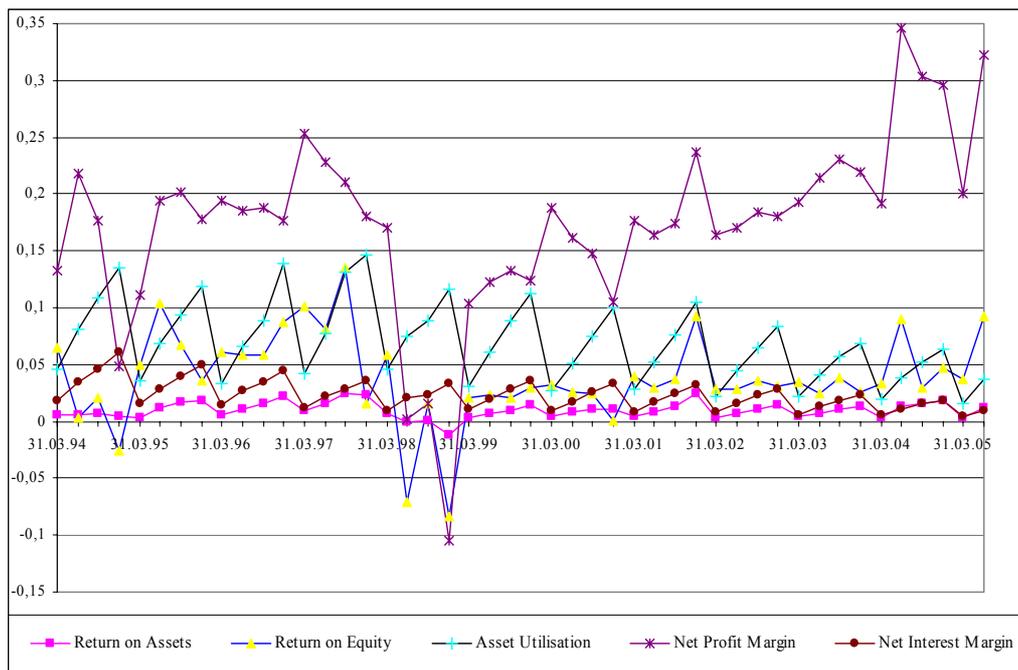

Compared to previous years, the growth rate of nominal indicators in the banking sector slowed down during 1998-2000, partly due to the changes in the external environment. With the deterioration of the economic environment in 1998, wrong economic and management decisions that had been made already surfaced in 1998 and resulted in the dropout of three banks from the banking market in July-October.

In this paper we present one of the possible approaches to such financial analysis. The following chart presents visually financial ratios of Estonian banks consolidated balance sheet and income statement. We investigate a number of indicators: the return on assets, the return on equity, the leverage, and the net results of the banks. The ratios are discussed below.

The following figure 4 presents visually financial ratios of Estonian banks consolidated balance sheet and income statement. The ratios are discussed below.

Profitability is an indicator of a bank's capacity to carry risk and/ or to increase its capital. Supervisors should welcome profitable banks as contributors to stability of the banking system. Profitability ratios should be seen in context, and the cost of free capital should be deducted prior to drawing assumptions of profitability.

**Figure 4. Financial ratios of Estonian commercial banks, 31.03.1994 - 31.03.2005**

Source: Bank of Estonia (authors calculations)

The consolidation of the banking sector and changes of the ownership structure resulted in a significant strengthening of banks' capital base and liquidity. The capitalization increased over 16% of weighted assets and it has continued to be at the same level. In addition, risk management and corporate governance practices were reviewed. All these developments led to the renewed increase of profitability in the banking sector in 1999. Additionally, the substantial deepening of financial intermediation has taken place, the balance sheet of commercial banks almost doubled during last three years. End of third quarter 1999, total assets of the banking sector were nearly 3 billion euros, which is 61% of GDP. The developments in the banking sector

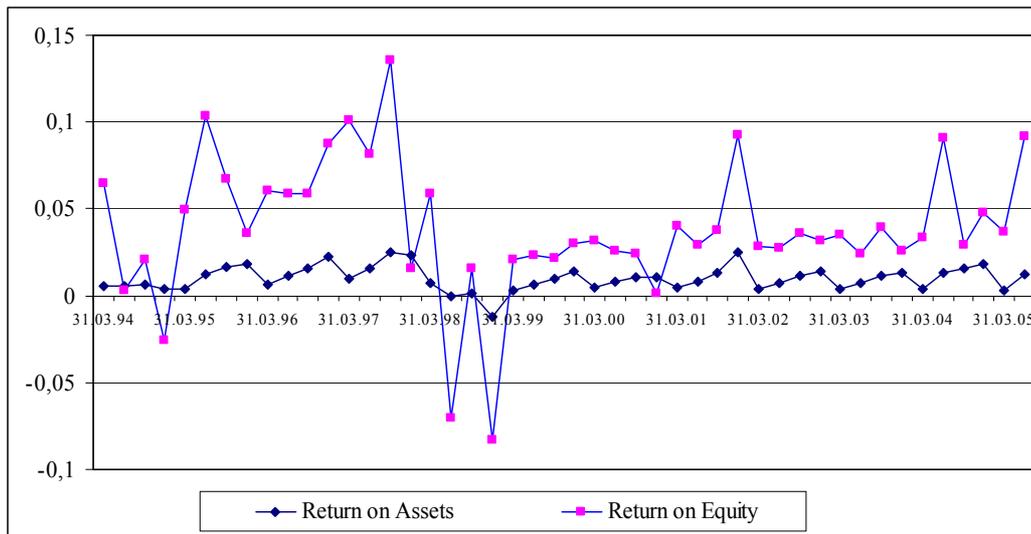

have been rapid, indeed, and the increased stability, integration and efficiency are important factors for sector's further progress.

Return of total assets (ROA) is one of the most frequently used by financial analysts. ROA measures the ability of bank management to generate income after all financial and non-financial costs and expenses for owners. Changes in ROA are usually the cause of most important changes in banks' performance and need a more detailed analysis.

Estonian domestic banks had a particular bad year in 1998 and 1999 when their combined ROA was -2, 4%. Naaborg and other authors examined to what extent foreign banks are more efficient and profitable in transition countries. Their general conclusion can be that both for domestic and the foreign banks there is an upward trend in ROA, while domestic banks were more sensitive to the economic and financial crisis in 1998 than foreign banks (Naaborg 2004).

As total assets present the volume of total resources available to the bank, ROA can be interpreted as an overall measure of banks' performance.

**Figure 5. Return on Assets (ROA) and on Equity (ROE) Estonian commercial banks, 31.03.1994 - 31.03.2005**

Source: Bank of Estonia

The book rate of return on equity is the most widely used and popular descriptor of the banks' performance, results from the viewpoint of owners (investors).

Both ROE and ROA are having significantly changing levels during the period under consideration. Highest consolidated returns were in 3rd quarter of 1997 (28, 8%) when lowest were in the end of 1998 (-7,5%). This

period was really difficult for all banks in Estonia, what can be seen also from the figure, as the total banking sector had losses.

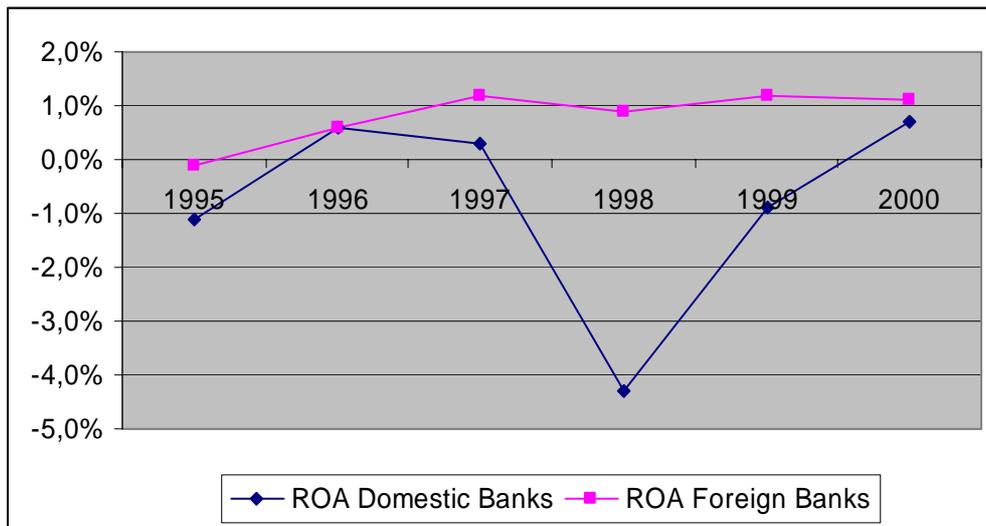

Returns are fluctuating in periods of approximately a year, although it is not exact. Large fluctuations are caused partially by the low equity requirement; also some insufficient control by Estonian Financial Authorities may be one of the reasons.

According to Claessens et al. (2001), foreign banks are more profitable and efficient than domestic banks in developing countries, while in developed countries domestic banks are more profitable and efficient than foreign banks. These differences can reflect a differential impact of informational (dis)advantages, customer bases, bank procedures as well as different relevant regulatory and tax regimes.

There are only few studies on the profitability and efficiency of the banking sector in the transition economies. Green et al. (2002) estimate the efficiency of domestic and foreign banks in Central and Eastern Europe, in terms of economies of scale and scope. They find that foreign banks are not really different from domestic banks and that bank ownership (foreign versus domestic) is not an important factor in reducing bank costs.

Naaborg (2004) examines to what extent foreign banks are more efficient and profitable in transition countries, they investigate a number of indicators at the aggregate level for both foreign and domestic banks. The first indicator reflects banks' profitability is the return on assets (ROA). Figure 6 gives the average ROA for foreign and domestic banks. It appears that the average ROA of foreign banks is higher than the average ROA of the domestic banks.

**Figure 6. Return on assets of banks in CEE countries: foreign vs. domestic banks, 1995-2000**

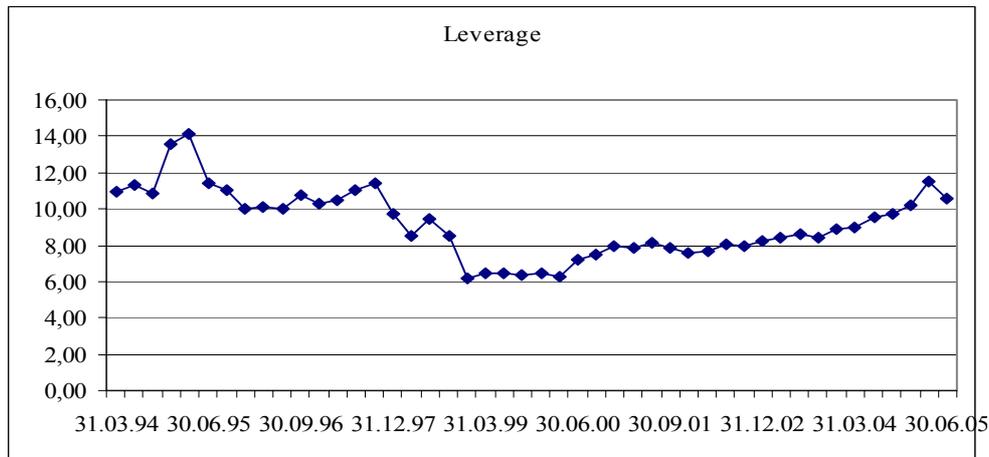

*Source: Naaborg 2004*

The picture is severely affected by bad results for domestic banks in 1998 and 1999. In all other years, the ROA of domestic banks did not diverge much from that of foreign banks. Figure 6 shows that the ROA of domestic banks tends to converge to the average ROA level of foreign banks. The general conclusion can be that both for domestic and for foreign banks there is an upward trend in ROA, while domestic banks were more sensitive to the economic and financial crisis in 1998 (moratorium from the Russian debt crisis) than foreign banks.

Financial leverage ratio measures how many kroons of assets the bank has per one kroon of equity and may be interpreted as a descriptor of the banks' gearing. On the Figure 7 leverage is presented.

**Figure 7. Financial leverage ratio of Estonian commercial banks, 31.03.1994 - 31.06.2005**

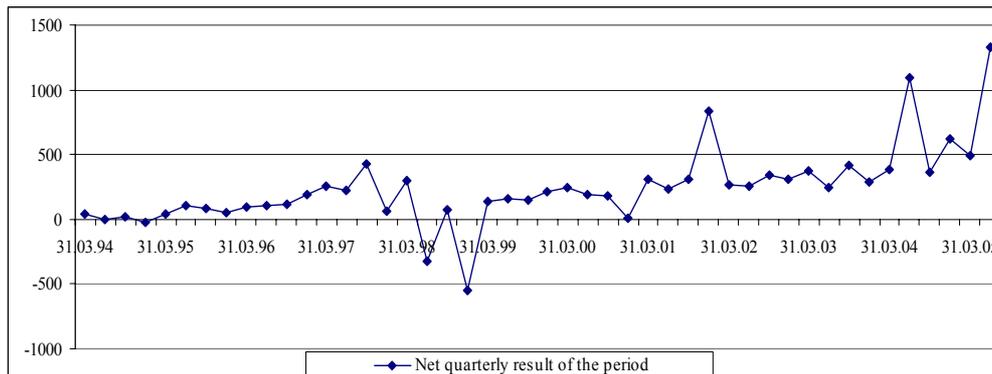

Source: Bank of Estonia (author's calculations)

Two different periods can be seen on the figure: the first one in periods 1994 to 1998 and the second from 1999 until today. The first period can be characterised as a period of significant fluctuations of leverage on higher level. The second presents more stable and balanced development stage. This first period was partially caused by small equity requirement, which enabled banks to achieve high leverage and, at the same time to take higher risks, what caused large fluctuations. Banks leverage ratio decreased substantially due to a Central Banks new equity requirements which forced banks to raise equity or to merge. Growth started again in 2000 and has stabilised after 2001.

Until 1997 the Estonian banking sector was characterised by a rapid nominal growth of total assets and loan portfolios. 1997 was the beginning of a new stage in the development of the Estonian financial sector, especially in the international context, which is confirmed by investment grade credit ratings assigned to Estonia. The rapidly growing economy boosted credit demand and also non-banking financial intermediation accelerated.

**Figure 8. The net quarterly result of the banks Estonian commercial banks, 31.03.1994 - 31.03.2005**

Source: Bank of Estonia

The net result of the banks is fluctuating on a yearly basis, caused by accumulation of the profit during the year.

The main factor of change in returns is the change of profit margin. If the difference between lowest and highest level of ROE is more than 3 times, the same difference in profit margin is more than 4 times. At the same time assets utilisation decreased approximately 10%. This is indicating to the improved cost control in Estonian banks as well as to the overall increase of banks efficiency. Decrease of the leverage influenced negatively ROE of banks in the period 1997 to 1998, but it decreased risks in banking sector causing the total number of banks to decrease.

Largest jumps in quarterly profits are in 1997 – 1998, when the backwash of instability of financial markets and collapse of sales to Russian market of main customers of Estonian banks caused profits to be either high or very low. In two quarters total result of Estonian banks was negative, the achievement what has been repeated any more.

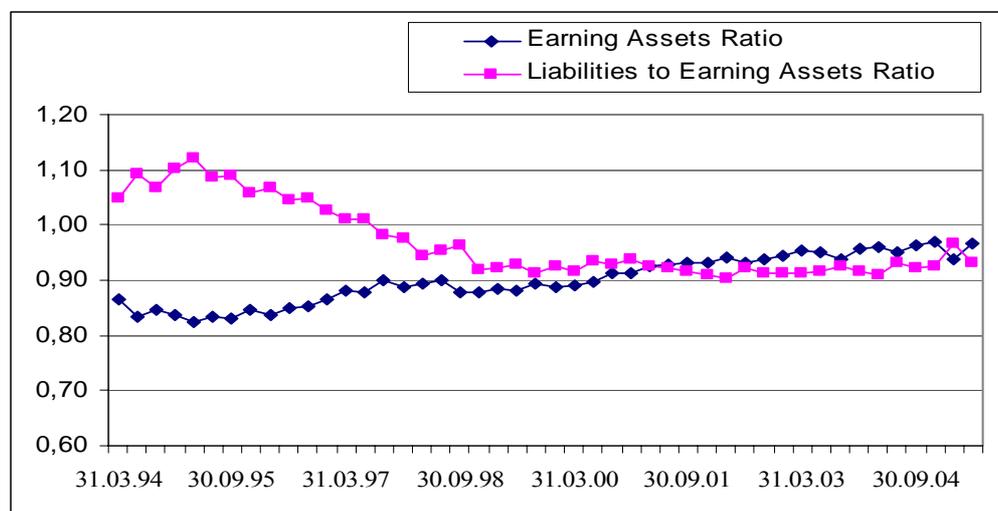

After that the banking sector has been stabilised, partly due to interference of Estonian Banking Authorities, partly due to obtaining of control by Scandinavian banks over Estonian major banks (Estonian Savings Bank, Hansapank, Estonian Union Bank, Optiva Bank).

The ratios, used for the graphs above are presented at the appendix 1.

Strong and stable net interest margins have traditionally been the primary objective of bank managers, and are still the primary determinant of intermediation efficiency and earning performance. An analysis of the interest margin of a bank can highlight the effect of current interest rate patterns, while a trend analysis over a longer period of time can show the effect of monetary policy on the profitability of the banking system. It can

also illustrate the extent to which banks are exposed to changes in interest rates, and thus the ability of management to effectively manage interest rate risk.

**Figure 9. Earning Assets Ratio and Liabilities to Earning Assets Ratio in Estonia**

Source: Bank of Estonia (authors calculations)

As you can see on the figure 9, there is the stable period after consolidation with foreign banks. Before the second crises in 1998-1999 there was a great difference between two ratios, after foreign banks entrance this difference almost disappeared.

The banking market concentration, being the share of three largest banks assets in total banks' assets, achieved more than 90% already in 1998. Foreign banks share in total assets of Estonian commercial banks increased dramatically and was 97, 4% at the end of 2000. The Estonian financial sector is clearly bank-oriented – the bank assets to GDP ratio was 68,2% and the banks assets share in total financial assets was more than 60% in the last years. Private credits by banks and other financial institutions increased considerably during the analysed period – a private credit by banks to GDP ratio was 38,7% and overall private credits to GDP ratio 49,7% in 2000.

At different times internationalisation has had various goals and forms. Besides the macroeconomic factors that rule the internationalisation of banks the ambitions of bank managers also play an important role. In the bankers viewpoint the motives of internationalisation can be divided into four groups (Rugmah and Kamath, 1987):

- Use the potential ability of a bank more entirely, for example, the domestic management and sales skills may enable banks to offer services abroad at lower costs. It also enables local companies, subsidiaries abroad to use competent information about the possibilities and conditions in the mother country.
- Use the reputation of the parent bank. The subsidiaries set up abroad may get competitive advantages as, by a rule, an international bank is considered more reliable than the local banks.
- Reduce banking regulations. In many cases the main purpose of setting up subsidiaries and branches abroad is to overcome the restrictions on moving capital abroad.
- Reduce risks. As economic situation, legislation political situation and other circumstances may change, being present will enable to recognise the risks in time and take necessary countermeasures.

There are several positive effects of foreign banks' entry into Estonia. Foreign banks entry has improved service innovation in Estonian banking. The largest Estonian banks are Hansabank and Union Bank, which both have a large share of foreign capital, have well-developed Internet banking services. A very positive spill-over from foreign banks is modern bank risk management. Foreign banks have made Estonian banks more trustable and lending from international markets has become less expensive for banks and also for banks' customers.

The Estonian banking market was quite competitive in the end of 1997, but today, after several mergers and bankruptcies, the Estonian banking market is excessively concentrated by international standards.

#### **4. Conclusions**

As there is tight connection between banking sector success and overall growth in GDP, it is difficult to say whether improved efficiency of Estonian banks was caused by stabilised macroeconomic environment or entry of foreign financial institutions has improved Estonian banks systems in the way that they were able to stabilise the whole economy.

It is clear that better risk management has stabilised returns of Estonian banks. As the banking sector was highly aggressive in periods 1994 to 1998, the returns fluctuated in large scale. After 1998 returns have stabilised.

After banking crises of 1998, Estonian banks have matured and they hardly can be named as transition economy's banks; style, performance and abilities are more close to Scandinavian tradition than to transition economy's habitants.

Estonian commercial banks have passed the same internationalisation stages as the banks of developed countries: first, establishing correspondent relations with the banks of other countries, then entering the international and capital markets, and finally, building up controlled units within the boundaries of other national banking systems.

Estonian banking sector is also opened to the invasion of foreign banks. The internationalization experience of the Estonian banks shows that the process is inevitable and useful at the same time for such a small country as Estonia.

The challenges for the banks after foreign investors' entry will be summarized in the form of following statements:

1. All three worldwide trends in the financial consolidation process also in the Estonian market: domestic consolidation, foreign entry and cross-border consolidation, and the formation of financial conglomerates and bank assurances;
2. An improvement of the risk profile, reputation and risk management of local banks and hence to financial stability in NMSs and a convergence with western standards;
3. Foreign banks entry has improved service innovation in Estonian banking;
4. The stable period in ratios after the second banking crisis 1998-1999 and consolidation with foreign banks;
5. An upward trend in ROA, while domestic banks were more sensitive to the economic and financial crisis in 1998 than foreign banks;
6. Foreign presence in banking is notably high in Estonia. On average, more than 70% of bank assets are foreign-owned in New Member States. Banks with foreign capital control around 97 per cent of the Estonian banking sector;
7. Correlation between foreign ownership and ROA in New Member States is 0,78 (ECB 2005). There is quite strong relationship between foreign ownership and return on assets. ROA is greater in Estonia than in other states.

## **Abstract**

*This study uses IPS test methodology to test for unit roots for the panel data and analyze the profit persistency in the Turkish Banking Industry. For this purpose, banks profit rates (ROA) employed in this study. As it is expected, results of the study indicate that, banks operating in Turkey have different speed of adjustment and long run profit persistency. Peer group analysis, has also shown that, they share different profit persistency. Hence, findings reveal that, banks have diverse market behaviour in the Turkish Banking Industry, which increases competition in the banking industry.*

**Keywords:** *profit persistence, banking sector, IPS test, Turkey*

## 1. Introduction

The role of banking industry in efficient fund transfer is more important for developing countries than developed countries. The need for efficient allocation of resources is the result of growth motives of the countries. Hence, to reach this task, it needs efficiently operating financial system and institutions. Since, financial markets especially capital markets and related financial institutions are not developed such a level that can eliminate asymmetric information and related problems, the role of banks in these countries gain more importance.

Efficiently functioning banking system provides better and low cost services to creditors and borrowers. Hence, facilitates transfer of funds in the economy. Among others, one of the most important prerequisites of efficiency is the competition. As competition increases in the market, firms try to allocate their productive resources as efficiently as possible. The aim of this effort is to strengthen their competitiveness in the industry. By this way, they can protect their ex post profit level and set up new entry barriers in the industry. Their successes in creating barriers will be proportional to profit level and hence, persistency of profits in the industry.

Since the banking industry is among the most regulated industries, we can assume that entry barriers have already existed. Therefore, we can expect higher profit persistency. Nevertheless, profit persistency is not only determined by regulatory environment. Sensitivity to micro and macroeconomic policies plays crucial role in competition and persistency of profits in the banking industry<sup>1</sup>. Therefore, to consider determinants of profits in a simple equation, like in other persistency studies, a reduced model of the profit function is used in our study.

This paper analyses profit persistency of a banking system in an emerging market economy, namely the Turkey. It uses time series analysis of twenty eight surviving banks for the years 1989 to 2003. The persistency of profits in the Turkish Banking Industry (TBI) is evaluated by using the net income after tax to total assets (ROA) as a profit measure. Study applies well established profit persistency methodology that has been using very widely to measure profit persistency in non-financial sectors (Mueller, 1977; Geroski and Jacquemin, 1988; Glen et al., 2001; Maruyama and Odagiri, 2002; Glen et al., 2003; Yurtoglu, 2004). Although we employ same methodology to measure profit persistency and hence, the competitiveness, different from

---

<sup>1</sup> Berger et al. (2002) find that, in addition to market power in input markets, regional macroeconomic shocks are also important for banks profit persistency in U.S.

previous studies, it is done for an emerging country's banking sector. The panel structure of data leads us to employ IPS test methodology for the unit root test which was developed by Im et al. (2003).

## 2. Methodology and Data

Similar to previous studies Yurtoglu (2004), Glen et al. (2003), Maruyama and Odagiri (2002), Glen et al. (2001), we also employ the following first order autoregressive equation to estimate the persistency of banks' profits. The critical reason of concentrating on the first order autoregressive equation is the insignificant lagged variables at a higher order which is common in many other studies.

The model of the study is:

$$\pi_{i,t} = \alpha_i + \lambda_i \pi_{i,t-1} + \mu_{i,t} \quad (1)$$

where  $\pi_{i,t}$  is derived as follows,

$$\pi_{i,t} = P_{i,t} - \bar{P}_t \quad \text{where} \quad \bar{P}_t = \sum_{i=1}^n P_{i,t} / n \quad (2)$$

In equation 2  $\bar{P}_t$  is the average profit rate of banks operating in the industry for the current year. Due to business cycles or macroeconomic changes, there would be an extensive variation in the profit rates of banks. Hence, these would have negative implications to the econometric analysis. Therefore, banks' profit level is normalized and controlled, by subtracting industry average  $\bar{P}_t$  at time t, from the profit rate  $P_{i,t}$  of bank  $i$  at time t.<sup>2</sup> Peculiarity of the banking system makes it more sensitive to business cycles, regulatory changes and other economic changes. Hence demeaning of data is becoming more important.

As indicated in persistency studies, for example, Geroski (1990), equation 1 is a reduced form equation, which contains implications of the other important determinants of competition (especially unobservable ones), like potential threat of entry. Therefore, the use of equation 1 in time series estimation eliminates the role of unobservable variables in the determination of competitive forces. Using profit rates as observable data therefore, not

---

<sup>2</sup> This normalization process is becoming more important for countries like Turkey, where economy is highly unstable due to political instabilities, balance of payment, budget deficit and inflation.

requiring unobservable data provides advantage to this equation. Nevertheless, its inability in the specification of different determinants of competitive forces can be evaluated as the weakness of the equation.

By regressing  $\pi_{i,t-1}$  on  $\pi_{i,t}$ , the impact of previous years profit rates to the current year profit rates can be estimated. In other words, the value of  $\lambda_i$  predicts the intensity of competition or speed of adjustment towards the mean profit of the industry. Hence, it can be used to measure the persistency of the profits in a particular industry or market. Given the condition of  $-1 < \lambda_i < 1$  the long-run profit rate or equilibrium profit rate of a firm, is provided by:

$$\pi_{i,p} = \frac{\alpha}{(1 - \lambda_i)} \quad (3)$$

The lower value of  $(1 - \lambda_i)$  implies, transfer of the previous year's profit rate to current year is highly usual. In other words, previous years profits can be carried over to the next year. Therefore, convergence or speed of adjustment process towards the norm of the industry is quite slow. In the industries where competitive forces exist and are functional, the value of  $\lambda_i$  is expected to be at lower values. According to Maruyama and Odagiri (2002)  $\lambda_i$  can be used to evaluate speed of adjustment and stickiness of the short run abnormal profits.

We propose that entry decision is determined by after tax figures. Therefore, in our return on assets (ROA) calculations, we use net income after tax. To consider the time and cross-section dimension of data, we employed panel data of 29 banks ROA from the TBS and have common run of 14 observations for the period 1990-2003. In persistency studies, time dimension of data is one of the prerequisite for the evaluation of the previous year's impact to current years.

### 3. Results

In time series analysis autoregressive models are commonly used for forecasting future values of an economic variable that contains information on their past values. However, to avoid spurious regression and inference mistakes, the Dickey-Fuller (DF) test or augmented Dickey-Fuller (ADF) test is required to test whether the series are stationary or nonstationary. Therefore, we first start our analysis by testing unit root hypothesis for our banks data, and then we check the serial correlation of our disturbances in equation 1 and finally, we investigate the lag structure of our equation.

The application of ADF test to panel data which has time and cross section dimension is well explained in Im et al. (2003). The test simply based on the average value of the augmented DF statistics. If there is no serial correlation, panel unit root test can also be done by using the DF test. In this study, the test will be based on the average value of the DF statistics. The standard DF statistic for each group is given by the t-ratio of  $\beta_i$  in the DF version of equation 1 which is given by:

$$\Delta\pi_{i,t} = \alpha_i + \beta_i \pi_{i,t-1} + \varepsilon_{i,t} \quad (4)$$

where  $\beta_i = \lambda_i - 1$  and  $\Delta\pi_{i,t} = \pi_{i,t} - \pi_{i,t-1}$ . An alternative hypothesis formulated as above equation, allows for  $\beta_i$  differing across groups and also allows for some of the individual series to have unit roots. Using the equation 4, we begin by estimating DF t-statistics for each bank. Then, we calculate the average value of the t-statistics from equation 4. The result is equal to -2.25 for the sample of 28 banks observed over the 1989-2003 period. Since the calculated t-statistics is lower than the critical value of the standardized t-bar test at the 1% level (-1.97), the null hypothesis of nonstationary ROA is rejected<sup>3</sup>. After the rejection of unit root, serial correlation of disturbances are analysed through Breusch-Godfrey LM test and Ljung-Box Q-statistic. In the light of these statistics, autocorrelation of disturbances in the first, second and third order is not observed in equation 1. Finally, to decide on the lag structure of equation 1, we use general-to-specific procedure and employ Akaike Information Criterion, Schwarz Bayesian Criterion and assessed the t-values of lagged coefficients and adjusted  $R^2$  of estimated equation (Erlat and Ozdemir, 2003; Enders, 1995). Most of the equations favoured to equation 1 as a more appropriate way of estimating persistency of profits in the Turkish Banking System.

**Table 1. Regression results, speed of adjustment and the estimates of long-run projected profit rate of the industry**

	$\hat{\alpha}$	$t(\hat{\alpha})$	$\hat{\lambda}$	$t(\hat{\lambda})$	$1-\hat{\lambda}$	$\hat{\pi}_{ip} = \hat{\alpha} / (1-\hat{\lambda})$	$\bar{R}^2$
Mean	0.017	0.76	0.44	1.76	0.56	0.03	0.16

Table 1 summarizes regression results of the equation 1. The estimated  $\lambda_i$  changes in between very high value of 0.74 and 0.03 with a mean of 0.44. The mean value of the speed of adjustment ( $1-\hat{\lambda}$ ) that is determined by  $\hat{\lambda}$  is 0.56 and significantly different from zero for about 53% of the sample. This shows that the convergence towards the norm is above

<sup>3</sup> Nonstationarity of the private and foreign banks are also rejected, however we could not reject it for state banks.

the average. Four of the banks in our sample have negative long run projected profit rate.<sup>4</sup> Nevertheless, 14 of them earn positive long run profit rate above the mean  $\hat{\pi}_{ip}$ , which is 0.03. Adjusted  $R^2$  explains more than 10% variation in the relative profit rates in 17 cases (61%) out of 28. Results of the study show that competition among the surviving banks is moderately high in the Turkish Banking Industry.<sup>5</sup>

Although general results are above, more specific results in terms of ownership provide could provide more insight to our analysis. Therefore, we extend our analysis by classifying banks operating in Turkey in terms of ownership. Then, we have three different classes such as, public banks, private banks and foreign banks.

In the following paragraph we evaluate the private banks profit persistency. For the evaluation purpose, we are going to use table 2 results. As can be seen estimated  $\lambda_i$  (0.43) is almost same with the industry average of 0.44. Nevertheless, smaller value of  $\hat{\alpha}$  (0.1) has shown its impact to long run persistency where  $\hat{\alpha}$  and  $\hat{\lambda}$  used together. The speed of adjustment process is also higher (0.57) than the industry average. Hence, private banks have lower long run profits persistency (0.02) than the industry average. This indicates that private banks are more competitive than the industry.

**Table 2. Regression results, speed of adjustment and the estimates of long-run projected profit rate of the private banks.**

	$\hat{\alpha}$	$t(\hat{\alpha})$	$\hat{\lambda}$	$t(\hat{\lambda})$	$1-\hat{\lambda}$	$\hat{\pi}_{ip}=\hat{\alpha}/(1-\hat{\lambda})$	$\bar{R}^2$
Mean	0.01	0.68	0.43	1.73	0.57	0.02	0.15

Foreign banks can have competitive advantages of having better access to foreign markets, technology and skilled bankers. However, factors like, customer relationship, information asymmetries and economic character of domestic country may have negative influences on their operations. Under such an environment we expect lower profit persistency for foreign banks operating in Turkey.

**Table 3. Regression results, speed of adjustment and the estimates of long-run projected profit rate of the foreign banks.**

	$\hat{\alpha}$	$t(\hat{\alpha})$	$\hat{\lambda}$	$t(\hat{\lambda})$	$1-\hat{\lambda}$	$\hat{\pi}_{ip}=\hat{\alpha}/(1-\hat{\lambda})$	$\bar{R}^2$
Mean	0.03	1.09	0.39	1.47	0.61	0.04	0.12

<sup>4</sup> For the US BHCs Roland (1997) find that, there are more BHCs persistently generating negative abnormal profits than BHCs generating positive abnormal profits

<sup>5</sup> Okumus (2002), profitability study also supports our findings.

Since  $\hat{\lambda}$  can be used to predict intensity of competition and speed of adjustment, results at above show that, competition in TBS is higher for foreign banks. In other words, they could not carry their previous year's profits to current year as their competitors. Although, they have higher speed of adjustment, interestingly their long run profit equilibrium is higher than the private banks. This is because of the constant  $\hat{\alpha}$  which represents competitive and permanent return of banks. As it is shown in table 3, this is higher than the industry and private banks average. Nevertheless,  $\hat{\alpha}$  and  $\hat{\lambda}$  t-value are statistically insignificant, therefore, this result can not be taken into consideration.

In our study, we employ three public banks which are currently operating in TBS. Although we have nonstationary problem with this panel because of data size, we would like to use it to provide some sensible findings. Having different motives than private and foreign banks, as it is expected results are fairly different than the other groups.

**Table 4. Regression results, speed of adjustment and the estimates of long-run projected profit rate of the state banks.**

	$\hat{\alpha}$	$t(\hat{\alpha})$	$\hat{\lambda}$	$t(\hat{\lambda})$	$1-\hat{\lambda}$	$\hat{\pi}_{ip}=\hat{\alpha}/(1-\hat{\lambda})$	$\bar{R}^2$
Mean	0	0.23	0.62	2.87	0.38	0	0.35

Due to operational inefficiencies and political interventions to public banks, we do not expect competitive and permanent return for them. This expectation is realized for public banks having zero for constant. Nevertheless, these are the very large banks that own large market share. Relatively high and statistically significant  $\hat{\lambda}$  value (0.62) of public banks, which reflects short-run profit actually do not reflect long run profit persistency. This statement is also approved by  $\hat{\pi}_{ip}$ , which shows long-run or equilibrium profit rate. Nevertheless, this means that they have slower adjustment mechanism than the private and foreign banks. And this could have negative implications to banking industry in general.

#### 4. Conclusion

The aim of the study is to investigate persistency of profits and hence, competition of the banking industry in Turkey. This investigation is done on different peer group basis. To carry out our study, we divide TBI into four groups. First group consist of all banks making the industry. We consider

private banks as or second group, foreign banks as third group and the fourth group represented by the public banks.

In our study, we use IPS test methodology to apply the ADF test for the unit root hypothesis to the panel data. The unit root hypothesis is rejected for our data except for the public banks. The general results for the industry indicates that long run mean profit rate for the industry is very close to zero therefore, in the long run persistency of profits does not exist in the Turkish Banking Industry. Hence, we can say competitive forces in the TBI are at work to eliminate the profits above the norm. Although this result is shared by the private bank's peer group, they are different for foreign and public banks.

## **Abstract**

*Cross-border mergers and acquisitions (M&A) are an important aspect of global foreign direct investment flows. Transnational corporations use them to strengthen their market position and to create transnational production networks. The aim of this paper is to describe M&A transactions in central and Eastern Europe after the year 2000. The key findings are that M&A transactions are weak in CEE countries compared to the global M&A activities and that the M&As are dominated by public transactions (privatisation deals). Local IT corporations are a notable exception as many local software developers offer innovative and progressive products.*

**Keywords:** *cross-border mergers and acquisitions, central and eastern Europe, Czech Republic, Slovakia*

## **1. Introduction**

The world economy is a complex economic system and is getting more and more complex every day. Global corporations create production and sales networks, which cross countries and continents. Cross-border mergers and acquisitions (M&A) are an important tool helping to create international corporate networks. The vast majority of cross-border mergers and acquisitions takes place in economically developed countries as these countries are home to the largest and most progressive transnational corporations. On the other hand, available data show that the number and value of cross-border M&As in developing and transition countries fall behind every year.

The aim of this paper is to analyse the role of cross-border mergers and acquisitions in the region of central and Eastern Europe between 2002 and 2004. The main goal is to identify the main trends in the field of cross-border M&As in central and eastern Europe and to show the most active countries not only in sales but in purchases as well. The paper devotes extra space to Slovakia and to the Czech Republic as these are the home countries of the author.

The region of central and eastern Europe for the purpose of this paper consists of 19 countries – Hungary, Czech republic, Poland, Slovakia, Slovenia, Estonia, Latvia, Lithuania, Romania, Bulgaria, Croatia, Albania, Serbia and Montenegro, Macedonia, Bosnia and Herzegovina, Russian federation, Ukraine, Moldavia and Belarus.

The data used for the analysis is taken from the statistical annexes of the most recent UNCTAD World Investment Reports (2004 and 2005). PriceWaterhouseCoopers reports on M&As in central and eastern Europe, Czech republic and Slovakia in 2003 and 2004 are used as an additional data source.

## **2. Cross-border mergers and acquisitions in the world in 2003 and 2004**

The year 2003 witnessed the continuing fall of cross-border M&As as they fell from 370 billion USD in 2002 to 297 billion in 2003 (decline of approximately 20%). to 297 billion USD in 2003 – a decline of 20%. There were only 56 mega deals (of 1 billion USD and over in transaction value) in 2003, a third of the peak number achieved in 2000 (see table 1). The largest

single deal was the acquisition of Household International Inc. (United States) by HSBC Holdings Plc. (United Kingdom) for 15.3 billion USD.

The number of cross-border M&As in 2003 was, with more than 4,500 deals, much lower than the number of greenfield projects. Three of the six countries leading in terms of the number of greenfield projects also led in cross-border M&As. The United States was the largest target country (722 M&A deals), followed by the United Kingdom (459) and Germany (296). In the developing world, China (214) ranked first (4th place in the world), followed by Hong Kong (China) (108), India (83) and Brazil (69). In terms of value, the top nine were all developed countries, followed by the Russian Federation and Hong Kong (China).

An important factor in the decline of FDI, and particularly of M&As, has been a slowdown or end in privatisation. The total sale of State-owned assets fell from about 50 billion USD in 2000 to less than 20 billion USD in 2003. Privatisation-related FDI in developing countries fell to one-tenth the level of 1998, from a record 33 billion USD that year to 3.5 billion USD in 2003. Liquidity and other problems at home lowered TNCs' interests in privatisation. At the same time, some developing countries, particularly in Latin America, became more sceptical of its benefits. Privatisation-related FDI in CEE declined as well<sup>1</sup>.

After several years of sluggish performance cross-border M&As grew in the world economy in 2004, when they rose by 28% and reached 381 billion USD. The number of cross-border M&A deals rose slightly (by 12%) and the total number of deals was around 5 100. There was a significant growth of mega M&A deals (value of the deal exceeding 1 billion USD) in 2004, which contributed to the overall growth of M&A transactions. The largest deal in 2004 was the acquisition of Abbey National (United Kingdom) by Santander Central Hispano (Spain) for 15.8 billion USD, almost the same value as that of the largest deal in 2003 but only one-thirteenth of the largest deal ever (the Vodafone-Mannesmann deal in 2000).

---

<sup>1</sup> Source: UNCTAD World Investment Report 2004

**Table 1 Cross-border M&As with values of over \$1 billion, 1996-2004**

Year	Number of deals	Percentage of total	Value (billion \$)	Percentage of total
1996	43	0,9	94,0	41,4
1997	67	1,3	129,2	42,2
1998	86	1,5	329,7	62,0
1999	114	1,6	522,0	68,1
2000	175	2,2	866,2	75,7
2001	113	1,9	378,0	63,7
2002	81	1,8	213,9	57,8
2003	56	1,2	141,1	47,5
2004	75	1,5	199,8	52,5

Source: UNCTAD World Investment Report 2005, p. 9

The growth of cross-border M&A transactions was more visible on the local rather on the global level. For example, M&A deals among EU-15 countries rose by 57% in 2004 and their total value reached 99 billion USD. In addition to low interest rates in major economies and rising corporate profits, the recovery of asset prices since 2003 (as reflected in the rise in stock exchange indices) contributed to the rise in M&As. Indeed, partly as a result of increased stock prices, the number of cross-border deals using stock swaps rose from 123 to 161 in 2004 (close to the number of such deals in 1999), accounting for 16% of the total value of cross-border M&As.

The growth in the value and number of cross-border M&As in 2004 was largely due to transactions taking place among developed-country firms: their value rose by 29%. In developing countries – where such transactions are normally less common, as fewer companies attract foreign investors and restrictions continue to be imposed on M&As – cross-border M&As also rose in 2004 by 36% in value, to reach 55 billion USD, two-thirds of the peak reached in 2001. There was a significant rise in cross-border M&A purchases in China and India, with a doubling of value in both countries, to record highs of 6.8 billion USD and 1.8 billion USD respectively. For the first time, China became the largest target country for cross-border M&As in developing countries<sup>2</sup>.

### **3. Cross-border mergers and acquisitions in central and Eastern Europe in 2002-2004**

Central and eastern Europe (CEE) emerged as a favourite spot for FDI in the recent years. Many companies (notably in the automotive industry and in electronics) decided to use the comparative advantages of the region and established there their factories in order to service the European markets. New production capacities in CEE are usually developed by greenfield projects, as suitable factories do not exist or they lack new technologies. Currently available data (collected by UNCTAD) confirm the mentioned fact, greenfield projects are getting to dominate the FDI inflows in CEE countries.

Cross-border M&A transactions can usually be divided into private transactions (a foreign private corporation buys controlling stake in a local private corporation) or public transaction (a foreign corporation buys controlling stake in a local public - state-owned or municipal – corporation). Data available in CEE states shows that M&A transactions are still dominated by public transactions – privatisation deals. UNCTAD surveys published in the World Investment report series show that between 1990 and 2003 approximately two thirds of total FDI inflows in CEE countries were covered by privatisation transactions. All CEE countries opened their privatisation processes in (in a larger or smaller extent) to foreign companies and sold lucrative state-owned companies in key sectors (ex. telecommunications or financial sector)

Review of data available about cross-border M&A transactions shows that between 2002 and 2004 the total value of cross-border M&A deals in which CEE countries acted as sellers fell constantly. In 2002 foreign corporations bought local companies in total value of 17 billion USD. In 2003 the value of sales fell by 16% and reached only 14,4 billion USD. The fall of cross-border transactions continued also in 2004 when M&A sales fell again by 14% reached 12,4 billion USD. Outward cross-border M&A transactions (companies from CEE region buying foreign corporations) were very unstable between 2002 and 2004 when the total value of outward cross-border M&A transactions rose steeply from 1,08 billion USD (2002) to 10,6 billion USD in 2003. The rapid growth was followed by a huge decline in 2004 when outward cross-border M&A transactions fell to 2,1 billion USD.

The main factor behind the falling cross-border M&A sales in CEE is the near end of privatisation transactions in central European countries. Hungary is a good example, as in this country privatisation finished around the year 2000 and the value of cross-border M&A sales falls constantly between 2002 and 2004. Similar pattern can be identified in the field of cross-border M&A sales in Slovakia, Czech Republic and Poland – these

countries conduct the last large privatisation transactions and cross-border M&As fall steadily in these states. On the other hand, privatisation activities were booming in Balkan states between 2002 and 2004 and states like Bulgaria, Romania or Albania recorded the highest cross-border M&A sales in their history. Romania is a fine example, as the year 2004 was marked by the huge privatisation sale of the Romanian oil company Petrom.

Outward cross-border M&As are negligible in CEE countries, as their share in the global M&As is very low (less than 1% in 2002 and 2004). The year 2003 is a rare exception, in this year the share of cross-border M&A purchases of CEE companies reached 3,5% of the global M&A transactions. The steep rise in outward cross-border M&A activities in CEE in 2003 was caused by the strong activity of Russian corporations. These corporations were accountable for 82% of the total outward cross-border M&A transactions in 2003.

Why are the cross-border M&A purchases so weak in CEE countries? The most important factor is the lack of strong local companies. M&As are usually dominated by transnational corporations and the number of strong local TNCs is very low in CEE. The most companies were in situation after the fall of the communist regime in 1989, as they were undercapitalised and lacked modern technologies. Large companies could not compete with successful transnational corporations from economically developed countries and were gradually purchased by them through privatisation transaction. Today, the majority of important local companies belongs to transnational networks and are losing their right to make independent strategic decisions. Business strategies of TNCs and M&A decisions are usually developed in the headquarters and local branches have only very limited authority in these issues. The situation is not likely to improve in the field of cross-border M&A purchases in the future; foreign TNCs will continue to dominate the economies of CEE countries.

**Table 2 Cross-border M&As in central and eastern Europe in 2002-2004 (billion \$)**

	Sales			Purchases		
	2002	2003	2004	2002	2003	2004
<b>Total</b>	<b>17 014</b>	<b>14 438</b>	<b>12 424</b>	<b>1 088</b>	<b>10 467</b>	<b>2 174</b>

*Source: UNCTAD World Investment Report 2005, p. 325-327*

The above-mentioned hypothesis can be easily proved. Currently, the most active M&A activities are found in Russia, where strong local oil and natural gas companies retained their independence and are gradually building a strong competitive position. The same is true for Hungarian companies

MOL (oil) and OTP (banking). These companies were not sold to in privatisation to a TNC and are owned by a wide array of domestic and foreign investors. That means that the business strategies of these companies are developed in Hungary and both companies aim to establish a strong regional position. MOL invested in Slovakia, Croatia, Romania and Poland, while OTP invested in Bulgaria, Slovakia and Romania<sup>3</sup>.

Another interesting questions is the relatively low share of private transactions on the incoming cross-border M&As in CEE countries. This phenomenon can be also traced back to the fall of the communist regime in 1989. There were no private corporations prior this date in CEE countries, so all corporations are relatively young (max. 15 years old). So foreign corporations outside the CEE region did not find (and still do not find) enough attractive domestic private companies. Most of the local private companies are small and offer no progressive technologies or know-how. This is the main reason why foreign TNCs turn their attention to other regions and do not seek M&A possibilities in CEE countries.

In spite of the low attractiveness of local corporations, there were several interesting acquisitions in CEE last years. The most attractive local private corporation can be found in the IT industry, especially in software development and internet services. Private companies in these areas focus on high quality human resources and often offer breakthrough technologies or products. Czech company Grisoft, provide of the well-known anti-virus software AVG is a good example, as the controlling stake of this local company has been purchased by a venture investment fund led by IT giant Intel for 52 million USD. Leading Slovak IT solution provider Delta E.S. could be another example. This local IT company has been sold to Israeli company Ness Technologies for 7,75 million USD.

---

<sup>3</sup> PriceWaterhouseCoopers states in his 2003 report on M&A activities in CEE – “There were a total of 43 transactions originating from the nine countries forming part of the research. This represents a decrease when compared to 54 transactions in 2002. Nevertheless, total capital invested from these countries has more than doubled, from approximately USD 500 million in 2002 to about USD 1.1 billion in 2003. The growth was even more significant when considering the three countries of the Czech Republic, Hungary and Poland from USD 0.6 million in 2001 to USD 630 million in 2003. Out of the 43 transactions, 21 were targeted in the region of the surveyed countries as well, which represents a slight increase compared to 17 deals within the region in 2002. The most active country in terms of transaction origination remained Russia with 21 deals. Further important outward bidders were Hungary with seven, and the Czech Republic and Poland with five deals each.”

#### 4. Cross-border mergers and acquisitions in Slovakia and Czech Republic in 2004

Overall, M&A in *Czech Republic* were quite strong in 2004; PriceWaterhouseCoopers<sup>4</sup> registered 185 transactions (163 in 2003 and 144 in 2002). These numbers include all M&A transactions, the share of cross-border M&As was only 53%. This meant 98 transactions in 2004 compared to 86 transactions in 2003. The total value of cross-border M&As reached 2,543 billion USD which is also comparable to 2003.

In 2004, there were only 12 privatisation deals, most of them executed by the National Property Fund. The biggest public sector transaction and the only one of an amount over USD 100 million was the sale of Unipetrol to the Polish concern PKN Orlen for USD 411 million. Although this transaction was completed in 2004, it is still subject to EU approval and has thus not been included among the 12 transactions of 2004. The second biggest privatisation was the sale of the National property fund's stake in Sokolovská uhelná to Sokolovská těžební for USD 97 million.

In 2004, the top investor country for private sector deals was Germany with 12 transactions, followed by Austria (nine), Netherlands (nine) and – the new high ranking country – Slovakia with nine deals. In 2003, the top foreign investors were Germany, Austria, and the USA, whose transactions fell from nine in 2003 to six in 2004.

There were eight outward transactions made by Czech companies in 2004, two in each of Poland, Russia and Slovakia and one in each of Spain and Lithuania. The values of these transactions were not disclosed. Czech investors also took part in privatisation in the region and made three acquisitions in Bulgaria and one in Slovakia. In addition to this, CEZ was active in Romania in 2004, but this transaction is to be completed in 2005.

According to the PriceWaterhouseCoopers survey about M&A activity in *Slovakia* in 2004, M&As on the Slovak market increased to 85 publicly disclosed private sector deals, ahead of 61 in 2003 and 51 in 2002. Of the nine CEE countries surveyed by PricewaterhouseCoopers, Slovakia ranked fifth as in 2003, after the Czech Republic, Hungary, Poland and Russia, in the number of private sector deals. Given the size of the Slovak GDP, this ranking is unsurprising. However, in terms of the growth of the number of transactions, Slovakia ranked first as it grew unparalleled 39%. The proportion of cross-border M&A transactions including foreign investors

---

<sup>4</sup> Source: Central & Eastern European Mergers & Acquisitions Survey 2004 – The Czech Republic

was 55% in 2004 which is below the 61% in 2003<sup>5</sup>. As privatisation is almost finished in Slovakia, it is not surprising that private transactions dominated M&A activities in 2004. There were only four notable privatisation transactions in 2004; all of them included privatisation of bus transport companies.

As in 2003 in 2004, the top investor country for private sector deals was Austria, followed by Czech Republic and Netherlands. There were eleven outward transactions made by Slovak companies in 2004, all of them to the Czech Republic, in particular two financial groups J&T (acquisition of 34% in PRE and 100% in football club Sparta Praha) and Penta (acquisition of betting company Fortuna and Severomoravské vodárny a kanalizace) were very active.

The largest cross-border M&A deals in Slovakia included the sale of a leading drug distributor company Fides to an investor from Germany (Phoenix International). M&A in the Slovak pharmaceutical industry was high, the other major transactions included the sale of drug maker Biotika Stará Lupča to Dutch company MEI Beheer and the purchase of minority shares in of Slovakofarma by multinational drug maker Zentiva. Again and as one might expect the manufacturing sector is attractive industry segment which consistently leads the interesting M&A transactions – for example, Tatramat sold 80% stake to German Stiebel Eltron, plus there were some divestitures of non-core assets, as sale of Thermosolar Ziar Ltd. Žiar nad Hronom to German Thermosolar Landshut,.

## **5. Conclusion**

Analysis of available data collected by UNCTAD and other international organisations show that M&A activities in CEE countries are weak compared to the level of these activities in economically developed countries. The main reason of this fact is that the region lacks financially strong transnational corporations. TNCs are very important for M&A transactions as the majority of M&As involves TNCs as buyers or sellers. Most important corporations in CEE countries underwent privatisation and today they belong into transnational networks. As a result they have lost their independence in business strategies and the most important corporate decisions are made in the headquarters outside the region. Available data also show that the local companies that are active in the field of M&As do not have a foreign majority owner and are able to conduct independent strategic decisions (MOL or OTP). Russian corporations in the field of oil and natural

---

<sup>5</sup> Source: Central & Eastern European Mergers & Acquisitions Survey 2004 – Slovakia

gas production are the main source of outward M&As in the region and it is likely that they will retain this position also in the future.

The time period between 2002 and 2004 also witnessed a slowdown of M&A sales in CEE countries. The main factor behind this trend is the approaching end of privatisation in central Europe (notably in Hungary, Slovakia and Czech Republic). Most state-owned companies have already been sold and public M&As are falling in this region every year. Private M&A transactions are not able to compensate the loss of public M&As as the number of interesting local companies is limited. The number of M&A sales will continue to fall or stagnate in the future as the privatisation will end in few years in most countries and the number of interesting companies is not likely to rise in the next years. IT companies could be a notable exception as many local software or internet developers offer progressive and innovative products.

## **Abstract**

*The last decade has witnessed an intense process of consolidation in the financial sectors of many industrial countries. This “merger movement” was particularly concentrated among banking firms and occurred in a global scope. As a consequence, many countries reached a situation of high banking sector concentration or faced a further deterioration of an already concentrated sector. Often a small number of large banks constitute more than two thirds of the national banking sector (e.g. measured by deposits). Banks compete in a differentiated loan market, hold reserves against liquidity shocks, and refinance in the interbank market. A merger creates an internal money market that induces financial cost advantages and may increase reserve holdings. We assess changes in liquidity risk and expected liquidity needs for each bank and for the banking system. Large mergers tend to increase expected aggregate liquidity needs, and thus the liquidity provision by the central bank. Comparative statics suggest that a more competitive environment moderates this effect.*

**Keywords:** consolidation of banking sector; credit market competition; bank mergers and acquisitions; bank profitability

## 1. Introduction

Till the end of last year, when British bank Abbey National Bank was acquired by Spanish Banco Santander Central Hispano for EUR 13,9 billions, were bank mergers and acquisitions in Europe infrequent. Long-term discussions about sale of German HVB Group, hagridden by loss credits, finished in May 2005, when Italian Bank UniCredito announced the submission of Offer. The presented price of EUR 19 billions belongs to the highest within European bank mergers and according to Mr. Profumo, director general of UniCredito; new merged bank will save 9000 from total 130.000 employees. It will be the Number 10 in Europe and Number 1 in middle and east Europe, with total market capitalization above EUR 43 billions. In 1999, Italian UniCredito already bought its competitors Banca Commerciale Italiana, but further consolidation on Italian market seems to be difficult, therefore they were looking for other investment possibilities in Germany, French and middle and east Europe. It is interesting to see, that the last merger should be realized between banks from countries, those prefer more domestic, as international acquisitions.

**Table 1 The biggest international bank acquisitions in Europe**

<b>Bank</b>	<b>Investor</b>	<b>Price (bil EUR)</b>
<i>HVB Bank (GER)</i>	<i>UniCredito (ITA)</i>	19,0
<i>Abbey National (UK)</i>	<i>Banco Santander (ESP)</i>	13,9
<i>Generale de Banque (BEL)</i>	<i>Fortis (BEL)</i>	11,6
<i>CCF (FRA)</i>	<i>HSBC (UK)</i>	11,2
<i>Robert Fleming (UK)</i>	<i>Chase Manhattan (USA)</i>	7,5
<i>Bank Austria Creditanstalt (AUT)</i>	<i>HypoVereinsbank (GER)</i>	7,2

*Source: Wall Street Journal Europe*

During recent years a lot of European banks were active in the territory of middle and east Europe with the aim, to build the retail network and use the opportunity to take part in a privatization process of state banks. Some of the players were not successful; others had problems at home or are still waited for last chance. Looking at the map of current status of banking market, there are only a few privatization options, as most of banks were already sold to foreign investors, but some of them could be sold. There are some remaining state banks in Serbia, Monte Negro, Kosovo and Rumania.

## **2. European bank market**

Since 1990, banking sector in middle and east Europe went through large transformation process, started with creation of two step banking system consist of central banks and commercial banks. The originally state owned banks were privatized, foreign banks obtained the licenses and opened offices, a new legislation framework was implemented included the effective bank supervision. The first foreign bank, which opened its office within the territory of east European countries, was Raiffeisenbank (1996 Budapest), and now the same bank (the first one with the domicile in EU) entry on the Belorussian bank market. The downfall of iron curtain in 1990 meant for Austrian banks the occasion of century. EU enlargement brings advantages for all countries, economic development for east and profit for west. Generally, not each country or industry field will win, but advantages will be more extended, unless disadvantages will be concentrated only to a few sectors. Finally, economy of middle and east European countries will grow, mainly due to domestic increase and EU enlargement effects and market expectations.

### ***2.1 Consolidation of banking industry***

At present international banks play the major role on middle and east European markets, whereby dispose of more then 90% market share in Croatia, Czech republic, Estonia and Slovakia, and more then 60% on other markets. Austrian and Italian banks are the most successful investors on those markets, whereas in Baltic countries dominate Scandinavian banks, but surprisingly not Germane, Netherlands or British banks. The Europe in bulk together with Turkey form the market with 750 millions of citizens. The “old EU” represent the market with 380 millions of habitants and average share of consumer credits on gross domestic product (GDP) reached 50%. The new 15 EU countries with population of 80 millions gained a share of consumer loans on GDP only 20%. That’s way there is a big potential for increase of consumer loans, credit cards and mortgages.

Even higher potential lies on the east, in Russia, Ukraine and Turkey, as on those markets lives approximately 300 millions inhabitants and share of consumer loans on GDP is lower then 5%. Turkey represents a very attractive market potential characterized by growing economy and boom of credit cards and loans. That reason influenced banks like UniCredito, HVB, Erste or GE Consumer Finance to star-up with banking business in this country.

**Table 2 Share of net profit of the Group created in middle and east Europe (2004)**

<b>Bank Group</b>	<b>%</b>
<i>Erste Bank Group (AUT)</i>	56
<i>Raiffeisenbank (AUT)</i>	51
<i>Bank Austria Creditanstalt (AUT)</i>	43
<i>UniCredito (ITA)</i>	19
<i>KBC (BEL)</i>	16
<i>Banca Intesa (ITA)</i>	12
<i>Société Générale (FRA)</i>	8

Source: UniCredito, BA/CA

Consolidation within banking sector on middle and east European markets continue. In June 2005, Bank Austria Creditanstalt announced that HVB Rumania would acquire Banca Commerciale Ion Tiriatic. HVB Romania holds assets of EUR 1,4 billions with 13 branch offices, while Banca Tiriatic brings 60 branch offices and total balance amount of EUR 706 millions. The last acquisition target in this region represented Delta Bank, the second largest bank in Serbia, which was acquired by Banca Intesa. Delta Bank will enlarge current network of 500 branch offices about additional 144. Another Serbian bank Jubanka was bought by Greek Alpha Bank and Novosadska Bank by Erste bank.

Currently there are only a few state owned banks in this region. In Rumania it is Banca Comerciala Romana, the largest bank with market share of 26%, which is subject of privatization since July 2005, and 11 potential investors registered interest. Another target could be Rumanian state saving banks CEC with more then 1600 branch offices and saving bank PKO in Poland. There are several other small private banks; those could be for sale, like Banca Transylvania (91 branch offices) in Rumania or Parex bank in Lithuania.

In Hungary OTP Bank, privatized through Budapest Stock Exchange (78% of shares are in hand of foreign institutional investors) means long-term acquisition target for investor. OTP announced its strategy being one of key regional player, that's way bought banks in Rumania, Slovakia and Bulgaria, and is going to open offices in other countries, for example in Czech republic. On the Hungarian market, OTP achieved dominant position, and dispose 25% of market share according to total assets, 30% share pursuant to deposit, 21% pursuant to loans and 35% on bank sector net profit. There are also other banks on middle and east markets, those would like to raise their market share, as those markets offer relative higher margins compare to old EU and still have non-saturated loan segment. Austrian Oberbank or

BAWAG, which bought Slovak Istrobanka, Czech Interbanka, Prague Office of Dresdner Bank, and will open new Office in Slovenia, indicated such interest. Leading Belgian Bank Fortis revised its firm strategy in Spring 2005, and its major priority is focused on new EU member states, where will open its Offices in Czech republic, Slovakia and Hungary, with the aim to increase the profit of the bank.

**Table 3 Bank mergers and acquisitions in middle and east Europe in years 2002-2005**

The other way, how to entry into engaged market, offers leasing services. The Spanish bank Banco Santander proved this strategy, when bought Czech company CCB Credit, proposing leasing and consumer loans.

Similar strategy seated French company Sofinco, member of Credit Agricole Group, by buying Czech leasing company ČP Leasing. The company is planning to extent its activities also in the field of consumer loans, as Czech republic accounted the biggest leasing market within middle and east European countries, similar to Austrian one.

## ***2.2 Banking markets on the east***

The latest trend in bank mergers and acquisitions is aiming on east markets. The further target of expansion represents un-saturated markets of Russia and Ukraine. The Russian Federation is as one of most interesting goal, mainly due to high level of GDP, the lowest individual income tax rate in Europe (13%), due to relevant average real wages growth and share of consumer loans on GDP only at 2% level. Actually Russia remarks the fastest economy growth during the last 10 years (5-7% in years 2001-2004). Russian banking industry is to atomize, there are more then 1100 registered banks, and on the other hand it is only 1/3 compared to 1995 stage. The half of deposits and 1/3 of loans are controlled by two state banks - Sběrbank a Vněštorbank. Gazprom Bank and private Alfa Bank maintain the other positions. Foreign banks currently holds limited market share on Russian financial market, only Raiffeisenbank a Citibank maintain visible position. The market consolidation could be foreseen in following years, because the trust of clients towards domestic banks is very low. Temporary collapse of banking market in 2004, caused by psychological factors, was a consistence of that. Presently we can observe the enormous increase of interest in Russia, the consumer credit market and credit card business enhance, is enough profitable and surprisingly low-risky (2%).

In 2004 were 154 registered banks in Ukraine and further 19 were in bankruptcy. The biggest Ukraine bank Privatbank, with total assets as of EUR 1,21 billions holds only 10% market share, followed by Aval Bank a Prominvestbank. After “Orange Revolution” took Ukraine EU direction, that’s way is interesting for foreign investors, as never before. The bank industry in Ukraine must undertake a lot of standards and regulations, accustomed in developed countries, and after that, the consolidation process could start. Currently only Austrian Raiffeisenbank, among all of foreign banks, holds 2,2% markets share.

Lately international banks pursued their sharpness on the biggest potential market – China. Citibank and HSBS already bought some shares in big local banks. American Express and MBNA, second largest credit card issuer in USA, are already in China. In June 2005, bank of America announced its purchase of 9% shares of China Construction Bank (CCB) for USD 3 billions. CCB realized important changes in latest years and new

shareholder will bring its know-how combined with bank operation, risk management, credit cards and retail banking. Other foreign banks try to obtain stake in more than hundred lower commercial banks, among them reputedly only 1/3 dispose of sound credit portfolio. China belongs to one of the fastest growing economies around the world with more than 1,3 billions inhabitants. Since 2007, in compliance with GATT agreement, China's banking industry should be liberalized and open to competition.

### ***2.3 Global banking trends***

Global banking world has been changed compared to status from 90-tees, due to technical evolution. New hardware and software has been implemented in banks and insurance companies, Internet became an essential part of everyday life. There were a lot of changes, but banks are still here and will be here also in the future. The key role in successful banking plays know-how and trust of public, but not only technology. The importance of technology for banks and insurance companies will increase, and managers are fully aware of value added given by technology progress. At the same time, the competition is growing; cost cutting programs are implemented, simultaneously run consolidation process. Banks will change current fixed cost models to more flexible assurance of sources through regional competence centers and using specialized company by outsourcing of some services.

Within the European banking industry could be seen following trends:

- Growth of local and global competition
- Entry into new markets and local increase would be important factor
- Fulfillments of new legal regulations (Basel 2, Money laundering Act..)
- Stock Exchange requirements on information obligations
- International support to IT and operations
- Necessity of multi-language technologies
- Managing of more countries from one place („Multi-entity operations“)
- Sales support through more business channels
- Simple integration of banking systems
- Fulfillment of shareholders requirement (cost cutting, profit increase..)
- Growth of sales and „cross-selling“
- Flexible reaction on markets needs

Building of profitable retail network and trust of clients will be more and more important part of relationship between banks and clients. After Internet euphoria time clients clearly show, that branch offices must remain an influential part of sales channels. In Europe, the further cutting of numbers of branch offices could be expected, but simultaneously will be changed their role and design. Banks are opening small branch offices and micro-offices; their role will consist in consulting and advise to clients in selection of bank products and services.

Corporate finance business is very competitive and margins are long term on lowest levels. Retail banking is growing fast, but equally increase the competition. The most visible trend in late years has been seen in SME segment combined with new offered services. Small and medium sized enterprises require only limited number of services, like overdrafts and investment loans, and system of payments. SME segment still offers interesting margins, even though with decline tendency. Private banking is also developing, whereby grows the number of wealthy clients on total population. The more difficult is to manage such portfolio of private clients, what requires round experiences and know-how. Identification of client needs, communication schemes and clear description of banking products, seems to be very crucial facts, except of attractive marketing and effective day work with information.

### **3. Slovak bank market**

The Slovak banking industry has remarked a dynamic development during last years, on the ground of implementation of know-how giving by foreign investors. At the same time corporate finance also moved forward, especially in point of required financial services. After restructuring of industry and strong FDI inflow, gradually grows the profitability of both industry and banking sector.

Per June 2005, there were 18 banks and 4 foreign bank offices active on the Slovak banking market. In respect to the entry of Slovak republic to European Union, Slovak National Bank presently register 81 notifications of foreign bank regulation authority about interest of foreign banks to run the business in Slovakia. Total assets of bank sector accounted SKK 1.333,3 billions (+14,65% compared to 2004 end year status) and generated the profit of SKK 7,57 billions, whereby the growth was incurred by accumulation of primary and secondary sources (current accounts and deposits). Banks holds loan portfolio of SKK 481 billions, each of that 6,6% are classified (total amount of adjusted items amounted SKK 26 billions).

**Table 4 Ranking of Commercial Banks in Slovakia (In SKK thd, per June 30, 2005)**

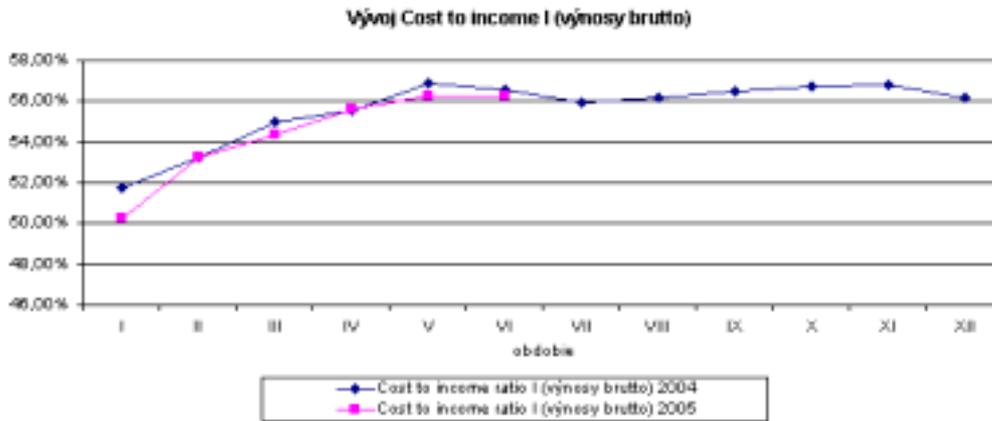

<b>Bank</b>	<b>Majority owner</b>	<b>Total assets</b>	<b>Deposits by clients</b>

### **3.1 Bank profitability/market segmentation**

Total yield assets of banking sector accounted SKK 1.246 billions per June 2005 (+14,2% compared to 2004 end year status), as the main increase was remarked in items bank-to-bank receivables (+ 32,78%), loan receivables (+ 8,72%), volume of securities (+8,6%) and foreign assets (+ 9,96%). Since 2004, the share of yield assets on total assets varies in band 93,3% - 94,0%. One of the key cost indicators, carefully measured by each bank represents cost to income ratio, inducted the amount of brutto yield in % absorb by general operating costs. The average value of cost to income ratio per whole banking sector reached 56,2% per mid 2005.

**Figure 1 Cost to Income Development**

The important part of total bank profits represent yields from fees and provisions. As margins by corporate loans dramatically decreased for the last three years, banks are forced to compensate this lower profit by higher fees and provisions. This trend could be watched also in first half 2005, as share of yields from fees and provisions on total bank yields jumped from 21,72% (December 2004) to 24,67% (June 2005). The income from fees and provisions cover 45,2% of general operating costs.

Looking at the market segmentation, the most rising market is featured in retail segment. Foreign investors have had good predictions by entry into Slovakian banking market, when they count with fast growing of credit for public. The total public indebtedness increases geometrically and till June 2005 achieved sum of SKK 136 billions. The splitting of loans is asymmetric, as first three banks holds 4/5 of total public debt. At present public debt in Slovakia attained only 10% on GDP, compared to average 50% in Euro zone. Interest rates by mortgage loans varies between 4,5% and 6,5% depending on creditworthiness. By consumer loans interest rates start by 5,2% and highest rates are by 20%.

In corporate business the high attention is dedicated to SME segment. In spite of the fact, that large corporate improved its financial position, some of them are financed from abroad, but generally they create higher profits and dependency on bank loans is therefore lower, the total amount of loans for the whole corporate sector is only slightly above the level from previous year. This is due to strong development of SME segment, where still bank could achieve interesting margins. Taking into account the banking sector as a whole, total increase of loans has been mainly caused by growth of public debts. In the latest years banks portfolios dominated big loans offered to large corporate, current trend force bank managers to compensate this decline by a large number of small loans, what is more laborious and costly, but solely

solution. Current level of interest rates will not allow to banks, maintain the same levels of margins as were in the past. Raising the share of loans on total assets could preclude the future decrease of profits, as presently banks hold a big amount of non-risk assets – state bonds and deposits by National Bank.

**Table 5 Volumes of public loans in 2004 and 1H 2005 in Slovakia (in SKK mln)**

Bank	Mortgages loans		Residential loans (not mortgages)		American mortgages loans		Consumer loans	
	2005	2004	2005	2004	2005	2004	2005	2004
<i>ČSOB</i>	496	280	–	–	186	–	354	730
<i>Dexia banka</i>	579	235	–	–	54	8	165	94
<i>HVB Bank</i>	145	126	38	–	–	–	29	39
<i>Istrobanka</i>	586	302	–	–	155	–	124	126
<i>Ludová banka</i>	278	194	–	–	83	–	337	107
<i>OTP Banka</i>	1 055	943	18	8	293	55	157	188
<i>Poštová banka</i>	–	–	–	–	–	–	271	0
<i>Slovenská sporiteľňa</i>	159	1 154	4 610	–	114	–	4 375	2 711
<i>Tatra banka</i>	2 593	1 398	–	–	1 206	–	1 226	1 214
<i>UniBanka</i>	404	328	–	–	–	–	110	57
<i>VÚB</i>	4 656	1 224	–	–	396	0	2 808	1 822

Since 2004, bank raised new product on the market – American mortgage loan, which is secured by mortgage, but the purpose is not specified. The most growing market was remarked by residential and mortgage loans. In 1H 2005, the growth achieved 4/5 from the total amount of mortgages loans in previous year. Banks put to credit SKK 11 billions of mortgage loans in 1H 2005 and hold totally SKK 50 billions of such loans in their balance sheets. Banks try to enable the access to loans for inhabitants, when partially canceled requirement of expert statements, especially in large cities. Some banks started to do their own statements, others declined fees. Generally banks try to shorten approval process and change internal rating levels inevitable for binding-of the rates. Except of the mortgage loans, client raised demand for consumer loans, in 1H2005 there was growth about SKK 7 billions, whereby the higher request will be expected before Christmas.

## 4. Conclusion

The other wave of mergers and acquisitions has started within the European banking industry, especially in middle and east European countries, but Russia and China are even more attractive countries. At the same time global banking sector has remarked a dynamic development during last years, on the ground of implementation of new technologies and the usage of Internet. Corporate business is very competitive with very small margins; more interesting segment is represented by SME. Faster movement could be seen in retail banking, mainly credit card business, mortgage and consumer loans. The future success of banks will be depended on the identification of clients' needs and building of the relationship between banks and clients.

Looking back over the past year, the Slovak banking sector was characterized by increasing sales, maximizing efficiency and cutting costs, majority of banks concurrently created a strong basis for continued successful business in the fields of retail and corporate banking. Besides expansion of the SME and municipal market segments, banks were also successful in reducing their non-performing loan portfolio and stimulating the domestic payment business. I am convinced, that in addition globalization, geographical proximity to other EU member states and consistent elimination of the differences in the economic and social background compared with other EU countries, it was already created a sound business environment for future growth and prosperity of banks, running business in Slovakia.

## **Abstract**

*This paper is aimed at the evaluation of selected indicators of Slovak banking sector in the segment of banks, which went through the process of restructuring and have a decisive share in the Slovak banking market. The analysis is aimed at evaluation of quantitative development of the balance value, development and state of the capital adequacy and classified claims of the transformed banks. Next to the evaluation of nowadays situation, there are also some basic development trends of the Slovak banking sector outlined in the paper.*

**Keywords:** *banks, investors, balance value, owners, capital adequacy, development*

## **1. Introduction**

The restructuring process of Slovak banking sector in the years 1999-2001 was aimed at recovery and privatization of selected banks with state ownership majority. Restructuring of these banks before privatization meant their recovery- recapitalization in the form of ordinary stock increase with state help, displacement of classified claims from credit portfolios of the banks to specialized consolidating institutions. The losing claims were replaced through state owned securities. This process led to an increase of the capital adequacy and a change of the asset structure in favor of more liquid assets. During the year 2001 these restructured banks were privatized. The successive privatization resulted in an increase of the foreign investors share in the banks total ordinary stock subscribed and in permanently provided financial means to subsidiaries of foreign banks. The foreign investors share in the banks total ordinary stock subscribed and in financial means provided by foreign banks to their subsidiaries rapidly increased in the researched time period and by the end of September 2002 represented 85.0%. This increase was caused by the entry of foreign investors into the banking sector.

## **2. Devepment of selected indicators in the Slovak banking sector**

After 2001 and after privatization of the biggest banks foreign investors gained<sup>1</sup> the ownership-majority in the Slovak banking sector. According to the volume of assets it means that the part of assets controlled by foreign owners amounts to more than 90 %, whereupon the part of the ordinary stock amounts to nearly 90 %.

---

<sup>1</sup> In the current, in Slovakia are active 22 banks: Slovak saving bank, General credit bank, Tatra bank, CSOB, ING Bank, HVB Bank Slovakia, First building saving bank, Uni Bank, Volksbank, Citibank (Slovakia), Dexia bank Slovakia, Istrobank, OTP bank Slovakia, Post Bank, VUB Wustenrot, Credit Lyonnais Bank Slovakia, Komerčni Banka Bratislava, CSOB biulding saving bank, Banka Slovakia, Commerzbank, Slovak guarantee and development bank and Eximbank. Beside this banks there are also 7 representations of foreign banks. In the structure of the mentioned banks are dominant banks with universal licence, represented are also specialized building saving banks. The ownership in the mentioned banks is private, except the Slovak guarantee and development bank, which has state capital at disposal. Foreign capital is represented in the majority of banks. Up to now the Post Bank is not privatized through foreign investors.

*Source: Annual Reports for 2005*

Owners of the banks are strong foreign banking groups - ING, HVB, Volksbank, Wustenrot, UniCredito. The Czech banking is represented through the fourth biggest bank Czech-Slovak commercial bank. Through a subsidiary is also represented the Komerčni banka. The Hungarian banking system is represented by a subsidiary of the biggest Hungarian bank OTP. The foreign investors come from the European economy space and from

USA. They are established in the majority of the 21 commercial banks and in 7 representations of foreign banks.

## 2.1 Balance Value

Development of the Slovak banking sector after the change of the ownership will be valued on the basis of the quantity, development of the balance sum concerning banks, which pass the process of transformation-banks, which with an important measure participate on the increasing of balance value for the entire banking sector. We will not value the whole structure of the balance, but only the parts on the side of assets and liabilities, which considerable influence the balance state of a concrete bank. It's about the biggest Slovak banks: VUB a.s., SLSP a.s. and the Slovak investment and development bank (after changing of the ownership OTP a.s.)

The balance value of the mentioned banks decreased in the period before recovery. In 1997 the balance was 385.755 Mio. Sk., in 1998 362.802 Mio. Sk. and in 1999 352.839 Mio. Sk. The reason was the entrepreneurial activity of banks. The banks recorded losses, the funds from clients stagnated. In 2000 the balance value reached the sum about 377.128 Mio. Sk. This increase of the balance value was connected with the recovery and with the renovation of the trustworthy of the biggest banks.

**Table 2: Balance sum of selected commercial banks to the 31.12.** (in million Sk)

	<b>2000</b>	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2004</b>
VÚB	165 287	174 162	194 716	191 338	218 837

IRB/OTP	27 389	21 344	18 959	25 106	33 873

Source: Annual Reports of SLSP, A. s., VÚB, A. s., IaRB, A. s., for 2000, 2001, 2002, 2003, 2004

**General Credit Bank VUB a.s.** strengthened it's standing on the Slovak banking sector. In 2001 there have occurred significant changes in the balance structure. The part of securities has increased by contemporaneous decrease of credit part. Part of credits has been moved to consolidating institutions in the frame of reclassification of credit portfolios. The entrepreneurial activities of the bank have been oriented to high yielded and less risky assets. The balance sum has increased in 2002 about more as 11 % against the year 2001. On the Slovak banking market the bank kept the 20 % stake. In 2003 the balance sum has decreased, which was caused by dropping of entire consolidated assets. In 2004 the VUB was very successful. The bank

strengthened business position and improved the finance results and became the most profitable bank in Slovakia. For the first time the bank received an award the best bank in Slovakia from the journals Euromoney and The Banker.

**Slovak saving bank (SLSP a.s.)** reached in 2001 a balance sum about 202,1 bln Sk, which was an increase about 9 % against the previous year. In 2002 reached the SLSP a balance value about more than 205 bln Sk. It can be said, that in 2002 the bank has been transformed to a modern banking institution, which his activity orientated to the client. The result was the reclassification of the branch-office net and the separation of the retail- and business banking. In 2003 the Slovak saving bank is beginning to manage the credit risk and to monitor the portfolio and there will be prepared in cooperation with other banks the first credit register for private persons in Slovakia. In harmony with the new Basle agreements about capital the saving bank is involved in this program through the Erste Bank for the implementation of this agreements. In 2003 the saving bank has determined the starting assumption for collecting of statements about not repaid credits and losses and proposed a new rating system for the retail business. The quality of the asset portfolio has in 2003 improved the part of the assets with a high risk level has decreased from 14,0 % in 2002 till 8,6 % in 2003. The assets are covered through correcting items and reserves about 101 %. The 2004 can be characterized as the most successful year for the bank concerning the increase of the balance sum. There was an increase against 2003 about 14 %. To the increase of the balance sum has contributed a good economic management just as the management of the credit portfolio. Changes in the legislature proposed so, that they will strengthen the position of the creditors and so there will be the guarantee, that claiming of credits will be more successful.

**OTP a.s.**, the activity of OTP (before privatization: Investment and development bank) was for a long period in a specific situation, to which the bank got in 1997. The bank was in a forced administration, managed by administrator authorized to perform the forced administration. Whereas the forced administration the bank activities have been subdued. After ending of the forced administration the activities of the bank have been renewed. In 2001 the privatization has taken place through a foreign investor and with the trying to reach a good position on the Slovak banking market. In 2001 the balance sum decreased by more than 6 bln Sk. The reason was the change of the asset structure and displacement of classified claims. High balance sum in 2000 was connected with the balance recovery of the bank and with the meaner of settlement of repo deals. Artificially has been inflated the volume of assets, when the National Bank of Slovakia came in a sterile position

against the banking sector. The balance sum of the bank reached in 2002 a value about 18,9 bln Sk, which was a decrease about 8 % in comparison with 2001. The reason was the transformation of the bank. In April 2002 the bank has been privatized. In 2002 the bank stated a loss, which occurred as consequence of building of correcting items and reserves on the property, bank claims and transformation costs. The 2003 was a successful year for the bank activities. The sources have been increased and also introduction of new credit products for the population and for the entrepreneurs. The stated reality has contributed to the increase of the balance sum, which reached in 2003 a value about 25 Bi. Sk. This tendency continued also in 2004. For this period is characteristic the consolidation, when on the Slovak banking sector the deposits have been moved from the banks to the administration companies. The strategy of the bank is to reach long-term partnerships with the clients, how the bank doesn't mean only entrepreneur clients or retail, but the bank is developing business contacts also with self-administration units. This strategy has been confirmed as correct, because the balance sum has increased and reached in 2004 nearly 40 Bill. Sk. To the increase of the balance sum have contributed about all the deposits of clients (plus 27 % yearly increase), issued securities (volume about 2,5 Bill.Sk) and granted credits.

## ***2.2 Adequacy of the own sources (capital adequacy)***

The capital of the bank is the most suitable source of protection against insolvency. In all sophisticated economies enjoy the bank capital a big attention. From the capital the bank can cover eventual asset-looses without threatening of the client deposits. But the condition is an adequate level of capital. The most important coefficient is the Capital Authorization Ratio (CAR) often named as Cooke - Ratio (capital-assets ratio), defined as ratio of capital to the sum of risky assets and credit coefficients of non-balance items.

Recommended balances are 0, 20, 50, 100 % resp. converting coefficients 0 - 0,2 - 0,5 - 1,0 how the concrete assignment of the balance to the given asset is in competence of each country. The rules of adequacy of the own sources have determined the „Basle Committee of Banking Supervision“.

Because his task is to cover of the credit risk, capital for its calculation has to be divided to three parts: own capital - supplementary capital - short term subordinated debt. For the calculation of the adequacy of the own sources is the supplementary capital limited to 100 % of the own capital or at least 50 % of capital must be own capital. Subordinated debt is

determined for covering of the market risk.

The level of capital adequacy depends directly proportional from volume of capital and indirectly proportional from the level of risky weighted assets and apart from balance items. The bank can influence the level of the capital adequacy (increase it) in double manner. Either through the increasing of capital or through decreasing the volume of weighted assets. Increasing of capital through issuing of securities by the same profit has the effect of decreasing of the value of the shares and with it to reduce the value of shareholder parts with the following negative response by them.

The bank can decrease the volume of risky weighted assets with sinking of granted credits with higher risk weights resp. the bank will prefer low risky activities for example acquisition of government securities, or the bank will undertake alternative activities, for example new credit deals, relative secure syndicated loans and others).

Low coefficient of capital adequacy is an advertiser that there is a high risk level of the bank activities. Internationalization of conditions for bank undertaking protects the banks against high risks. If there is interest to maintain the same competition conditions in the banking sector, similar measures as the indicator of capital adequacy have to be settled for all institutions, which offer their services, similar to the bank activities.

**Table 3: Capital adequacy in chosen banks (in %) in Slovakia**

	<i>1988</i>	<i>2000</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>
VÚB	0, 30	16, 10	35, 20	33, 50	23, 40	-
SLSP	6, 60	12, 10	21, 10	22, 50	24, 25	16, 84
IRB/ OTP	- 27, 80	12, 50	53, 60	76, 20	33, 43	17, 20

*Source: Annual Reports of SLSP, A. s., VÚB, A. s., IaRB, A. s., for 1988, 2000, 2001, 2002, 2003, 2004*

In 1988 no one of the transforming banks reached the necessary level of capital adequacy (adequacy of the own sources). The IRB (Investment and Development Bank) came even into red figures as capital adequacy reached the level minus 27,8 %. Bad results reached also the Slovak Saving Bank (SLSP) and the General Credit Bank (VUB). To the unfavorable capital adequacy in the mentioned banks have contributed above all losing debts and a low level of the own capital in connection to the high risk assets.

In 2000 the banks reached the required level of capital adequacy. This development positive influenced the running reclassification of the credit portfolios in these banks. After changing of the owners the banks reached each year the required level of the capital adequacy.

OTP reached in 2002 the capital adequacy on the level 76,2 %. The bank fulfilled the coefficient of the capital adequacy above the standard, which was caused with it, that the bank was in 2002 privatized and very circumspect granted credits which risk level has a direct impact on the level of the mentioned coefficient.

### 2.3 Classified claims

The highest part of losing claims on the entire claims was in Slovakia in 1990-2000 in transforming banks mainly in VUB,SLSP and IRB. The lowest part of losing claims was in Building Saving Banks (BSB). The reason is the reality that the BSBs began with selling of their products in 1992. The BSB grant the standard building credit after six years of the client's saving on the account of building saving. That means, that in the observing period the clients didn't repay the building credits, resp. the volume of the repaid credits was in this period still relatively low and therefore the banks didn't register any classified claims.

**Table 4: Classified claims from 1993 till 2003 (in million Sk)<sup>2</sup>**

<sup>3</sup> In the years 1998-2000 the announced classified claims are reduced by created correcting items.

The part of transforming banks on losing claims was in 1997 represented by 68,13 % and in the first quarter of 1998 already by 68,58 %. The break happened in 2000 after reconstruction of credit portfolios in the announced banks. From the balances have been displaced the losing claims into the consolidating institutions and have been replaced through state owned securities.

**Table 5: Displacement of credits to consolidating institutions (in million Sk)**

Bank	Displacement of credits		
	to KOBL	to Slovak consolidated	together
General credit bank	7 602,8	58 641,3	66 244,1
Slovak saving bank	2 398,1	29 998,1	32 396,2

<i>Losing claims</i>	1 802	3 513	1 249

Source: Annual reports of VÚB, A. s., SLSP, A. s., OTP, A. s.

As conclusion we can state, that through the reclassification of the credit portfolios the mentioned banks recovered with the consequence, that the granted credits in the period after the privatization changed the structure and by it also the classification in unit classification grades. Favorable is also the development of the balance value and the quality indicator- the adequacy of the own sources.

### **3. Tendencies of banking development**

Foreign capital established in the Slovak banking sector is the promise, that the banks will enterprise in a comparable level with sophisticated countries. New trends of banking enterprise are determined above all with advancing globalization. Globalization<sup>4</sup> is supported by development of new technologies, which cause the retreat of traditional branches and expansion of mainly services, including financial services.

The current financial world has the tendency above all to

---

<sup>4</sup> Globalization stated the mutual association, mutual connections and dependencies between the parts of the world system. Initially the term globalization means only an economic appearance, which characterized the unceasing spread integration and interaction of national economics and will be realized in frame of the international market and financial flows. In last time, the phenomenon globalization always more means as a spiritual and cultural connection, as a virtual reality without boundaries, which make it possible to contact countries, societies, people and others from the opposite ends of the globe. In literature we can find very often three aspects of globalization: technological, economical and political. Technological aspect of globalization follows from the connection in development of communications- and computer technology, the economical aspect follows from the movement on the capital markets which eases the existence of multinational companies and the political aspect is the combination of market and democracy.

universalization, supported though globalization processes<sup>5</sup> and at the same time in frame of universalization to a consistent specialization by granting of services.

The Slovak banking sector is a universal one, where prevail small banks in view of capital volume. These banks will have the problem to keep standing in existing competition on the field of universalization. The foreign shareholders should ease the banks to adapt them in this area, above all from a long term view. If the banks here not succeed there can start mergers and acquisitions between our banks, resp. very small specialization above all by little banks. The question is, if the banks will be able in the current competition to gain new clients resp. to maintain the old clients and if their can resist against the pressure to reduce the costs and to increase the productivity and effectiveness.

The question is also, if the banks as granting institutions of financial services will be able to keep in the future their sovereign position, or in consequence of the a. m. influences the banks will gradually loss this position.

The bank as finance mediator on the base of it's own information about market, clients, their needs and habits, their economic situation - was able in the best way to valuate the free capital of clients resp. to advise clients in professional way, who need free capital, which is temporary available on the market. This advantage the banks are losing with development of information technologies. Today, the economic subjects can receive information without effort (for example by means of internet), which was in the past possible only for banks resp. other institution of the financial market.

In the world is the trend of decreasing the part of bank credits and loans on the whole volume of bank credits and loans to the private persons and enterprise subjects<sup>6</sup>. The reason is a big boom of alternative sources for

---

<sup>5</sup> Global tendencies of world development in the banking area and the 21. Century restrict the following connections (Sometimes it's very difficult to distinguish, if there is a reason, or the consequence of globalization or if there is an appearance, which directly not connected with globalization, but in the final consequence it's determined through the effect of globalization): consolidation of banks and financial institutions, securitization and desintermediation - as appearance of the securitization trend, financial innovations- financial derivatives and automatization of banking operations, internationalization - forming of overnational economic units, institutionalization - dominant standing will get institutional investors, for example pension funds, insurance companies, investment funds, intellectualization and reform of bourse systems.

<sup>6</sup> In USA, which predetermines the trends of development of the world economy, decreased the part of banking credits on the whole granted credits to private persons and entrepreneurial subjects from 36 % in 1974 to 22 % in 1994. This trend continues till the present time.

financing of enterprise activities.

The ordinary reaction of banks to this reality:

- Merging to bigger units and at the same time the banks connect their activities with other branches of the financial market: with pension funds, administration companies, insurances and others and through it they strengthen their capital stock.
- Increasing the quantity of granted services.
- Spreading of activities to big geographical distances. Managing of banks about big distances required a thorough information and managing system.
- Acquiring of new information systems, which make it possible to take very quick moves of funds and that leads to a big increase of their quantity and with it to an increase of transfers and to increase the quantity of new financial products.
- Decreasing the number of their branches and subsidiaries for economic reasons. They will be replaced through full-automated centers.
- In spite of mentioned measures, the part of traditional banking activities is going down. The failures of profits the banks therefore try to replace through new business activities, resp. through increasing of fees for granted services.

The banks lost almost their monopoly position on the market for granting of financial services. The big banks are not able to compete to small flexible and creative subjects, which are able more flexible to adapt to new technologies and make profit from it. The banks have competitors in other sectors of economy, which are active in research and innovation area and are able to adapt new technologies in very short time and to make a profit from it. The banks very often in consequence of their complicated structure of connections and processes are not able to react to the changing surroundings and to the constantly changing needs of clients.

The radical changes in the banking sector are availed in connection with transition from paper money to money in form of dates - electronic, digital, cybernetic, which takes with it the development of technologies (cash money obvious very early don't vanish, but the size of their using is gradually decreasing).

Also direct settlement between different economic subjects will be obviously in near future already limited, resp. will exclude the link between - the bank as mediator of said operations. That can be a risk not only for the

commercial banks, but also for currency authorities, the central banks, which task is to coordinate the quantity of money in the country.

#### 4. Conclusion

In the current world a lot of non-banking subjects is active in traditional banking spheres. A big advantage they have against the banks is, that they are less regulated (the banking system is in market economy the most regulated branch) and are often more flexible and innovative. If the banks want in this competition to maintain their position, it is inevitable, exactly to identify the needs of their clients and as quick as possible to adapt them. Obviously the banks should grant their clients a whole set of financial services. The banks should more grant classic bank products, which follow from traditional active and passive operations. Other services they have to leave to companies, which can grant such services more flexible and effective. Further space for banks in their activities opens in their subsidiaries, resp. in cooperation with external companies. The banks have the possibility, to cover them with a set of products and to grant them complex services from consulting services through granting of financial products, controlling till risk management. In that way the client should gain a whole set of services of good quality to attractive prices and the banks will gain clients of good quality for a long term.

## **Abstract**

*The paper presents the characteristics of Romanian banking system reform between expectations and achievements. The role of the first bank institution of the country is being disclosed but there are also a series of considerations towards the second level of the banking activity, that is the commercial banks. The main trends which characterize their evolution during the transition years are brought into discussion, trends of which, the most indicative in our opinion are the concentration and the segmentation. These positive trends, concerning the improvement of the general economic environment, as well as the concentration of the stock holdings of The Romanian National Bank towards the qualitative sides of the surveillance process, have left their mark on the evolution of the indicators which define the state of our banking system. The economic- financial indicators as well as those of bank discretion certify that the Romanian banks have made significant steps towards the criteria imposed by the European integration.*

**Keywords:** *reform, banking system, European integration, concentration, segmentation*

## 1. Introduction

One of the professors who had in his hands the management of the economic education before and after 1989 stated in one of his books that: “the most far-reaching and permanent slogan, as well as the less defined one, is the reform. In the name of the reform there have been taken correct decisions, but the worst errors of politics and management have also been done”[3]. In this context, we find it necessary to express our opinions concerning the strong points and especially the weak ones of the contradictory process which had as main goal the creation of a new banking system, which, in the opinion of some important economists, represents one of the restrictions of including the Romanian banks in the select club of the western banks.

The first steps which foreshadowed the placing of our banking system on the competency pedestal have grown up together with the elaboration of the laws concerning the bank activity and the status of The National Bank of Romania, that is laws number 33/1991 and 34/1991, which have been completed afterwards by laws no 101/1998 and 108/1998. Naturally, once the two laws were adopted, the premises of a new banking system on two levels have been formed, premises of western origin, competitive premises in our opinion, the system “type mono-bank” being abolished [2]. As a consequence, the levels of the banking system have as pylon, on one hand, the issuing bank – The Romanian National Bank – and, on the other hand, the commercial banks which function as universal banks. The National Bank of Romania, as central bank, has taken over from its former balance all the extern assets, and from the intern assets the governmental credits. As means of covering, it has taken over the external passives from the balance, the monetary mass and a significant part of the structure “personal funds and other funds”.

The commercial banks, newly created, have taken over from the assets of the central bank the non-governmental credits, and, as a means of covering, the deposits of the non-banking clients from the passive, where the weight was hold by the deposits of the population with 48% of the monetary mass [2]. Hoping that we are closer to truth, in our opinion, we consider that the above mentioned author takes into consideration only the assets taken over by The Romanian Commercial Bank. The other banks having the status of universal banks have taken over the entire inheritance of the past specialized banks. The new commercial banks have taken over the entire portfolio of credits offered before to the enterprises with public capital, credits which were out of the spirit in which the crediting activity would have to act in the future. Moreover, taking into account the fact that the commercial banks had to face since “swaddle” a reduced capitalization base,

the funds of the banks from the past on which they started functioning represented only 5.5% of the passive, and taking into consideration the harmful effects or the “devastating” effects of the inflation, the natural erosion suffered by this “survival core” starts appearing.

## **2. A view on strong and weak points of banking system reform**

Nevertheless, we shouldn't omit the fact that, in order to stimulate the competency, using the new legislation, new banks with public, mixed, private, local or foreign banks which opened in Romania their own branches. The new banks could only start their activity only after they had obtained an authorization to function, a document issued by The National Romanian Bank, more exactly by the Commission of Settlement and Surveillance, an organism which issued norms and settlements concerning the volume of the social capital, the minimum amount of payment at the moment of subscription, as well as the forming of reserve funds and prevention of risks. The opening of branches of some banks by foreign judicial persons has been settled by the law concerning the functioning of foreign branches and organizations.

Without any doubt, an economy in "resuscitation" in order to go through a road from imprisoning to freedom, could not offer a proper environment in order to reshape and develop the banks. The road from the order economy to that of market hasn't been easy for anyone. The difference was in the traps of this road as well as in the chosen means to go through it. For Romania we believe that many internal and external factors have put their print on this road, the consequence being the strong and the weak points as well as the climbing and descending of the banking system. Thus, among the weak points of the reform, we mention the most significant ones:

- the slow rhythm of the process of legislative and institutional reconstruction compared to other countries from Central and Eastern Europe;
- the low financial power of the new banks, appeared especially because of a reduced capitalization as well as because of some credits taken over from the old banks;
- the insignificant competency in the newly created banking system, some banks holding the majority of credit market;
- the lack of experience and the inherited mentality, which is often not sensible to the new;
- the weak development of territorial network;

- the lack in the consistency of the concept of bank autonomy, lots of decisions being adopted under the pressure of politics;
- the contradictory behavior of bank managers related to the orientation of investments towards the public area and not towards the private one;
- eluding the most basic principles of bank discretion, that is giving credits only on political interests or mainly personal ones.

Among the strong points of the reconstruction of the banking activity, full of content, and full of effects in the real economy, we mention the following:

- the abandoning of centralized planning. The road towards the market economy has created multiple possibilities of assertion but new responsibilities as well, especially towards the capitalization of resources congruent with the criteria of economic performance and profitability;
- the orientation of activity, taking into account the principles of the bank marketing, towards the customers' desires. The commercial banks have the possibility to offer various products and services, in accordance with the market requirements, trying to satisfy the consumers' preferences. The fact that the bank institutions connect to the vectors of market coagulates the general tendency of evolution of the Romanian economy towards a performance one, connected to the circuits of international banks;
- the stimulation of competency between banks. The new economic environment has obliged the commercial banks to compete when dealing with the interests, the commissions, specific to the products and services that they offer to the consumers. The competency environment promotes the quality of services and encourages the assimilation of new ones. The quality and the price of products and services offered by banks feel the impact of competency, a phenomenon which favors the evolution of bank products market in order to assimilate the features specific to a market of consumer;
- the assimilation of a performance bank politics. The competency between banks and the discretion norms promoted by The National Bank of Romania have favored the banks which, while functioning, have assimilated and selected healthy managerial procedures, combining the criterion of a maximum profit with that of a bank discretion;
- attracting a higher number of specialists by a strict selection. Once new banks appeared, once the activity of the existing ones multiplied, the number of hired persons has raised, the banking field becoming one of the most dynamic areas, a phenomenon considered positive, taking into account

the decline of the other areas of economy.

Noticing the multitude of weak points, which we consider consistent, but especially the strong ones, offers us the logical support in order to present the steps on the road towards the reform of the banking system.

### **3. The structure and characteristics of actual Romanian Banking System**

What we should mention is that the responsibilities presented in the bank laws adopted after December 1989, have been put again, after almost a century, on the shoulders of the first bank institution of our country. They can be synthesized as it follows: The National Bank of Romania is the central bank of the Romanian state "having a key position in the banking field, around which all the agents of monetary and financial life gravitate, every citizen who uses a banknote or a coin bearing the marks of the country and of its unique emission bank"[4]. In its quality of central bank, The National Bank is the unique issuing institute of the country, which settles and leads the monetary, currency politics, the credit and payment politics, assuring the surveillance of the banks which it authorizes to function. Its responsibilities find their support in the functions which it exerts, that is: the emission, the circulation and the withdrawing of monetary signs; the stabilization and promoting the monetary politics foreseen by the state authority; the administration of the currency politics; the administration of management having the quality of bank of the banks – bank of Romanian state; the settlement and surveillance of payment system. Concerning the second level of the banking activity, that is the commercial banks, we consider that the main trends which characterize their evolution during the transition years would be: their numeric growth, creating the branches, agencies networks, developing the information structures and new departments specific to the modern banking system, that is those with management and marketing, all in order to raise the profitability and to consolidate the market position.

But, we have to remember that, although the territorial extension hasn't been one of the most rapid ones, the number of operative units compared to the number of inhabitants places Romania behind the other European countries. For example, in countries part of the European Union, an operative unit reverts to 1,700 inhabitants, in countries from Central Europe to 11,000 inhabitants, while in Romania the amount is of 23,500 inhabitants.

The developing of information infrastructures as well as of new departments, like those of management and marketing, have induced changes in the evolution of bank system, the most indicative ones being the

concentration and segmentation. At the end of 1998, at almost 8 years after the beginning of the reform which had as main objective the reconstruction of the system, the 4 banks with majority of capital and the House of Economies and Consignments were still dominating the market, holding almost 70% of the assets and 56% of the social capital from the system. In the following years, as a result of the information of table 1, the market share of the above mentioned banks was lower taking into account the number and the banking operations.

**Table 1 The volume and the share of operations coming from banks with majority state capital at 31.12.2000**

<i>Banks with majority state capital</i>	<i>Assets</i>		<i>Social capital</i>		<i>Deposits and attracted availability</i>		<i>State title in portfolio</i>	
	<i>mld. lei</i>	<i>%</i>	<i>mld. lei</i>	<i>%</i>	<i>mld. lei</i>	<i>%</i>	<i>mld. lei</i>	<i>%</i>

<i>Total bank system</i>	223785	100	13765	100	163590	100	44230	100

*Source: the state banks hold almost a half of the total deposits. The Financial Paper, 30.01.2001, page 5.*

The leader position of the four banks is relevant, first of all because they held together at the end of year 2000 a share of 44.3% of the balance assets in the banking system, with a value of 99,136.9 milliards lei of a total of 223,785.4 milliards lei.

Although the banking sector did not meet any major structural modifications in 2003, the extension of the market share (at 62.5%) was influenced by the raise of the bank assets, as a result of deposits coming from the non-banking persons, but also as a result of an increase in the personal funds. Once the biggest bank with state capital is privatized, The Romanian Commercial Bank, the share held by the private sector will be more than 28%.

The main feature of the Romanian bank system remains its concentration, a number of five banks (The Romanian Commercial Bank, BRD - Groupe Societe Generale, Raiffeisen Bank, CEC, ABN Amro Bank), dominating the market at the end of 2003, with a share of 61.7% of the total assets, 56.8% of the total of credits and 62.6% of the total of deposits, as it can be observed in table no. 2.

*Source: The Romanian National Bank, Annual Report, 2004*

An important modification has been produced to the weight level hold by the assets of the banks with foreign capital or with foreign majority capital in the total of assets of the banking system, with an increase of 3,9 points per cent comparative to the year 2003, reaching a share of 62,1% at December 31, 2004.

Favorable evolutions have also been observed as regards the capitalization degree of the banking system (an increase of 12,5% at the end of 2004 comparative to 2003), as a main result of a consolidated position of some banks with foreign capital on the local banking market but also as a result of banks obligation to reach until May 31, 2004 a minimum level of the own funds of 370 milliards lei.

The realities from the countries with a functional market economy showed that the process of bank concentration, attained by fusion and acquisitions, is not only natural but necessary as well, having a sinuous evolution, being marked by twitches.

In Romania, this process is only in the beginning phase, having numerous barriers that have to be overpass. New ways of action are necessary, ways which should favor the consolidation of small banks with assets which aren't higher than 1% of the assets of our banking system. Therefore, we agree with the concept that, at a level of bank assets of almost 10 milliards USD, the present number of banks is too high, the best number being between 20 and 30. Nevertheless, we believe that we should enhance the assets and not to reduce the number of banks. On the other hand, the majority of those involved in the management of Romanian banks seem to be aware of the fact that, in the context of our integration in the European structures, the solution is represented by the concentration of resources by fusion or acquisitions or by the attraction of some investors with a highly financial potential.

The effects of the concentration on the bank activity are clear, especially during economic recession, the small banks being affected in the first place. They do not have the necessary resources to develop modern infrastructures which would allow them to offer integrated financial services in order to stimulate the personnel and the shareholder. Another important aspect is represented by the structure of the clients' portfolio, which cannot be optimized. The small banks, because they can not offer important credits, are obliged to address the small and middle enterprises, which are also exposed to the shocks in economy. The necessity of concentration is therefore vital especially in the moments of crises, no matter how it is built, by an increase of the social capital or by fusion.

Similar to the concentration tendency, the segmentation one, that is the restructuring of banking activity on larger levels, is a natural attendant of the modernization process. The existence, besides the commercial banks, of specialized banks will offer the premises of a greater bank management, and, in the end, of profitability.

In Romania, taking into consideration the dimension of bank market, all types of specialized banks which exist in the developed countries can not be established in a short period of time. Nevertheless, we consider that at least some of them should function, thus having a great impact on other key branches of our economy, like: agriculture, constructions and, especially, the external exchanges. We believe that in the following years the economic raise will have as support the export of goods and services and not the internal

consumption, and, from here, the necessity of a specialized bank in the finance of exterior commerce. The housing demand will also be higher and it will impose the creation of an institution which would stimulate the savings. The agriculture has to be based, in the context of our integration in The European Union, not on "budgetary subventions" but on a "reimbursed" banking finance. That is why it is imperative to form one or more specific banking institutions.

The positive trends concerning the development of the general economic environment, as well as the concentration of the actions of The National Bank of Romania on the qualitative process of surveillance, have put their mark on the evolution of the indicators which define the status of our banking system, indicators presented in table no 3.

**Table 3 The evolution of the main economic - financial indicators and those of bank discretion**

<i>Name of indicators</i>	<i>1999</i>	<i>2000</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>

*Source: The National Bank of Romania, Annual Report, 2004*

The increase of financial intermediation led to an increase of credit risk in the banking system, which was reflected in the growth of the general risk rate and of the credit risk rate as well as in the diminution of solvency rate (but this is maintained to a comfortable level, significantly outrunning the reference share accepted on the international plane). The dynamic evolution of the crediting activity did not imply a deterioration of the portfolio of credits quality; on the contrary, the share of the residual debts in the total of credits (net value) has been reduced with 0,11 points per cent comparative to the end of 2002, up to 0,32%. The banking system profitability was situated above the inflation rate in 2003, provided that the profit increased in nominal terms by 15,6%, its reduced dynamics comparative to that of 2002 (18,3%) being determined by: the reduction of

the distance between the rates of active interests and those of the passive interests to the operations with the non-banking and nongovernmental clients from 17,6 points per cent in December 2002 to 14,7 in December 2003; the implementation of the new regulation concerning the classification of credits that emphasized the banking effort for provisions; substructure investments made by the majority of banks.

The increase of the crediting activity was revealed in the aggregate volume of the financial result of 2003 (13290,5 milliards lei), superior to the one registered in the previous year (12498,1 milliards lei), the main source being the net interest incomes. Nevertheless, the profitability indicators (ROA and ROE) were situated on a scale of increasing values in the further period after having implemented the new regulation of credits classification and provisions (from 1,2% in January to 2,1% in December in ROA case and, from 8,4% to 17,0% in ROE case).

#### **4. Conclusion**

The favorable trends registered by the main indicators of banking system evaluation were pointed out by the representatives of The International Bank, The International Monetary Fund and The European Commission. According to these evaluations, the banking system presents a good capitalization, it has a raised liquidity and it is well supervised, the supervision authority possessing an appropriate administrative capacity, qualified personnel and a fine management. The banking system was considered resisting to the potential market and credit risks, the exposure to the currency and interest risk having a reduced level provided that banks balance their net currency position and the interest rate is variable. The dynamic of the crediting activity did not affect the solidity of the banking system, the prudential indicators – an increased rate of solvency (20%), a higher liquidity (more than 3), the level of residual credits (less than 1% of the credits portfolio of the banks) – indicating a considerable resistance to impacts. We believe that the positive trends of the economic-financial indicators and those of bank discretion have as support the favorable evolution of the following factors:

- the raise of the capitalization level as a result of the finalization, at the end of 2002, of the second level of increasing the minimum social capital of banks, as well as the consolidation of the financial position of the foreign shareholders for different banks. The significant presence of the private sector was felt at the level of capitalization of banking system, the share of this segment in the total of the capital reaching 74.3% [5] at the end of 2003;

- the expansion, especially in the last part of the analyzed interval, of the balance assets, accomplished especially in the area which deals with the customers. After many years, the structural dynamic of the asset enhances the change in attitude of the banks in the orientation of their resources and their placing on the credit market for a short period;

- the raise in the quality of managerial act. The raise during the last three years of the general risk rate shows the expansion of the crediting activity. But, this raise has been accompanied by a positive evolution of the bank capitalization, the personal funds of the banks assuring a level of solvability situated above the limits settled by the central bank for the well – capitalized banks. So, the expansion of the credit portfolio was not to the prejudice of its quality. Moreover, the credit risk has a positive trend, a level recorded at the end of the analyzed interval being in the segment of banks with a rating of 1;

- the diminution, especially in the last year of the analyzed period, of the distance between the active interest and the passive ones specific to the operations with non-banking clients and to the efficiency of alternative placing using the state titles and the deposits placed at the central bank. Correlated with an alert rhythm of raising the bank assets and the personal funds, this adjusting of distance led to an easy contraction of the capitalization indicators;

- the polarization, taking into account the rating, of the big banks, on its superior level. Although they were still in majority at the end of the analyzed period, the banks with rating 2 have decreased their share in the total bank asset in the favor of those with rating 1.

As a conclusion, by their level, the economic-financial indicators and those of bank discretion testify that the Romanian banks have made significant steps towards the criteria imposed by the European integration.

## **Abstract**

*Romania has been selected among the 10 Central and Eastern European candidates for EU membership and is expected to join the Community in 2007. Romanian financial institutions have to face today adaptations and opportunities and banking business in the country seems fairly attractive to foreign banks. The paper highlights the rise and the development of banking in Romania and covers the period from 1865, when the first modern commercial bank was established to present days when the Romanian banking system will become a part of a larger EU banking structure.*

**Keywords:** *Banking system, privatization, Romania*

## **1. Introduction**

The banking system is of particular importance to the Romanian economy being a key factor in our future development. Romania's admittance into the EU structures, depends on a large extent on its capacity to produce a sustainable economic growth which must be backed up by a reliable banking system which is capable of answering back both to the internal and external influences. This work paper wants to underline that all the current strategies regarding the banking system aims at increasing its competitiveness and, at the same time, plans to eliminate all the obstacles which stand in front of Romania's integration.

## **2. The history of the Romanian banking system and its beginnings**

The first modern commercial bank was established in the Romanian Principalities in 1865 under the name of The Bank of Romania. The bank was organized as a limited joint-stock company, with subscribed capital worth FF 25,000,000. The Bank of Romania was initially set up as an issuing and commercial bank by the English and French investors who governed the Banque Imperial Ottomane. Four years later, the Romanian Government revoked the Bank of Romania's monopoly of issue. Accordingly, this institution operated further as a private commercial bank until its liquidation in 1948 by the communist regime.

The establishment of a modern-type banking system, designed to replace money lenders and trade houses that had developed healthily before the mid of the 19th century, was a slow process until the setting up of the National Bank of Romania.

On April 17, 1880, Parliament voted and passed the foundation law of the first banking institution, which was to play a major part in the economic development of the country.

The new institution called also "The Bank of Banks" fully matches as functions and organization the similar institutions in the Western countries. Since its establishment and up to World War I, the National Bank played a major part in financing the banking system by means of discount credits.

The National Bank of Romania was established at the initiative of the Liberal Party in order to grant credits in high demand after the Independence

War (1877), and providing financial stability for the country. The National Bank of Romania was designed not only to play the role of state financing and note issuing, but also to perform purely commercial banking functions. In compliance with the provisions of the law governing its establishment, the new banking institution was a joint-stock company, with the Romanian government holding 1/3 of the capital stock (shareholders holding the remainder). These provisions precluded foreign shareholders from sharing the National Bank of Romania's capital, closely following the principle of domestic control over the national economy required by the liberals. In 1901, The National Bank of Romania became a private institution. Under the Liberal Party's control, the National Bank of Romania played a significant part in the foundation of the Romanian modern type banking system and contributed to the strengthening of the Romanian bourgeoisie economic position.

The economic progress that accompanied the consolidation of the Romanian state and the support provided by the National Bank of Romania accelerated the establishment of private commercial banks, especially during the period that preceded the outbreak of World War I. The number of commercial banks increased to 215 in 1914, from 3 banks existing in 1880. If the setting up of the National Bank of Romania and long-term credit institutions were done only with domestic capital, in turn, foreign capital would be involved substantially in the creation of the new private commercial banks. Accordingly, in 1914, German, Austrian, French, Belgian and English banking institutions held 40 percent of the Romanian commercial banks' capital.

On the eve of World War I, the Romanian banking industry was highly concentrated, being dominated by 9 leading commercial banks, called "the big Romanian banks". In 1913, these banks held 70 percent of the total commercial banks' resources, while 188 small and middle-sized banks held the remainder of the total resources. Taking into account the origin of the capital, the composition of the group of "the big Romanian banks" was the following: 4 banks with national capital (Banca Agricola, Banca Comertului from Craiova, Banca Romana de Scont, Banca Romaneasca), 4 banks with foreign capital (Banca Generala Romana, Banca de Credit Romanesc, Banca Comerciala Romana, Banca Romaniei), and one bank with foreign and domestic capital (Marmorosch Blank & Co. Bank).

After World War I, under national oriented policies promoted by the Liberal governments, the weight of the foreign capital in the banking system declined in relative terms. Despite this capital trend, the banks with foreign interests maintained significant positions in the banking system and were able

to better identify profitable investments than their Romanian-controlled competitors.

Significant for the spectacular boom of the Romanian banking system by then was the rise in the number of the joint stock banking companies from 215 in 1918 to 1122 in 1928.

The financial and banking system was well organized in those years, offering the favorable pre-requisites for obtaining on the eve of 1938 competitive economic indexes in general as well as in many specific fields, as compared with to the standards reached in the other European countries.

During 1931-1932, the banking sector felt the repercussions of the economic crisis due to its close links with the industry. Banks' supervision was almost nonexistent. This state of affairs contributed to the collapse of some large banks, but generally the banks with foreign interests withstood the shocks.

In order to strengthen the banking system, the Romanian Parliament passed "the Law on the organization and regulation of the banking commerce", on May 8, 1934. Under this law, The National Bank of Romania was deeply involved in drafting measures for recovering the banking system by liquidating non-viable credit institutions and merging institutions weakened by the crisis. Consequently, the number of banks was diminished from 893 in 1933, to 523 in 1937 and 246 in 1944.

After 1934, the state intervention in regulating the banking sector forced the foreign-controlled banks to comply with imposed requirements and to apply a policy in line with Romania's general interests.

Characteristic of the interbella activity of the National bank was its financial support for the country's economic rehabilitation, for the swift accumulation of capital, for the strengthening of domestic industry, for the unprecedented expansion of the financial market, the growth of Romanian exports and participate on in wide-scope international transactions.

Soon, after the communists took the power in Romania according to the Decree Law no. 197/1948, all the Romanian and foreign-controlled banks were liquidated, except for the National Bank of Romania, the National Company of Industrial Credit and the Savings Bank.

The 1934 banking law being abrogated, the remaining banks continued their activity under the provisions of the Commercial Code and their specific laws. In the years that followed, the Romanian banking system was organized as a mono-bank system, typical to a centralized economy. It is noteworthy that in the 70s, during a period of economic liberalization two foreign banks were allowed to establish branches in Romania: Manufacturers

Hanover Trust (the branch being now part of the Chase Manhattan Bank network), and Societe Generale.

### **3. The Romanian banking system nowadays**

The actual Romanian banking system enjoys a two-tier structure, involving the National Bank of Romania (NBR) and the banks. This new banking system was introduced in December 1990, marking the first step of the banking reform process, when the NBR assumed the traditional central bank's functions and its previous commercial operations were transferred to the newly established the Romanian Commercial Bank.

The issuing of the Law on banking activities (33/1991) and the Law concerning the Statute of the National Bank of Romania (34/1991) represented the beginning of the organization of the banking system in accordance with the market economy principles.

The legal framework of the banking system was reshaped and improved in the first half of 1998, when three banking laws were enacted: the Banking Law (No. 58/1998), the Statute of the National Bank of Romania (No.101/1998) and the Law on Bankruptcy Proceedings for Banks (No. 83/1998). By the enactment of the new legislation, together with the Law on privatization of state-owned banks (no. 83/1997), the weaknesses of the former legislative framework were corrected in order to ensure a sound and stable banking system, to strengthen the independence of the NBR and its enforcement powers and to improve the exit mechanism for ailing banks.

The National Bank of Romania is aiming at full harmonization of the legal framework for banking activity with European Union regulations, in order to facilitate the European integration of Romania.

During the last decade, the main characteristics of the banking system have been concentration and segmentation. Despite the increasing number of banks over the recent years, there are four banks dominating the market, which account for approximately 60 percent of the banking sector's assets, more then 60 percent of the deposits and more then 60 percent of the paid- in capital at the end of June, 2000.

The former commercial banks have changed themselves and have become real commercial banks for the market economy. In 1990, the former commercial banks have been established as follows: Banca Comerciala Romana SA, Banca Romana de Comer Exterior SA, Banca Agricola SA, Banca Romana pentru Dezvoltare SA and many other new commercial banks have also been established, such as Banc Post SA (state capital), Mind Bank SA (private capital).

Until August 9<sup>th</sup>, 2005, the National Bank of Romania has authorized 39 banks, Romanian legal entities, to render banking services. (see Annex no. 1).

The NBR tries to stimulate, within the legal framework, the establishment of branches and subsidiaries of foreign banks, as they play an important role in developing the range of banking services and improving their quality.

There are different kinds of banks when considering capital that can apply for banking licenses issued by the NBR:

I. Romanian banks, of which:

a). fully or majority state-owned capital, out of which:

- fully state-owned capital (e.g. Savings Bank);
- majority state-owned capital (e.g. Romanian Commercial Bank);

b). fully or majority private capital, out of which:

- fully or majority domestic capital
- fully or majority foreign capital

II. Foreign banks branches, such as ING Bank, United Garanti Bank International, Banque Branco-Roumaine.

At the end of August 2005, there were 39 banks, Romanian legal entities, including 8 branches of major foreign banks. This number rose significantly from 7 banks in 1990.

### ***3.1 The National Bank of Romania***

In accordance with the Law No. 101/1998, the National Bank of Romania is a public institution, with legal personality, entitled to establish branches, subsidiaries and agencies. The main responsibilities of the NBR are the followings:

- to ensure the stability of the domestic currency with a view to maintaining price stability;
- to issue currency as legal tender in Romania;
- to design and implement the monetary, foreign exchange and credit policy;
- to participate on behalf of the State in external negotiations on financial, monetary and payment matters.

The National Bank of Romania is mainly engaged in the following activities:

- licensing commercial banks, both foreign and domestic, and monitoring their activities on a monthly basis;
- keeping the Romania's international reserves;
- elaborating the balance of payments;

- setting the level of reserve requirements of commercial banks, which in turn influences the liquidity of the financial system;
- establishing the foreign exchange policy of the State, setting exchange rates, licensing and supervising legal entities authorized to conduct foreign exchange transactions.

The National Bank of Romania is headed by a Board of Directors and its current management is entrusted by the Governor. The Board of Directors consists in the governor, the First Deputy Governor as Vice-Chairman, two Deputy Governors and five members. The members of the Board of Directors are appointed and replaced by Parliament on the recommendation of the Prime Minister.

On a permanent basis, the National Bank of Romania co-operates with the international Monetary Fund and specialized consultants provided by the World Bank, as well as with other organizations in developing policies and procedures governing the Bank's operations.

### ***3.2 Banks - A Main Part of the Romanian Banking System***

Under the provisions of the Romanian Banking Law, with subsequent amendments, a bank represents a credit institution authorized to perform mainly the activity of collecting funds from both legal and natural persons through deposits or negotiable instruments payable on demand or on maturity as well as that of granting credits.

The European Union countries utilize the concept "credit institution" in order to define the above activity. The credit institution represents an undertaking whose business is "to receive deposits or other repayable funds from public and to grant credits for its own account".

No entity is allowed to perform any banking business within the Romanian territory, without the National Bank of Romania's previous authorization. Banks, Romanian legal entities, as well as branches of foreign banks may perform, within the limit of the authorization granted, the following operations:

- Open accounts in RON and in foreign currencies;
- Receive demand, time and notice deposits;
- Loan agreements (grant short, medium and long term loans and credit lines in RON and in foreign currency), factoring operations and discounting of trade bills;
- Carry out banking operations in Romania and abroad;
- Issuance and management of the instruments of payment and credit;
- Payments and settlements;
- Financial leasing and funds transfers;

- Issuing guarantees and assuming commitments;
- Issue and operate credit cards;
- Buy and sell government securities;
- Transactions on their behalf or in their clients' account with: negotiable money instruments (cheques, bills of exchange, certificates of deposit), foreign currencies, financial derivatives, precious metals, securities;
  - Management of clients' portfolios;
  - Securities custody and management;
  - Renting of security safe boxes;
  - Financial, banking consulting and Electronic banking.

### ***3.3 Privatization of the banking sector***

Romanian commercial banks began their operations with relatively specialized portfolios, reflecting their pre-1989 concentration in particular economic sectors. However, this initial specialization has diminished as the banks competed with each other and new banks entered the market. A number of new banks with private Romanian or mixed capital have been licensed to begin operations. The privatization process of the major state-owned commercial banks started in 1998. Law on bank privatization (Law No. 83/1997) established the legal framework for the transfer of state-owned banks to the private sector and the improvement of their financial situation.

The privatization of the banking companies may be achieved in one of the following ways:

1. Increasing the share capital, through contribution of private capital in cash, on the basis of public offer or private investment;
2. Selling the stock administered by the Authority for State-Owned Equity Management and Privatization, only in cash, with full payment, towards: Romanian individuals; foreign individuals; Romanian legal persons with private majority capital; financial investment companies; foreign legal persons with private majority capital; a combination of the two methods described above.

The National Privatization Authority is the administrator of state equity in the banks' capital. A privatization commission is set up in the case of commercial companies in which the state is shareholder. The privatization commission shall supervise the privatization operations and ensure the observance of transparency, consistency and objectivity of the principles. The privatization of such companies shall be based on the valuation reports and feasibility studies drawn up by a specialized company in accordance with international standards.

In compliance with Law No. 83/1997, the process of bank's privatization in which the state is a shareholder carries on. In 1999, the

privatization of state-owned banks represented one of the key objectives of the structural adjustment program supported by the World Bank and the International Monetary Fund. In this respect, the privatization process of Romanian Development Bank and Banc Post was completed in the first semester of 1999. The majority interest (i.e. 51 percent) in case of Romanian Development Bank was sold to the French bank Societe Generale, while General Electric Capital Corporation and Banco Portugues de Investimento acquired the controlling interest (i.e. 45% ) in Banc Post. In this way, private capital in the two banks accounts for 90 percent and 83 percent respectively.

Privatization of the Agricultural Bank ended with the sale, on April 12, 2001, of the state equity holding to the consortium made up of Raiffeisen Zentralbank Osterreich A.G. (93.13 percent) and the Romanian-American Enterprise Fund (5.7 percent). Referring to the stage of privatization process of Romanian Commercial Bank, the privatization strategy was approved in 2001 by the empowered institutions (National Authority for State-Owned Assets Management and Privatization, Ministry of Development and Prognosis, Ministry of Public Finance and the National Bank of Romania) and will be completed in the following years.

The privatization is beneficial for all parties involved, ensuring banking know-how and expertise transfer, introduction of new or improved banking products, improved efficiency for bank's assets, harmonization of bank's quality services with internationally recognized standards, banking network development included, a more efficient integration of the Romanian banking system into the international one, thereby facilitating access to world financial markets.

#### **4. Recent developments and perspectives**

During the previous years, The National Bank of Romania had the following objectives:

- Achievement of lasting macroeconomic stabilization together with the revitalization of the financial market for an efficient allocation of the resources, transparency of information, and achievement of economic equilibrium. The National Bank of Romania considers that the well functioning of a complete market system in Romania is a condition for a lasting economic growth.
- The foreign exchange market liberalization by allowing all the authorized banks to be dealers in transactions and via exchange rate liberalization.

Large foreign exchange purchases by the National Bank of Romania made in order to avoid nominal appreciation of national currency led to the increase of the foreign exchange reserves:

- The capital market experienced a large increase in trading on both levels of The Stock Exchange, and of RASDAQ. The main reason for the development of the capital market was the increase of the shares demanded from the non-resident corporate investors, bolstered also by the increasing number of listed companies.

- The monetary policy conducted by the National Bank of Romania aimed to ensure macroeconomic stabilization, specially the decrease of the inflationary effect of price liberalization, the restoring the central bank's credibility to regain the confidence in the national currency and, to achieve the remonetization of the economy.

The efficiency of the monetary policy was sustained by the following achievements:

a) Release of the monetary policy from the quasi-fiscal constraints consisting of directed and preferential credits;

b) Integration of the monetary policy in the macroeconomic policies;

c) Achieving of a healthy currency issue based on improving of the National Bank of Romania portfolio by increasing the net foreign assets and the foreign reserves;

d) Improvement in the transmission of the monetary policy measures by the liberalization and development of the financial markets, especially of the money market;

e) Achieving real-positive interest rates and maintaining those levels;

f) Improvement and completion of the legal framework for the regulation of the banking and central bank's activity by drafting of the Banking Act, the Bank Insolvency Act, Bank Privatization Act, and the National Bank of Romania Act.

In the next years, the National Bank of Romania will focus its efforts on carrying out a stable policy and a macroeconomic stability, as well as on correlating the macroeconomic policies with measures taken in the privatization and structural adjustment areas.

The orientation of the National Bank of Romania reflects also important performance concerning: a) Guiding the monetary policy towards price stability; b) Creation and development of financial markets; c) Carrying out the open account convertibility of the national currency; d) Increase the international reserves; e) Consolidating its formal and operational independence.

Concerning the monetary policies, the program of the National Bank of Romania is a part of the economic program of the Government. This program has as major objective to reduce the inflation rate and to achieve lasting macroeconomic stability. Other objectives of the program are: to improve the quality of the banking sector by supervision and regulation; to improve the banking information and payments system, by modernization of

the settlement and clearing system; harmonization of the payment system operational procedures with the new banking legislation; modernization and expansion of the services rendered by the banking information system.

The National Bank of Romania will pay a special attention to the developments in the Euro-area and will monitor the consequences of starting stage III of the Economic Monetary Union. As a central bank of a country candidate for the European Union (EU), the National Bank of Romania will strive both to carry on implementation of domestic reform and to ensure the legal, institutional and procedural harmonization with its correspondent entities in the EU.

The National Bank of Romania will become a member of European System of Central Banks (ESCB) at the moment of accession to the EU. Romania will be in the position to adopt Euro only after it has complied with the convergence criteria stated in the Treaty. The task of NBR will differ from one stage to another. There are to be no essential changes in the NBR activity since the central bank will be an ESCB member with derogation during the period between accession to EU and acceptance to the Euro area.

Consequently, the NBR governor will not attend the meeting of Governing Council, but only the General Council, which has a consultative role. The NBR will keep on maintaining the price stability and will have to look the currency exchange policy as an issue of general concern. Therefore, Romania will have to participate to the exchange rate mechanism of EU - MCE II. According to the circumstances, this participation may take place immediately after accession or later.

National Bank of Romania will become a full member of ESCB only after Euro will replace RON. So NBR will no longer define the monetary policy, as our central bank will implement the unique monetary policy established by the Governing Council. But the NBR governor will be a member of this Council, thus being part of the decision-making process related to the monetary policy. NBR will have the same task of prudential supervision, issuing coins, having and establishing international relations with different institutions and effecting any financial operations for various entities. NBR will also manage the official reserves after the transfer of share-quota to the European Central Bank.

## **5. Conclusion**

The banking system in Romania after 1989:

- the new banking system started on December 1, 1990

- two levels: NBR as a central bank and the commercial banks
- the Law on banking activities (33/1991) and the Law concerning the Statute of the NBR (34/1991) according to the market economy principles
- the former commercial banks changed and new commercial banks were established
- the new laws were introduced in 1998: 58/1998 and 101/1998
- new regulations of the banking system: Law 375/2002 and Law 101/1998 was modified

## Abstract

*When banking sector crash occurs during the financial crisis, losers are not only the customers, owners of the companies or governments...etc., the employees of the banks are also losing. In the period between the February 2001 crisis and August of the same year, and for a month following the attacks on September 11, till today, more than 50 thousand bank staff lost their job in Turkey. Bank number decreased from 81 to 48 and employment in Turkish banking sector decreased from 174,442 in 1999 to 124,030 until 2004. Bank number is decreased 48 in 2004 due to closures of banks or mergers and takeover. Employment is increased to 129,887 by May 2005. The number of banks operating in the banking system was 48 in January-June 2005. Of which, 35 were commercial banks, 13 were non-depository banks. This process was very painful for the jobless bank staff and for their family members. The aim of this study is to discover the Turkish bank staffs' current situation and to focus on unemployment problem in Turkish banking sector.*

**Keywords:** Banking Sector, Crises, Employment, Turkey

## **1. Introduction**

This paper aims to analyze the Turkish bank staffs' current situation and focuses on unemployment problem during the 2001 financial crisis in Turkish banking sector. In order to achieve this aim, firstly, the 2001 financial crisis general outlook and Turkish labour market situation during the crisis should be analyzed. This is the subject matter of second section and third section. Then, employment situation in Turkish banking sector should be analyzed in fourth section. Later, governance of privatization process and policies related with the employees of the closed banks should be taken into consideration in fifth section. Lastly, we added some conclusion to the paper in sixth section.

In this study we tried to assess the initial socio-economic impact of the 2001 crisis, with particular emphasis on the unemployment problem of bank staff. This covers a wide range of issues comprising labor market indicators such as unemployment in Turkish banking and decline in real wages of employed bank staff.

The study is based on a qualitative assessment and adopts a before and after methodology of comparing the situation before the crisis with the situation afterwards. Evidence of the effects of economic crises mixed. There are claims that the effects of the earlier 1994 crisis were still felt as late as 1998, with large foreign trade and public sector deficits and high rate of inflation.

Furthermore, at the top of list of structural factors are heavy demographic pressures and the labor market dominated by agriculture and large urban informal sector which is characterized by very large inter-sectoral and interregional productivity differentials and a slow pace of employment creation.

## **2. The 2001 Financial Crisis General Outlook**

The 2001 crisis was the worst economic crisis in the Turkish nation's republican area since 1923 which resulted in a 7,5 percent decline in the economy.<sup>1</sup>

In January 2000, with the aim of eliminating high and chronic inflation, the Turkish government launched a stabilization program with the support of the International Monetary Fund (IMF). The key to the disinflation

---

<sup>1</sup> H. Kaan NAZLI, Banking on Turkey, The National Interest, Vinter 2004/05, p. 114.

program was the introduction of a new exchange rate-based stabilization (ERBS), characterized by a pre-announced exchange rate and a built-in exit strategy, which envisaged a gradual and smooth transition to a flexible exchange rate. The program entailed tight monetary and fiscal policy as well as the implementation of structural reforms. Of all the structural reforms, the most important was related to the restructuring of the banking system. The timing of which as will be discussed had some important consequences for the November crisis.<sup>2</sup>

The imported question is that, what caused to the November 2000 and February 2001 financial crises. We can describe four different causes related with:

- Turkey initiated an extensive disinflation program, the aim of this program was to decrease the inflation rate to a single digit by the end of 2002. It relied exclusively on a nominally pegged (anchored) exchange rate system. But, introduction of a reliable atmosphere of exchange rate program was not achieved,
- Uneconomic behavior of Turkish banks without a smooth auditing system,
- Structural weakness of the 2000 disinflation program,
- Short-term deposit accounts of banks and huge amount of debts, taken as syndication credits which means foreign capital and this capital movements depends on the reliable financial markets.

Generally, banking crises comes together with the other type of economic crises in the emerging market countries. Shortly, the weak banking system caused economic crisis of Turkey in 2001.<sup>3</sup>

Colombia, Peru and Uruguay in 1982, Turkey in 1994, 2000 and 2001 faced with exchange rate crisis caused banking and stock exchange crisis. Argentina and Chile in 1980, Mexico and Venezuela faced with banking crisis caused exchange rate crisis and public finance crisis. Scandinavian countries in 1990s, Mexico in 1994 and 1995 and lastly Asean countries like Taiwan, Malaysia, Indonesia and South Korea in 1997 both the banking crisis, exchange rate crisis and capital market crisis came together at the same time.

As below Table 1 shows us that financial crises occurs both in developed countries and emerging markets countries. But, there are more economic crises in emerging market countries than developed countries such as exchange rate crises of currency collapses and banking crises. Also, crises may occur as exchange rate crises and banking crises together. Average recovery periods are also higher in emerging market countries and Gross Domestic Products (GDP) losses are big.

**Table1: Financial Crises and Impact of The World Economy**

The crisis in November 2000 and February 2001 aggravated the problems that some of the banks in Turkey were already facing. At the end tenth number of commercial banks taken over by Savings Deposit Insurance Fund (SDIF). Foreign and domestic investors pulled out enormous sums of money from the Turkish financial market within a matter of days. This rush to withdraw funds came about nearly a year after Turkey introduced a

disinflation program predicated on an ERBS which was designed and supported by the IMF.

The Turkish government weathered the crisis in November with the financial support of the IMF and was able to hold on to the exchange rate peg. Three months later, however, turmoil in the market forced the government to abandon the peg. In the months that followed, the currency collapsed, unemployment soared, and Turkey faced the worst economic contraction it had seen in decades. In the case of the November crisis, panic was caused by the policies of the newly created banking supervision agency and the subsequent liquidity problems of a mid-sized bank. In February, it was the prime minister's statement that Turkey was in the midst of a "political crisis" following his disagreement with the president that triggered financial panic.

Following the demise of the exchange rate-based disinflation program, the newly appointed Finance Minister in Turkish Government Cabinet, Kemal Derviş (former vice president of the World Bank) submitted a new letter of intent to the IMF. On May 15, Derviş announced the invigoration of a new stabilization effort under the guidance of a program entitled "Turkey's Transition Program: Strengthening the Turkish Economy".

The new program would be the continuation of the previous disinflation program and would be backed by a series of "structural reforms" aimed at strengthening the banking system and at transforming the "old ways of economic policy making". However, the September 11 terrorist attack undermined the implementation of this new program, affecting investors' perceptions adversely. The Turkish government requested, in turn, a new three-year, stand-by arrangement for offsetting the detrimental effects of the external shock.

The IMF accepted the new letter of intent dated January 18, 2002, by providing a considerable amount of financial support. The last two stand-by arrangements should clearly be regarded as the continuation of the disinflation program launched at the end of 1999, even though they were implemented after its failure. IMF offered \$7.5 billion of new loans (and \$10.4 billion overall) for Turkey; Discussion of talks between Turkey and the European Union regarding Turkey's membership in the Union; role of poor regulation of Turkish banks on the country's unstable economy.

The main framework of the program itself, as well as the crisis episode, has been a source of debate since its very beginning. In particular, it was alleged by the former deputy managing director of the Fund, Stanley Fischer, that the difficulties in Turkey relate more to the banking sector and to the deterioration of macroeconomic fundamentals rather than any errors in

program design. In particular, according to Fischer, The recent difficulties in Turkey relate more to banking sector problems, and the failure to undertake corrective fiscal measures when the current account widened.<sup>4</sup>

The main reason for the financial crisis in February 2001 was the number of instances of malpractice in the banking sector, which collectively brought about a major liquidity crunch. The state intervened to take over a clutch of collapsed banks and poured millions of dollars into saving a corrupted banking system. One of the outcomes of all that, and one stressed by the IMF, was the establishment of a 'show and tell' system under which banks were obliged to be audited and have the size of their particular credit holes measured by outside experts. What this produced was a surprisingly healthy picture of the surviving banks.<sup>5</sup>

The combined effects of September 11th and sluggish growth have underlined or accelerated job trends that were already under way. Employment in finance soars and plummets with the markets.<sup>6</sup>

### **3. The Turkish Labor Market During The 2001 Crisis**

The adverse production trends had the most significant impact on the labor market. A distinctive feature of the 2001 crisis was the mass redundancy of labor. Reductions in the working week and laying of workers temporarily with or without pay was the common practice. The severity of the 2001 crisis was such that a large number of workers lost their jobs, especially during the first few months of the crisis. This was the combined result of firms under financial strain either reducing their workforce or going out of business altogether. The evidence on the number of redundancies is rather patchy, with estimates from different sources varying by a wide margin. Detailed information on the profile of employees made redundant during the crisis in particular their distribution by age, gender, and labor market status is not available from official sources.

According to Ministry of Labor data published in February 2002, just one year after the emergence of the crisis, 1,567,000 persons who were unemployed, 390,000 were made redundant during the year. At the other extreme, another estimate covering the two years until August 2002 put the

<sup>5</sup> Jon GORVETT, There may be trouble ahead, *Middle East*, Jan2003, Issue 330, p. 30.

<sup>6</sup> *Economist*, What September 11th did, and what it didn't, 2/19/2005, Vol. 374 Issue 8414, Special section pp. 7-10.

total number of enterprises going out of business at 600,000 and the number of workers who lost their jobs as high as 2.3 million. According to figures given by a trade union, Seluloz-iş, for the largest three provinces (Istanbul, Ankara, and Izmir), in the first few months of the crisis until May, a total of 1,414 enterprises went out of business, resulting in 42,000 workers losing their jobs, with the automotive and machinery sectors hit particularly hard.

Estimates for the banking sector alone put the number of workers fired at around 50,000. In mass media, a sector in which labor-shedding reached unprecedented levels by Turkish standards, around 5,000 workers lost their jobs during 2001. Engineers and architects, with nearly 50,000 in their ranks made redundant, represent another major category of workers hardest hit by the crisis.<sup>7</sup>

A survey conducted by the research team of one of the major opposition parties, the Republican People's Party (RPP) indicates that 50 percent of these were single, 75 percent male, 25 percent university graduates, 40 percent high school graduates, and a massive 96 percent working in the private sector at the time, mostly in textiles, banking, and construction.

As expected, in the face of the increasing financial difficulties of firms and severely falling domestic demand, the severe contraction in production led apart from labor shedding to a virtual halt in recruiting in the private sector. A sharp drop in job openings in the public sector aggravated this. The affect of the crisis on employment, though, was by no means uniform across different production activities. Construction was most severely affected, with employment declining by a massive 18.3 percent during 2001. In the manufacturing sector, for which we have more detailed information, the index of employment (1997 = 100) declined sharply from 89.1 in 2000 to 81.6 in 2001. The RPP survey results, indicating that 23 percent of the workers made redundant during the crisis were replaced by new recruits, prove the same point.<sup>8</sup>

Similar to the 1994 crisis, public sector employment served as an instrument of crisis management. The public sector, whose role in employment creation had been in decline due to the process of privatization and trends towards small government, also cut back its recruitment. This probably hit recent university graduates most severely. On the other hand,

<sup>7</sup> Fikret ŞENSES. Economic Crisis as an Instigator of Distributional Conflict: The Turkish Case in 2001, *Turkish Studies*, Summer2003, Vol. 4 Issue 2, p. 99.

<sup>8</sup> The Republican Peoples Party (RPP)' announced in May 2002 on people who became unemployed as a result of the crisis. Prepared by Science' Management and Culture Platform of the RPP.

with almost perfect job security in the public sector, it was perhaps not surprising to see that this sector did not contribute to the level of unemployment during the crisis. The large number of applicants for public sector jobs, though, indicated greatly reduced job opportunities during the crisis.

The data given by the Turkish Employment Service, the number of applicants and the number of those registered as actually unemployed dropped during 2001. However, the Household Labor Force Survey results indicate that the number of unemployed persons increased considerably, from 1,455,000 to 1,892,000 during the same period.

Based on the Household Labor Force Survey results, the rate of unemployment increased from 6.3 percent in the last quarter of 2000 to 10.6 percent in the corresponding period in 2001, with the rate increasing further to 11.8 percent in the first quarter of 2002. The rise in unemployment was accompanied by a change in the profile of the unemployed, with the share of young and educated persons increasing sharply.

The effect of the crisis may not, however, be fully reflected in the unemployment rate for at least two reasons. First, some of those who lost their jobs, especially white collar female workers, might have deemed their prospects of re-employment to be rather slim and dropped out of the labor force altogether, joining the ranks of the other discouraged workers. Second, since persons who worked even one hour during the week before the survey was conducted were considered as employed, the unemployment rate does not capture the full extent of labor market slack. One would assume that these trends in the labor market might also have swollen the size of the informal sector. However, the share of selfemployed persons and unpaid family workers in total employment which may be taken as an indicator of the size of the informal sector increased only slightly, from 45.1 percent in 2000 to 45.8 percent in 2001.

As in previous crises, a major effect of the 2001 crisis on the labor market was a sharp drop in real wages. During the 1994 crisis, the real wages and salaries fell in both the public and private sectors to such an extent that it took several years to revert back to the pre-crisis levels in the private sector and even longer in the public sector. The rate of decline in real wages in 2001 was also very large, reaching an average of 14.4 percent in the manufacturing sector

The effect of the crisis on the working population was by no means confined to those groups discussed above. Although not systematically documented, there were reports of deteriorating working conditions for workers facing threats of redundancy, including longer working hours

without pay, reductions in money wages, delays in the payment of wages, and offers to give holidays earlier than usual. In addition, employers encouraged early retirement and resignation. Workers were probably tempted to succumb to these propositions for fear of losing their severance pay should the firm go bankrupt. The RPP survey showed that only 42

percent of workers made redundant during the crisis could receive their severance pay, and there were reports that many of those who could receive it had payments dispersed over time thereby eroding their real value severely due to high inflation.<sup>9</sup>

In the most recent crisis, in 2001, GDP plummeted by 7,5 %. In February that year the lira was devalued by about 40% in a week and short-term interest rates briefly touched an annual rate of 7,500%. The official rate of unemployment 10% is widely acknowledged to be unrealistically low. Due to there are considerable underemployment in agricultural sector.

Unemployment seems destined to get worse before it gets better. 700,000 new jobs need to be found every year to keep the unemployment level constant. That number is set to rise as the working population continues to grow. If the government meets its target of 5% growth for each of the next three years, it will create 1.65m jobs over that period, just enough to mop up the increase in the working population. But the labour force could be swelled further by large numbers of workers coming off the land as Turkey invests in its agricultural sector and increases productivity. Agriculture currently accounts for 33.2% of all jobs but only 13.4% of GDP. If the workforce was cut to match the sector's contribution to the economy, 4.4m jobs would have to be found elsewhere.

Some Europeans have nightmares about hordes of unemployed Turks roaming freely across the European Union (The EU) and undercutting native workers' pay. But in reality there is little evidence that immigration harms the natives' job opportunities. Rather, EU countries should be welcoming young Turkish workers, especially where populations are declining. Those workers will help to make sclerotic economies more flexible and keep up contributions to state pay-as-you-go pension schemes.<sup>10</sup>

#### **4. Employment Situation in The Turkish Banking System During The Crisis**

The stabilization program was miss-managed and the economy moved to the brink of collapse in November 2000. Interest rates on bonds, which quadrupled in that period, caused severe damage, especially to banks that invested heavily in T-Bills and Government Bonds. Three banks, including the fifth largest private commercial bank, Demir, were taken over by the BRSA and placed under the administration of the SDIF in the final quarter of 2000. Thus, the number of private commercial banks declined to 28 from 31 throughout the year. Then there came official announcements to the effect that unhealthy banks were to be removed from the system. Tension was gradually eased and hopes appeared set to rise again.

Eight more banks were taken over in 2001. Finally all banks confronting direct injury were eliminated from the system. Due to certain mergers and sell-offs, the decrease in the number of private commercial banks was limited to 6 banks.

Some banks such as Pamukbank found themselves in deep mud. The BRSA ultimately took Pamuk over in mid-June. Those takeovers and mergers consequently pulled down the number of banks (including development & investment, state and foreign) in the system to 53 in 2003, from an all-time high of 81 in 1999. The number of mergers and acquisitions increased in 2001 and 2002.

The major protagonist of this era was the SDIF. Six of the taken over banks were merged under Sumerbank and sold to Oyak, Bankekspres was acquired by Tekfenbank, Demir was sold to HSBC and Sitebank was transferred to Novabank. Interbank, Esbank and Etibank, which were merged under Eti and placed on sale, failed to attract any bids, leading to its banking license being revoked. Toprak and EGS banks are merged into Bayindirbank, which is the BRSA's asset management body.

It was not just the SDIF banks that underwent mergers. Those conglomerates having more than one bank started private commercial bank mergers. Dogus Group triggered the process via merging Korfezbank into Ottoman Bank, and thereafter the two into Garanti Bank. Cukurova Group made an unsuccessful attempt to locate Pamukbank inside Yapi Kredi, as the operation was rejected by the BRSA to protect Yapi Kredi's shareholders. Another merger came from two development and investment banks with identical shareholder structures. Sinai Yatirim Bank was merged under TSKB

at the end of 2002. And Finansbank's acquisition of its little sister Fibank in 2003.<sup>11</sup>

The country's "big four" Garanti Bank, Is Bank, Yapi Kredi Bank and Ak Bank were also rumoured to be in negotiations with foreign interests. Firstly, HSBC moved in to buy Demirbank. One of Turkey's largest holding companies Dogus owned one of the "Big Four", Garanti, plus two other smaller banks, the Ottoman Bank and Korfez Bank merged, then joined with Garanti bank. Also, Yapi Kredi and Pamukbank, both owned by the Cukorova Group, tried also merge. But the result was not successful. However, mergers between banks that are not part of the same group seem less likely.<sup>12</sup>

Turkey's banking regulator assumed control of two of the family's banks, named, Imar Bank and Ada Bank, alleging Uzan and his sons had misappropriated \$5.9 billion in 2004.<sup>13</sup>

Since 2001 February's financial crunch, Turkey's beleaguered banking system had been gone through some dramatic and rapid changes. With the pressure full on for the country's financial institutions to do some serious redeploying, particularly as they had been widely singled out as the major factor in the country's recent economic crisis, Turkey's banks were in the market for serious foreign buy outs, partnerships and mergers.

Since 1980s the Turkish banking sector experienced a significant expansion and development in the number of banks, employment in the sector, diversification of services and the technological infrastructure. The number of banks increased from 43 in 1980 to 66 in 1990 and to 79 by the end of 2000. 5 banks under the management of the Saving Deposit Insurance Fund (SDIF) were merged under Sumerbank bringing the number of banks to 74 by mid-May 2001. Of these 74 banks, 56 banks are deposit money banks and 18 are investment and development banks. Of the 56 deposit money banks, 4 are state banks, 26 are private domestic banks, 18 are private foreign banks and 8 are under the SDIF. Total employment in the banking sector has increased from 125 thousand in 1980 to 154,000 in 1990 and to 170,000 in

Note: \* Banks are ranked as their belongings to groups on 30 June 2005

\*\*\* Figures included number of the employees of the closed banks

Source: Banks Association of Turkey (BAT) [www.tbb.org.tr](http://www.tbb.org.tr)

Considering commercial banks group, the percentage of the university graduates and post-graduates was 52 percent in state-owned banks, 67 percent in privately-owned banks, 76 percent in foreign banks. The same ratio was 72 percent in non-depository banks.

**Table 2: Bank Employees By Education (December 2002-June 2005)**

	Primary school		Secondary school		University graduates		Post-graduates	
	2002	2005	2002	2005	2002	2005	2002	2005
Commercial banks	1520	1928	51.048	43,953	62.844	76,007	<b>2.917</b>	3,528
State-owned banks	420	311	21.534	18,402	17.595	19,567	609	800
Privately owned banks	958	1507	25.956	24,050	38269	51,954	<b>1.686</b>	2,359
Banks in the Fund*	65	8	2.042	200	3.583	186	<b>196</b>	7
Foreign banks	77	102	1.516	1,301	3.397	4,300	<b>426</b>	362
Non-depository banks	140	92	1.355	1,163	3.054	2,824	<b>393</b>	392
Total	1660	2020	52.403	45,116	65.898	78,831	<b>3.310</b>	3,920

The sector employed 154,000 staff in 6,500 branches in 1990; it now employs 123,000 staff in 6,000 branches. The numbers peaked in 2000 with 170,000 staff and 7,800 branches, then declined rapidly. The productivity gains were

achieved in the post-crisis 2001-03 period during which personnel numbers declined by 28% and branch numbers by 24%.<sup>15</sup>

## 5. Governance of Privatization of State Owned Banks in Turkey

Turkish Employment Organization – ISKUR provided a labor redeployment services to jobless bank-workers who have been displaced by the privatization of SOEs, including secondary layoffs, to assist them in rapidly re-entering the labor market. More than 3 thousand jobless bank employees attended to project and educated to find a new work in banking, insurance and other financial sectors. Project will be continued during the next three years<sup>16</sup>.

As Table 4 shows us that total cost of the banking sector crisis in 2001 reached to the sum of 53.2 billion US Dollars. Huge amount of the cost borned by restructuring of the state banks and private commercial banks transferred to the SDIF.

The first Privatization Social Support Project started in 2001. PSSP I, helped to support the Government's effort to disengage itself from production activities and thus foster the continuing development of the private sector in Turkey. The World Bank approved a US\$465.4 million (Euros 360 million) Second Privatization of Social Support Project Loan (PSSP II) for Turkey in June 14, 2005. The project's main objective was to support the Government's privatization program through mitigating the social and economic impact of the privatization of state-owned enterprises (SOEs). The Government's privatization program aimed to enhance the efficiency and competitiveness of the Turkish economy and thereby help in meeting the market demands of EU accession. The Privatization Administration had been in charge of the overall implementation of the project, which was composed of the following components:

- **Job Loss Compensation:** This component ameliorated the temporary social and

economic impact on workers displaced during the privatization of SOEs. It financed severance and related payments, as regulated by law, to workers displaced by job loss due to the privatization of SOEs.

- **Labor Redeployment Services:** This component provided labor redeployment services

to workers who have been displaced by the privatization of SOEs, including secondary layoffs, to assist them in rapidly re-entering the labor market. The

component financed a variety of labor redeployment services, including job counseling and placement services, retraining, temporary community employment (managed by the Turkish Employment Organization - ISKUR), small business assistance services, and small business incubators (managed by the Small and Medium Industry Development Agency, KOSGEB).

- Management, Monitoring and Evaluation: The objective of this component was to

monitor the impact of labor redeployment services and manage the PSSP II effectively as a whole. The component financed surveys to evaluate the effectiveness of the labor redeployment services in mitigating the social costs of labor redundancies resulting from employment and privatization on selected communities; and undertake in-depth socio-economic analyses of specific communities where privatization has taken place.

## **6. Conclusion**

The Turkish banking experience has clearly shown that during the 2001 crisis, real wages declined and non-wage adjustments which were confined largely to the adoption of flexible arrangements like part-time work, subcontracting to firms some of bank jobs, reduction of working hours through paid and unpaid forced holidays. But, job losses all together were a new phenomenon. Since the crisis of 2000-2001, many other reforms have been implemented in financial sector of Turkey.

Now, employment is increasing in Turkish banking sector, again. But, not enough to hire all the jobless old bank staff. Only a small part of them reemployed since the recovery started after the crisis. Since, the emergence of the crisis, 1,567,000 persons who were unemployed, 390,000 were made redundant during the crisis year, the total number of enterprises going out of business at 600,000 and the number of workers who lost their jobs as high as 2.3 million. Also, during the crisis, GDP plummeted by 7,5 %, the lira was devalued by about 40% and short-term interest rates briefly touched an annual rate of 7,500%. The official rate of unemployment reached to 10%§ but realistelz low.

Recently started unemployment insurance payments is not enough to compensate their economic and social losses. Most of them went to find another job in other firms or sectors. They can work only in marketing, accounting, finance and foreign and domestic trade departments...etc., but, a few of them were lucky enough to find a work. Still, unemployment rate remains very high among them.

Losers were not only the employees of the banks, the owners of the banks also, lost their capital and some of them judged and went to in prison. After the 2001 crisis the coalition government lost at the following election. Three of the coalition parties even not gained a sit in the Turkish parlement. The main reason for the financial crisis in February 2001 was the number of instances of malpractice in the banking sector, which collectively brought about a major liquidity crunch. The state intervned to take over a clutch of collapsed banks and poured millions of dollars into saving a corrupted banking system.

The effect of the crisis on the working population was by no means confined to those groups discussed above. Although not systematically documented, there were reports of deteriorating working conditions for workers facing threats of redundancy, including longer working hours without pay, reductions in money wages, delays in the payment of wages, and offers to give holidays earlier than usual. In addition, employers encouraged early retirement and resignation. Workers were probably tempted to succumb to these propositions for fear of losing their severance pay should the firm go bankrupt.

Today, unemployment seems destined to get worse before it gets better. 700,000 new jobs need to be found every year to keep the unemployment level constant. That number is set to rise as the working population continues to grow. If the government meets its target of 5% growth for each of the next three years, it will create 1.65 million jobs over that period, just enough to mop up the increase in the working population. But the labour force could be swelled further by large numbers of workers coming off the land as Turkey invests in its agricultural sector and increases productivity. Agriculture currently accounts for 33.2% of all jobs but only 13.4% of GDP. If the workforce was cut to match the sector's contribution to the economy, 4.4 million jobs would have to be found elsewhere.

## Abstract

*Credit insurance provides companies with concepts and solutions for their outstanding trade receivables, protecting risks of insolvency and protracted default. In addition to this, credit insurance protects cash flow and this helps the companies in their financing needs. Historically, credit insurance was a part of state export policy to protect receivables of domestic investors in abroad. State offered credit protection throughout Export Credit Agencies (further: ECA). The role of ECA has changed because private credit insurers offered marketable risks. Therefore, commercial business offered by major ECA was privatized due to EU requirements. ECA still play an important role in the non-marketable insurance business. The 100% subsidiary of Exportní a garanční úvěrová pojišťovna, a.s. (EGAP), Komerční úvěrová pojišťovna EGAP, a.s. (KUPEG), which is with 51% the Czech market leader in the commercial credit insurance, will be privatized in an official tender in 2006. The potential investors shall contribute to more competitive position, enable to access Czech exporters both commercial databases and worldwide network. Although the tender is considered as minor in comparison to larger privatizations like Czech Telecom or CEZ, it represents an important milestone for all global credit insurance players.*

**Keywords:** *Credit insurance; Export Credit Agency*

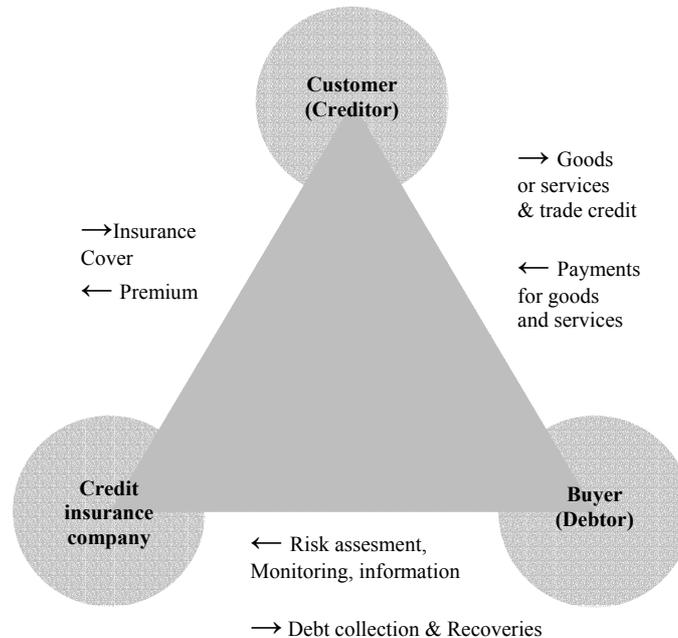

---

<sup>1</sup> The author of this paper is Managing Director of Atradius Czech Republic and her opinion is merely academic and its must not express the opinion of Atradius Group.

## 1. Introduction

“Credit insurance provides companies with coverage for outstanding commercial receivables, protecting against risk of buyer default or insolvency of the buyer. In addition to managing credit risk, credit insurance supports financing needs: by reducing the risk of non-payment of trade receivables, a firm can borrow at lower interest rates.” (SwissRe, 2000:3).

**Figure 1 Credit Insurance Triangle**

Historically, credit insurance was a part of the state export policy to protect receivables of exporters and to increase competitiveness of domestic producers. In the meantime, private investors entered the market and cover so-called marketable risks. In the following chapters, I would like to discuss the role of the state in this business and explain why private sector has changed the industry on the example of ongoing privatization process of the State Export Agency EGAP.

## 2. Credit insurance market

### 2.1 State Export Credit Agencies

In the beginning of the 20<sup>th</sup> century, the private sector was not willing to financially support and to transfer the risk of domestic exporters, which led to establishing of state Export Credit Agencies (further ECA). The first one was Export Credit Guarantee Department (ECDG) established in the UK in 1919. Similar activities in several countries followed. Core markets like France, Italy, Spain, and the UK formed the International Union of Credit and Investment Insurers, called the “Berne Union”, which offered exchange of experience within the finance and investment industry, improved risk assesment and underwriting techniques.

The Berne Union comprises of around 45 member states from around 40 countries and its members cover nearly 95% of total global premium income. The Berne Union members provide mainly the coverage as follows:

- (b) Export Credit Insurance for both political<sup>2</sup> and commercial risks (insolvency and protracted default coverage).
- (c) Investment Insurance (or long-term coverage, exceeding in general 2 years), which protects investments in abroad (e.g. power plants, water pipeline in Iraq, railways etc.). Long-term risk includes higher share on political risk and is closely related to governmental relationships and state policy.
- (d) Project Finance: states through its export credit agencies enable to finance and to stabilize larger projects and their cash-flows in abroad. In the Czech Republic, For example, this is governed through the cooperation between local Export Credit Agency EGAP and Czech Export Bank CEB.

The three above-mentioned types could be also distinguished from the reinsurance type of view in two groups:

- Marketable risks: Reinsurance through commercial reinsurers as MunichRe, SwissRe, AtradiusRe etc.
- Non-marketable risks: Insurance is ceded to the state budget.
- Combined risks. This is combination between the two above-mentioned types; this could be offered only by ECA’s,

---

<sup>2</sup> Political risks are mainly war, strike, terrorism, restrictions on transfer of foreign exchange (e.g. Argentina in 2003) and default by governments. However, the definition varies from one insurer to another.

because commercial insurers do not buy state reinsurance. However, after privatization process, many newly established entities are co-owned by the state and therefore are able to cover the risk from both, state and commercial resources. In the Netherlands, for example, after privatization of local ECA The Nederlandsche Credietverzekering Maatschappij N.V. (further: NCM) by Atradius, Atradius continued and developed underwriting of non-marketable risks for the Dutch state. Atradius DSB is the official Export Credit Agency of the Netherlands since 1932 and cover more than € 1.5 billion of Dutch mid- and long-term exposure (more than 12 months) export transactions insured annually (outside OECD).

The distinction between marketable and non-marketable risks is based on the type of reinsurance. In contrast to other insurance lines, credit insurance is strongly dependent on reinsurance appetite. In general, commercial reinsurers are more focused on short-term risks with maximum length of 2 years. Difficulties to find a reinsurer, who is willing to take over e.g. bonding risks lasting over 5 – 7 years, has led recently to significant decrease in bonding products offer in the building and construction industry in Germany and the Nordic States. Credit insurers cede in general 70 – 90% of the risk underwritten, mainly due to higher volatility of the industry, which has direct relation to the business cycle, which is discussed in the following chapter.

## ***2.2 Globalization of credit insurance***

The credit insurance business as a financial sector is facing the negative influence of the cyclical business development worldwide and in particular, in the Western Europe. The prices of the credit insurance are growing; on the other hand, the insurance coverage is shrinking because of the decreasing buyers' solvency.

The rating of the insurer goes hand in hand with his creditworthiness. In general, we can say that during depression and recession of the business cycle falls the rating of insurance companies, because they are facing increasing claims ratios<sup>3</sup> and their financial position is weakening. Since the Enron scandal are the rating agencies under heightened scrutiny (Swiss Re, 2003:3).

---

<sup>3</sup> Claims ratio (%) is the proportion between claims provisions and claims paid to the premium written.

Dr. David Laster in his sigma study highlights that ratings in the non-life insurance industry have deteriorated markedly in recent years. “The share of industry capacity rated AAA has fallen, on capital-weighted basis, from 38% in 2000 to 17% at present.” (SwissRe, 2003:13).

Looking ahead to 2004, the global macroeconomic picture remains challenging. Although the global economy might be expected to improve towards the end of 2003, boosted by fiscal and monetary stimuli mainly in the US, there remain significant risks. The current account deficit in the US is growing to new record levels, private indebtedness is high and increasing, there is an evident danger of deflationary tendencies spreading in some industrialized countries, and geopolitical risks are still on the agenda. Volatility seems to be the only phenomenon that will last for sure.

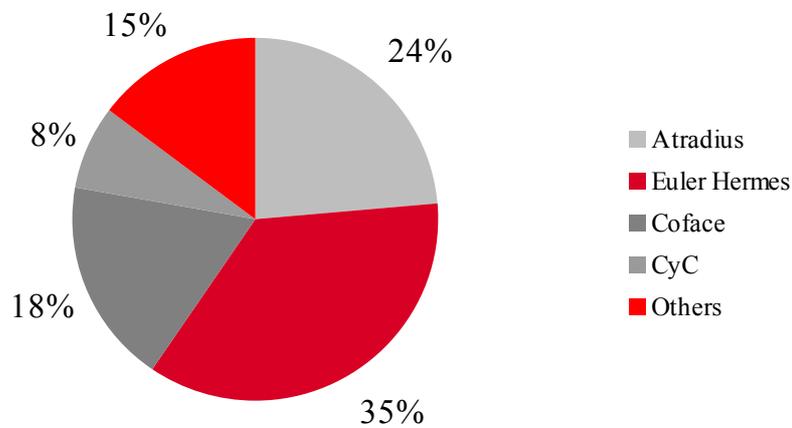

From the view of the credit insurance industry globalization has started in the 90’s. The sector dominated by leading German and French commercial insurers at the end of the 80 has though mergers and acquisitions.

One of the reasons for this market behavior was a high appetite for increase of market share. Mergers are often intended not to use synergies but to buy profits. “The aim was to purchase a profit. They do not want synergies. They want to purchase profit and add them to their own profits. And this is done ten times a year.” (Wisniewski, 2003: 298).

### ***2.3 Commercial credit insurance market***

In the early 50’s, first commercial credit insurers have started their business. Among the most known names are German insurers Hermés or Gerling, Dutch NCM or French Namur. At the end of 90’s, the global market consisted of ten larger insurers. From this high number of insurers only three leaders remained and the market became oligopoly. Gerling purchased Namur and NCM and then became Atradius; Hermes is now a part of the EULER Group.

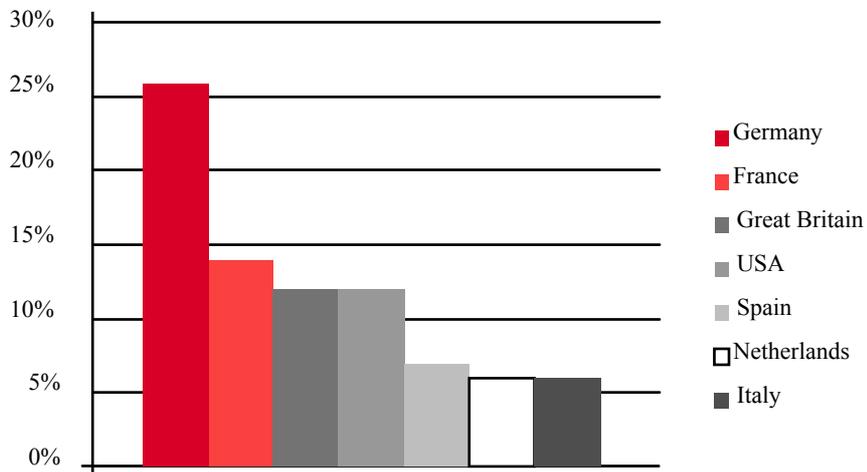

**Figure 2 Commercial Credit Insurance market (2004)**

Source: Atradius.

Atradius is negotiating its cooperation with Spanish ECA Crédito y Caución and Seguros, which represents 8% of the worldwide market share. This will lead to further concentration in the market. Although, speaking in terms of “global” market, we should have a look at the risk spread and main countries of buyers, which are insured through insurers.

**Figure 3 World Credit Insurance Market by Largest Countries**

Source: Atradius.

Surprisingly, worlds largest economies, like China, the US or Japan are not present. This depends on (1) different techniques and instruments used for credit protection (the US market is mainly bond-driven, credit insurance plays there still minor role, also due to strong regulated market) or (2) very strong remaining regulation (China – still very strong market protection continues, Japan, the Japanese market was directly entered by Euler Hermés or Atradius in the early 2005). However, as you can imagine, global players are seeking for all opportunities to increase their market coverage.

The question is whether the industry is indeed as global as it may be likes to think it is. The success of international companies invariably relies on focused local presence and knowledge that effectively makes them nationals. The Czech Republic, for example, has been famously home of two fierce competing insurers for 5 years (1998 – 2002), both representing the worldwide biggest credit insurance group EULER Hermes (34% market share).

The additional effect of mergers is that industry leans on the risk spread. Today, global customers have no other options than to choose one of the market leaders. This leads with an increasingly tendency to a growing risk exposure, which might influence the risk management, ratings and reinsurers' behavior.

Some observers could note a lack of competition in the credit insurance market. This lack of competition could stifle innovation, prompt insurers to underestimate in their businesses, or lead to inefficient pricing services. Two salient features of an imperfectly competitive market – high economic profit and barriers to entry – are characteristics of the credit insurance market.

#### ***2.4 EU enlargement***

The EU enlargement remains on the top of all global economic influences. The main contributions for business will be the emergence of a European market place. A wide range of administrative hurdles like customs or different laws will fade away. For the Eastern European countries new business partners will arise, in the contrary, the firms will be forced to provide competitive business conditions. The credit insurers will be able to provide the cover without having a local license; however, the law will become more comprehensive. The EU enlargement consists of an additional psychological aspect: The Western economies will be forced to consider the Eastern Europe as a part of a whole, the distinction between West and East will unquestionable disappear. In addition to this, states will be forced to

follow European directives and to privatize marketable credit insurance. This is going to happen in all the new EU member states. I cannot state an example, because we follow all the processes at a very early stage.

Both mentioned major influences, EU regulations and globalization, are main triggers for decision of the Czech government to privatize the marketable credit insurance to face the increasing competition.

### **3. Export Guarantee and Insurance Corporation (EGAP)**

#### ***3.1 History and role***

“EGAP offers credit insurance against the non-payment caused by political and commercial risks. Their activity is carried out with State support on the one hand and based on authorization following from the Act No. 58/1995 Coll., on Insuring and Financing Export with State Support as amended, and the commercial principle on the other, i.e. without State support and with the reinsurance concluded with leading foreign reinsurers. The activity of EGAP enables Czech exporters (...) to offer to their clients the payment terms comparable with the competition.” (EGAP. 2005:6).

#### ***3.2 ECA as an interesting aim for investors***

EGAP holds its successful market leadership in the marketable credit insurance over more than 10 years, its share in the commercial business has decreased slightly to 51% in 2004, and its claims ratio varies between 55 and 60%, which is slightly above average.

The other two players, Atradius and Euler Hermés share the remaining market share in relation 1:3. Coface has not entered the Czech market at all; although this was announced many times in the past and acts just as a credit information agency. However, there is no clear methodology, which offers a transparent insight into market shares and result presentation. Czech Insurance Association (CAP) offers a half-yearly insight into figures, which do not represent difference between marketable and non-marketable risks, therefore the presentation of the final result may sometimes differ, which strongly depends on the origin of source.

### ***3.3 Privatization of EGAP***

#### **3.3.1 Establishment of KUPEG**

In compliance to European Union's Communication on the short-term export credit insurance Czech Export Credit Agency EGAP established a 100% subsidiary named Komerční úvěrová pojišťovna EGAP, a.s., "Commercial Credit Insurance Corporation EGAP" (further: KUPEG), where marketable risks were transferred in October 2005.

KUPEG was established as a joint stock company under Czech Commercial Code and Insurance Legislation, whereby in the initial period EGAP shall act as its sole shareholder. KUPEG should take over the entire commercial operations of EGAP, which have been reinsured in the market with major international Reinsurers.

Spinning off the EGAP marketable risks operations into KUPEG should enable, in a subsequent step at a later stage (first half of 2006), to seek a suitable strategic partner, who should ultimately become the majority shareholder in KUPEG, whereby EGAP intends to keep a blocking minority share (in the Parliament, minimum of 30% of stake was approved) in its equity. In selecting a strategic investor, EGAP will seek a trade buyer, i.e. a company already operating in the credit insurance sector, which is financially strong, avails of an extensive database of information on buyers worldwide, and has an intention to develop the credit insurance business in the Czech Republic and in the region. EGAP aims to carry out the divestment transparently and with a "level playing field" for bidders to comply with any applicable EU guidelines or regulations.

#### **3.3.2 Estimated privatization procedure of KUPEG**

The initial point of the process to select a strategic partner was the date when KUPEG obtains its Court Registration and became a stock company. There is an important condition precedent to be met – an apparently minor change in the specific legislation, which would clarify the possibility to sell a majority stake in the Subsidiary. The relevant bill is already in the Czech Parliament and is supposed to be approved and signed by the President in December 2005 at the latest.

Although EGAP representatives describe this change as a minor and less relevant, the amendments to the Act 58/1995 Coll. will enable EGAP to start with reinsurance of commercial (marketable) risks and to continue with insurance SME. Those changes will definitely have impact on the future position of the winner of the tender, because he may increase its competitive offer with insurance of non-marketable risks, and use less expensive

reinsurance sources (which are in this case the state budget). As I mentioned before, reinsurance plays a significant role in the credit insurance business and therefore influences the technical result of each insurer. Having opportunity to transfer non-marketable risks or more riskier commercial business to the state will contribute to less competitive market and probably will lead to problems with the EU authorities.

After the Amendment of the Law has been passed, the Czech Government as the sole shareholder of EGAP will first select an advisor and then approve the selection criteria for the strategic partner and privatization of the stake in EGAP KUPEG as such. In an optimal schedule, this Government approval will coincide with the start of operations of KUPEG.

The process of selecting a strategic partner will be broken into three stages and EGAP will be carrying it out with the assistance of an advisor where appropriate. There will be a committee overseeing the whole process. EGAP wishes to keep the process transparent, therefore during each stage all bidders involved in that stage should receive the same information: no bidder should have more than another and nothing should be proffered to one that is not proffered to all. This rule should apply from the time it has been publicly declared that EGAP will be seeking an investor in KUPEG, until a preferred bidder is selected. However, it is publicly known that both EGAP and KUPEG are cooperating with a French credit insurer Coface and use their database. Although Coface purchases its information to each global insurer, KUPEG shares with them data and offers its products with the explanation that this is a product of independent cooperation within Credit Alliance (association of ECA's). Again, this may improve position of Coface in the bidding process. To avoid any speculations, EGAP and the Czech government must state the selection criteria as transparent as possible.

The bidding or tender process consists of three stages:

First stage consists in requests for expressions of interest and selection of potential bidders, then selection of potential bidders fitting basic criteria and meeting the basic preconditions. All the major market players expressed their interest in the process, which means that at maximum three investors will be interested: Atradius, Euler Hermés and Coface. No other investors will be selected into the second stage, although there were some speculations on PPF (owner of Ceska pojistovna), because traditional insurers do not offer this special insurance line at all.

Second stage consists in a selection of short-listed bidders. The purpose of Stage 2 is to cut the field of potential bidders down to a manageable size, whilst also ensuring that suitable candidates get through to Stage 3. Third stage consists in a selection of a preferred bidder. The purpose

of Stage 3 is to prevent from speculation on releasing information to competitors within due diligence process.

The whole selection process of the strategic partner can be estimated to run during the first half of 2006.

#### **4. Conclusion**

The worldwide credit insurers are observing the latest developments in the Czech credit insurance market. After spin-off of the division of marketable risks of EGAP into KUPEG, the Czech government announced that a privatization process will follow. An investor from narrow credit insurance market will be selected (Euler Hermés, Atradius or Coface), which will enable Czech exporters and producers to get access to competitive information databases, competitive products and prices. However, the Czech government should prepare the whole selection criteria very transparently because both EGAP and KUPEG are collaborating with Coface, which has not entered the Czech credit market at all and might be in possession of insider information. The privatization process is the first in the Eastern European countries.

## **Abstract**

*In today's competitive world, most of the banks accept that increasing employee satisfaction, enhancing service quality and customer satisfaction are of pivotal importance to their survival and growth. This study aims to develop and tests a model which examines the effect of empowerment and self-efficacy on job satisfaction by using Turkish frontline employees in the banking industry of Northern Cyprus. Also, the study tries to assess the impacts of job satisfaction on the affective commitment and service quality provided by the organizations in the research content. Results reveal that employee self efficacy has significant and positive impact on the job satisfaction. On the other hand, employee empowerment by management staff has significant but negative effect on management commitment to service quality. Empirical results also suggest that management commitment to service quality has significant but again negative effect on perceived service quality by bank customers. Implications of these results for bank chiefs and avenues for further research are also discussed in the study.*

**Keywords:** *Empowerment, Self Efficacy, Job Satisfaction, Service Quality, Cyprus.*

## 1. Introduction

Employees are essential in the service industry out of serving to the reputation of the companies. Thus, their position is very important in providing service quality and satisfaction of customers. Since frontline employees are at the core of the service delivery; the success is highly depend on their performance (Zeithaml et al., 1988; Schneider, 1980). Moreover, as it has been stated by Tax and Brown (1998), a considerable amount of customer complaints is initiated with frontline employees; and therefore, these organizations need to develop customer focused strategies. Otherwise several mistakes and failures might occur and could result in double deviation from expectations (Boshoff and Allen, 2000; Kotler et al., 1999; Bitner et al., 1990).

Banking and financial services are an important part of the services industry and became sophisticated as new information technologies are adopted in the banking and finance industry. The creation of new information technologies also leads to an improvement in service quality efforts in the banking and finance industry, that is, financial institutions start to give more qualified services to their customers as they benefit from new technologies. Therefore, improvement in service quality naturally is expected to have a positive impact on customer satisfaction. Developments in information technologies, on the other hand, force the institutions in the banking and finance sector to revise and restructure their services by adopting new developments. For example, today, internet banking is the most important facility provided by banks around the world. However, as electronic banking becomes more prevalent, customers still tend to measure a bank's service quality in terms of the personal support they receive, rather than the technical support (Araslı et al., 2005). Thus, services provided by the bank personnel are a major component of service quality and customer satisfaction also in this sector. Since new technologies are important component of the banking industry today, customers are likely measure the level of service quality by the service that they get from bank personnel.

This study aims to develop and tests a model, which examines the effect of empowerment and self-efficacy on job satisfaction by using Turkish frontline employees in the banking industry of Northern Cyprus. Additionally, the present study tries to assess the impacts of job satisfaction on the affective commitment and service quality provided by the organizations in the research content.

Empowerment refers to a situation in which the manager gives employees the discretion to make day-to-day decision about job-related activities (Hartline and Ferrell, 1996). By allowing contact employees to make these decisions, the manager relinquishes control over many aspects of the service delivery process.

Hartline and Ferrell (1996) define job satisfaction as “pleasurable emotional state resulting from the appraisal of one’s job as achieving or facilitating the achievement of one’s job values”. The conceptual domain of job satisfaction is broad, because it includes “all characteristics of the job itself and the work environment which salesmen find rewarding, fulfilling, and satisfying, or frustrating and unsatisfying”. Operationally, job satisfaction consists of several facets, including satisfaction with the supervisor, work, pay, advancement opportunities, co-workers, and customers. Although some studies examine the effects of these facets separately, others average across facets to create a global measure of job satisfaction.

As a key part of social learning theory, self-efficacy refers to an employee’s belief in his or her ability to perform job-related tasks. The importance of self-efficacy lies in its ability to raise employee performance. Self-efficacy grows stronger over time as the employee successfully performs tasks and builds the confidence necessary to fulfil his or her role in the organization. As self-efficacy raises, employees use more effort, become more persistent, and learn to cope with task-related obstacles. Empirical studies confirm that self-efficacy has a strong, positive relationship with employee performance (Hartline and Ferrell, 1996: 54). It is therefore reasonable to expect that contact employees who possess strong self-efficacy beliefs are more likely to create favourable service encounters than those who do not.

Management commitment to service quality (MCSQ) can be defined as encompassing the conscious choice of quality initiatives as operational and strategic options for the firm, and engaging in activities such as providing visible quality leadership and resource for the adoption and implication of quality initiatives. It involves two components: 1) a strong personal commitment to quality improvement and 2) a visible and active involvement in the quality-improvement process. Several authors identify commitment as an important component of successful market relationships because it gives rise to co-operative behaviours (Dwyer et al., 1987; Morgan and Hunt 1994; Garbarino and Johnson 1999). Although some theorists have argued that MCSQ is the single most important determinant of whether good service is

delivered to customers, it has generated little empirical research. Perhaps, the only test of the MCSQ construct fail to find a direct relationship between MCSQ and service quality (Parasuraman et al., 1990). A probable reason for this finding is that the relationship between MCSQ and service quality is indirect. Theory suggests that managers must first possess a personal, affective commitment to improve the firm's service quality. Managers who exhibit this commitment are more likely to take initiatives that help the firm and its employees deliver superior quality. Example of these initiatives include creating more flexible processes, dedicating resources to the improvement effort, promulgating a quality-oriented vision throughout the firm, and rewarding employees for their efforts and commitment to the process.

Management of service quality is about determining the stages of service quality that we can deliver and then promising and delivering that quality of service to customers. Service quality is suggested as the difference between customer expectations and perceptions of service (See Hartline and Ferrell, 1996; Parasuraman et al., 1985; 1988).

The island of Cyprus was divided in 1974 following Turkey's peace operation and Turkish Cypriots formed their own state in the North of Cyprus. The TRNC (Turkish Republic of Northern Cyprus) was founded in November 15, 1983 which is a non-recognized state having a considerably small economy with limited natural resources, a small internal market, and is widely vulnerable to external economic changes. The political and economic isolation of the TRNC created a substantial burden in terms of its foreign trade and international relations with countries other than mainland Turkey. The economy is plagued by over employment in the public sector and economic focus is on agriculture, tourism and higher education sector (Lockhart, 1994). The contribution of the services sector in North Cyprus was approximately 52.3% of GDP in 2002 (SPO, 2004). The Turkish Lira (TL) of Turkey is the official currency of North Cyprus. Therefore, monetary policy is managed by the mainland Turkey and the economy is highly vulnerable to any changes in the Turkish economy.

There are currently thirty two banks operating in North Cyprus of which two are public banks, seventeen are private commercial banks, five are branch banks from Turkey, one is a development bank, and seven are private commercial banks that have already been transferred to the savings deposit insurance fund. On the other hand, seven banks have been liquidated as a result of the banking crises in North Cyprus in the late 1990s. Additionally, there are 34 offshore banks and 5 offshore firms operating in North Cyprus

(Katircioglu, 2002). Total deposits generated by the banking sector in North Cyprus were around 81.5% of Gross National Product (GNP) in 2002. And the contribution of financial institutions was 4.8% of GNP in 2002 (SPO, 2004).

After the emergence of higher education sector apart from 1980s, banks in North Cyprus started to employ more qualified people compared to the past times. In parallel to the qualified workforce in the banking industry, the banks in North Cyprus have experienced a transition to adapting new technologies after banking crises that occurred in the late 1990s. For example, besides Turkish originated banks, some Turkish Cypriot banks also started to provide internet banking facilities to their customers, and majority of them started to provide credit cards and many shopping facilities with those credit cards. That is, currently, banks in North Cyprus are focusing their efforts on attracting new customers and stimulating economic spending by the introduction of credit cards which allow customers to make a wide range of purchases on an instalment basis (Arasli et al., 2005).

This paper is organized as follows: Section 2 defines data and methodology, section 3 gives and discusses the results, and section 4 concludes the study.

## **2. Data and Methodology**

This study employs and revises the original instrument of Hartline and Ferrell (1996) in order to analyze inter-relationship between the triangle of Supervisors, customer-contact employees (frontline employees) and customers in the banking sector of North Cyprus. As can be seen from appendix Table 1, a total of 43 questions were asked to respondents of which 17 questions were asked to supervisors, 16 to customer contact employees and 10 to customers of the banks.

Using those questions management commitment to service quality and empowerment for bank chiefs and/or supervisors; employee self efficacy and employee job satisfaction for customer contact employees; and customers' perceived service quality for customers were also measured as in the original instrument of Hartline and Ferrell (1996).

In this study, general to specific modeling approach is used to access three interfaces of the service process: management-employee, employee-role, and employee-customer relationship in the banking sector of North Cyprus. This approach examines the attitudinal and behavioral responses of

customer and frontline employees (customer-contact service employees) that can influence customers' perceptions of service quality, and equally access the relationship between these responses and two formal managerial control mechanisms which are: empowerment and management commitment to service quality as mentioned before.

The banks are selected for this study as sampling frame because the delivery of banking services requires considerable customer contact. Twelve banks in North Cyprus were targeted for this study. Four Supervisors and bank chiefs (or supervisors) were conducted to carry out the survey. The distribution of these supervisors and customer-contact employees according to their banks are as below:

**Table 1. Distribution of Supervisors and Employees in the Banks as Selected for This Study**

Data sample	Supervisor		Employee	
	Frequency	Percent	Frequency	Percent
1) T.İşbank.	4	8,3	10	8,9
2) HSBC	4	8,3	9	8,0
3) K.T.K.M.B	4	8,3	9	8,0
4) İktisat Bank	4	8,3	9	8,0
5) Universal	4	8,3	9	8,0
6) Mez.Koop	4	8,3	9	8,0
7) Limasol	4	8,3	9	8,0
8) Vakıflar	4	8,3	9	8,0
9) Halk Bank	4	8,3	9	8,0
10) Ziraat Bank	4	8,3	9	8,0
11) Öğretmenler	4	8,3	10	8,9
12) Şeker Bank	4	8,3	11	9,8
Total	48	100	112	100

On the other hand, customers who benefit from banking services are randomly selected for this study. Detailed demographic distribution of respondents including supervisors and employees is provided in Table 2:

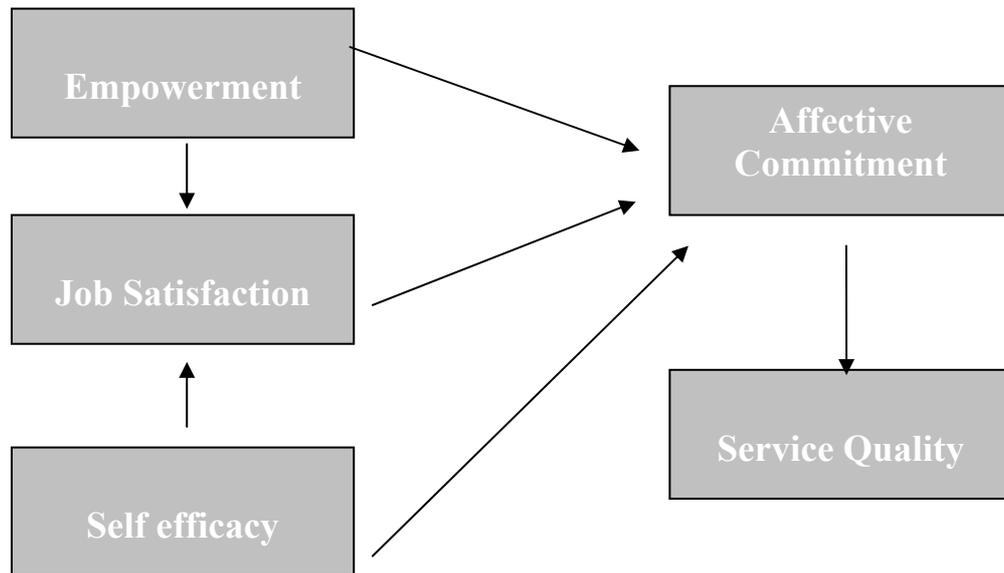

**Table 2. Demographic Profile of Sample**

	<b>Supervisors</b> n =48		<b>Employee</b> n = 112		<b>Customer</b> n = 203	
	Frequency	%	Frequency	%	Frequency	%
<b>Sex</b>						
Female	20	41.7	59	52.7	72	35.5
Male	28	58.3	53	47.3	131	64.5
<b>Age</b>						
18 to 24	-	-	10	8.9	156	76.8
25 to 30	10	20.8	42	37.5	31	15.3
31 to 36	23	47.9	41	36.6	-	-
37 to 42	13	27.1	19	17.0	8	3.9

University	12	25.0	55	49.1	169	83.3
Academic	5	10.4	2	1.8	21	10.3

Before conducting the main quantitative survey, a pilot study has been carried out in order to test and enhance the questionnaire validity, wording, sequence, and layout. In this pilot study, 20 questionnaires were collected. These had already been used to estimate response rate and to become familiar with respondents.

The conceptual model and the related hypotheses of the present study are given below:

**Figure 1. Hypothetical Conceptual Model**

Using the above conceptual model, this study will test the effect of empowerment by management staff and self efficacy of employees on their job satisfaction and then the individual effects of these three items on affective commitment. Lastly, the effect of affective commitment on the perceived service quality of customers will also be tested. Therefore, the hypotheses of this study can be set as follows:

H<sub>1</sub>: Empowerment by management staff exerts a significant and positive effect on frontline employee job satisfaction.

H<sub>2</sub>: Self-Efficacy of employees exerts a significant and positive effect on their job satisfaction.

H<sub>3</sub>: Job Satisfaction of employees has a significant and positive effect on affective commitment of management to service quality.

H<sub>4</sub>: Empowerment by management staff has a significant and positive effect on their affective commitment to service quality.

H<sub>5</sub>: Self-Efficacy of employees has a significant and positive effect on the affective commitment of management staff to service quality.

H<sub>6</sub>: Affective Commitment by management staff to service quality has a significant and positive effect on service quality as perceived by their customers.

The respondents for this study were selected from the employees and their supervisors who work in the banks as shown in Table 1 and their customers who benefit from the services of the banks operating in North Cyprus. The number of employees who work in manager, bank chief or executive position selected for this study is 48 people and the number of employees working in customer-contact services is 112 people from various banks based on stratified sampling method. On the other hand, 203 customers were randomly selected from each bank for interview that live in different regions of North Cyprus and benefit from the services provided by banks.

The revised instrument as developed by Hartline and Ferrell (1996) is provided in Tables 3, 4 and 5. Seven-point Likert Scale was employed to measure each construct. First, “Strongly Disagree to Strongly Agree” scale was used for constructs, Management Commitment to Service Quality, Empowerment and self efficacy. Second, “Extremely Dissatisfied to Extremely Satisfied” scale was used for Job Satisfaction. And finally, fifth, “much worse than I expected to much better than I expected” scale was used for the construct of Perceived Service Quality.

As mentioned before, the questionnaire includes different constructs which are asked to managers, employees and customers separately. For example, manager data includes management commitment to service quality and empowerment; employee data includes employee self efficacy and employee job satisfaction; and customer data includes customers’ perceived service quality.

After the original questionnaire of Hartline and Ferrell (1996) was distributed to respondents, the results were typed in SPSS 10.0 software. On the other hand, LISREL 8.3 was also used in this study as it is linked with SPSS to run factor analysis. By the help of factor analysis, it is clearly seen which factors or items in the questionnaire are loaded or not.

Data were analyzed through the use of frequencies, descriptive statistics such as means and standard deviations by SPSS software, and reliability analysis, exploratory factor analysis, correlation and regression

analysis by LISREL 8.30. Simple regression analysis was preferred in this study instead of path analysis due to the limited sample size. Reliability analysis shows the reliability level of the questionnaire to be distributed. Factor analysis shows which constructs or factors are loaded and are ready for analysis. Correlation analysis shows the degree and direction of linear association among the factors. And simple regression analysis shows the effects of independent variables on dependent variable via regression models.

To assess factor, correlation and regression analyses across all three samples (supervisors, employees and customers), the employee and customer responses were aggregated (averaged) and matched with the manager responses to create a single data set in which the cases represent bank units (12 banks) rather than respondents. These procedures resulted in a final sample of 12 banks, as can be seen from Table 1, to be used for correlation and regression analysis. This is why simple regression was preferred in this study (See Hartline and Ferrell, 1996, for more details).

### **3. Results**

Prior to testing hypotheses of this study by regression models each construct will be evaluated by factor analysis if they are loaded or not. Table 3, 4 and 5 display factor loadings and t-values for supervisors, employee and customers data respectively.

In Table 3, factors loadings are generally greater than 0.50 and their t values are statistically significant since they are higher than 2.00 by Nunally (1967). However, there are items which are not loaded as shown by NL, therefore they are extracted from analysis in regression models. Cronbach alpha and reliability alpha values show that this construct in Table 3 are ready for analysis since they are higher than 0.50 by Nunally (1978).

**Table 3. Supervisor Data (n= 48)**

<b>Management Commitment to Service Quality (MCSQ)</b> (Cronbach's $\alpha$ = 0.84; Construct reliability = 0.85)	Factor Loading	t-value
MQ1 I feel strongly about improving the quality of my organization's services	NL	NL
MQ2 I enjoy discuss quality-related issues with people in my organization	1.00	23.76
MQ3 I gain a sense of personal accomplishment in providing quality services to my customers	0.90	19.98
MQ4 I explain to all my employees the importance of providing high quality service to our customers	0.79	16.20
MQ5 I often discuss quality-related issues with people outside of my organization	NL	NL
MQ6 Providing high quality services to our customers should be The number on priority of my organization	NL	NL
MQ7 I am willing to put in a great deal of effort beyond that normally expected in order to help my organization deliver high quality services to our customers	NL	NL
MQ8 The way I feel about quality service is very similar to the way My organization feels about quality	0.67	13.01
MQ9 I really care about the quality of my organization's service	NL	NL
<b>Empowerment (EMPOWER)</b> (Cronbach's $\alpha$ = 0.74; Construct reliability = 0.64)	Factor Loading	t-value
EM1 I allow employees completely freedom in their work	0.92	20.77
EM2 I permit employees to use their own judgment in solving problems	0.75	15.25
EM3 I encourage initiative in my employees	NL	NL
EM4 I let employees do their work the way they think best	NL	NL
EM5 I assign tasks, then let employees handle them	0.78	15.97
EM6 I turn employees loose on a job, and let them go to it	0.97	22.95
EM7 I allow employees a high degree of initiative	0.76	15.53
EM8 I trust employees to exercise good judgment	0.95	21.86

NL: Not Loaded

Table 4 display factor loadings and t-values for employee data:

**Table 4. Employee Data (n= 112) (Continued)**

<b>Employee Self-Efficacy (SELFEFF)</b> (Cronbach's $\alpha= 0.75$ ; Construct reliability = 0.75)	Factor Loading	t-value
SE1 My job is well within the scope of my abilities	NL	NL
SE2 I did not experience any problems in adjusting to work at this organization	0.81	15.02
SE3 I feel that overqualified for the job I am doing	NL	NL
SE4 I have all the technical knowledge I need to deal with my job, all I need now is practical experience	NL	NL
SE5 I feel confident that my skills and abilities equal or exceed those of my colleagues	NL	NL
SE6 My past experiences and accomplishment increase my confidence that I will be able to perform successfully in this organization	0.77	14.20
SE7 I could have handled a more challenging job than the one I am doing	NL	NL
SE8 Professionally speaking, my job exactly satisfies my expectations of myself	0.78	14.46
<b>Employee Job Satisfaction (SATIS)</b> (Cronbach's $\alpha= 0.86$ ; Construct reliability = 0.87)	Factor Loading	t-value
JS1 Your overall job	0.82	16.96
JS2 Your fellow workers	0.76	15.02
JS3 Your supervisor (s)	NL	NL
JS4 Your organization's policies	0.71	13.81
JS5 Your support provided by your organization	NL	NL
JS6 Your salary or wages	0.67	12.67
JS7 Your opportunities for advancement with this organization	NL	NL
JS8 Your organization's customers	0.95	21.27

NL: Not Loaded

In Table 4, all of the factor loadings are again greater than 0.50 and their t values are statistically significant. Again Cronbach and reliability levels are higher than 0.50. However, there are again some items which are not loaded as shown by NL.

Table 5 display descriptive statistics for employees: Factor loading, t-value:

**Table 5. Customer Data (n= 203)**

<b>Customer Perceived Service Quality (QUALITY)</b> (Cronbach's $\alpha$ = 0.67; Construct reliability = 0.57)		Factor Loading	t-value
SQ1	Receiving prompt service from our employees	NL	NL
SQ2	Never being too busy to respond to your request	0.79	21.28
SQ3	Employee behaviors that instill confidence in you	NL	NL
SQ4	The safety you feel in transactions with our employees	NL	NL
SQ5	The courteousness of our employees	-0.80	-21.64
SQ6	The ability of our employees to answer your questions	NL	NL
SQ7	The individual attention you received from us	-0.99	-30.81
SQ8	The personal attention you received from our employees	NL	NL
SQ9	Having your best interests at heart	-0.82	-22.33
SQ10	The ability of our employees to understand your specific needs	-0.91	-26.46

NL: Not Loaded

In table 5, factor loadings are above 0.50 and their t values are greater 2.00. However, only items SQ2, SQ5, SQ7, SQ9 and SQ10 are usable in this study.

Table 6 gives correlation matrix that shows the interaction between each construct. The table gives correlation analysis results as well as means scores and standard deviations for each construct. Mean value of MCSQ is 6.56. This means that Supervisors have positive intentions for management commitment to service quality where they generally agree with this construct items. Mean value of empowerment is 4.33 which mean that Supervisors have positive intentions for empowerment where they medium agree with this construct items. The minimum mean score is 4.33 for Empowerment.

The maximum mean score is 6.56 for MCSQ. This means that Supervisors have positive intentions for affective commitment for their employees. On the other hand, employees have also positive intentions for self-efficacy where they generally agree at 6.21 mean score. Mean value of job satisfaction for employees is 5.77. This means that employees have positive intentions for their job satisfaction.

**Table 6. Correlation analysis results**

Measure	Mean	SD	1	2	3	4
1.Mcsq	6.56	1.26				
2.Empower	4.33	0.85	-0.874			
3.Selfeff	6.21	0.66	-0.148	0.230		
4.Satis	5.77	0.94	0.389	-0.305	0.611	
5.Quality	5.86	0.80	-0.579	0.514	0.585	0.032

And the mean value of service quality as perceived by employees is 5.86. This indicates that customers have generally founded bank services better than they expected from their banks.

Correlation matrix shows that perceived service quality of customers is positively correlated with empowerment for employees by their supervisors and job satisfaction of employees. It means that as empowerment and job satisfaction increases, the perceived service quality of customers will increase as well. However, a negative correlation was obtained between perceived service quality of customers and management commitment to service quality.

Finally, Table 7 gives the results of simple regression analysis as hypothesized in this study:

**Table 7. Hypothesized and Final Models of Service Employee Management: Structural Parameter Estimates (n= 12)**

Hypothesized Model				
Path	Hypothesis	Coeff.	t-value	R <sup>2</sup>
EMPOWER → SATIS	H <sub>1</sub> (+)	-0.18	-1.01	0.31
SELFEFF → SATIS	H <sub>2</sub> (+)	0.42	2.44**	0.61
SATIS → MCSQ	H <sub>3</sub> (+)	0.39	1.34	0.39
EMPOWER → MCSQ	H <sub>4</sub> (+)	-0.52	-5.68*	0.87
SELFEFF → MCSQ	H <sub>5</sub> (+)	-0.10	-0.47	0.02
MCSQ → QUALITY	H <sub>6</sub> (+)	-0.27	-2.25**	0.34

\* and \*\* indicate respectively significant levels at alpha 0.01 and 0.05 .

According to Table 7, employee self efficacy has positive and significant effect on their job satisfaction as well, thus H<sub>2</sub> is validated in this study. Again, empowerment by management staff has significant but negative relationship on their affective commitment, thus, H<sub>4</sub> is not validated in this study. That means that empowerment by management staff given to employees does not have a positive effect on their commitment of service quality. And lastly, management commitment of service quality has again significant and negative effect on service quality as perceived by customers, thus, H<sub>6</sub> is not validated again. On the other hand, H<sub>1</sub>, H<sub>3</sub>, and H<sub>5</sub> again were not validated according to the results of this study.

Figure 2 shows the results of conceptual model set for this study according to the research implemented in this study as also introduced previously in this study:

**Figure 2. Hypothetical Results of Conceptual Model**

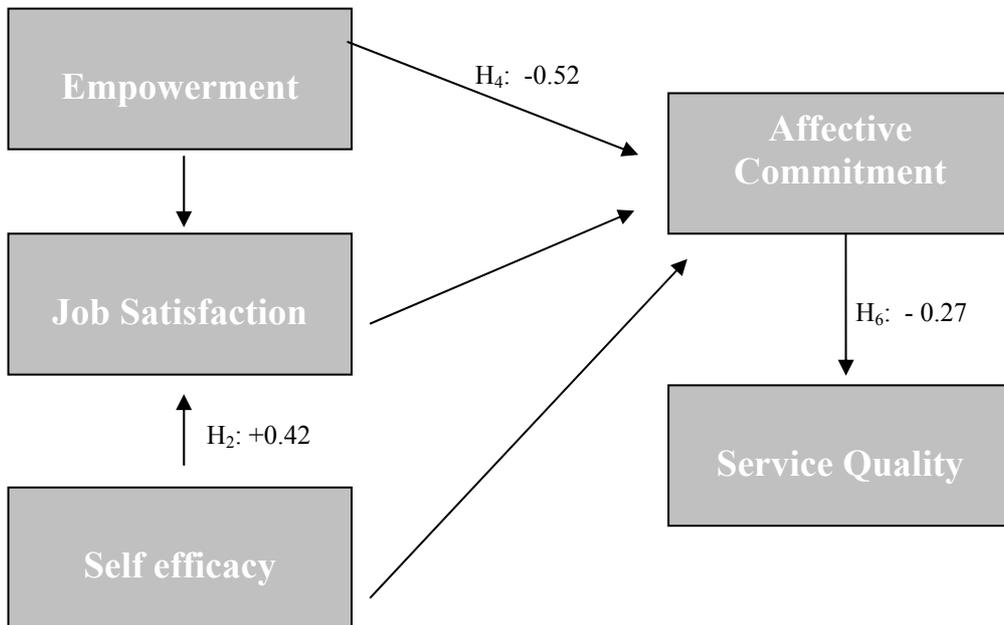

Figure 2 shows that only three hypotheses that were tested via simple regression analysis were found significant. However, two of them are in inverse directions. Thus, only the second hypothesis has been validated according to the results of this study. That is, self efficacy of employees has positive and significant effect on their job satisfaction.

#### 4. Conclusion

This study empirically investigated the relationship between bank chiefs, employees and customers interface in the banking industry of North Cyprus by using revised construct of Hartline and Ferrell (1996). The descriptive analysis that mainly includes mean scores indicates that management personnel and employees in the banks of North Cyprus which are selected for this study has positive intentions about the arguments provided by the constructs of Hartline and Ferrell (1996). And, generally speaking, customers who benefit from banking services are generally satisfied from their banks in North Cyprus.

Additionally, according to the findings of the study, the hypotheses which were run in this study were not generally validated except one mainly due to the small sample size of bank chiefs and employee data which are in parallel to the study of Hartline and Ferrell (1996). Results of this study revealed that employee self efficacy leads to a better job satisfaction of them. Furthermore, management commitment to service quality has significant but negative impact on the perceived service quality by customers. On the other hand, empowerment of employees by management staff exerts significant and negative effect on management commitment to service quality. This indicates the situation that empowerment does not exert a positive impact on employee satisfaction by management in the sample selected for this study. And lastly, management commitment by management staff has significant and again negative effect on perceived service quality by customers according to the results of this study.

The most important limitation of this study is the limited sample size. Due to the limited number of banks in North Cyprus and great difficulty in reaching and convincing bank personnel, this study was put on limited sample size. Therefore, as a suggestion for further research, it can be recommended to expand this study for the whole population size for bank personnel and for greater size of customers in order to test the validity of the instrument of Hartline and Ferrell (1996) for the banking industry of North Cyprus. However, it can easily be said that the results are in parallel with the results of Hartline and Ferrell (1996). And lastly, this type of study can be implemented in both sides of Cyprus to make a comparison between Turkish Cypriot and Greek Cypriot banking industries.

## **Abstract**

*Cross-border mergers and acquisitions have not been a major feature of the EU banking sector with the dominance of domestic consolidation. The introduction of the euro, the globalization of financial markets and the technological advances have led to acceleration in the process of European banking integration. An important concern arises about the driving forces behind the current banking consolidation wave in Europe in the context of international banking expansion. The aim of this paper is to identify some countries or characteristics of countries that will affect the trends of foreign direct banking investments via mergers and acquisitions across Europe. We use a panel data of cross-border banking mergers and acquisitions in the main European countries from 1987 to 2004. Moreover, we distinguish between receiving and investing countries of cross-border banking investments in Europe. Considering the internationalisation banking literature, we test whether the characteristics of home and host countries would affect cross-border banking investments within Europe. The findings confirm the importance of banking market concentration as a determinant of further international growth of European banks. The European deregulation seems to have exerted a greater influence on foreign banking investments across Europe.*

## 1. Introduction

The European banking landscape has experienced a profound restructuring since the mid 1980s and still is substantially changing. The change has been driven by a tremendous technological progress, the ongoing national and European deregulation, the implementation of the European Monetary Union (EMU) and ongoing globalisation (Bis (2001)).

The gradual elimination in most countries of barriers to international capital flows, jointly with a general relaxation of barriers to operating across geopolitical borders has made possible the ongoing expansion of international financial institutions.

Allowing the production of financial services at large distances from the home country headquarters, the new communications, information and financial technologies have helped banking institutions to take advantage of these relaxed geopolitical barriers. As well, the globalization of no financial economic activity has increased the demand for the services of multinational financial institutions, capable to follow customers operating in foreign countries.

For a number of reasons, domestic banking mergers and acquisitions (M&As) have long outnumbered cross-border banking in European countries. First, most countries have historically used regulations to discourage foreign entry – for example, by requiring foreign banks to hold excess amounts of capital, or by requiring branches of foreign banks to adhere to both home country and host country regulations. Second, the difficulty to operate in a foreign country is also due to the differences in language, business customs, laws and the problems associated with distance that made such investments less valuable. Third, domestic banks might form combinations in order to gain the scale needed to make future cross-border acquisitions themselves or to compete more effectively against potential foreign entrants (*Berger et al, 2004*).

The experience of the European community constitutes a unique case for the investigation of international trade in banking services and cross-border banking activity. The Treaty of Rome in 1957 created the basis for the existence of a European common market. The First Banking Co-ordination Directive of 1977 created a framework for a single European banking market by eliminating differences in banking regulations and practices across the Member States of the EU.

A license from the national authority was needed in most countries to operate in the market. The Second Banking Co-ordination Directive of 1989 introduced a single banking license for operating across the European Union,

aimed at liberalizing the trade of financial services across Europe. Therefore, a bank authorized to operate in a member country could operate in any other member countries without any further local authorization. However, national European governments can not formally allow foreign banks entry that involves the acquisition of national banks<sup>2</sup>. Given the important obstacles to cross-border banking activity, some studies (Berger, 2000; Boot 2002) outline the limited relevance of the traditional economic rationale to explain the banking movements abroad. In this respect, recent research tried to provide an alternative argument, specific to the international banking growth strategies. In other side, the recent changes in the macro environment suggest that pan-European consolidation is likely to accelerate:

- i. The ECB and European Commission are actively pushing for the creation of an integrated financial system to better allocate capital across Europe and increase competition in banking services.
- ii. Regulatory harmonisation has increased significantly compared with the last ten years (Basel II, IAS/IFRS) making accounts much more transparent and reducing “regulatory” risks”.

In this context, consolidation activity among European banks significantly increased within the last decade and in particular within the last two years.

In this paper, we study the determinants of cross-border banking M&A activity in Europe, given the context of the recent phase of banking internationalisation. Using the data of banking M&A operations over the period (1987-2004), we perform the analysis of countries’ characteristics in order to explain cross-border investments by banking institutions in Europe. Our contribution consists in distinguishing between investing countries and the target countries of foreign banking acquisitions. Considering the theory of comparative advantage, we have tested whether some countries have, and/or some characteristics of countries yield, advantages at receiving foreign banking investments or investing abroad via cross-border M&As.

The remainder of the paper is organized as follows. The next section highlights the previous empirical evidence on cross-border banking activity and sets up the theoretical background for the empirical analysis of M&As trends. Section 3 describes the data set and presents the results of empirical analysis on the characteristics of countries concerned by cross-border banking M&A activity.

---

<sup>2</sup> The recent attempts by BBVA and ABN Amro to acquire the Italian banks BNL and Antonveneta constitute a good example of this situation.

## **2. Theoretical and empirical research on cross-border banking**

An important research on banking consolidation in Europe examined the external factors that facilitate European banking integration and consolidation. These factors include (i) the globalisation of the international financial system due to the liberalisation of international capital movements and financial deregulation within countries; (ii) major technological advances, particularly in the field of data processing; (iii) improvements in the cross-border regulatory environment linked to the Single Market Programme and the introduction of the euro. Other studies focus on the motivations of banks to expand in foreign markets and the obstacles that they face to be so efficient and competitive as the domestic institutions.

### ***2.1 Theoretical background of cross-border banking activity***

Previous research has emphasized the importance of barriers to entry as a main determinant of cross border banking movements. Regulatory restrictions in the host country have been often mentioned as a barrier to entry in multinational banking. A pre-requisite for entering a foreign country is obviously, that the national authority allows the entry. As it has been previously noted, regulatory barriers were formally removed within European Union through the Second Banking Directive. Nevertheless, factors as the existence of hidden restrictions, as well as non-regulatory barriers could at least partially isolate national banking sectors from competition (Balandon, 2000).

Many theoretical and empirical studies focused on the motivations of international banking. According to the results of research on international banking activity, the banking motivations to expand on foreign markets (through M&As) can be classified in four main rationales:

- servicing exporters from the home country
- servicing foreign subsidiaries of home country clients
- participating in the host country's capital markets
- participating in the host country's banking system or banking consolidation process.

A main motive for *foreign banking investments* is to provide banking services to home country clients. The range of banking services typically offered would include the provision of information about the general and economic conditions for doing business in a particular foreign country and, above all, the collection of receivables for home country exporters. The rationale of this behaviour would be the need to preserve existing banking relationship in the

home country before they could be eventually substituted by a new banking relationships (Williams, 1997).

Banks following their clients' multinational expansion has been widely considered as a main motivation of cross-border banking movements. Grubel (1977) applied the theories of foreign direct and international trade to the internationalization of banks that provide the theoretical explanation. According to this explanation, multinational banks go abroad to service their domestic customers who have gone abroad. Information asymmetries regarding local banks about the client's financial needs would constitute a main ownership advantage for the foreign bank.

The Eclectic theory provides the theoretical framework of international banking based on the three concepts: ownership advantage, location advantage, and internalization advantage. The presence of these advantages allows the foreign bank to overcome the advantages possessed by the domestic banks due to incumbency. Given the basic characteristics of the financial services industry, the eclectic framework predicts that banking institutions are more likely to move across international boundaries via foreign direct investment rather than by cross-border trade.

Ownership advantages are resources or production processes to which firms in the host countries do not have access. These proprietary assets that are typically knowledge-based are crucial factor to prompt foreign direct investment because given the possibility to move knowledge-based assets across great distances at low cost, and to be applied to multiple plants at low marginal cost. These advantages in the form of intangible, customer-specific, and knowledge-based assets are important for providing credit to small- and medium sized enterprises (SMEs);

Location advantages are conditions in the host country that make it profitable for a multinational enterprise to produce in the host country rather than producing at home and export to the host country (Berger et al, 2004). Some examples of location advantage are cheap factor prices in the host country; high transportation costs; import quotas and tariffs; and better access to the host country customers. The factors relative to location advantages in multinational banking include differences in regulatory structures, the geographical dispersion of the bank's client base, leading to banks following their retail customers, information collection, and access to a skilled pool of labors.

Internalization advantages are conditions, which preclude a firm from simply licensing its 'knowledge capital' to a host country firm. For example, the existing flow of information resulting from the bank-client relationship would not be pre-empted by a potential competitor bank according to Casson

(1990). The underling hypothesis to this point of view is to consider the bank's information network and its infrastructure of skills that correspond to the personal contact, as one of the main advantages of a multinational bank. Therefore, owning information-gathering centers in a variety of locations can enhance these advantages. Williams (1997) considers the ability of the multinational bank to institutionalize and learn from this network of information as source of its comparative advantage.

Banks have traditionally played a major role in domestic and international capital markets. The growing expansion of commercial banks towards the securities business should make this trend to continue and even increase in the future. Accordingly, some authors have suggested that banks will establish facilities abroad with the aim of participating in the host country's capital market<sup>3</sup>. Hence, banks would funnel internationally the savings originated in the home country through cross-border acquisitions and have access to the domestic customers more easily. The greater possibilities of diversification available at an international level would justify this behaviour.

Participating in the host country banking consolidation should be a quite straightforward motivation for cross-border acquisitions. Accordingly, banks would enter in foreign countries to carry out the typical commercial banking activity lending and accepting deposits. The less concentrated foreign markets are more likely to be the targets of cross-border banking investments.

## ***2.2 Previous evidence on international banking activity***

Previous research on international banking provides empirical evidence on the following issues: the limited economies of scale and synergies achieved on cross-border M&As, the difficulties associated to cross-border banking activity, the performance of international banks in foreign markets and the strategic rationale of international banking growth. The empirical evidence on cross-border banking M&As confirms the consensus view that cross-border deals add limited value. The academic research on cross-border acquisitions of financial institutions in developed countries suggests mediocre post-merger financial performance at best. Examining cross-border operations in Europe, Beitel and Schiereck (2001) found that the associated combined bidder and target value changes were generally zero or negative, compared with domestic mergers, which combined values were positive on average.

A study of U.S. M&As provides some evidence consistent with fewer benefits from cross-border M&As. De Long (2001) found that mergers

---

<sup>3</sup> see Heinkel and Levi, (1992); *Focarelli et al*, (2000).

combining two firms from different geographic areas create less shareholder value. Similarly, the risk-reduction benefits from cross-border bank mergers seem to be no significant as they have little impact on the volatility of stock returns as proved by *Amihud et al.(2002)*. Whereas most empirical studies on efficiency of foreign banks in developed countries found that the domestically owned banks are more efficient, Berger et al. (2000) show the possible exception for U.S banks. In a European study, Vander Venet (1996) found that the foreign institutions have about the same efficiency on average as domestic institutions while a few studies have proving the same evidence. The research on cross-border banking efficiency in developing countries finds different results from those in developed countries. One study of foreign banks in over 80 countries, made by Claessens et al. (2001) reveals that foreign-owned banks have relatively high profitability in developing countries.

The empirical evidence consistent with the hypothesis of limited gains from cross-border M&As are due to the obstacles faced by foreign-owned institutions that limit their efficiency. Accordingly, Buch and DeLong (2004) found that the banks in highly regulated markets are less likely to be the targets of cross-border acquisitions. The results of their study suggest that the cultural differences and the distance tend to discourage this type of operations. Therefore, these kinds of structural factors act as barriers to cross-border lending and borrowing by banks, considering the results of Buch (2001, 2003).

Berger and Smith (2003) detected another obstacle related to the preferences of the customers for the services provided by the local banks. The domestically owned banks have the advantage to have better knowledge of the local conditions and information about domestic customers. In this respect, foreign affiliates of multinational corporations operating in European countries usually choose domestic banks for cash management (i.e., liquidity and short-term financing) services. Other studies have argued that cross-border consolidation within Europe may be deterred by political factors, cultural differences, the use of different payment and settlement systems, and remaining differences in capital markets, taxes, and regulations across the countries (Boot, 2003; Bandon, 2000).

Many empirical studies confirm the hypothesis of ‘following-the client behaviour’ as driving factor of banking internationalization (Grosse and Goldberg, (1991); Wengel, (1995); Brealey and Kaplanis, (1996)). Concerning the latter argument, Casson (1990) has argued that U.S banks expanded offshore to follow the expansion of U.S manufacturing firms. This empirical research supports servicing home country exporters as a determinant of foreign banking expansion. However, the results of Stanley &

al. (1993) and Seth & al, (1998) suggest that this strategy is not the only motivation explaining cross-border M&As. Focarelli and Pozzolo (2001) argued that this motivation is only relevant for small banks, while the behaviour of larger banks is determined by diversification policies.

Previous research has revealed the existence of large and well-developed capital market in the home country, as a determinant of banking expansion abroad. Accordingly, De Paula (2002) suggest that the internationalization of banks could also be explained by the strategy of universal banks seeking to diversify their activities in the financial markets of the host country through the acquisition of majority, controlling stakes or the acquisition of minority. Accordingly, economic conditions in the home and the host countries seem to be key determinants of the foreign banking investments.

A study of Focarelli et al (2001) provide some evidence consistent with the explanation of banking internationalization that is due to increased banking competition caused by financial deregulation. The results of their study suggest that countries with developed financial markets are more likely to be at the origin of cross-border M&As. The empirical evidence reveals that banks expand to countries where the potential economic growth is stronger and the banking sector is less efficient. De Félice and Revoltella (2003) provide some evidence consistent with the importance of regulatory environment and the degree of concentration in the host country and the domestic country of international bank as decisive factor of its strategies to go abroad.

The results of Berger et al. (2004) found empirical evidence of the theories of international trade (*the theory of comparative advantage, the new trade theory*) as theoretical framework to explain cross-border financial M&As. They found that the characteristics of EU countries are determining factors of foreign financial investments as having implications on the comparative advantage of foreign banks.

### **3. Empirical evidence on cross border banking M&As in Europe**

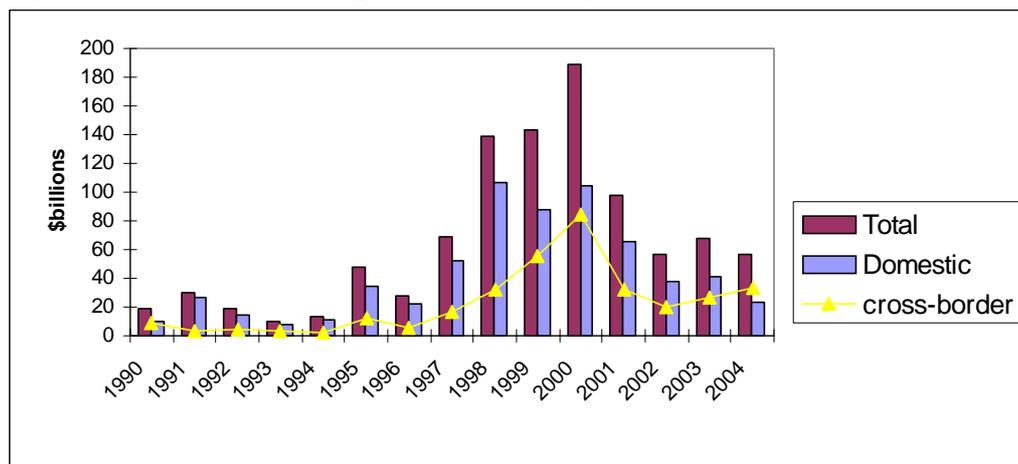

The purpose of our empirical tests is to investigate the patterns of foreign direct investment via cross-border banking M&As through Europe. Unlike most previous researchers, we focus our analysis on international banking expansion in the main European countries only the foreign banking investment through cross-border M&As.

### 3.1 European Banking M&As trends

The data of M&A trends displayed in Fig1 show a significant mergers and acquisitions activity among large credit institutions took place in the run-up to and the early years of the Monetary Union (1998-2000). During 2003, M&As activity in terms of value stabilised at levels comparable with those seen in 2001 and 2002 (ECB, 2004). Around 70% of the entire transactions volume between 1985 and 2000 is related to national focused banking M&As. European banking institutions thus seem to consolidate their national markets first to become powerful enough to stand the arising competition of a single European market of financial services<sup>4</sup>.

In 2004, the percentage of domestic M&As activity in the banking sector fall to 42% of the total value of M&A transactions. The recent acquisition of Abbey National by SCH explains to some extent this new trend in M&A activity of European banks. This transaction and the recent ongoing deals between BBVA, ABN Amro and the Italian banks (BNL, Antonveneta ) suggest more attention on cross-border M&As and arise the question of the future deals between EU financial institutions.

**Figure 1: Value of banking M&As in Europe**

Source: Thomson Financial Securities data and author's calculations

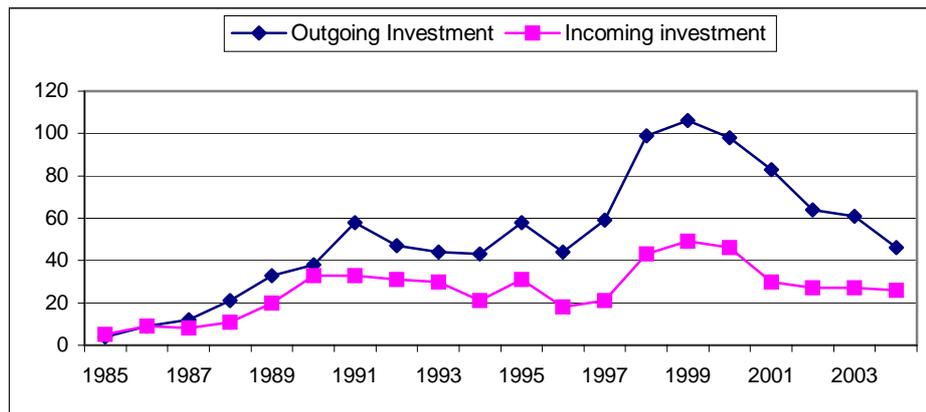

In order to identify the determinants of cross-border M&As in EU, we focus our analysis on investing and receiving countries of foreign banking investments. The data of M&As are taken from the Thomson Financial Securities Data database on M&As from 1985 to 2004. However, the

<sup>4</sup> Compared to other sectors, banks lack substantially behind with regards to the share of cross-border operations of total M&As (Focarelli and Pozzolo, 2000).

regression analysis begins from 1987 due to data limitations for other variables.

According to the assumption of Berger et al (2004), we consider the M&As in foreign countries as outgoing banking investments and the M&As of foreign banks or Credit institutions in a European country as incoming banking investments. These data for the EU Banking sector as a whole are displayed in Figure 2 that reveals a net investing banking sector with an excess of outgoing investments<sup>5</sup>.

**Figure 2 : Number of cross-border banking M&As in EU countries (1985-2004)**

Source : Author's calculations based on Thomson Financial Securities Data (2005).

We examined the foreign banking investments in the main European countries (EU) without making restrictions on the target activity of cross-border banking M&As. Thus, we estimate that our data has the advantage to provide a geographic diversification's indicator of banking activities. In this respect, we will test the effects of local countries characteristics on broadening banking scale and scope through cross-border M&As.

<sup>5</sup> This situation could be influenced by the effect of pan-European banking acquisitions. The number of cross-border M&As in EU include the cross border banking investments between European countries.

**Table 1 : Foreign banking investments (cross-border M&As) in EU (1985-2004)**

Countries		(1) Incoming investments (target )	% Total EU (%)	(2) Outgoing investment (Investor)	% total EU	(3) = (2) – (1) Net level of cross border investment

*Source : Author's calculations based on Thomson Financial Securities Data (2005).*

Table 1 displays the aggregate transaction value and the number of M&As for the period 1985- 2004 in all EU banking systems and their net level of internationalisation. The data of cross-border banking activity reveals

some EU banking systems as net investing and others as net receiving of foreign banking investments. The first group include Belgium, Germany, Spain, Netherlands and Sweden, which have higher level of outgoing investments in terms of number and global value of M&As than receiving banking investments. In other side, Greece, Ireland, Portugal, UK and Denmark are considered as receiving countries taking into account the number of cross-border M&As.

Nevertheless, the high value of outgoing investments in some countries (Italy, UK) suggests the large scale of cross-border acquisitions in the main European countries. The high level of receiving banking investments in France, Austria, Luxembourg and Finland is consistent with this assumption of large cross-border deals in these countries. Considering the number of cross-border M&As, we found the same countries as investing countries.

The differences between the number and the value of M&As illustrate the importance of target and investing countries characteristics as determinant of the net level of their internationalisation. In this respect, some target countries of incoming banking investments have some comparative advantage that explains the high number of cross-border M&As in these countries. The data are consistent with the assumption that these countries have more banking institutions with the potential to make cross-border acquisitions or which are attractive targets for cross-border M&As. As illustration, we note that the large European countries as France, UK, Spain, Germany and Italy have the highest share of cross-border investments. This result suggests that the scale of M&A operations in these countries have been important.

The degree of concentration of the banking systems and the characteristics of their countries are determinant factors in cross-border banking investments. The discussion about other determinants of cross-border banking movements within Europe is presented in next section.

### **3.2 Model, data and variables**

To investigate the determinants of international banking investments in Europe, We test the following model using the data of cross-border M&As for the period (1987-2004).

$$BKEXP_{i,t} = a + \sum_{i=1,N} \alpha_i CountryiDummies + \sum_{i=1,N} \beta_i x_{it} + \varepsilon_{i,t}, \quad i = 1, N; \\ t= 1...T \quad (1)$$

$$BKIMP_{j,t} = b + \sum_{i=1,N} \alpha_i \text{Country}j\text{Dummies} + \sum_{j=1,N} \beta_j x_{jt} + \varepsilon_{j,t}, i = 1, N; \\ t= 1...T \quad (2)$$

Where  $i = 1, N$  indexes the home country of foreign banking investments;  $j=1,N$  indexes the receiving countries of cross-border banking investments and  $t = 1, \dots, T$  indexes the year the M&A was announced. The explicative variables displayed in the Table 2 are chosen on the basis of the theoretical and empirical evidence discussed above.

The dependant variable in the first regression ( $BKEXP_{i,t}$ ) equals the number of cross-border M&As in year  $t$  of banking institutions from the country  $i$ . In the second regression, the dependant variable equals the foreign banking investments in the European country  $j$  through cross-border M&As.

**Table 3: Summary statistics for regression variables, 1987-2004**

The explicative variables ( $x_{i,t}$ ) and ( $x_{j,t}$ ) correspond respectively to the home and the host countries characteristics of cross-border banking movements through M&A operations. These variables include indicators about the economic and regulatory environment of these countries:

- NBKA: Number of cross-border banking acquisitions of other banking institutions.
- CONC: The share of domestic operations in the total of banking M&A is considered as indicator of the market concentration of the country's banking industry.
- PIBGROWT: annual GDP growth as indicator of economic conditions in the home and the host countries of foreign banking investments.
- LPIBCAP: the natural log of GDP per capita is an other indicator of economic environment.
- PEXP: the ratio of exports to GDP is an indicator of the non-financial firms exports activity.
- PIMP: the ratio of imports to GDP reveals the importance of international firms presence in the target country of foreign banking investments.
- OPEN: the ratio of total exports and imports to GDP measures economic openness.
- INFL: inflation rate in home and the host countries of foreign banking investments
- DERGLM: a 0,1 dummy take the value 1 after the year that restrictions to cross-border movements of capital are eliminated.
- FBD: 0,1 dummy variable that take value 1 from the year that the First Banking Directive was implemented in the European country
- SBD: 0,1 dummy variable indicating the year of the Second Banking Directive implementation.

We assume at a given date that two countries having similar observable characteristics will have approximately the same number of cross-border M&As. The coefficients  $\alpha_i$  and  $\alpha_j$  reveal the countries specific effects on their outgoing and incoming foreign banking investments. Considering the Hausman tests, we estimate the equation (1) using Fixed effects Model and Random effects Model for equation (2). The Table 3 and 4 display the different specifications of the two equations. The Panel data contains 252 observations for 14 European countries. The United Kingdom was excluded because of missing observations relative to regulatory characteristics. The methodology of tests can be explained by the aim of our study to identify the investing and receiving countries in EU of cross-border banking investments. We assume that the country characteristics increase the likelihood to be at the origin of foreign banking expansion or the target of cross-border M&As.

### 3.3 *Expected signs*

The signs of the equations (1) and (2) coefficients are predicted considering the empirical results and the literature discussed above. According to the new trade theory literature, banking FDI are more likely into and out of highly developed countries. This assumption implies positive coefficients on LPIBCAP and PIBGRWTH.

Considering the hypothesis “to follow customer abroad” as motivation of foreign banking investments, we predict that the degree of trade openness would be positively correlated with cross-border banking activity. This assumption implies positive coefficients on EXP, IMP and OPEN variables.

Given the law of comparative advantage, the country environments that foster strong banking institutions, more likely to have a competitive advantage over their competitors in the destination market allow them to invest abroad. This implies positive sign on LPIBCAP. Accordingly, the large banks formed from previous banking mergers reach the sufficient scale to expand their activities in other foreign markets. This implies a positive coefficient on NBKA.

The previous evidence on cross-border banking suggests that highly developed economies may also be more attractive for foreign banking investments. Therefore, the same sign of coefficients on the above variables would be expected in equations relative to incoming banking investments.

The signs of coefficients on some other variables (INFL) are ambiguous and different between the two equations *a priori*. The hypothesis that high domestic banking consolidation may increase banking incentives to expand in foreign market, suggests a positive correlation between the degree of banking concentration and the outgoing banking investments. However, the less concentrated markets are more likely to be the targets of foreign banking investments, which imply negative coefficients on CONCj.

In order to distinguish countries which are more likely to be as investing or as receiving country of cross-border investments, we include Country i and country j Dummies in our regressions. The positive coefficient on country i Dummies suggests that country is less likely to be the target of cross-border acquisitions. On other side, the coefficients on country j Dummies are interpreted as indicator of European countries which are more attractive to foreign banking investments.

The First banking directive and the Second banking directive aimed to liberalize the trade of financial services across European borders and to increase the integration of the European banking market. In this respect, the

sign of PDB and SDB will be positive as measure of European banking integration that facilitate the cross-border banking movements. Considering the positive effect of liberalizing capital movements on cross banking investments, we expect that the coefficient on DERGLM be also positive.

### ***3.4 Estimation results***

The empirical results of different specifications of the equation 1 are displayed in Table 3 showing the determinants factors of outgoing banking investments in Europe.

The positive coefficients statistically significant on NBKA confirm our predictions. This result is due to the coexistence in the same countries of specialised banking institutions with the diversified institutions, acquiring other financial institutions in foreign markets.

The empirical results confirm the motivations of banking institutions to follow their customers in foreign markets with generally positive and statistically significant coefficients on PEXP. As expected, the degree of trade openness is positively correlated with cross-border banking investments as suggest the positive coefficient on OPEN<sup>6</sup>.

The coefficient on PIBGROWT is negative, contrary to our predictions. However, this coefficient is not statistically significant and the sign of this coefficient become positive when we estimate the specification (4) of the equation (1) using a fixed effect model. This result reveals limited evidence on the positive effect of economic development in the home country of banks on their expansion abroad. However, the negative coefficient on inflation rate is generally statistically significant, which suggests the importance of this indicator of country's economic environment as driving factors of cross-border banking activity.

---

<sup>6</sup> The result concern the coefficient on OPEN, relative to fixed effects model specifications' which are not reported in the Table 3.

*Sources: Annual data from 1987 to 2004 based on Thomson Financial Securities Data, Mergers and Acquisitions on-line Database (2005); DataStream Database (2005) and the author's calculation.*

The results provide empirical evidence of the hypothesis that banking deregulation process and the implementation of the Second banking Directive has encouraged the cross-banking investments in European Union countries.

Contrary to our predictions about the necessity to consolidate the domestic banking industry before investing in foreign markets, the coefficient on CONC is negative. This result is partly due to the method of calculating

<sup>a</sup> The coefficients are \*significant at 10%; \*\* significant at 5%; \*\*\* significant at 1%.

the concentration indicator, which implies a negative correlation with the number of cross-border M&As. The low degree of banking concentration comparing to the important cross-border banking investments in some European countries is another possible explanation for this surprising result.

The positive coefficients on countries Dummies and statistically significant suggest that these countries has comparative advantage as investing countries according to the analysis of Berger et al (2004). Accordingly, Germany, France, Spain are likely to be at the origin of cross-border M&As. The coefficient on Italy Dummy is also positive but not significantly different from zero. The countries having negative coefficients statistically significant and considered as receiving countries of cross-border banking investments are Luxembourg, Denmark, Netherlands and Ireland. The rest of countries Dummies are negative and not significantly different from zero.

Table 4 displays the estimation results of different equation (2) regressions. The negative coefficient on the concentration indicator is consistent with the predictions of larger potential of consolidation in less concentrated countries that are likely to be the targets of cross-border M&As. The coefficients on economic environment indicators (PIBGROWT, LPIBPOP and INFL) are generally negative for all regressions of the equation (2) and not significantly different from zero. This result suggests that low inflation for a European country could encourage the investments of foreign banks in this country. Nevertheless, the economic growth of the target's country seems not to be an attractive characteristic for cross-border banking activity across Europe. Contrary to the results of estimating the determinants of outgoing investments, only the positive coefficient on DERGLM is statistically significant although the coefficient on SDB is also positive.

The positive coefficient on PIMP and OPEN are significantly different from zero for all regressions of the equation (2). This result confirm the hypothesis of customer following behaviour as motivation of cross-border banking movements through M&As.

The negative coefficient on Luxembourg Dummy significantly different from zero is consistent with the previous result relative to the regression of outward banking investments.

France, Spain and Italy dummies are the only positive coefficients significantly different from zero in the regression (5). This result suggests that banks in these countries have comparative advantage, which allows them to expand in foreign markets. The rest of country j dummies are negative excepting Germany, Finland and Sweden.

#### 4. Conclusion

The creation of European Monetary Union, the relaxation of barriers to operating across geopolitical borders and the development of new technologies of communications has led to an acceleration of banking integration process in Europe. In this context, a sharp increase in M&A activity is the widespread trends seen in the European banking sector.

The analysis of foreign investments by banking institutions based on cross-border banking M&A data reveals the investing and receiving countries of these investments in Europe. The first group includes Belgium, Germany, Spain, Netherlands and Sweden, which have higher level of outgoing investments in term of number and global value of cross-border M&A operations than incoming investments by banking institutions. In other side, Greece, Ireland, Portugal, UK and Denmark are considered as receiving countries of banking investments in view of the number of acquisitions.

The empirical tests of the determinants of foreign investments by banking institutions confirm the hypothesis of following clients' behavior as motivation of their expansion in other European countries. The economic growth in the target country seems to be a determinant factor for foreign acquisitions by banking institutions. The low inflation appears an important characteristic of home and host countries of cross-border banking investments within Europe.

The opportunities offered by other European markets appear to be determinant factor of pan-European banking consolidation. The low degree of concentration of banking sector increases the potential for acquisitions by foreign banks, which will contribute to the banking consolidation in the host country. However, the results are not consistent with the hypothesis about the limited margins for consolidation within national boundaries as a driving factor of banking expansion on the EU market.

The results of analysis show a positive correlation between geographic expansion of banking institutions and the diversification of their activities. The European banks seem to focus on banking activities consolidating their domestic position before expanding their activities in the EU market. The deregulation process and the implementation of the second banking directive appear as important factors which largely contributed to accelerate these cross-border movements within Europe.

## **Abstract**

*The capital adequacy concept leads off a risk measuring in the banks and investment firms, and subsequently from determination of an appropriate capital requirement of these institutions. The Banking Advisory Committee of European Union, which was established in 1979, is one of the most important authorities within European Union. It comprises the most significant authority of regulation and supervision in Europe with empowering to issue binding directives. The aim of this article is to show how the European Union responds Capital Accords Basel I, New Basel Accord and Basel II. The substance is on the Capital Adequacy Directives CAD I, CAD II and CAD III. The CAD I included market risk, risk of counterpart, foreign currency risk and risk of large exposures. The CAD II included commodity risk and internal models for calculating of capital requirements, it responds to New Basel Accord. CAD III responds to proposals included in Basel II.*

**Keywords:** *capital adequacy, own funds, market risks, minimal level of capital to cover risks, investment companies.*

## 1. OFD and SRD Directives

Steps taken by European Union in the field of capital requirement have come from commands of Basel Committee for Banking Supervision.

European Union passed two directives in 1989 as reaction to Basel I:

- » Council Directive 89/299/EEC of 17<sup>th</sup> of April 1989 **on the own funds of credit institutions**, also called **OFD Directive**,
- » Council Directive 89/647/EEC of 18<sup>th</sup> of December 1989 **on a solvency ratio for credit institutions**, also called **SRD Directive**.

Overhead mentioned directives took a leaf from Basel I with an identical approach to credit risk.

The first directive (OFD Directive) defined own funds and the second directive (SRD Directive) specified risk weights for individual sorts of assets.

The conception of capital adequacy is named in EU Directives as solvency ratio and capital is named as own funds.

## 2. Capital Adequacy Directive I (CAD I)

In European Union has been born need to define minimal capital requirements for investment institutions (the same for both banks and investment firms).

Furthermore, Basel Committee for Banking Supervision has also recommended market risk to take under capital requirement. Thus, under the conditions the Council Directive 93/6/EEC of 15<sup>th</sup> March 1993 on Capital adequacy of investment firms and credit institutions has been passed. This directive is also named CAD I.

### *2.1 Reasons for passing CAD I Directive*

The reasons for passing directive CAD I could be summarized to seven main points:

- » creation of common standards for capital requirement of banks and investment firms,
- » to give a definition of separate risks for different sorts of financial instruments and for different business positions,
- » the same capital requirements for the same market risks of banks and investment firms,
- » common standards of monitoring and managing credit engagement of banks and investment firms, particularly in banking book,
- » creation of the standards for own fund of credit institutions and investment corporations,

- » need of common rules of consolidation of financial institutions with regard to market risk,<sup>1</sup>
- » the effort to remove barriers between investment banking and commercial banking in the interest of individual approach to them under the terms of regulation and supervision.

**CAD I prescribed mainly conditions for capital requirement for investment firms.** It also related to banks but only on those activities, which were integrated to business portfolio (trading book). Also the Directives OFD and SRD were linked with these activities.

## ***2.2 The conception of trading book***

The conception of trading book was significant for CAD I like that in the case of New Basle capital accord. The trading book includes financial operations (short-term operation on own account and providing financial services). Another items, mostly credit and deposit operations belong to banking book. Separation of classical banking operations and operations on the financial markets was related to growth of market risks, followed from the operations on the financial markets.

## ***2.3 The CAD I followed market risks, position risk, settlement/delivery risk, risk of counterpart, foreign currency risk and risk of large exposures.***

Credit and share risk were divided into general and specific ones.

**Position risk** was defined as preponderance of covered (uncovered) positions of institution over its uncovered (covered) positions within the same group of stock and debt instruments and identical time-limited contracts.

**Risk of the marketable debt instruments** is shown on the base of net currency position, in which the debt instruments are denominated. The general risk is appointed:

- » on the maturity-based of instruments,
- » on the based of modified duration if the institution uses this way, systematically.

**Share risk** is determined on the based of gross position, which is sum of all net covered and net uncovered positions. Capital requirement for general risk is 8%, for specific risk is 4% (in some precisely defined cases, it is possible to decrease capital requirement to 2%).

Settlement/delivery risk

---

<sup>1</sup> Council Directive 92/30/EEC of 6th April 1992 on the supervision of credit institutions on a consolidated basis is not related to cases, when a group contains more investment firms without bank.

**Settlement/delivery risk** arises from a price differences between agreed price and possibility of change in market price during the time to maturity of business. It depends on a number of working days till the date of settlement.

**Counterpart risk** follows from a situation, where counter-party is not able to fulfill its own liabilities from concluded contracts.

**Foreign exchange risk** can be sets out in two steps:

1. the net open position of institution is calculated in each currency,
2. the net uncovered and covered position are converted through spot exchange rate to reporting currency and such a sum of covered and uncovered positions will be created.

If an institution's overall net foreign-exchange position exceeds 2% of its total own funds, it shall multiply the excess by 8% in order to calculate its own funds requirement against foreign-exchange risk.

**Other risks** represent independent part, which includes for example low business turnover risk or risk from low revenue at the level which is not sufficient to cover overheads. Therefore, investment firms shall be required to hold own funds equivalent to one quarter of their preceding year's fixed overheads (when a firm has not completed a year's business, the requirement shall be a quarter of the fixed overheads figure projected in its business plan).

**CAD I was not monitoring market risk at a level of credit and stock instruments of the banking book.**

#### ***2.4 The investment companies***

The investment company has an important position under the terms of CAD I, where is defined like corporate body with regular activities oriented to providing investment services for third-country investment firms on a professional bases.

The directive also enables to add subjects which are not corporate bodies between investment companies. Investment companies are not that subjects which only receive and transmit orders from investors without holding money or securities belonging to their clients and which for that reason may not at any time place themselves in debit with their clients.

Initial capital of investment firms had been appointed subsequently:

1. **ECU 125 000**, if institutions provided one of the following activities:
  - » the reception and transmission of investors' orders for financial instruments,
  - » the execution of investors' orders for financial instruments,

» the management of individual portfolios of investments, provided that they do not deal in any financial instruments for their own account or underwrite issues of financial instruments on a firm commitment basis.

2. **ECU 50 000**, if firm was not authorized to hold clients' money or securities, or to deal for its own account.
3. All other investment firms should had initial capital of **ECU 730 000**, mainly those of them which running activities beyond the terms of first point.

The member states of European Union could divide single items of own funds of the credit and financial institutions by that way their national supervision authorities decided within the scope of EU recommendations. Regardless of legally and accounting terminology the items of the own fund had to fulfill the following signs:

- » the credit institution had them at itself disposal for covering ordinary banking risks anytime,
- » there were keeping account of them,
- » the subordinated funds could not exceed 100% of core funds and also had to contain clause of inferiority and their maturity should not be less than 5 years.

CAD I should been implemented within the member states of European Union till the end of the year 1995. The most of them did not meet this date. Great Britain was the first country which implemented CAD I in practice. On the other hand, Germany was the last country implemented this directive.

### **3. Capital Adequacy Directive II (CAD II)**

CAD II represents a revision of CAD I following New Basel Capital Accord – amendment of Basel I. Target was to avoid different regime of members and non-members of Basel committee on banking supervision within European union.

CAD II was adopted in 1998 and was focused on two main areas:

1. internal models of banks and
2. commodity risks.

### ***3.1 Reasons for passing CAD II Directive***

Reasons why to adopt CAD II may be summarized into several areas:

- necessity to incorporate commodity risks or commodity derivative risks designed for trading into trading book,
- to allow institutions to use their own risk management and risk measurement models to measure risks more accurate,
- to evaluate gold positions (and their derivatives) of the institutions similar to the foreign currency and foreign currency derivatives positions,
- a detailed modification of the non-balance items,
- improvement of the OTC derivative regulation, possibility to include risk mitigation effect,
- necessity of consistent regulation over the lending institutions and investment firms in OTC derivatives area,

### ***3.2 Commodity risks***

Investment firms with their main activity focused on commodity trading are not subjects to neither CAD II nor investment firms Directive .

Capital requirements connected to commodity risks are related to necessity to defend lending and investment institutions depositors and lenders. These institutions are not primarily focused on commodity operations. Capital requirement per commodity is 15% of the net covered/uncovered position multiplied by current commodity price and 3% of a gross position, covered plus uncovered, multiplied by current commodity price.

### ***3.3 Internal models***

To apply internal models by an institution must be approved by regulator.

According to CAD II possibility to exercise internal models is connected to several risks:

- position risks,
- foreign currency risks,
- commodity risks.

Regulator may allow institution to use internal models for the purpose to calculate capital requirements for **specific risks in debt and stock trading positions**, if internal models fulfill **additional (along with obligatory) conditions**, which are:

- model explains price volatility in portfolio,
- model evaluates concentration in portfolio structure,
- model is verified by reverse testing.

Regulator authorize institution to use risk management internal models only if these **obligatory conditions are reached**:

- institution has risk management unit, independent of trade units, and they report directly to the head management,
- risk management internal models is integrated into everyday process of risk management and cooperate with head management,
- head management actively participate in risk management process, executive officers responsible for checking reports should be authorized to lower positions of the relevant traders to help to decrease the risks,
- institution should have enough crew able to work with complex models,
- model accuracy control and model reliability control is needed,
- strict program for crisis situation testing and their evaluation by head management,
- internal audit concerning model reliability judging.

In reverse testing, VaR (Value at risk) calculated by internal model is compared every day (not including weekends). Daily change calculated for portfolio at the end of the day is taking into account. Reverse testing on theoretical changes of portfolio value is done by comparing the portfolio value at the end of a day and portfolio value at the end of a next day, while portfolio position remains unchanged.

Minimum value of the multiplier is 3 and it grows in dependence on number of overruns during the last 250 trading days. Overrun means daily change of the portfolio value that is greater than VaR calculated for the same day by internal model. Overruns are calculated either on real or theoretical changes of portfolio value.

#### **4. Capital Adequacy Directive III (CAD III)**

Goal is to provide unified application of the new concept for capital adequacy in banks and financial institutions within EU. CAD III respond to Basel committee on banking supervision and its ratification of the Basel II in 2004 (26.6.2004). This document established **operation risk** defined as a risk of operating system failure as well as some forms of human factor failures. There are three ways to calculate capital needs to cover this risk:

- simple, based on a gross profit percentage,
- advanced, dividing trade activities into 8 groups,
- developed, based on institution's own calculations.

CAD III represents union title for recodification of the SRD<sup>2</sup> directives and CAD II. The new projection of the directive was introduced to Council of the EU by European Commission in 2004 (19.7.2004).

This document increases the role of the regulation on consolidated basis over cross-border groups. There is also emphasis on regulators' cooperation. Newly found The Banking Advisory Committee of European Union will play important role in this context.

## 5. Conclusion

Main point of capital adequacy in CAD Directives is measuring of risks of credit institutions and investment firms and valuation minimal level of capital to cover them. The aim of capital regulation is health of financial system and protection of depositors and investors. Basel Committee on Banking Supervision has defined as first the capital adequacy. Basel accords respond to condition of banks. Principle "the same capital has to cover the same risk in banks and investment companies" is implemented to Capital Adequacy Directives. CAD Directives were prepared on conditions of investment companies and for operations of trading book in banks. In conditions of national banking and financial systems of many countries are implemented the same capital accords with different result. The reason is in different access to application of capital adequacy rules (Basel Accords or CAD Directives) in diverse territorial parts. Different access to application of capital adequacy rules shows next table:

	<b>Bank</b>	<b>Financial institution</b>
<b>EU members and members of Basel committee on banking supervision:</b> (Great Britain, Belgium, France, Germany, Luxembourg, Netherlands, Sweden, Italy)	New Basel Accord + CAD	CAD
<b>EU members outside G10:</b> (Austria, Denmark, Finland, Greece, Iceland, Ireland, Norway, Portugal, Spain)	CAD	CAD
<b>Basel committee members outside EU:</b> (USA, Canada, Japan, Switzerland)	New Basel Accord	No international agreements

---

<sup>2</sup> SRD directive was amended in 2000 and figures under the number 2000/12/ES

## **Abstract**

*Risk attitude profiling is an essential step in the financial advising process. It provides an understanding of the investor's attitude and tolerance for investment risk. Data collection on risk attitudes is commonly collected from an investor's choice between uncertain outcomes of a risky investment. However, responses are conditioned by a well documented behavioural bias in decision making under uncertainty known as "framing". Individuals develop internal frames of reference as a simplifying behavioural heuristic when faced with decision making under uncertainty. The framing of attitudinal survey questions will condition an investor's response to risk attitudes. Alternative frames can reverse attitudinal responses to the same choice. This paper examines the significance of framing in the risk attitude profiling process. We argue the need for alignment between the external framing of questions and the investor's internal frames appropriate to a particular class of investment decision. Misalignment may bias attitudinal responses and lead to inappropriate investment advice. We analyse this within the context of providing advice for superannuation (pension) investment. A class of investment decisions with a common purpose, long time investment horizon, individual choice and large capital sums.*

**Keywords:** *Personal Finance; Framing, Risk Attitude; Superannuation; Behavioural Finance.*

## 1. Introduction

The assessment of risk attitudes and tolerances of potential investors is now required of all financial advisors. But current practices are severely criticised for their lack of psychometric validity and omission of significant behavioural factors that characterise financial investment decision making under uncertainty [(Callan and Johnson, (2002), McCrae, (2004)]. A crucial omission that may invalidate the interpretation and application of risk attitude profiles as a basis for subsequent financial advice, is a behavioural factor known as ‘framing’.

The term framing refers to how choices are put to a decision maker. Framing first evolved from Kahneman and Tversky (1979) in prospect theory and then more formally in (Kahneman and Tversky, 1986). The main issue raised within prospect theory is the notion that the desirability of alternatives is altered by their framing, such that risk choices can be manipulated through alternative framing methods.

Two consistent findings emerge from behavioural finance studies regarding how individuals deal with outcome uncertainty or financial risk when making financial decisions. Kahneman and Tversky (1984) demonstrated that individual attitudes towards financial risk are conditioned by how the uncertain outcomes are expressed or ‘framed’ to the respondent – a characteristic known as external framing. Subsequent studies confirmed the phenomenon of risk attitude reversal associated with opposing frames. Risk tolerance (risk loving) observed when uncertain outcomes are expressed in terms of gains, wins or survival may reduce to risk aversion when equivalent outcomes are framed as losses, costs or failures.

A second group of studies demonstrates that individuals tend to adopt behavioural heuristics or ‘general behavioural rules’ to simplify the complexity of financial choices dominated by outcome uncertainty and information overload. One such heuristic is the grouping together of decision situations with common characteristics and the use of common attitudinal ‘internal frame’ of reference that may emphasise the loss or gain aspects of uncertain outcomes for all such decisions. Individuals simplify choice decisions in that class by using the same risk attitude or risk tolerance level considered appropriate to that frame of reference. The dominant risk attitude applied to particular sets of decisions may vary drastically between sets.

This paper suggests that the aforementioned behavioural principles have significant implications for the risk attitude assessment process (risk

profiling) now required of financial advisors when recommending a specific or well defined set of financial choices such as superannuation. Risk attitude profiling is essential as it provides the financial advisor with an understanding of an investor's attitude towards investment risk and establishes a 'reasonable basis' for subsequent investment advice.

A concern in the risk profiling process is a misalignment between external and internal framing. Misalignment can occur when the external 'frame' used to express a financial choice problem in a profiling instrument does not correspond to the respondent's normal internal frame for that category or class of financial decisions. Since external framing can cause risk attitude reversals for equivalent situations, misalignment may produce completely inappropriate risk attitude profiles for that decision context.

This exploratory study examines the significance of framing as a decision making heuristic in the risk attitude profiling process. Current legislation that governs the processes which financial advisors must adhere to, including risk attitude profiling omit behavioural factors. An example of this is framing. We argue the need for an alignment between the external framing of questions in the risk attitude profile and the investor's internal frames appropriate to a specific class of investment decisions. To highlight this we use superannuation or pension investing as a class of investment. We have selected this class of investment as it forms the majority of an investor's wealth, has a common purpose (to attain the highest retirement income), an approximately defined long term investment horizon and individual choice of investment strategy. Moreover, we believe that superannuation is an appropriate example, as financial advice and recommendations may be in conflict with attitudes that do not agree with economic objectives.

Our analysis is structured as follows. Section two defines the process of risk profiling and briefly reviews the financial risk attitude profiling requirements placed upon financial advisors by the legislation and the lack of guidance on process control. Section three defines heuristics, with the types of framing in decision making literature also identified. Section four analyses the unique investment aspects of superannuation, illustrating the need for alignment between internal and external frames. Section five concludes with a main summary of the paper and future research directions

## **2. The Financial Services Industry & Risk Attitude Profiling.**

In 2001, the Australian Federal Government introduced sweeping reform of the financial services industry to combat rampant self-interest,

fraudulent practices, inadequate training, excessive fee structures and a pervasive lack of transparency, disclosure or accountability. Any individual or organisation providing financial advice of any nature is required to have minimum knowledge standards, with respect to the advice they are giving. The legislative foundation for this reform is the Financial Services Reform Act (FSR Act) of 2001 (Commonwealth of Australia, 2001).

In common with legislation in the UK, USA and many European countries, the foundation of the advisor-client fiduciary relationship laid down in the Act is an absolute requirement for an advisor to act in a client's 'best interests'. The burden of proof rests on the financial services provider. An advisor must make reasonable attempts to gather sufficient information from the client about their financial and other relevant circumstances to establish a 'reasonable basis' for subsequent financial advice and to show that the advisor has always acted in the client's 'best interests'. Penalties for contravention include large fines and deregistration depending on offence severity.

Under the Act, the terms 'best interest' and 'reasonable basis' expressly include notions of psychological and behavioural, as well as economic, well-being. Both the FSR Act and Section 851 of the Corporations Law require financial advisors to make 'reasonable attempts' to define and consider an investor's risk attitudes or 'tolerances' in relation to a specific financial objective before providing financial advice.(section References). Risk attitude profiles aim to provide financial advisors with a means to assess an investor's attitude and tolerance towards investment risk. Any subsequent advice, product recommendations or other services must then accord with those attitude profiles, as these risk attitude and tolerance profiles are shown to fundamentally condition client choice between alternative financial decision alternatives (Kahneman and Tversky, 1984).

The purpose of the risk attitude profiling process is to provide the financial advisor with an understanding of an investor's attitude towards investment risk. Unfortunately, the FSR Act gives no guidance on the risk profiling process other than a requirement for collection of information directly from the client. The vacancy is problematic since the majority of current risk profiling practices have been strongly criticised as ad hoc processes that lack internal consistency, remain psychometrically untested and characteristically ignore behavioural biases that characterise human financial decision making under uncertainty. Current profiling procedures often produce inaccurate, invalid attitudinal assessments that lead to gross mismatches between financial advice and a client's actual risk preferences.

## ***2.1 Financial Risk Defined***

Financial risk refers to uncertainty about investment outcomes. The outcome may be return on investment, capital growth or loss or failure to meet an expected target. The greater the uncertainty about the outcome the greater the financial risk. The most common measure of this concept is the volatility of investment returns around their expected value as given by their standard deviation. As return volatility or (loss probability) increases so does the financial risk associated with the outcome. Choices between investments depend upon the expected level of return and the volatility or uncertainty attached to that return. The summary measure is usually expressed as risk-adjusted returns.

Finance theory holds that higher absolute returns are preferred to lower returns and lower volatility preferred to higher volatility. However, individual choice of the optimum risk-return combination among alternative investments will be uniquely determined by each investor's attitude towards, or tolerance of financial risk.

## ***2.2 Risk Attitude Profiling***

The process of identification, measurement and categorization of a client's individual risk attitudes and tolerances is known as risk profiling. Legally, risk attitude profiling is a requirement and necessity of financial advice as deemed by the FSRA Act (2001) and the financial services hand book (ASIC, 2003). To identify attitudes towards uncertainty a financial advisor must identify preferences for risk through choices under uncertainty. However, each individual may approach or edit information differently to others when faced with choices, even given the same choices. Risk attitudes contribute to an understanding of the investor's psychological "comfort". This integration of attitudes or behavioural dimensions to rational models seems to be juxtaposed. Therefore, when developing an understanding of investor's attitudes and how they are formed, investment advisors need to be aware of behavioural biases involved in responses to the risk attitude profiling process. Consideration of behavioural biases such as framing addresses the issue of psychological comfort. In other words, considering the investor's level of comfort with investment decisions.

Unfortunately, neither PS 175 nor the FSRA Act provide any guidance as to how to conduct risk attitude profile assessments. Nor do they address the issue of incorporating behavioural aspects of decision making into the risk assessment process which can affect the validity (framing effects) and relevancy of risk profiles. To understand how the process is

threatened by framing effects, it is worthwhile to briefly examine what are risk attitudes and how they are measured.

### **2.3 Risk Attitudes**

Investment risk profiling provides a measure of an individual's 'attitude' towards financial risk. But the concept is not easy to define. The Act refers to levels of 'tolerance' of investment risk rather than using the term 'risk attitude'. However, the two terms are often used inter-changeably in the sense that risk attitude profiling provides a means of measuring individual tolerances of different levels of financial risk. The terms 'risk averse', 'risk neutral' and 'risk loving' are used to refer to the spectrum of attitudes.

The concept relates to the psychological or behavioural 'comfort' or 'well being' of an individual in making investment decisions. Definitions of the concept are inherently context dependent. In neo-classical portfolio theory, an investor's risk profile is reflected in the shape and position of their utility indifference curves which then uniquely determines an optimal portfolio choice. The optimal portfolio is determined through a tangency solution with the risk-return frontier of efficient portfolios positions given by "the point on the efficient frontier at which the one of the investor's indifference curves just touches the frontier" Sharpe (1997).

In contrast to this rather mechanistic approach, behavioural researchers emphasise the 'psychic comfort' aspect of attitudinal measurement, as in the following definitions:

*"The maximum amount of uncertainty that someone is willing to accept when making a financial decision"* (Grable, 2000), and *"Risk tolerance is the degree to which an investor is willing to accept the possibility of an uncertain outcome to an economic decision"* (Harlow and Brown, 1990). More recently, Callan and Johnson (2002) define risk attitudes as, *"The degree to which a client is willing and able to accept the possibility of uncertain outcomes being associated with their financial decisions"*.

Implicit in all these definitions is the trade-off between risk, as measured by the uncertainty of a return and the level of expected return, which is commonly referred to as the risk premium. This aspect of risk attitudes is emphasised in the work of researchers such as [(Cordell, 2001), (Bodie, Kane and Marcus, 2003) and (Jahnke, 1999)]. Therefore, assessment and measurement of investor's risk preferences requires a risk attitude profiling process. Emphasised across all definitions of the concept is the notion that the risk attitude profiling process is an attitudinal measure.

Importantly, the quality of this measure can be threatened by the process of measurement or data collection. The process of data collection and the investor's heuristics used to make decisions under uncertainty also need to be addressed.

#### ***2.4 Attitude Reversion***

Risk attitude profiling process is an attitudinal measure whose psychometric validity depends upon the process of data collection and measurement. The data collection process of risk attitude profiling involves responses to questions on uncertainty, aiming to measure attitudes towards uncertainty. Data collection always and unavoidably involves "framing" of questions. Framing refers to how choices are put to the decision maker. In their development of prospect theory Kahneman and Tversky (1979) showed that the manner in which choices are framed alters their desirability, such that risk choices can be manipulated through alternative framing methods. Questions may be framed in terms of gains or losses, positive or negative returns, and long versus short term (narrow framing). Consequently, the results of any risk attitude profiles are determined by the framing of questions used to collect data about risk preferences. Framing a problem under uncertainty in terms of a loss context may provide a complete reversal in response to an identical decision in a profit context. If risk attitudes are prone to preference reversals, then financial advice and recommendations based on responses may not truly reflect or cater for the investor's psychological and financial well being.

#### ***2.5 Legal Requirement of Risk Attitude Profiling***

Under the FSR Act, the purpose of risk profiling in financial advice is two-fold. Primarily, risk attitude profiles are a means of ascertaining an investor's attitude towards uncertainty as an integral part of a client's psychological 'comfort level'. Under the FSRA Act's definition of a "client's best interests", consideration of behavioural and psychological well-being, as well as economic benefit must occur. Risk attitude profiling achieves this.

Secondly, risk attitude profiling satisfies the legislative requirement placed on investment advisors to establish a 'reasonable' basis for all subsequent advice (FSRA Act, 2001; ASIC PS 175). Risk attitude profiles form an integral part of that "reasonable basis" of advice. All subsequent financial advice on asset allocation and portfolio selection (investment products) must conform to that 'reasonable basis'. A "reasonable basis" of advice essentially draws on the investor's attitudes towards investment risk and their tolerance of it under the concept of 'relevant circumstances'. PS 175 defines an investor's relevant circumstances as:

- (a) tolerance to the risk of capital loss, especially where this is a significant possibility if the advice is followed; and
- (b) tolerance of the risk that the advice (if followed) will not produce expected future benefits (PS 175.104, ASIC, 2003).

One criticism of the above definitions, in particular (a) is the focus on capital loss. An investment perspective should also incorporate volatility of returns which some industry bodies such as the Financial Planning Association (FPA) adopt. Moreover, PS 175 and the FSRA Act do not provide any guidance as to how to conduct risk attitude profile assessments, nor do they address the issue of incorporating behavioural aspects of decision making into the risk assessment process. In order to understand how the current process is threatened by framing effects (behavioural biases), it is worthwhile to briefly examine some of the current forms of risk attitude profiling.

### **2.6 Current Risk Attitude Profiling Techniques**

Current profiling processes produce only the broadest of attitudinal categories. Industry practice is to distinguish only four profile categories that range from a low end of “risk averse”, through “risk neutral” onto ‘risk tolerant’ and “risk seeking” at the high end. Anecdotal evidence suggests that industry interests rather than the client’s focus dominate such divisions. Financial advisors typically use these four categories as a basis for recommending portfolio products already pre-packaged as ‘conservative’, ‘balanced’ and ‘growth’ portfolios based on relative percentages of asset classes in each (see table one below).

**Table 1- Investment Product Risk Profiles**

<i>Assets</i>	Risk Profile		
	<i>Conservative</i>	<b>Balanced</b>	<b>Growth</b>
Domestic Equities	15%	30%	50%
Global Equities	10%	25%	50%
Fixed Interest	40%	35%	-
Property	5%	5%	-
Cash	30%	5%	-

This table illustrates an example of the risk profiles of investment products that are broadly categorised as; “conservative”, “Balanced” and “Growth”. The assets represent the percentage of a portfolio for each risk

profile. It should be noted that this table is a guide and not indicative of all risk profiles as labelled below.

The major use of these profiles by financial advisors is for recommending selection from available investment products. Once completed, financial advice on portfolio selection with respect to a specific financial objective must be consistent with the investor's risk attitude profile.

### **2.6.1 Criticisms of Current Practice of Risk Profiling**

The forms of risk attitude profiling range from primitive qualitative interpretations of statements, to highly quantitative measures of attitudes to financial risk (Roskowsi, 2003). Even during interviews, investment advisors are capable of framing questions by presenting them in one form (e.g. in terms of gains, separate investments, etc). This leads to biased responses which may not necessarily reflect the investor's true risk attitudes. Consequently, an advisors interpretation of responses are then placed against standardised portfolios e.g. table one, and portfolios with risk profiles similar to the investor are recommended. A criticism of such an approach, is that if questions on risk attitudes were framed so as to yield risk seeking responses, a totally different risk profile would be formed to a question framed in opposing terms. This in turn determines the type of portfolio an advisor recommends.

#### *Portfolio Matching*

There are two primary methods by which risk profiling data can be obtained to identify risk attitudes and preferences. One method is to examine a number of alternative efficient portfolios, and explain to the investor the investment risks associated with them and, then choose among this sample of portfolios (investment products). Sharpe (1997) asserts that this is universally done in institutional practice.

This form of risk attitude profiling is a simplistic one-step approach at combining the investor's risk attitudes, investment objectives and preferences into asset allocation and recommendations. Whilst it meets the requirements of the Act, it does not meet any of the principles of risk attitudinal measurement as Callan and Johnson (2002) alluded to.

The second method categorises risk profiling by the data gathering technique; either structured questionnaires or semi-structured interview/discussion. Advisors use either a combination or one of these types of methods as a starting point for identifying risk attitudes. The semi-structured interview method may be used by itself or as a method of "probing" and contextualising responses to the preceding structured questionnaire (Roskowsi, 2003).

Even with interviews, investment advisors are capable of framing questions by presenting them in one form (e.g. in terms of gains, separate investments, etc). This would lead to biased responses which may not necessarily reflect the investor's true risk attitudes. Consequently, an advisors interpretation of responses would then be placed against standardised portfolios such as those in table one and, be recommended portfolios with risk profiles similar to the investor. A further criticism of an approach such as this is that if questions on risk attitudes were framed so as to yield risk seeking responses, a totally different risk profile would be formed. In turn, an advisor would recommend a "growth" type portfolio.

The above form of investment product selection or 'portfolio matching' faces strong criticism in the financial planning literature. There are several reports from industry bodies and government regulators. Most notable, however, is the *Quality of Advice Survey*, conducted by ASIC in 2003. This survey involved over 100 investors or participants that actually received financial advice from financial advisors. Each financial plan and consultation between advisors and investors were then rated by academics, legal and financial services professionals. More than 50% of reviewed plans were either classed as "borderline" to "very bad". A discerning result from the survey was that some financial plans and advisors provided reams of generic information and failed to show how the recommended strategy and action was appropriate for the client. Portfolio matching provides a recommended strategy for a set of generic set of risk attitude questions.

### *Interviews*

Callan and Johnson (2002) report that client-centred interviews and conversations are often the primary data collection tool for risk profiling by financial advisors. This data then allows the financial advisor to gain an initial insight into the investor's attitudes towards certain types of risky investments. They provide a technique to probe the comfort levels of investors associated with investment choices between alternative types of investments or asset classes that are characterised by return uncertainty.

Once the advisor has more meaningful understanding of the investor's attitudes, more possible valid questions about specific investment products that match the investor's level of expected performance and optimism can be used to further confirm risk attitudes (Callan and Johnson, 2002).

This type of assessment provides the financial advisor with subjective and intuitive estimates of the investor's investment needs and objectives that are relevant to their financial decisions. One discerning outcome of this method is the subjective interpretations as well as questions that investment advisors have in the process. The questions on choice under uncertainty may

be framed in manner that necessarily does not represent the investor's true attitudes.

#### *Advisor interpretations of Risk Profiling*

Research into investment advisors interpretations of risk tolerance is limited. Pioneering work by Snelbecker et al (1990) found that given a hypothetical investor's statements, financial advisors make substantially different interpretations. This finding is concerning for investors who receive and act upon advice from one advisor, despite theoretical variability in the validity of advice. Thus, interviews and informal discussions with investors regarding their previous and current investments are not scientific or objective and do not provide any substance for investment advisors to provide recommendations on.

These conflicts highlight several substantive criticisms levelled at unstructured data gathering approaches for risk attitude profiling. The process results in an ad hoc, unsystematic, often undocumented data collection that is completely subjective and open to wide variations in qualitative assessment attitudinal results very dependent upon the individual advisor's perceptions of risk attitude responses.

#### *Questionnaire Method*

There is a plethora of psychological literature on the collection, measurement and interpretation of attitude scales. There are a number of well developed attitude scaling techniques now available as generalised instruments. But the development of similar instruments in the financial risk attitude profiling area is limited to a few studies exemplified by Grable and Lytton (1999, 2003) and Roskowski and Snelbecker (1990). However, there is an increase in the number of standardised computer based risk attitude profiling systems. This is a direct reflection of the current inadequate state of practices, which the industry has been left to do without any guidance from government regulators (albeit through the FSRA Act). Presently, there has been no comparison between the different risk attitude software profilers that examine their psychometric and construction validity. Although, the firm FinMetrica submitted their software for psychometric and validity tests, yielding positive results (ProQuest 1999).

The questionnaire process is similar to the interview method, but it provides a quantitative result. A questionnaire will have between 10-20 questions relating to financial experience and scenarios that describe possible outcomes of investments. Questions that involve choices between risky outcomes are spanned over a spectrum extending from risk averse to risk tolerant behaviour. Behaviours are based on hypothetical or experience based situations. Grable and Lytton (2003) empirically demonstrated the validity of

a 13 item risk assessment instrument (questionnaire). This study found that the responses to this instrument were correlated with portfolio ownership. That is there was a significant relationship between equity ownership (proxy for risk) and risk attitudes. An example by from Grable and Lytton (2003) is presented.

An experienced based question refers to attitudes towards certain investments. For example: In terms of experience, how comfortable are you in investing in stocks or stock mutual funds?

- a. Not at all comfortable
- b. Somewhat comfortable
- c. Very comfortable

With regard to attitudes toward “risk” a question may ask:

When you think of the word “risk” which of the following words come to mind first?

- a. Loss
- b. Opportunity
- c. Uncertainty
- d. Thrill

The above question is framed in terms of losses and highlights external framing, which is manipulation of presented choices. If asset allocation advice and recommendations is based on such questions, then the revealed risk attitude maybe biased in the manner which choices were given to them (e.g. positive or negative). As a consequence, the revealed risk attitude may be in conflict with the particular class of investment the investor is considering, and hence, provide the financial advisor with a misleading and inappropriate basis to provide advice from.

Responses are answered through likert scale type responses. Each question has a score allocated to its response, with a high score indicating that the investor is risk tolerant, and a low score meaning they are risk averse. The scores are then totalled and compared to benchmarks or “profiles”. The range that the investor falls within denotes their risk attitude profile. Model portfolios or portfolios of asset classes that display similar levels of risk are then recommended.

We have shown that current risk profiling methods are susceptible to interpretive bias that may lead to substantively different risk attitude assessments. This is due to the nature of data collection involved risk attitude profiling. Framing in data collection cannot be avoided. Therefore, to reduce

framing effects to establish more reliable and accurate measures of risk preferences we must examine framing and its implications on risk attitudes, in particular “internal” framing. This will be discussed now.

### **3. Framing Effects and Risk Attitude Profiling**

The current risk attitude profiling methods used in both industry and research shown above, rely on a question and answer approach to measure individual investor’s uncertainty towards investment decisions. Kahneman and Tversky (1979) and much of the literature on decision making under uncertainty showed that risk preferences are influenced by how problems are presented. In terms of risk attitude profiling, framing is unavoidable. Current practices have illustrated that all forms of risk attitude profiling involve some form of question framing. By examining framing and in particular the effect of internal framing on decision making under uncertainty, emphasis needs to be placed on the need to recognise internal frames as part of the risk attitude profiling process. Doing so will provide a better means of understanding an investor’s risk preferences, as well as advice that is relevant to a class of investment.

#### ***3.1 Framing Formally Defined***

Kuhberger (1998), defined framing as a subjective, internal process determined by the situation’s contextual and individual factors. Elliot and Hayward (1998) define framing as “any manipulation of factors causing a change in an individual’s frame such that a predictable behaviour is effected” (pg, 232). These two definitions are consistent with the original constructs of prospect theory. To illustrate this Kuhberger et al (2002) found that by manipulating a problem in order to describe the same situation in an opposite context, revealed attitudes were reversed. In terms of financial advising and risk attitude profiling this is a significant problem, particularly when considering long-term savings for investments such as superannuation or retirement income. Risk attitudes reveal that an investor may be “risk-averse” to a particular decision problem. Although this may just be their natural (internal framing) decision making response to choices with risky outcomes.

From the review of current risk attitude profiling methods, it is evident that in the data collection process, investors are faced with a choice. The two options are a certain outcome and a gamble with known probabilities. Options are expressed in monetary terms or that of total wealth. The investor’s selection of a certain outcome versus a gamble reflects their risk attitudes. When making decisions with alternative choices with given probabilities, the chosen path will reveal something about one’s attitude

toward risk (Kahneman and Tversky, 1984). Preference for the certain outcome would result in a risk “averse” attitude, whereas selection of the gamble would reflect a “risk seeking” attitude. This demonstrates the unavoidability of framing when seeking responses to risk attitudes.

### **3.1.1 Relevance of Framing in Financial Decision Making**

Risk attitude profiles reveal an investor’s tolerance for investment risk. As mentioned in the previous section “framing” and its effects are unavoidable. Lebouf and Shafir (2003) define a framing effect as, “to occur whenever different descriptions of the same decision situation lead to different preferences” (p.78). Research has been plentiful and thorough, for reviews see (Kuhberger, 1998, Levin, Schneider and Gaeth, 1998) whom provide an excellent analysis of this issue. Framing effects are robust in numerous choice domains including medicine, project resource allocation, consumer choice, and gambling (Roskowsky and Snelbecker, 1990). But application to financial risk and risky decisions is an emerging discipline. Therefore, we need to look at more researched areas to assist in understanding how attitudes are formed.

Whilst the aforementioned areas may have life or death consequences in terms of the choices decision makers are faced with, economically the same is true for financial decisions. In terms of superannuation, if economically optimal investment decisions are not considered in an investment choice, the severity of that choice may be equivalent to a medical choice, between life and death. We will highlight this in our next section. There is a need for an understanding and incorporating framing in risk attitude profiling, as it is prominent in many choice domains.

This leads us to advocate and consider “internal” frames as part of the risk attitude profiling process. Kahneman and Riepe (1998) in their review of biases of judgement and decision making, acknowledge that individuals use their own heuristics in the coding and editing phase of analysing choices under uncertainty. Whilst these heuristics may not conform with rational decision making, to the individual they are correct. If these heuristics are used consistently, then individuals will continuously make errors in choice, or preference reversals. A further role of the financial advisor is to educate clients to make more optimal decisions and to be comfortable with them emphasising the importance to understanding and acknowledging internal

### **3.2 Internal Framing**

Internal framing or “self-framing” refers to how decision makers (investors) “themselves spontaneously encode and frame a choice problem” (Wang, 2004). Internal framing is a behavioural heuristic to simplify complex decisions characterised by outcome uncertainty. The above analysis illustrated that framing is unavoidable in the risk attitude profiling process. However, as eluded by researchers [(Elliot and Archibald, 1989, Levin, Schneider and Gaeth, 1998, Thaler and Johnson, 1990)] when investigating the manner in which decision makers frame choice outcomes and risk preferences, findings show individuals prefer positive to negative frames.

Kuhberger (1998) asserts that the “loose” definition of framing as, “an internal event that can be induced not only by semantic manipulations but may result also from other contextual features of a situation and from individual factors, provided that problems are equivalent from the perspective of economic theory” (pg, 24). Internal framing may be adopted in any context. If a choice is presented in terms of either gains or losses, individuals may select the certain or risk averse option because their natural tendency is to be risk averse, even though it contradicts economic rationality.

For financial advisors and the current risk attitude profiling processes, internal framing has implications. The major issue for the financial advisor regarding internal framing is that the need to ensure an alignment between the external framing of questions and the investor’s typical internal frames when making decisions under uncertainty. Misalignment can result in inappropriate responses, attitude recognition and inappropriate advice for a particular class of investment.

#### **3.2.1 Internal Framing as a Heuristic**

Heuristics is a process whereby individuals use short-cuts to make complex decisions. Heuristics are problematic due to their inclination to introduce bias into decision making (Shefrin, 2000). This bias is encouraged by past events (representativeness) which are stereotypes of judgement. An example of this is investors focusing on short term volatility for long term investment (such as superannuation). The short term volatility may be viewed unfavourably, however, over the long term volatility could prove to be insignificant. Short term volatility for long term investment strategies such as investing predominately in equities is relatively, not of much consequence as the same decision would be over a short term (Bodie, 1995). Adopting heuristics means that when faced with a choice, individuals use their common heuristics (based upon past behaviour and experiences) to assist them in making decisions, even if doing so leads to a preference reversal. To

determine if a framing effect occurs, the choice must provide the same “acts, outcomes, and contingencies” associated with decision that lead to preference reversals (LeBoeuf and Shafir, 2003).

Thaler and Johnson (1990) examined systematic phenomena to determine how prior gains and losses can affect subsequent choices. When confronted with a choice asking individuals to consider the effect of previous investment outcomes, individuals do not always conform with prospect theory. Significantly, the authors found that a prior gain often induces individuals to accept gambles, the authors naming this behaviour as the “House-Money effect”. This is at odds with prospect theory which found people to be risk-averse in the domain of gains. Another finding was that when faced with losses, the gamble was less attractive. However, if there was an opportunity to break-even or recoup prior losses, this seemed attractive. A similar study by Fox and Dayan (2004) provided similar results. In terms of superannuation investment, investors need to consider the choice of their decision in terms of their total investments.

Mental accounting is another example of using of internal heuristics in decision making. Thaler (1999) found investors to segregate information about their investments. Doing this leads investors to value investments differently and, hence change their attitudes towards risk for various investments. For example an investor that is relatively young may not take as much risk for their long term investment strategy when in fact they are quite risk tolerant for short term investments. This is their natural internal frame. No matter how questions maybe framed in the risk attitude profiling process, investors may still elicit attitudes that are not rationally consistent with a particular class of investment they seek advice on.

There is literature that postulates individuals have internal frames. Individuals will work through a choice in the same manner irrespective of different problems facing them. Arguments of this type of nature are based assumption that “problem frames are an integral way people think about decisions” (LeBoeuf and Shafir, 2003). (Kuhberger, 1998) goes further by defining internal framing as an event that can be induced by both semantic manipulations as well as contextual features of a situation, provided the problems are equivalent from an economic perspective.

If choices to situations involving uncertainty reveal risk attitudes then the contextual features also play a role in determining choice. In the process of risk attitude profiling, the internal frames must be aligned with external frames or the context of decision making. The decision facing investors must be specific to a particular investment class. Or it will not provide an indication of their actual attitudes.

### **3.2.2 External Framing**

External frames initially evolved from prospect theory, where Kahneman and Tversky (1979) manipulated the same problem to yield different responses and attitudes towards risk. Whilst probabilistically the chance of risky outcomes occurring is the same irrespective of the frame (gain or loss, certainty versus uncertainty, etc), the manner in how these choices are presented differ only in context. However, the difference in context leads individuals to interpret outcomes and utility associated with choices differently (Bazerman, 1998).

Conversely, internal frames are those that individuals adopt, irrespective of the decision they face. Individuals adopt heuristics to make decisions, as was shown by the House-Money effect and Mental Accounting. Using heuristics such as this may at times, not lead to optimal choices given the choices for a specific situation. The reason for this is that external frames used to describe a problem of choice under uncertainty do not correspond to the particular internal frame that an investor adopts. As a result there will be biased responses to decisions.

Current risk attitude profiling data collection methods involve framing, in particular that of external framing. Examples as seen in Grable and Lytton (2003) were given. These examples whilst not representative the types of questions asked in the data collection process, still highlight the issue of framing. Given some of these differences we will now examine some of the consequences of misalignment in financial advice recommendations.

### **3.3 Consequences of Misalignment**

Under current risk attitude profiling techniques, the major consequence of misalignment is the false categorisation of investor profiles and hence, recommendations based on these risk profiles. However, the current prevalence of broad attitudinal scales with only four categories means misalignment in frames makes drastic mis-classification unlikely. Typically, variation would be only in terms of one class at most, and if risk adjusted returns between adjacent classes of portfolios are similar, the chance of misalignment is further mitigated.

Misalignment between external and internal frames arises from the current data collection procedures. Investor's internal frames determine the choices under uncertainty they select. Financial advisors then subjectively interpret these choices, with this interpretation at risk of being in opposition to the investor, causing misalignment. One possible way to overcome this

misalignment given current risk attitude profiling practices, is education of the investor by the financial advisor. In particular, education should include information regarding the existence of behavioural biases and the conflicts these biases may cause in choice and economic optimisation. This may be achieved through illumination of the behavioural biases investors display during the risk attitude profiling process. Alignment of investor's psychological and behavioural "comfort" with investment strategies for optimising economic objectives is thereby assured.

To illustrate our argument further we will briefly examine superannuation investment and the need for an alignment between internal and external framing of questions in the risk attitude profiling process.

#### **4. Unique Characteristics of Superannuation Investment**

To illustrate the need for alignment between the external framing of questions in the risk attitude profiling process and the investor's internal frame to a class of investment decision an example will be used. The class of investment we have selected as an example is superannuation or pension investment. In Australia, retirement investing is mandatory and termed superannuation. Superannuation is so termed because of the propensity for Australian investors to take retirement investments as a "lump-sum" rather than a stream of income. Superannuation investment is primarily a defined contribution retirement income vehicle. There are a few defined benefit schemes remaining, but most new superannuation investments are defined contribution based. Superannuation investment was selected as the example for a number of reasons. Primarily was been selected as it is the largest investment that individuals have (aside from the equity in their place of residence). Secondly a large proportion of the population is approaching retirement (the "baby boomers"<sup>1</sup>) and finally with the onus of investment decision making placed on the individual investor<sup>2</sup>. Characteristics that make this class of investment unique to other types of investments are; it has a common purpose (goal), long-term investment horizon, individual choice and involves large capital sums. These will be very briefly discussed to highlight how a misalignment of internal and external frames may affect the financial advice.

---

<sup>1</sup> "Baby Boomers" refers to people born within the years 1945-1950 (immediately after WWII).

<sup>2</sup> An example of this is Choice of Fund legislation. This legislation allows employees to select where their mandatory contributions are invested. This will come into full effect on July 1, 2005.

#### ***4.1 Purpose of Superannuation Investment***

The objective of superannuation investment is to maximise the net accumulated wealth in the accumulation period (employment years), subject to the investor risk attitude profile. This enables the investor to achieve the highest possible retirement income. Currently, investor's superannuation is based on contributions paid into a defined contribution fund by their employer, which is managed by a financial institution. Investors also have the choice of voluntary contributions that supplement that of their employers. Investments can also be made outside of the superannuation domain for the same purpose of accumulating funds for retirement. However, superannuation provides investors with tax effective incentives such as lower capital gains taxes on investments and tax concessions on income tax, if contributions to superannuation are made from gross salary. Incentives such as those just described aid investors to maximise their net contributions. To achieve this though, investors must be comfortable with their investment strategies.

#### ***4.2 Long-Term Investment Horizon***

Superannuation investing is definite long term investment. Investments can span over 40 years and begin at the individual's commencement of full-time employment<sup>3</sup>. At the conclusion of employed life, investors can receive superannuation benefits in terms of lump sums, annuities or pensions. During the accumulation period, investors are unable to access their funds or receive any associated cash flows from their investments. Thus, over time investor's could possibly make choices based on relatively large capital sums. Risk attitudes must be considered with respect to large capital sums that can not be accessed as well as time involved until they can be. If investors followed traditional economic models they would be able to plan and smooth consumption of wealth over their lifetime. This, however, does not largely occur, resulting in governments having to implement retirement income policies, such as superannuation investing. Such phenomenon has been named as *imperfect self-control*, and is been in the behavioural finance literature of (Fisher and Statman, 1997) and (Statman, 2002).

A long-term investment horizon highlights the need for an alignment between an investor's internal frames and external frames of risk attitude profile questions. For example a superannuation investor elicits a risk averse attitude in a risk attitude profile. This attitude is interpreted by a financial

---

<sup>3</sup> Any individual earning over \$450 per month is entitled to a 9% superannuation contribution, on the behalf of their employer.

advisor as someone who would invest in relatively safe (low volatility) investments throughout their investment horizon, and is inappropriate considering the objective of superannuation and economic rationality. The risk attitude is inappropriate as investors need to maximise their terminal wealth. To achieve this they would need to invest passively in growth assets during their investment horizon, or accumulation period.

#### ***4.3 Investment Risk***

In many defined contribution retirement systems throughout the world, investors are faced with the onus of investment risk, requiring them to select their own desired investment strategy and, accept the returns associated with the particular choice they have made. The onus of investment risk couples with investment choice gives the investor the ability to select investments and strategies that are consistent with their financial objectives. As mentioned previously another example of framing was “naïve diversification”. If an investor uses this as an internal frame to allocate assets evenly, then when presented with a choice between investments that have low volatility and return, they should do the same. Again, this highlights the issue of misalignment between internal and external frames. In terms of superannuation investment, presenting choices between investments that do not offer much growth for a compounded long term investment may not be suitable to eliciting risk attitudes. Furthermore, doing so may bias responses that are economically irrational. Responses are biased in the sense that they relate to choices that are financially contradicting. The alignment of a risk attitude profile for a class of investment such as superannuation would need to utilise a broad range of investment strategies, to identify the investor’s internal frame. Prudent advice (taking life style considerations into account) would be against naïve diversification.

#### ***4.4 Preservation of Superannuation Funds***

Complementing compulsory contributions is *preservation* of accumulated funds. To stop investors from early withdrawals, taxes have been placed on accumulated funds to deter investors from accessing their future income sources. Conversely, investors are able to access and consume funds immediately outside the superannuation domain. If there were no accessing to superannuation funds then the objective of this specific type of investment is compromised. In their review of the behavioural finance literature, (Mullainathan and Thaler, 2000) found that given the wants and needs of most individuals over their lifetime, sacrificing current consumption for retirement is not a priority. Policies such as forced savings and preservation assist investors with self-control and planning for their

retirement needs. Superannuation investment envisages that investors remain focused on their goal of reaching the highest attainable retirement income stream. To achieve this, investors must be comfortable with an investment strategy that will enable them to achieve their objective and tolerate the risks of such a strategy over their investment horizon. Preservation of superannuation funds is a unique investment characteristic that makes this type of investment unique to other investment types that complements the forced superannuation savings thereby assisting investors to achieve the maximum attainable goals subject to their risk attitude profiles.

With respect to risk attitude profiling, internal frames found by may cause investors to be more risk seeking even in the gain domain (Thaler and Johnson, 1990). For financial advisors this is critical when reviewing investment strategies over an investor's life-cycle. If investments in superannuation have been performing considerably well, then a risk attitude profile, of the investor may change to a risk seeking attitude, when faced with choices under uncertainty. The new risk attitude profile may contradict previous assessments. Financial advisors should consider this change and consequently frame subsequent choices in terms of losses to see if this attitude is representative of all outcomes.

We have illustrated very briefly some of the unique investment characteristics of superannuation investing. By examining some of the issues surrounding risk attitude profiling we have highlighted the potential misalignment that risk attitude profiles may have when considering investment decisions for a specific class of investment. This misalignment will result in biased responses that do not characterise the investment decisions at hand. In particular, this analysis illustrates that specific investment purposes require specific risk attitude profiles reflecting the characteristics of the investment at hand.

## **5. Conclusions & Future Research**

This paper examined the significance of framing as a decision making heuristic in the risk attitude profiling process. Current risk attitude profiling processes are fundamentally flawed behaviourally. We concentrated solely on data collection and framing influences. Through our example of superannuation investment we showed that framing may lead to adverse consequences both economically and behaviourally. Current data collection procedures are also used to manipulate investors to fit into pre determined portfolios.

We argued that there needs to be an alignment between the internal frames of investors and the external frames of questions in the risk attitude profiling process. To illustrate this we used superannuation investment as an example to highlight the critical aspect of misalignment between internal and external frames of a particular investment class. If investors make choices under uncertainty adopting internal frames, irrespective of the decision and outcomes available to them, bias will result in investment advice. Other notable behavioural biases including mental accounting and the House Money effect were shown to be examples of heuristics used in decision making when problems were presented in frames. Of note, behavioural biases that may influence risk attitudes are not limited to those aforementioned.

The analysis of internal frames being part of investment decision making for individual investors is restricted to superannuation portfolio construction advice and recommendations. We illustrated the unique aspects of superannuation investment and illustrated how the external framing of questions can result in biased results due to the internal frames individual investors adopt.

At present whilst there have been limited studies into the interaction of internal or self framing and the measurement of risk attitudes/tolerances, we believe the two complement each other. From the review of current practices it is apparent that framing of questions is unavoidable. This being the case, framing effects need to be recognised and considered in the interpretation of risk attitude results. Results of this process are critical in the financial advising process, as current and subsequent advice (asset allocation) is based on risk attitudes. Furthermore, the example of superannuation investing highlighted the need for a specific risk attitude profiling processes for individual classes of investment objectives. Generic risk attitude profiles may produce grossly biased responses that are economically contradicting.

This study is only the beginning of examining what constitutes internal frames and their impact on financial decision making. We believe that there should be some attempt to describe this empirically and on a more conceptual basis. This paper is will attempt to do so for the benefit of the financial services industry and investors.

## **Abstract**

*Credit risk is the possibility of loss incurred as a result of a borrower or counter party failing to meet its financial obligations. In the event of a default, a bank generally incurs a loss equal to the amount owed by the debtor, less any recovery amount resulting from foreclosure, liquidation of collateral or the restructuring of the debtor company. Credit risk prediction decisions are important for the financial institutions involved due to the high level of risk associated with wrong decisions. The process of making credit risk prediction decision is complex and unstructured. The existing models for prediction financial credit risk do not capture the learned knowledge well enough. In this study, we analyze the beneficial aspects of using fuzzy database for credit risk prediction decision.*

**Keywords:** *Fuzzy system; Credit risk prediction; Fuzzy database.*

## 1. Introduction

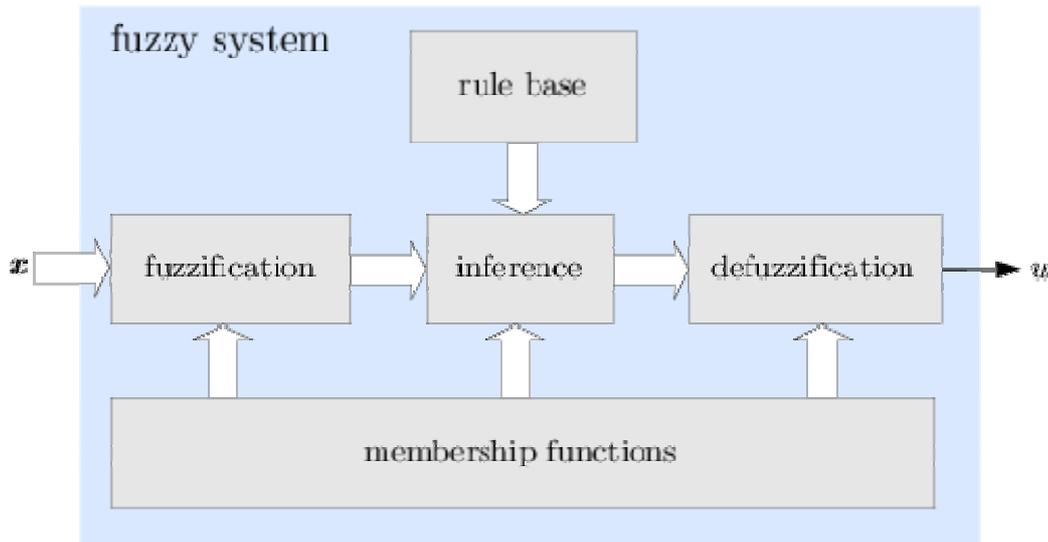

Credit risk is the risk of loss due to a counterparty defaulting on a contract, or more generally the risk of loss due to some "credit event". Credit risk is sometimes also called default risk. In business, almost all companies carry some credit risk, because most companies do not demand up-front cash payment for all products delivered and services rendered. Instead, most companies deliver the product or service, and then bill the customer, often specifying net 30 payment, in which payment is supposed to be complete on the 30th day after delivery. Credit risk is carried during that time. Managing credit risk is important for any company, and significant resources are devoted to the task by large companies with many customers (whether they be businesses or individuals). For large companies, there may even be a credit risk department whose job it is to assess the financial health of their customers, and extend credit (or not) accordingly [7].

In the process of analyzing credit-risk, the party involved in making the decision investigates factors that may lead to default in the repayment of loan. Credit-risk prediction decisions are inherently complex due to the various forms of risks involved. The existing models for prediction financial credit risk do not capture the learned knowledge well enough [1-3,5]. This paper analyzes the beneficial aspects of using fuzzy database system for credit risk prediction decision and organized as follows: Section 2 provides an overview of fuzzy system components and fuzzy database system for this problem. Section 3 includes a conclusion and future extensions of this study.

## 2. Fuzzy System

In this section, we briefly discuss the fuzzy database system as well as the components of this system and fuzzy search model. Fuzzy system is form a system that is easy to use, with good performance. Fuzzy system is drawn as a black box with some inputs and an output. Figure 1 shows the contents of a fuzzy system.

**Figure 1: Components of a fuzzy system.**

Now it is clear, what is in this black box. The input signals combined to the vector  $\mathbf{x} = [x_1, x_2, \dots, x_q]^T$  are crisp values, which are transformed into fuzzy sets in the fuzzification block. The fuzzification comprises the process of transforming crisp values into grades of membership for linguistic terms of fuzzy sets. The membership function is used to associate a grade to each linguistic term.

The output  $u$  comes out directly from the defuzzification block, which transforms an output fuzzy set back to a crisp value. Using a fuzzy system as a controller, one wants to transform this fuzzy information into a single value  $u^*$  that will actually be applied. This transformation from a fuzzy set to a crisp number is called a defuzzification. The set of membership functions responsible for the transforming part and the rule base as the relational part contain as a whole the modeling information about the system, which is processed by the inference machine. The core section of a fuzzy system is that part, which combines the facts obtained from the fuzzification with the rule base and conducts the fuzzy reasoning process. This is called a fuzzy inference machine. This rule-based fuzzy system is the basis of a fuzzy controller [4,6]. As well as fuzzy database system contains a fuzzy search model for our study, which is described bellow.

## 2.1. Fuzzy search model

A practical realization of fuzzy query required the development of a model, method, and algorithm of fuzzy querying in MS Access on the basis of FQUERY. The suggested system allow processing fuzzy queries of kind and the linguistic quantifier e.g. “above”, “approximately”, “good”, “very good”, “good enough”, “around” etc.

The implementation of the fuzzy query is done by the following formular:

$$Poss(a_1/a_2) = \max_u \min(\mu_{a_1}(u), \mu_{a_2}(u)) \in [0,1] =$$

$$= \begin{cases} 1 - \frac{ml_1 - mr_2}{\alpha_1 + \beta_2}, & \text{if } 0 < ml_1 - mr_2 < \alpha_1 + \beta_2 \\ 1, & \text{if } \max(ml_1, ml_2) \leq \min(mr_1, mr_2) \\ 1 - \frac{ml_2 - mr_1}{\alpha_2 + \beta_1}, & \text{if } 0 < ml_2 - mr_1 < \alpha_2 + \beta_1 \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

So by considering  $a_1, a_2$  as flat fuzzy numbers which  $a_1=(ml_1, mr_1, \alpha_1, \beta_1)$ ,  $a_2=(ml_2, mr_2, \alpha_2, \beta_2)$ . Where  $ml_1, mr_1, ml_2, mr_2$  are the mean values.  $\alpha_1, \beta_1$  and  $\alpha_2, \beta_2$  are the left and right spreads of the fuzzy numbers  $a_1$  and  $a_2$  respectively.

$\mu_{a_1}(u)$  and  $\mu_{a_2}(u)$  are membership functions of the linguistic values  $a_1$  and  $a_2$  respectively. By using Visual Basic for Application of MS Access, the membership functions are calculated (formula (1)).

## 3. Conclusion

Fuzzy systems, including fuzzy logic and fuzzy set theory, provide a rich and meaningful addition to standard logic. Many systems may be modeled, simulated, and even replicated with the help of fuzzy systems, not the least of which is human reasoning itself. In this paper we have analyzed the beneficial aspects of using fuzzy database system for credit risk prediction decision. The kernel of the discussed system is Access DBMS and programming language Visual Basic. The purpose of the future work will be addition of neural network control system to our present study.

## **Abstract**

*The ever changing environment in which banks exist and function generates new opportunities, but also more complex and various risks as a challenge for traditional banking management. The present paper focuses on the importance of banking risks management as a key factor of success for Romanian banks, especially on the background of new risk facets in the contemporary economy. Monitoring is seen as an important share of the management process in banks and the monitoring of credit risk is particularly highlighted in the paper. Low quality credits have a high disturbing potential and this is the reason for which their causes and possible solutions are brought into analysis.*

*In order to value the opportunities and face the exigencies and risks that the European integration process and the globalization phenomenon induce in the banking sector, Romanian banks must develop efficient systems for reviewing and reporting the implementation of their credit policy, the quality and characteristics of their credit portfolios being one of the key success factors of a bank.*

**Keywords:** *banking risks management; monitoring; credit risk.*

## **1. Introduction**

The ever changing environment in which banks exist and function generates new business opportunities, but also more complex and various risks as a challenge for traditional banking management. These risks are to be managed by banks as adequately as possible in order to face competition and foster economic growth in the private sector.

Banking risk is a phenomenon present in the entire banking sphere and represents the uncertainty of achieving a certain level of profit or the probability to incur a loss. Banking risk can be generated by various operations and procedures and must be analyzed as a complex of factors, often interdependent, with common causes and chain effects. It is permanently changing and evolving in its complexity, adding to the traditional components new ones such as financial, operational, strategic, country, human and fraud risks.

## **2. New facets of banking risks management in the contemporary economy**

The conditions that accompany the occurrence of banking risks are determined by a complex of factors which depend upon: the general economic trend, changes in the organizational structure of the bank, adopting financial decisions, political and economic circumstances. The occurrence of banking risks determines a decrease in profit and income for shareholders and, consequently, the bankruptcy of the bank or its acquisition by another bank.

The Basel Committee has identified eight categories of risks: credit risk, country risk, transfer risk, market risk, interest rate risk, liquidity risk, operational risk, legal risk and the reputation risk.

The contemporary era is dominated by the "risk management episode" in the banking system and risk management is a very important and difficult task for banks' management teams, covering a broad spectrum, from strategic planning of capital, asset and liabilities management to business management.

In order to generate profit, commercial banks must face risks that are specific to this process, while observing prudence requirements expressed by the national regulating authorities, justifying their exposure to risks and dimensioning risk in a way that the potential loss generated by its occurrence could be considered normal for the activity, for the internal and external

reputation of the bank. Banks must permanently monitor risks and balance sheet accounts. Their success in monitoring definitely depends on the organizational framework which should be likely to facilitate monitoring in particular and risk management in general.

We must point to the fact that banking literature does not draw a clear line between risk management instruments and monitoring instruments for the banking risks. We therefore consider it useful to distinguish between monitoring banking risks, i.e. identifying, assessing and controlling policies and practices regarding risk management in a bank, which allow for early detecting of potential problems and managing banking risks, i.e. the methods that are used for administrating banking risks with a view to eliminating, avoiding, dividing and financing them, as well as to decreasing exposure to risks. The demarcation line is even more important for banks management given the fact that high-quality monitoring of banking risks is likely to ensure the target area of risk management.

### **3. Exigencies regarding the use of monitoring tools and techniques for credit risk in Romania**

We consider that among the various risks that influence the activity of commercial banks in Romania, it is relevant to deepen the analysis of credit risk. Credit risk has been a factor with high destabilizing potential against the proper functioning of Romanian banks.

The environment in which Romanian banks function becomes more and more complex and intricate and leaves open way for tempting credit offers in terms of low exigencies regarding the quality of debtors and the required guarantees. This considerably increases the premises for credit risk to occur.

Credit risk can be defines as the probability of non-reimbursement or partial reimbursement for the interest, the principal or both of them. This type of risk is specific to banks whose main function is granting credits. No matter how high the level of assumed risks is, losses can be minimized if only credit operations are organized in a professional manner.

Credit risk must be assessed via comparison with the profit that the bank expects to gain by granting the credits; direct benefits consist of interests and fees charged against the principal, while indirect benefits consist of initiating or maintaining relationships with certain clients that are likely to open new deposit accounts or to require new and more diverse services.

The most important function of banking management is that aiming at the control and analysis of credit portfolio quality, given the fact that the low

quality of credits is one of the main causes of banks' bankruptcies and requires permanent informing of the managing boards on the results of the analysis process on credits quality. This allows for early detecting and correction of various problems.

The managing boards of Romanian banks should take care that the crediting function that they implement serves three fundamental objectives:

- credits are granted on a safe basis so that they will be reimbursed;
- the amounts are invested in a profitable manner to the benefit of shareholders and the protection of depositors with the bank;
- credit needs of the economic agents and natural persons are met.

It is also necessary to revise credit operations, given the fact that the integrity and the credibility of the crediting process depends on objective decisions that can ensure an acceptable risk level vis-à-vis the expected return. The revising must include a detailed credit analysis, the criteria on which granting credits is based, price policy, credit ceilings, guarantees for all types of credits, as well as methods for reassessing guarantees. Revising credit requests offers new clues on the quality of credit assessing systems.

We consider that the management teams of Romanian banks should pay attention to the important role that human resources play in this process, in order to better identify the personnel that is suitable for monitoring credit risk in terms of qualifications and skills.

There are also needed efficient systems for revising, reporting and informing the managing boards of banks on the way in which credit policies are implemented, on the quality and characteristics of banks' credit portfolios, which gives a picture of the market share, the demand for the products and services of a bank, its business and risk strategy, as well as its potential for granting credits.

In order to accomplish a correct analysis of the way in which the quality of credit portfolio evolves in time, and of the impact that it exerts on the profitability, capital adequacy of a bank and clients' trust, Romanian banks calculate the following categories of indicators for quantifying credit risk:

- $\text{non-reimbursed credits} / \text{total credits} \times 100$  : it is expected to get as close as possible to 0;
- $\text{low-quality credits} / \text{total credits} \times 100$  : the optimal value is the minimum one given the fact that low-quality credits negatively influence the activity and the financial results of banks and the economic system;

- reserves for credit losses/total credits x 100, this indicator shows the expectations of the managing board regarding the trend in the quality of credits portfolio;
- contingencies for credit losses/net losses x 100, this indicator reflects the level of prudence adopted by banks in performing their credit policy;
- gross profit/ contingencies for credit losses x 100, i.e. the cost incurred by a bank in order to cover the credit risk.

Romanian banks monitor the quality of their credits portfolio via periodical auditing depending on the credit rating depicted from the credit documentation. Monitoring allows for early detecting of potential problems generated by credits that do not generate income for the bank and that are considered as non-performing, when there are delays in the reimbursement of either principal and interests or both of them.

#### **4. Non-performing credits in the Romanian banking system - causes and solutions**

For a long period of time, the lack of performance in the crediting activity, as one of the main causes of the successive bankruptcies, has been present in the Romanian banking system.

There are certain reasons that can explain the worsening of the credits portfolio quality. The main explanations that have been identified for the Romanian banking system, especially for the period between 1990 and 1999 are:

- the "internal" crediting operations that consisted of granting numerous credits to banks' managers and shareholders, thus disobeying the sound crediting principles;
- disobeying sound crediting principles by consciously granting credits with high risks for hunting very high incomes in a competitive environment or because of personal conflict of interests;
- accepting and ignoring high risks in the idea that they will not come up anyway, which is a very frequent problem, especially that credits are the main source of income for banks;

- having incomplete and/or incorrect information regarding the solicitants and granting credits without a solid analysis of the client's financial situation;
- the lack of attention in supervising old, familiar clients, basing the credit granting on verbal information and not on financial evidence, by optimistic interpreting of weak points and the successful solving of problems in the past;
- ignoring alarm signals regarding the client, the economy, the region or the sector and refusing to apply the necessary laws and regulations at the appropriate time;
- inefficient supervision and incomplete knowledge of the client's activities and situation during the crediting interval, because it often happens that an apparently sound credit in the beginning turns into a problematic one and generates losses because of inadequate supervision;
- technical incompetence, consisting of the lack of capacity of credit officers to analyze financial documents, to collect and assess relevant data;
- weak credit selection process, consisting of: granting credits for which the amount offered by the bank out of the total investment cost exceeds clients' own capital; granting credits based on the assumption of successful finalization of a certain transaction and not on the quality of the client; granting credits to companies placed in problematic areas from an economic point of view; granting credits based on uncertain collaterals.

An important direction concerning the minimization of banking risks consists of maintaining a “granular” structure of the placement portfolio, which means drawing an optimal balance between assets, according to their potential degree of risk. From this perspective, one can suggest an optimal structure based on 30% of low risks credits and 30% medium risk credits. For high risk assets a level of 40% is usually calculated. On the other hand, banks must constantly aim at varying the attracted resources, especially in what deposits are concerned.

The capacity of Romanian banks' managing boards to correctly administrate banks' assets is a key factor for their success on the market. Given the fact that there are still low quality credits in the portfolios of Romanian commercial banks, it is obvious that they are preoccupied by identifying, monitoring and solving them along with minimizing their potential losses.

The portfolio of low-quality credits offers information on the quality of the total portfolio as well as on the crediting conditions of a certain bank. Its analysis points to the following aspects:

- the causes that have generated the worsening of the credit portfolio quality, which can contribute to identifying the possible corrective measures to be taken by the bank in the future;
- ranking low-quality credits according to their duration and types of clients, from the point of view of their sector of activity;
- assessing every low-quality credit in order to establish the actions necessary to improve the clients' capacity of reimbursing the credit and/or monitoring the schedule of reimbursement;
- assessing the impact of low-quality credits on the profit and loss account of the bank in order to anticipate the extent to which the bank could be affected by the worsening of its assets quality.

We must emphasize the fact that the main criterion for credit granting remains the client's capacity to generate positive cash-flows, as a primary source for reimbursement, thus placing on a second position the material guaranties.

In order to diminish risks, a periodical and strict analysis of the portfolio quality is necessary, as well as drawing up the necessary reserves. An immediate option could be the insurance of credits against the non-payment risk, made by specialized institutions (the Romanian Guarantee Fund for the private investors, the Rural Credit Guarantee Fund, Eximbank, insurance and re-insurance companies).

The credit risk dispersion can be achieved by unionizing the loans with other banks from Romania or abroad, as well as the diversification of clients and credit types. In order to avoid the danger of concentrating credits in a certain field of activity, it is necessary to establish some limits in exposure, on the basis of scoring type analysis models, according to the indices that are relevant for assessing various sectors' performance.

These indices could include, for example:

- non performing credits' share in total ongoing credits;
- the quality of the loans portfolio;
- the volume of risk-specific fare;
- the share of loans granted to the private sector in total credits.

## **5. Conclusions**

The changing environment in which Romanian banks function generates new business opportunities, but also more complex and diverse risks, which are a challenge for the traditional approaches of banking management.

A competitive market economy can only function with profitable, well-consolidated banks and well prepared to face multiple risks. We have considered necessary to distinguish between the management methods and the monitoring tools of banking risks and we have focused in the present paper on the instruments and techniques that are used for identifying, assessing and controlling policies and practices regarding the management of credit risk by the Romanian banks.

Credit risk must be assessed as compared with the profit that banks expect to gain when granting credits. The most important function of banking management is that aiming at controlling and analyzing the quality of credits portfolio, especially that the latter has been one of the main causes of banks' bankruptcies in Romania.

In order to value the opportunities and face the exigencies and risks that the European integration process and the globalization phenomenon induce in the banking sector, Romanian banks must develop efficient systems for reviewing and reporting the implementation of their credit policy, the quality and characteristics of their credit portfolios being one of the key success factors of a bank.

## **Abstract**

*The e-banking or on-line banking is a service provided by many banks and credit unions that allow to conduct banking transactions over the Internet using the information and communication technology. Continuing technological innovation and competition among existing banking organisations and new entrants have allowed for a much wider array of banking products and services to become accessible and delivered to retail and wholesale customers through an electronic distribution channel collectively referred to as e-banking. However, the rapid development of e-banking capabilities carries risks as well as benefits. To minimize legal and reputation risk associated with e-banking activities conducted both domestically and cross-border, banks should make adequate disclosure of information on their web sites and take appropriate measures to ensure adherence to customer privacy requirements applicable in the jurisdictions to which the bank is providing e-banking services.*

**Keywords:** *e-banking; risk; new banking products*

## 1. Introduction

Banking organisations have been delivering electronic services to consumers and businesses remotely for years. Electronic funds transfer, including small payments and corporate cash management systems, as well as publicly accessible automated machines for currency withdrawal and retail account management, are global fixtures. However, the increased world-wide acceptance of the Internet as a delivery channel for banking products and services provides new business opportunities for banks as well as service benefits for their customers.

But, can we appreciate that everything is ok in e-banking? *This study revealed that indeed ebanking could become the major form for payment systems in organizations as technologies will improve to create a fully secure environment.* In this moment, we believe that e-banking is only a supplement of traditional methods. This paper suggests, that not only is it probable to use e-banking but that networks (especially Internet) will promote the quick development of such a services.

Electronically-based payment systems have been in operation since the 1960s and have been expanding rapidly as well as growing in complexity. However, in most of the major industrialized countries, an inverse relationship exists between the volume and the number of transactions handled electronically. Typically, of business payments around 85-90% or more of monetary value will be processed electronically, while less than 5-10% of the total number of payment transactions will be handled in this way.

This has been due to four related factors: (1) proprietary closed networks were developed by banks to handle large and increasingly internationally based payments systems; (2) large value payments are increasingly associated with foreign exchange and global securities transactions, thereby becoming divorced from underlying world trade; (3) large value payment systems were not designed nor are they cost-effective for small value payments; and (4), paper-based non-automated payment systems remain an established part of accepted business practice for varying institutional reasons, thereby remaining ingrained in the economic system.

Electronic banking (e-banking) is the newest delivery channel of banking services. The definition of e-banking varies amongst researches partially because electronic banking refers to several types of services through which a bank's customers can request information and carry out most retail banking services via computer, television or mobile phone (Daniel, 1999; Mols, 1998; Sathye, 1999). Burr, 1996, for example, describes it as an electronic connection between the bank and customer in order to

prepare, manage and control financial transactions. Many authors appreciate that Internet banking (e-banking) is defined to include the provision of retail and small value banking products and services through electronic channels as well as large value electronic payments and other wholesale banking services delivered electronically.

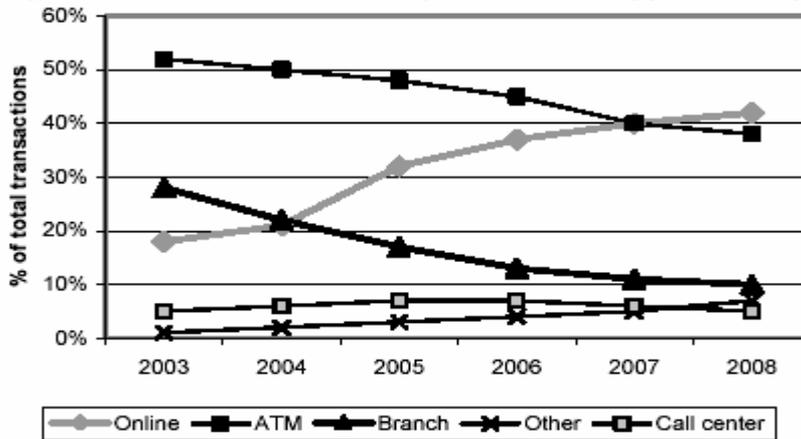

Electronic banking can also be defined as a variety of the following platforms: (a) Internet banking (or online banking), (b) telephone banking, (c) TV-based banking, (d) mobile phone banking, and (e) PC banking (or offline banking). In this paper, the ATM (Automated Teller Machine) channel is also added to the research.

## 2. Levels of e-banking business

According to researchers, in the late 2002, Internet bankers represented 37 percent of Internet users and online banking services now attract 18 percent of all European adults (Forrester, March 2003). Forrester projects that the number of Europeans using online banking will double to reach almost 130 million users in five years — a total of 21 percent. While online banking penetration in the Nordic countries and the Netherlands will climb to 60 percent of Net users in 2003, Italy and Greece, which had fewer than 5 percent of adults banking online a year before, struggled to achieve a situation with a third of Net users banking online in 2003.

According to Forrester, a typical European bank has the following perspective (Figure 1) — in six years the proportion of transactions made online will exceed 40% of all transactions, while the transactions in the traditional branches will be below 10% (Forrester, June 2003).

**Figure 1 Transaction volume by channel in a typical European bank**

Source: Forrester, June 2003

Despite their problems, some important steps are also in the developing countries where the average of e-banking penetration by the end of 1999 was close to 5% (World Bank Survey, 2001) and up to 15% in 2004. The Internet is experiencing rapid growth which is being largely driven by new commercial users of the network. Other commercial on-line services provided by companies such as CompuServe, America On-line and Prodigy are also expanding rapidly.

Continuing technological innovation and competition among existing banking organisations and new market entrants has allowed for a much wider array of electronic banking products and services for retail and wholesale banking customers. These include traditional activities such as accessing financial information, obtaining loans and opening deposit accounts, as well as relatively new products and services such as electronic bill payment services, personalised financial “portals,” account aggregation and business-to-business market places and exchanges. Notwithstanding the significant benefits of technological innovation, the rapid development of e-banking capabilities carries risks as well as benefits and it is important that these risks are recognised and managed by banking institutions in a prudent manner.

Generally we appreciate that there are three levels of e-banking business:

- ✚ **Basic information e-banking**/web sites that just disseminate information on banking products and services offered to bank customers and the general public;
- ✚ **Simple transactional e-banking**/web sites that allow bank customers to submit applications for different services, make queries on their account balances, and submit instructions to the bank, but do not permit any account transfers;
- ✚ **Advanced transactional e-banking**/web sites that allow bank customers to electronically transfer funds to/from their accounts pay bills, and conduct other banking transaction online.

In the past several years, many economists have considered the impact of the digital revolution on the money and banking system, and by extension the macroeconomy. Although many of the papers on e-money and e-banking have contained useful insights into these developments, they have also tended to paint an incomplete and even confusing picture. The application of information technology to money and banking raises many interesting questions. But to make further progress in understanding the economic effects, we need to advance in a very important area: what is the risk management for e-banking?

### **3. Categories of risk in e-banking**

In many ways, e-banking is not unlike traditional payment, inquiry, and information processing systems, differing only in that it utilises a different delivery channel. Any decision to adopt e-banking is normally influenced by a number of factors. These include customer service enhancement and competitive costs, all of which motivate banks to assess their electronic commerce strategies. The benefits of e-banking are widely known and will only be summarised briefly in this document.

E-banking can improve a bank's efficiency and competitiveness, so that existing and potential customers can benefit from a greater degree of convenience in effecting transactions. This increased level of convenience offered by the bank, when combined with new services, can expand the bank's target customers beyond those in traditional markets. Consequently, financial institutions are therefore becoming more aggressive in adopting electronic banking capabilities that include sophisticated marketing systems, remote-banking capabilities, and stored value programs. Internationally, familiar examples include telephone banking, automated teller networks, and automated clearinghouse systems. Such technological advances have brought greater sophistication to all users, commercial and "the man in the street".

A bank may be faced with different levels of risks and expectations arising from electronic banking as opposed to traditional banking. Furthermore, customers who rely on e-banking services may have greater intolerance for a system that is unreliable or one that does not provide accurate and current information. Clearly, the longevity of e-banking depends on its accuracy, reliability and accountability. The challenge for many banks is to ensure that savings from the electronic banking technology more than offset the costs and risks involved in such changes to their systems.

While financial institutions have faced difficulties over the years for a multitude of reasons, the major cause of serious banking problems continues to be directly related to lax credit standards for borrowers and counterparties, poor portfolio risk management or a lack of attention to changes in economic or other circumstances that can lead to a deterioration in the credit standing of a bank's counterparties.

Banks need to manage the credit risk inherent in the entire portfolio as well as the risk in individual credits or transactions. Banks should also consider the relationships between credit risk and other categories of risks. For any transaction on capital market, business or economic transaction in generally, there are seven categories of risk:

- Strategic;
- Credit;
- Market;
- Liquidity;
- Operational;
- Compliance/legal/regulatory;
- Reputation.

The most important category of risk management for e-banking services is operational risk. Operational risk is the risk of direct or indirect loss resulting from inadequate or failed internal processes, people and systems or from external events. The main causes for operational risk can be:

- ✚ Inadequate Information Systems;
- ✚ Breaches in internal controls;
- ✚ Fraud;
- ✚ Unforeseen catastrophes.

The inadequate information system can result from general risks or from application oriented risks. The general risks can include physical access to the hardware, logical access to the information and communication technology systems, emergency management or from an insufficient backup recovery measures-mitigate the consequences of system failures.

Application oriented risk can be one result of one from following error situation:

- Data not correctly recorded due to system errors;
- Data not correctly stored during period of validity;
- Relevant data are not correctly included;
- Calculations which are basis for information are not correct;
- Due to systems failures the information processed by the application is not available in time.

For the risk result from fraud management, at e-banking level, we can meet one of the following categories:

- ✚ Check fraud;
- ✚ Debit card fraud;

- ✚ Electronic Payment fraud;
- ✚ ATM Deposit fraud;
- ✚ Account Take-over/Identity Theft.

For e-banking are many obstacles in detecting fraud, like financial or human resource shortage, high volumes of claims, transactions or other information to be analyzed, cookie-cutter detection methods that miss new or unusual instances or lack of in-house expertise or training. According to Office of Comptroller of the currency, the proportion of national banks in the world that provide e-banking services, was 21% in 1999, 32% in 2000, 41% in 2001, 47% in 2002 and more than 50% at the end of the year 2002.

The reliable customer authentication is imperative for e-banking. Effective authentication can help banks reduce fraud, reputation risk, and disclosure of customer information and promote the legal enforceability of their electronic agreements. There are many methods to authenticate customers, like:<sup>1</sup>

- Passwords & PINS;
- Physical devices such as tokens;
- Biometric identifiers;
- Digital certificates & Public Key Infrastructures.

#### **4. The principal risk management challenges identified by EBG2**

The Electronic Banking Group of the Basel Committee on Banking Supervision (EBG) noted that the fundamental characteristics of e-banking (and e-commerce more generally) posed a number of risk management challenges:<sup>3</sup>

- The speed of change relating to technological and customer service innovation in ebanking is unprecedented. Historically, new banking applications were implemented over relatively long periods of time and only after in-depth testing. Today, however, banks are experiencing competitive pressure to roll out new business applications in very compressed time frames – often only

---

<sup>1</sup> Stoica, M., Risk management for E-banking, International Workshop IE&SI, Timisoara, 2003, p. 39

<sup>2</sup> EBG - The Electronic Banking Group of the Basel Committee on Banking Supervision

<sup>3</sup> see - [www.iwar.org.uk/pipermail/infocon/2003-July/000392.html](http://www.iwar.org.uk/pipermail/infocon/2003-July/000392.html)

a few months from concept to production. This competition intensifies the management challenge to ensure that adequate strategic assessment, risk analysis and security reviews are conducted prior to implementing new e-banking applications;

- Transactional e-banking web sites and associated retail and wholesale business applications are typically integrated as much as possible with legacy computer systems to allow more straight-through processing of electronic transactions. Such straight-through automated processing reduces opportunities for human error and fraud inherent in manual processes, but it also increases dependence on sound systems design and architecture as well as system interoperability and operational scalability;
- E-banking increases banks' dependence on information technology, thereby increasing the technical complexity of many operational and security issues and furthering a trend towards more partnerships, alliances and outsourcing arrangements with third parties, many of whom are unregulated. This development has been leading to the creation of new business models involving banks and nonbank entities, such as Internet service providers, telecommunication companies and other technology firms;
- The Internet is ubiquitous and global by nature. It is an open network accessible from anywhere in the world by unknown parties, with routing of messages through unknown locations and via fast evolving wireless devices. Therefore, it significantly magnifies the importance of security controls, customer authentication techniques, data protection, audit trail procedures, and customer privacy standards.

The e-banking risk management principles identified in the Report of EBG, fall into three broad, and often overlapping, categories of issues. However, these principles are not weighted by order of preference or importance. If only because such weighting might change over time, it is preferable to remain neutral and avoid such prioritization.

**A. Board and Management Oversight<sup>8</sup> (Principles 1 to 3):**

1. Effective management oversight of e-banking activities;
2. Establishment of a comprehensive security control process;
3. Comprehensive due diligence and management oversight process for outsourcing relationships and other third-party dependencies.

**B. Security Controls (Principles 4 to 10):**

4. Authentication of e-banking customers;
5. Non-repudiation and accountability for e-banking transactions;
6. Appropriate measures to ensure segregation of duties;
7. Proper authorisation controls within e-banking systems, databases and applications;
8. Data integrity of e-banking transactions, records, and information;
9. Establishment of clear audit trails for e-banking transactions;
10. Confidentiality of key bank information.

**C. Legal and Reputational Risk Management (Principles 11 to 14):**

11. Appropriate disclosures for e-banking services.
12. Privacy of customer information;
13. Capacity, business continuity and contingency planning to ensure availability of ebanking systems and services;
14. Incident response planning.

**5. Security is of major importance to all online consumers, not only for ebanking transactions.**

The main goal of any company is to maximize profits for its owners, and banks are no exception. Automated e-banking services offer a perfect opportunity for minimizing costs (see Table 3).<sup>4</sup>

---

<sup>4</sup>Olga Luštšik, Can e-banking services be profitable?, Tartu University Press, Tartu, 2004, p 26

**Table 1 Unit costs for transactions in different distribution channels**

Channel	Europe average (Forrester 2003)		US average (Booz 1996)		Nordea (Finland, Dynamo 2001)		Union Bank (Estonia, Toomla, 2003 )

*Source: Olga Luštšik, Can e-banking services be profitable?, Tartu University Press, Tartu, 2004, p 27*

According to a survey by Booz, Allen and Hamilton (1996), an estimated cost providing the routine business of a full-service branch in the USA is \$1.07 per transaction, compared to 54 cents for telephone banking, 27 cents for ATM and 1.5 cents for Internet banking. In the Nordea Bank, Finland, one online transaction costs the bank an average of mere 11 cents, compared to \$1 per transaction in the branch (Dynamo..., 2001).

The difference in net cost between the US and Finnish banks can be explained by Finland's smaller population and the scale effect in case of the USA. Forrester research (June 2003) covered Europe's largest banks and found that on average online transactions cost 14 times less than those made by branch tellers'.

Security is of major importance to all online consumers, not only for ebanking transactions. Though they also worry about unpleasant content or spam, their foremost concerns relate to security. Viruses, credit card number theft, interception of data, collection of personal details and identity theft received most mentions in a survey in the UK. The attitude is similar in most European countries.

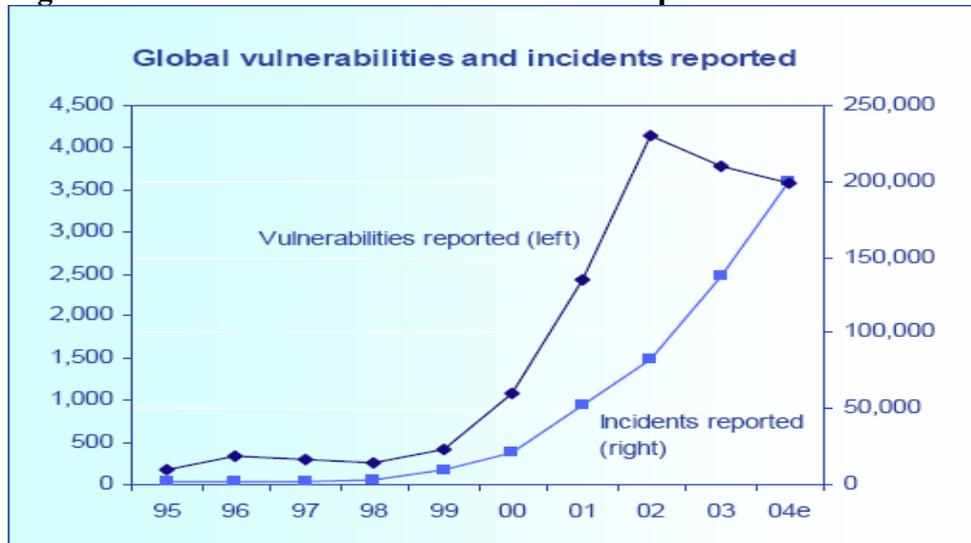

**Figure 2 Percentage of UK online consumers concerned about security**

Source: [www.forrester.com](http://www.forrester.com), 2004

Security vulnerabilities are part of web reality, however. The success of the internet has attracted a rising number of hackers and other scallywags. Given the wide-spread use of automated attack tools against internet-connected systems, the overall damage is potentially much larger than the reported vulnerabilities and incidents indicate at first glance.

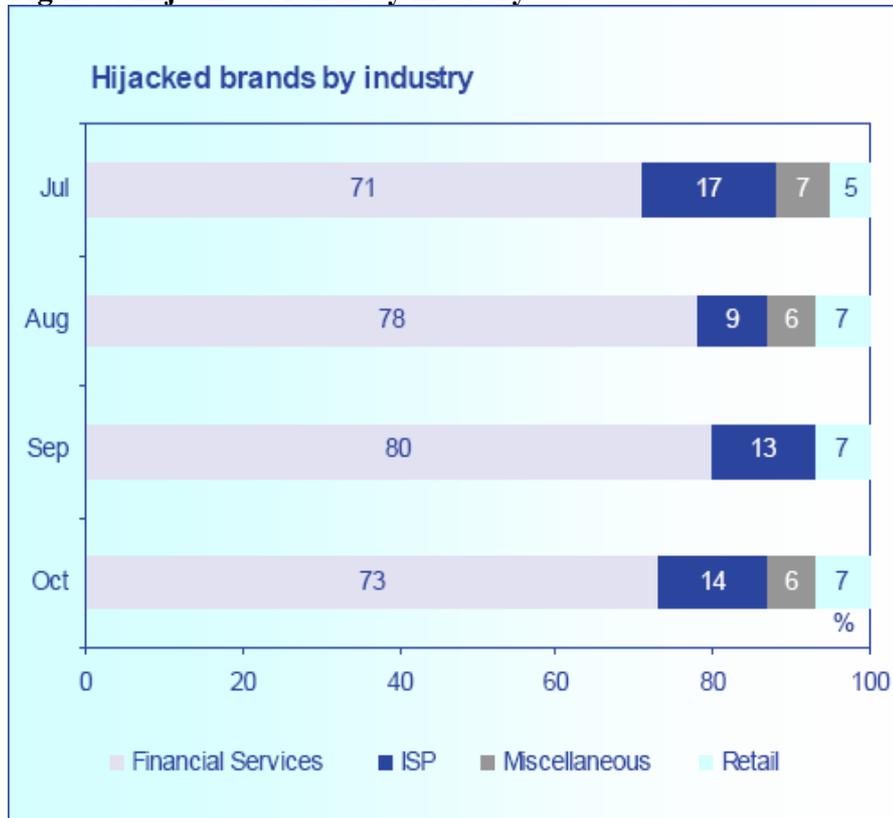

**Figure 3 Global vulnerabilities and incidents reported**

Source: [www.dbresearch.com](http://www.dbresearch.com), 2004

The most targeted industry for phishing attacks is financial services. This holds from the perspective of total number of unique baiting sites as well as from the number of companies targeted. The financial services sector represents 73% of all brands hijacked in October 2004. Sites of internet service providers (ISP) rank second with 14% in October, followed by retail brands.<sup>5</sup>

**Figure 4 Hijacked brands by industry**

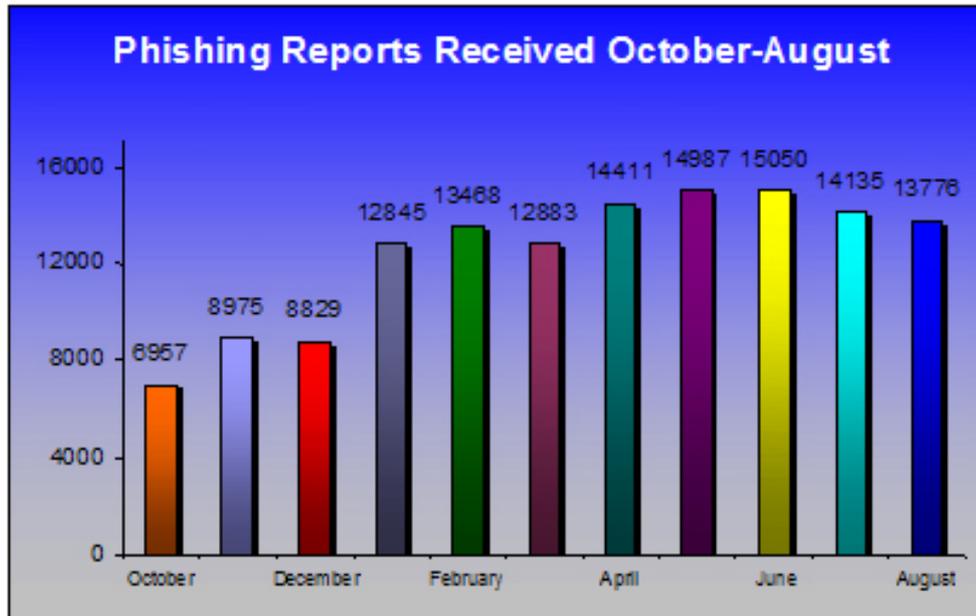

Source: *www.antiphishing.org*, 2004

Phishing attacks use both social engineering and technical subterfuge to steal consumers' personal identity data and financial account credentials. Social-engineering schemes use 'spoofed' e-mails to lead consumers to counterfeit websites designed to trick recipients into divulging financial data such as credit card numbers, account usernames, passwords and social security numbers.

<sup>5</sup> Deutsche Bank Research, E-banking snapshot, in Digital economy, no 12, dec 2004, available at <http://www.dbresearch.com/servlet/reweb2>

Hijacking brand names of banks, e-retailers and credit card companies, phishers often convince recipients to respond. Technical subterfuge schemes plant crimeware onto PCs to steal credentials directly, often using Trojan keylogger spyware. Pharming crimeware misdirects users to fraudulent sites or proxy servers, typically through DNS hijacking or poisoning.<sup>6</sup>

**Figure 5 New and Improved Phish Tracking 2005**

source: <http://www.antiphishing.org/>

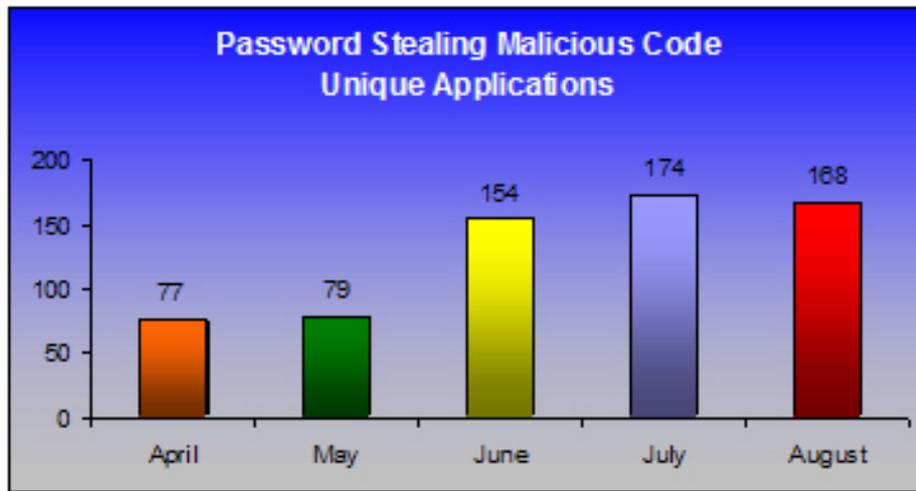

Also, the figures offer an important information: the crimeware growth remains strong.<sup>7</sup>

---

<sup>6</sup> see <http://www.antiphishing.org/>

<sup>7</sup> see <http://www.antiphishing.org/>

**Figure 6 The Crimeware growth remains strong**

source: <http://www.antiphishing.org/>

A bouquet of measures is necessary to meet the threat. Banks must combine multiple instruments to keep – or regain – their online customers’ trust. Only best practices should be followed to minimise the hazards. Technology is an important weapon, business processes must be analysed and improved, and – most important – customers should be educated and reassured.

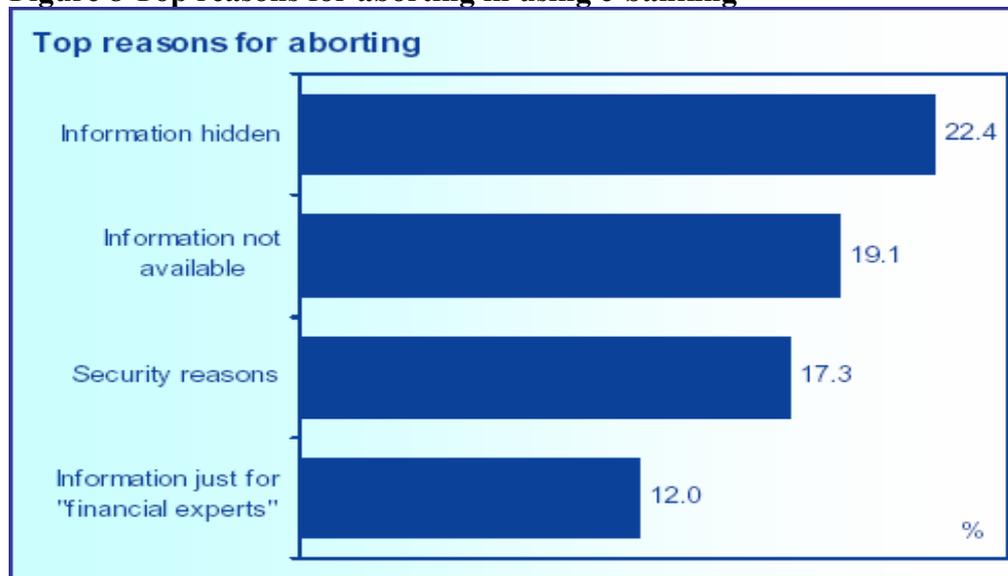

**Figure 7 Instruments to meet the threat**

Instruments to meet the threat	
<b>Technology</b>	Log analysis tools Alert services E-mail validation Web site verification
<b>Screening of customer contacts</b>	Check - Links in e-mails - 3rd party services for sending e-mails - Automated e-mail responses - E-mail campaigns
<b>Customer education</b>	Explain threats to customers Advise customers (technology and habits)

Source: DBR, Forrester, 2004

There is another important reason that could affect many potential users of e-banking. Complexity of online banking sites may turn customers away. A startling 92.6 percent of German internet users regularly abort their visits to bank websites according to an Emnid survey. The top reason for aborting is that they cannot find the information they are looking for because it is hidden or not available.

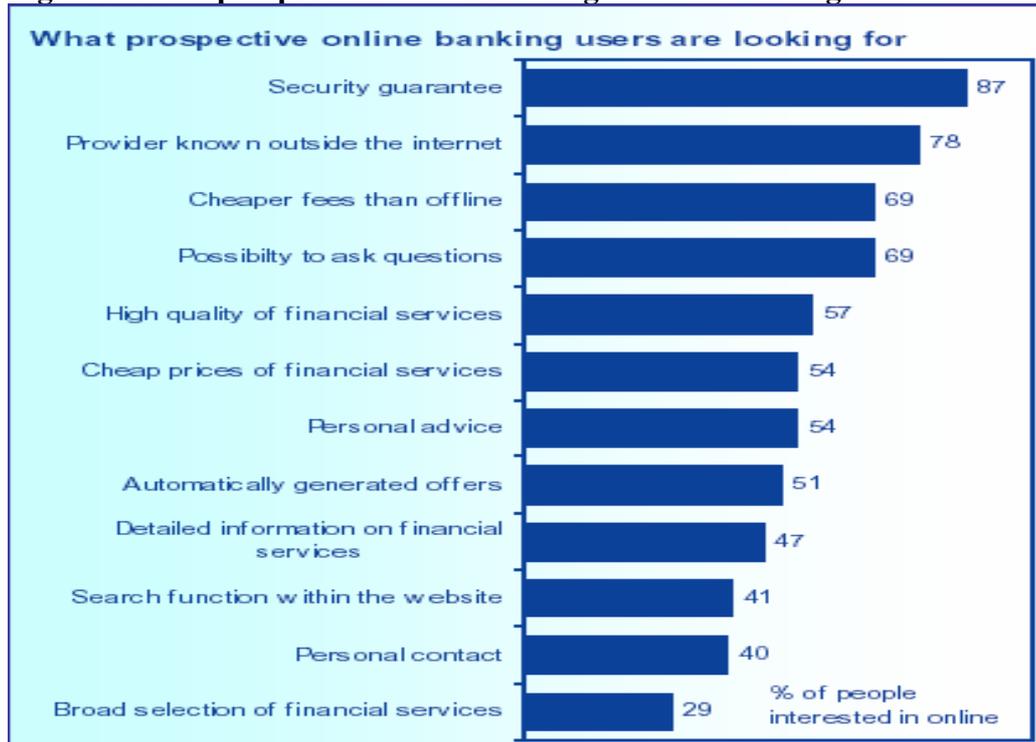

**Figure 8 Top reasons for aborting in using e-banking**

Source: <http://text.tns-global.com>

Banks should therefore convince more of their customers to go online. Of those offline customers who are interested in online banking, almost 90% find a security guarantee crucial. A well-known offline brand and relatively cheaper fees are also considered very important. Surprisingly enough, only 29% find a broad selection of financial services important in this context.

**Figure 9 What prospective online banking users are looking for**

Source: <http://text.tns-global.com>

## 6. Conclusion

The information technology (IT) revolution of the last 2 decades of the 20th century led to a proliferation of personal computers (PCs), servers, modems and other associated electronic data terminal equipment. The use of high bandwidth fiber optic cabling to provide integrated services coupled with modems and switching devices has improved speed of connection via the Internet and the growth in Internet Service Providers (ISPs) has increased accessibility.

This rapid growth and expansion of IT and telecommunication networks and interconnectivity encouraged the introduction of electronic services and non-more so than in the retail trade and in the provision of electronic banking.

Banks, like all other commercial organizations are in business, primarily, has to make a profit for their shareholders. Whilst banks have always offered the means of depositing and retrieving currency or currencies

for individuals, and usually within set opening hours, the fundamental business of banks is to make a profit from using monies on deposit within their system. They do this by buying or selling currencies at a mark-up, or mark-down depending on whether the customer is buying or selling and by loaning amounts of money at a predetermined or negotiated rate of interest. In addition, banks offer other services such as insurance cover, buying and selling securities, government bonds and stocks and shares.

All of these transactions have, until more recently, been conducted on the bank's premises and most transactions include a fee for financial services and advice. Now, through the advent of on-line services customers have greater choice and do not need to be tied to one financial institution or another. For example, customers can shop around, via the Internet, to find the best deal on home or car insurance, on interest rates on current and deposit accounts and, on buying and selling shares. Importantly, consumers can move banks if and when they do not receive the level of service they might reasonably expect from institutions that are handling their money. Indeed, it could be suggested that customer loyalty to one company or organization is dead and the idea of a 'one-stop-shop' for all financial services does not appear to make much sense unless that is the services on offer are highly competitive.

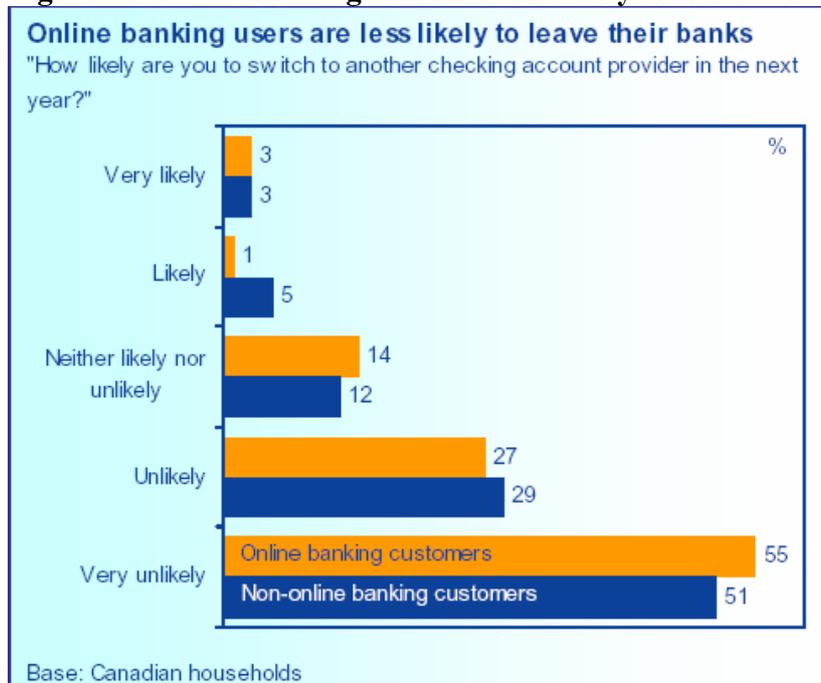

Over the last few years European banks have spent billions of euros on new electronic channels. However, after some years of excitement it was clear that the banks' long-awaited skyrocketing profits from this area would not be netted.

There are other drawbacks to the use of electronic systems. One of the biggest problem areas with Internet banking appears to be with the security and safeguarding of information exchanged between customer and bank. Indeed, the Federal Reserve Board of the US banking system expressed concern that the use of electronic banking could expose banks, their customers and their transactions to electronic interception and possibly interference leading to fraud. Therefore, banks need to conduct regular risk assessments, keep customers informed and, perhaps, be prepared to offer compensation if private information is made public.

With these entire problems one question is very important: online banking users are stimulated to develop or to leave their banks. Online banking users are less likely to leave their banks. Online banking appears to be the retail channel that is especially promising in cultivating customer loyalty: online banking users are less likely to switch their checking account provider than their offline counterparts. Only 4% of Canadian online households say they are likely or very likely to switch their provider. The corresponding figure for offline households is twice as high (8%). While

these results come from North American customers they are likely to also apply in the European context.

**Figure 10 Online banking users are less likely to leave their banks**

Source: [www.antiphishing.org](http://www.antiphishing.org), 2004

It's important to follow some important policy implications/recommendations:

1. Establish a comprehensive security control process.
  - ✚ Authentication of e-banking customers;
  - ✚ Appropriate measures to ensure segregation of duties;
  - ✚ Establishment of clear audit trails for e-banking transactions;
  - ✚ Non-repudiation and accountability for e-banking transactions.

2. Centralized-back office to free staff time in sales and services areas and to consolidate process consistently across the organization.

3. Develop automated credit authorization system by developing appropriate credit scoring system and cash-flow scoring system to reduce operating costs, improve asset quality, and increase client profitability. One of the major benefits of credit scoring system is that lenders can make credit decisions without necessarily obtaining financial statement, credit reports, or other time-consuming and hard-to-get information. In particular, the financial statements of SMEs are often not complete and difficult to get. Banks can more closely align their specific credit policies and marketing strategies with the analytics, making the decision process more cost-efficient. (I.e., Fair,

Isaac has developed a credit scoring system specialized in SME finance—SBSS 5.0 (small business scoring services), which has been increasingly used by many banks as their SME credit decision making model.)

4. Comprehensive due diligence and management oversight process for outsourcing relationships and other third-party dependencies.

5. Integrate cross-border e-banking risks into the bank's overall risk management framework.

6. Legal and reputational risk management

[1] Appropriate disclosures for e-banking services;

[2] Privacy of customer information;

[3] Capacity, business continuity and contingency planning to ensure availability of e-banking systems and services;

[4] Incident response planning;

[5] Segregation of duties;

[6] Due diligence on risk assessment

Risk identification and analysis should direct the bank to adopt appropriate oversight and review guidelines, operating policies and procedures, audit requirements, and contingency plans. These risks can be mitigated by adopting a comprehensive risk management programme that incorporates a sound strategic plan. Importantly, the extent of a financial institution's risk management programme should be commensurate with the complexity and sophistication of the activities in which it engages. Essentially, a bank which offers a simple information-only site is generally not expected to have undertaken the same level of planning and risk management as institutions that engage in more complex activities. Many of these risk categories have been identified in the Basel Committee's Core Principles for Effective Banking Supervision, published in September 1997.

E-banking presents new administrative control requirements and potentially increases the importance of existing controls. Management must evaluate its administrative controls to maximize the availability and integrity of e-banking systems. E-banking information can support identity theft for either fraud at the subject institution or for creating fraudulent accounts at other institutions. Institutions should consider the adequacy of the following controls:

- Segregation of e-banking duties to minimize the opportunity for employee fraud;
- Dual-control procedures especially for sensitive functions like encryption key retrieval or large online transfers;
- Reconciliation of e-banking transactions;
- Suspicious activity reviews and fraud detection with targeted review of unusually large transaction amounts or volumes;

- Periodic monitoring to detect websites with similar names, possibly established for fraudulent purposes;
- Error checks and customer guidance to prevent unintentional errors;
- Alternate channel confirmations to ensure account activity or maintenance changes are properly authorized;
- Business disruption avoidance strategies and recovery plans.

To protect banks against business, legal and reputation risk, e-banking services must be delivered on a consistent and timely basis in accordance with high customer expectations for constant and rapid availability and potentially high transaction demand. The bank must have the ability to deliver e-banking services to all end-users and be able to maintain such availability in all circumstances. Effective incident response mechanisms are also critical to minimise operational, legal and reputational risks arising from unexpected events, including internal and external attacks that may affect the provision of e-banking systems and services. To meet customers' expectations, banks should therefore have effective capacity, business continuity and contingency planning. Banks should also develop appropriate incident response plans, including communication strategies that ensure business continuity, control reputation risk and limit liability associated with disruptions in their e-banking services.

At the end, we must not forget that E-banking can not only improve the access to finance, but also:

- allows access to finance with better and more competitive rates;
- use online banking as new delivery tools to improve access to finance and alleviate financial constraints;
- as a regulatory authority, focus on core principles and Basle capital accord.

# LIQUIDITY RISK MANAGEMENT

**Victoria Firescu**

University of Pitești  
Street Targul din Vale, no. 1  
Pitesti, Arges, 110040  
Romania  
e-mail:firescuvictoria@yahoo.com  
telephone:+0040070035680

## **Abstract**

*Liquidity risk management is a key banking function and an integral part of asset liability management process. The importance of liquidity transcends the individual institution, because a liquidity shortfall at a single institution can have system wide repercussions. Banks are particularly vulnerable to liquidity problems, on an institution –specific level and from a systemic-market viewpoint. Diversification of funding sources and maturities enables a bank to avoid the vulnerability associated with the concentration of funding from a single source. The framework for liquidity risk management has three aspects: measuring and managing net funding requirements , market access and contingency planning.*

**Keywords:** *assets , liabilities, liquidity, banking legislation, , cash flow*

## **1. Introduction: The Need for Liquidity**

Liquidity represents a bank's ability to obtain needed funds to efficiently accommodate the redemption of deposits and other liabilities. The price of liquidity is a function of market conditions and the market's perception of the inherent risk of borrowing institution. It is in the nature of a bank to transform the term of its liabilities to different maturities on the asset side of the balance sheet. The actual inflow and outflow of funds do not necessarily reflect contractual maturities. A bank may therefore experience liquidity mismatches, making its liquidity policies and liquidity risk management key factors in its business strategy. Liquidity risk management therefore addresses market liquidity rather than statutory liquidity. A bank's net funding includes its maturing assets, existing liabilities and stand by facilities with other institutions. Liquidity risks are normally managed by a bank's asset-liability management committee (ALCO), which must therefore have a thorough understanding of the interrelationship between liquidity and other market and credit risk exposures on the balance sheet. Understanding the context of liquidity risk management involves examining a bank's approach to funding and liquidity planning under alternative scenarios. As a result of increasing depth of inter bank (money) markets, a fundamental shift has taken place in the attitude that the authorities have toward prudent liquidity management. Supervisory authorities now tend to concentrate on the maturity structure of a bank's assets and liabilities rather than solely on its statutory liquid asset requirements. The level of liquidity deemed adequate for one bank may be insufficient for another. Thereby, the liquidity lack problem could be solved but the real problem is obtaining the price of these liquidities. The lack of liquidities, although apparently a conjuncture factor results from a serial of structural correlation of the resources and investment of the bank.

## **2. Optimizing the bank activities by correlating the asset and liability operations**

In day-to-day operations the management of liquidity is typically achieved through the management of a bank's assets. In the medium term, liquidity is also addressed through management of the structure of a bank's liabilities.

Maturity mismatches are an intrinsic feature of banking, including the short-term liability financing of medium-term and long-term lending. The crucial question is not whether mismatching occurs-because it always does-

but to what extent, and whether this situation is reasonable or potentially unsound. Put another way, one can ask how long, given its current maturity structure, a bank could survive if it met with a funding crisis, and what amount of time would be available to take action before the bank became unable to meet its commitments. These questions should be asked by banks, regulators, and, ultimately policymakers. This aspect of liquidity risk management also implies that access to the central bank, as the lender of last resort, should be available only to solvent banks that have temporary liquidity problems. An increased mismatch could be due to problems in obtaining long-term funding for the bank or could reflect a deliberate decision based on the bank's view of future interest rate movements. For example, banks tend to increase their short-term mismatches if they expect interest rates to fall.

The focus of such an analysis is not only the size of the mismatch but also its trends over time, as these could indicate if the bank has a potential funding problem. If deposits are composed primarily of small stable accounts, a bank will need relatively low liquidity. A much higher liquidity position normally is required when a substantial portion of the loan portfolio consists of large long-term loans, when a bank has a somewhat high concentration of deposits, or when recent trends show reductions of large corporate or household deposit accounts. Also, bank should increase its liquidity position, when large commitments have been made on the asset side and the bank expects the client to start utilization. Liquidity needs usually are determined by the construction of a maturity ladder that comprises expected cash inflows and outflows over a series of specified time bands. The difference between the inflows and outflows in each period provides a starting point from which to measure a bank's future liquidity excess or shortfall at any given time. The success of the banking activities depends on the efficient binding between the assets and liabilities. The comparison and correlation can be realized considering:

- the resource mobilize and use
- the crediting price

The time of mobilization and use of the liquidities is strongly connected with the liquidity position of the bank being a way to work against the liquidity risk. To have liquidity conditions, the bank must assure the balance on every segment ( $A_1=L_1$ ;  $A_2=L_2$ ; .....;  $A_n=L_n$ ), not just the whole balance on ensemble ( $A=L$ ).

Table 1 presents a possible structure depending on the different time of use.

**Table 1**  
**The structure of the banking assets and liabilities on the different time of use.**

Period	Effective liabilities	Assets		Net liabilities		
		accumulated	Effective	accumulated	Effective	accumulated
-1 week	4800	4800	4200	4200	600	600
8days-1 month	6400	11.200	5000	9200	1400	2000
1-3 months	8600	19.800	5400	14600	3200	5200
3-6months	5800	25.600	4200	18800	1600	6800
6months-1year	2000	27.600	2400	21200	-400	6400
1-3years	1000	28.600	3400	24600	-2400	4000
Over 3 years	1400	30.000	5400	30000	-4000	0
	30.000	30.000	30000	30000	0	0

There is a seeming balance.

To truly appreciate the situation we will calculate the liquidity index.

The liquidity index =  $\Sigma$  counterbalanced liabilities :  $\Sigma$  counterbalanced assets

Between the assets and the liabilities there is a satisfying correlation if the counterbalanced liquidity index is 1 or close to it. If the index is far from 1 it means that covering long term assets out of short term resources ultimately represents an deficient management.

$$K = \frac{(4800 \times 1) + (6400 \times 2) + \dots + (400 \times 7)}{(4200 \times 1) + (5000 \times 2) + \dots + (5400 \times 7)} = \frac{92400}{117400} = 0,787 \quad (1)$$

The presented index is an instrument of global analyse. It is required the analyse out of distinct sequences that appear from the different engaging time of assets and liabilities.

The liquidity position is a low but talking index obtained through the difference between the liquidities and the assets and the liquid liabilities like "Net effective liabilities" out of table 1.

Another challenge for liquidity management is contingent liabilities, such as letters of credit or financial guarantees. These represent potentially significant cash outflows that are not dependent on a bank's financial condition.

The existence of multiple currencies also increases the complexity of liquidity management, particularly when the domestic currency is not freely convertible. In principle, a bank should have a management (i.e.,

measurement, monitoring and control) system for its liquidity positions in all major currencies in which it is active.

The liquidity index shows the commitments of the bank on the crediting market, the way that immediate reimbursing loans must be paid d from new resources.

The crediting price, the level of the current interest is an important criteria on correlating the assets with liabilities.

Obviously, the bank is interested in its working and performance the difference between the sum of the cashed and paid interest

In the condition when the bank practice is used on a relatively big scale the flowing interest we have the sensitive assets, liabilities, interest influenced by the market interest change.

To analyse the correlation between the assets and liabilities we must calculate the rate of sensibility as a report between the sensitive assets and liabilities. The below 1 rate expresses the bank dependence on the sensitive liabilities which can act in the direction of growth with the interest expense. In another way, the sensitive interest impact determines a difference between the assets and liabilities, a gap for which' s covering you must draw in resources.

To example, we take the following situation:

	<b>Interest rate</b>	<b>interest</b>
<b>Assets</b> <b>9800</b>	12,50%	1225
<i>Liabilities</i> 8600	10,90%	937,4
<i>Gap:</i>	1200	287,60

The coverage index of the lack of liabilities in sum of 1200 is calculated by operation:

The gap coverage rate:

$$\text{Interests: } \text{Gap} = 287,60 : 1200 \times 100 = 23,96\% \quad (2)$$

By some foreign authors opinion, the presented situation can be shown in the following way:

The bank is considered to have sensitive liabilities of 125.000 thousands m.u. with an 14% interest put in the situation of raising this interest at 16%.

It must be determined the minimal interest level in use the credits given this way in summarizing 110.000 thousands for which appliance in the beginning was an 17,5% interest. The bank has an 10.000 m.u. capital, unusable assets in sum of 45.000 m.u. out of 320.000 m.u.

The fixed interest is 10,5% on the liabilities and 15,5% on the assets. The bank estimated costs and bank profit of 7900 thousands m.u. By all this data the balance sheet equality is: :

$$45.000(\text{ unusable assets})+165.000(\text{fixed interest assets})+110.000(\text{sensitive interest assets})=320.000 \quad (3)$$

$$10.000(/\text{capital})+185.000(\text{fixed interest liabilities})+125.000(\text{sensitive interest liabilities})=320.000 \quad (4)$$

The income and expense equation is :

$$(A_{NS} \times D_{NS}) + (A_S \times D_S) = (P_{NS} \times D_{NS}) + (P_S \times D_S) + CPB, \text{ where:}$$

$A_S, P_S, D_S =$  assets, liabilities ,sensitive interests

$A_{NS}, P_{NS}, D_{NS} =$  assets, liabilities ,nonsensitive interests

$CPB =$  costs and bank profit

In the first place, we have:

$$(165.000 \times 15,5\%) + (110.000 \times 17,5\%) = (185.000 \times 10,5\%) + (110.000 \times 14\%) + 7900 = 44.825 \quad (5)$$

Because of the sensitive interest change, the equation becomes:

$$(165.000 \times 15,5\%) + (110.000 \times X\%) = (185.000 \times 10,5\%) + (110.000 \times 16\%) + 7900 = 44.825 \quad (6)$$

$$A_S \times D_S = 44925 - (165.000 \times 15,5\%) = 19.350 \quad (7)$$

$$D_S = (A_S \times D_S) : A_S \times 100 = 19.350 : 110.000 \times 100 = 17,59\% \quad (8)$$

It is observed that the engaging of the assets and liabilities do not change.

The interest level modifying goes to expense modifying, which determines a fit of the income based on the sensitive interest. Banking legislation normally contains specific liquidity requirements that banks must meet. These prudential requirements should not be viewed as the primary method for the management of liquidity risk; the opposite in fact is true.

Typical liquidity regulations are:

- a limit on the loan-to-deposit ratio;
- a limit on the loan-to-capital ratio;
- guidelines on sources and uses of funds;
- liquidity parameters; for example, the liquid assets should not fall below "x" percent or rise above "y" percent of total assets;

- a percentage limit on the relationship between anticipated funding needs and available resources to meet these needs; for example, that the ratio of primary sources over anticipated needs should not fall "x" percent.
- a percentage limit on reliance on a particular; for example, that negotiable certificates of deposit should not account for more than "x" percent of total liabilities.
- limits on the minimum/maximum overage of different categories of liabilities; for example, the average maturity of negotiable certificates of deposit should not be less than "x month"

### **3. Liquidity Risk Management Techniques**

Banks should regularly estimate their expected cash flows instead of focusing only on the contractual periods during which cash may flow in or out.

An evaluation of whether or not a bank is sufficiently depends on the behavior of cash flows under different conditions.

Liquidity risk management must therefore involve various scenarios.

The "going-concern" scenario is ordinarily applied to the management of a bank's use of deposits.

A second scenario relates to a bank's liquidity in a crisis situation when a significant part of its liabilities cannot be rolled over or replaced.

A third scenario refers to general market crises, wherein liquidity is affected in the entire banking system, or at least in a significant part of it.

Table 3 provides a simple forecasting tool for liquidity needs under normal business conditions, under conditions of liquidity crisis and under conditions of general market crisis.

Diversified liabilities and funding sources usually indicate that a bank has well-developed liquidity management. The level of diversification can be judged according to instruments types, by type of fund provider and geographical markets

All banks are influenced by economic changes, but sound financial management can buffer the negative changes and accentuate the positive ones.

In practice, however, it may be difficult to obtain funding when a dire for it exists. Certain unusual situations also may have an impact on liquidity risk, including internal or external political upheavals, seasonal effects, increased market activity, sector problems and economic cycles.

Management must have contingency plans in case its projections prove to be wrong. Effective planning involves the identification of minimum

and maximum liquidity needs and the weighing of alternative courses of action to meet those needs.

Large banks normally expect to derive liquidity from both sides of the balance sheet and maintain an active presence in inter bank and other wholesale markets. They look to these markets as a source for the discretionary acquisition of short-term funds on the basis of interest rate competition, a process that can help them meet their liquidity needs. Conceptually, the availability of asset and liability options should result in a lower cost for liquidity maintenance. The costs of available discretionary liabilities can be compared to the opportunity cost of selling various assets, since banks also hold a range of short-term assets that can be sold if necessary. These assets also serve as reassurance to the potential suppliers of funds, thus enhancing a bank's ability to borrow.

The major difference between liquidity in larger and smaller banks is that, in addition to deliberately determining the asset side of the balance sheet, larger banks are better able to control the level and composition of their liabilities. They therefore have a wider variety of options from which to select the least costly method of generating required funds. Discretionary access to the money market also reduces the size of the liquid asset buffer that would be needed if banks were solely dependent upon asset management to obtain funds.

When large volumes of retail deposits and lending are at stake, outflows of funds should be assessed on the basis of probability, with past experience serving as a guide. Banks with large volumes of wholesale funds can also manage liquidity through maturity matching. This means that an appropriate degree of correspondence between asset and liability maturities must be sought, but not that an exact matching of all assets and liabilities is necessary.

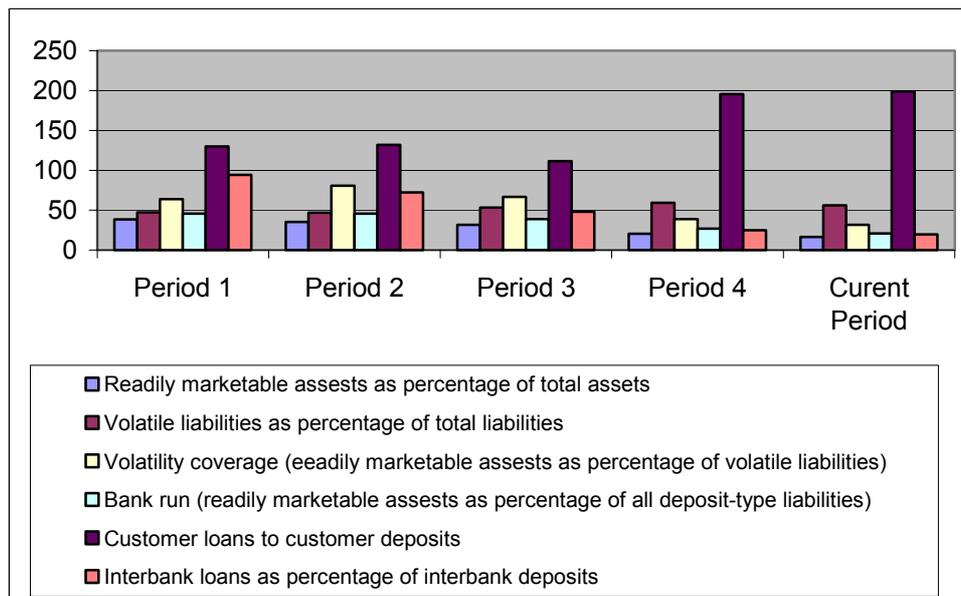

Figure 1 and Table 2 illustrate the liquidity management of a bank and the bank's liquidity position has deteriorated over time.

**Table 2 Liquidity ratios-percent**

<i>Liquidity</i>	<i>Period 1</i>	<i>Period 2</i>	<i>Period 3</i>	<i>Period 4</i>	<i>Current Period 4</i>
<i>Readily marketable assets as percentage of total assets</i>	38,5	35,40	231,79	20,53	16,31
<i>Volatility liabilities as percentage of total liabilities</i>	47,74	46.85	53,28	59,17	55,99
<i>Volatility coverage</i>	63,89	80,66	66,70	38,88	31,44
<i>Bank run</i>	45,77	45,68	38,67	26,62	20,94
<i>Customer loans to customer deposits</i>	130,06	132,05	111,62	195,68	198,82
<i>Inter-bank loans as percentage of inter-bank deposits</i>	94,24	72,54	78,20	24,64	19.60

The percentage of loans funded from the bank's own sources has steadily decreased. In contrast, the percentage of volatile liabilities has increased and volatility coverage has become significantly worse.

**Fig. 1 Liquidity position of a bank**

In reality, a bank's position and reputation within the financial community influence its liquidity options. This connection is based on many factors, the most crucial of which is the bank's past and prospective

profitability. Properly understood, a maturity profile can be a useful indicator of a bank's position and may yield important information, for example when a sudden increase in maturity mismatches occurs. However, maturity profiles should be analyzed in conjunction with information about the bank's off-balance-sheet business, management objectives and systems of control.

**Table 3 Maturity ladder under alternative scenarios**

	<i>Normal Business conditions</i>	<i>Bank specific crises</i>	<i>General Market- Crisis</i>
<i>Maturing asset(contractual)</i>			
<i>Interest receivable</i>			
<i>Asset sales</i>			
<i>Draw downs</i>			
<i>Other(specify)</i>			
<i>Cash inflows</i>			
<i>Total inflows</i>			
<i>Maturing liabilities(contractual)</i>			
<i>Interest payable</i>			
<i>Disbursements on lending commitments</i>			
<i>Early deposit withdrawals</i>			
<i>Operating expenses</i>			
<i>Other(specify)</i>			
<i>Total outflows</i>			
<i>Liquidity excess(shortfall)</i>			

Although the acquisition of funds in a market at a competitive as profitable banks to meet the expanding customer demand for loans, the misuse or improper implementation of liability management can have severe consequences.

Preoccupation with obtaining funds at the lowest possible cost and with insufficient regard to maturity distribution can greatly intensify a bank's exposure to the risk of interest rate fluctuations.

Another critical aspect of liquidity risk management is dependence on a single source of funding, known as concentration risk. A bank has a few large depositors and one or more withdraw their funds, enormous problems will occur if alternative sources of funding cannot quickly be found. Most banks therefore monitor their funding mix and the concentration of depositors very closely, to prevent excessive dependence on any particular source. The sensitivity of banks to large withdrawals in an uncertain environment cannot be overemphasized. Regulators increasingly are focusing on mismatches in liquidity flows and on the ability of banks to fund such mismatches on an

ongoing , rather than on statutory liquid assets and traditional access to the central bank.

An appraisal of a bank therefore must give adequate attention to the mix between wholesale and retail funding and , in connection to this, to the exposure to large depositors and whether or not an undue reliance on individual sources of funds exists. By calculating the percentage of the short-term mismatch that large deposits represent an analyst can obtain a picture of the sensitivity of the bank or of the banking sector as a whole to withdrawals by large supplies of funds. The proportion of wholesale funding to retail funding is another means of measuring sensitivity to large depositors. Overall, the increasing volatility of funding is indicative of the changes in the structure and sources of funding that the banking sector is undergoing.

To assess the general volatility of funding, a bank usually classifies its liabilities as those that are likely to stay with the bank under any circumstances; for example, enterprise transaction accounts and those that can be expected to pull out if problems arise. The key issues to be determined for the latter are their price sensitivity, the rate at which they would pull out and which liabilities could be expected to pull out at the first sign of trouble.

## **5. Conclusions**

The changes that appear necessary within the bank's culture and managerial practices, given the nature and relative complexity of liquidity risk management, , including as applicable:

- the need for full sponsorship by the board and executive management;
- the necessary enabling culture in which every manager is expected to consider risk, that is, to identify, measure and report on risk exposure;
- the changes that appear necessary after the assessment of evaluation, monitoring and reporting systems that cover critical risk functions.
- the convenience of adopting appropriate risk objectives for each function and for the bank as a whole;
- the need to institute a formal process for the general manager and the board to review and evaluate all expected and unexpected liquidity risks;
- the convenience of designating a member of senior executive management for overseeing the liquidity risk;

## **Abstract**

*The last research on dynamic demand for local public goods depending on the median voter does not give value to the transformation of the capital structure and the nature of the local public goods. Those reports admit the static hypothesis of a median voter's model based on the total consumption of his own income in each period. However, that is not realistic because the median voter demand depends on the level of public goods available. As a result, this demand changes and becomes intertemporal. Indeed, the median voter does not totally consume his income in each period, but he saves a share which constitutes the intertemporal constraint of the decisive agent. On the other hand, the time introduction operates on the local public good nature of which use extends throughout many periods of time (durable local public goods). However, this capital accumulation involves the municipality to plan the recurrent charges in order to assure the continuity of the use of local public goods. The dynamic of cost operation is similar to a technical debt.*

**Keywords :** *Budgetary dynamic, Financial gearing, Local public account, Durable local public, Median voter.*

## 1. Introduction

The modelization of the financial behaviour of the local communities lies on a basis model of the median voter. In that very static model, the expense in local public goods of the local community is immediately covered by the local tax that balances the budget each year. For that reason, the static modelisation of the expensive choice doesn't mark out the operation section of the budgets.

Nonetheless, time is a mechanism that doesn't make immediacy possible. Indeed, every choice made in the real world involves a postponement between the end of an action and the instant the decision was made. The consumption of the durable goods, like the local public good, takes a long time. From that point of view, taking into account the temporality needs to consider the investment line of the budgets. From that moment on the issues of investment and of its financing are raised. As an aftermath, the intertemporal local expensive choice of the median lies an optimal arbitrage of the means of financing which are, for instance, local tax ( final ressource ) and borrowing (temporary ressource).

However, the credit standard and the disappearing of the financial gearing from the mid 80's (Guengant, Josselin, 1999) led the local communities to focus to the recent times on fiscal levy to the detriment of public loan. Within the context of weak interest rates and of a financial environnement fueled by the competition of european financing sources, arbitrary in favor of public loan could help local communties to benefit a lever effect, in the sens of Modigliani-Miller (M-M, 1958). Furthermore, the use of public loan rather than tax has the advantage of postponing the burden between the current and future taxpayers ( tax effect) or to pre finance a fiscal feed back on investment thanks to the increase of the future bases (basis effect). Choosing public loan cannot be considered as a will be to spare the current taxpayer or to postpone the consequences of investing : constructing a secondary school or residences will be useful to many generations of users/taxpayers.

This paper is about the choice of the funding structure concerning the investment request for local public goods. This investment request can be seen as the result of the preference of the median voters since Borcharding and Deacon (1972).

The investment decision requires from the local government a correct estimate of the demand for local public goods. In dynamics, the risk of inadequacy between demand and supply for local public goods is showed trough the increase of the local tax deduction on taxpayers. From this point of view, we can wonder about the budgetary impact of a misjudgement of the demand for local public goods. Indeed, the risk of overvaluation of current

and future demand can lead to a possibility of insolvency of the local public budgets.

The dynamic analysis for demand of local public goods the medium voter pattern is a very new theme in France. Most of the patterns made so far have been instant section (Rosa, 1984 ; Rocaboy, 1994 ; Baudry, Leprince and Moreau, 2001 ; Métais, 2001).

During the last decade many reports have been published in the United States, Sweden, Norway and Finland<sup>1</sup>. The authors tried to verify on the empirical view the existence of the intertemporal decision at a local level. But all those searching studies have in common to keep on the theoretical level the hypothesis of the static model of the media

This paper is different from those searching studies in two main aspects: the introduction of the concept of stock required by the median in each period and the local budgetary dynamic. Indeed, in lack of public loan, the annual equality of outgoings and incomings is a condition of budget static balance. The opportunity to borrow changes the nature of the balance. The opportunity to borrow changes the nature of the balance, that must be analyse in a pluriannual perspective. The time introduction operates on the nature of the local public good whom use extends throughout many periods of time.

Thinking from a financial behavior conception in terms of flows to a conception in terms of stocks causes a change in the use of the local public good that's now extended throughout time. The durable goods will be analysed in the first part. Then, in a second part, we shall go root from the model of medium static demand to a general model of intertemporal demand general pattern.

## **2. Frame of theoretical analysis : theory of durable goods and dynamic budgetary**

In definition, in the static model, only one period was mainly taken in account. From this moment, we tried to determine on the one hand, the level of the publics goods required, on the other hand the level of public goods which was offered. In the current case, we have to notice that the local public good inherently does services in a sequence of periods. Therefore, the local public good can be considered as a durable good. we considered one period and the we searched to find in the one hand the level of public demanded, and the other hand the level offered by the municipality. Here, we must to take in

---

<sup>1</sup> See Holtz-Eaking and Rosen ( 1989-1991,1993) ; Holtz-Eaking and al. (1994); Newey and Rosen (1989); Dahlberg-Johansson (1998-2000); Borgea and al.(1993, 1996); Borge-Tovmo (2001); Moisisio (2002).

account the nature of local public good which isn't short-lived but gives back some services on rest of period. So local public goods can be considered as durable goods.

Durable goods help a long, lasting use throughout time, contrary to non durable goods, subject of the median static model.

Furthermore, the imposition of the median electorate involves that they consume their whole income in each period. However, this is simplifying enough insofar as the median makes a request which depends on the level of the public goods available. The consequence is that the request of the median electorate changes and becomes intertemporal. The income of the median is not entirely consumed in each period. There is percentage saved which is going to allow to constitute the intertemporal imposition of the decisive agent.

So, it's interesting to notice how the median, who should represent the local community, makes his expense choice when the analysis period goes beyond the year. For the same reason that it's possible to adapt the consumer choice standard theory to the intertemporal choice study, it's also possible to extend the median model to a dynamic model of local expensive choices.

### ***2.1. Dynamic pattern of the local financial behaviors***

All along the local communities existence, theoretically never-ending, the median voter remain decisive. He has an intertemporal preference function,  $U$ , defined as such :

$$U_t = u(x_{m_t}, k_t) \tag{1}$$

With,  $t = 1, 2, 3$  to write it simply;  $x_{m_t}$  is the median private consumer;  $k_t$  correspond to the local public facilities stock desired by the median during the period  $t$ . In order respect, in dynamic, the reasoning involves to consider local public facilities stock,  $K_t$ , more or less divisible. So, we get the following division function on the local communities :

$$k_t = \frac{K_t}{N_t} \tag{2}$$

Moreover, in the static pattern, the median income was totally divided in every expense without considering the possibility to delay or advance the purchase day. So, he spends a part of his income to spare that could be used to increase money ingoings or to purchase financial assets.

If  $s_t$  spare at  $t$  periods,  $y_{mt}$  the median private income,  $T_t b_{mt}$  the tax paid by the median to finance public facilities of the period.

To explain the median intertemporal behaviour, it's easy to reason in the frame of a simplified pattern where the choices are taken back on 3 periods marked out by three dates  $t = 1, 2$  and 3. The current period for future date. We put :

$$s_1 = y_{m1} - x_{m1} - T_1 b_{m1} \quad (3)$$

$$s_2 = (1 + r_1)s_1 + y_{m2} - x_{m2} - T_2 b_{m2} \quad (4)$$

$$s_3 = (1 + r_2)s_2 + y_{m3} - x_{m3} - T_3 b_{m3} \quad (5)$$

We get :

$$s_3 = (1 + r_2)(1 + r_1)[(y_{m1} - x_{m1} - T_1 b_{m1}) + (y_{m2} - x_{m2} - T_2 b_{m2})] + y_{m3} - x_{m3} - T_3 b_{m3} \quad (6)$$

Where  $r_t$  indicates the real interest rate, measuring the median net gain when he delays his consumer. The median voter wins because of the nominal interest rate that pays for saving later, but he may lose if the prices increase.

If the median is selfish, there'll be no heritage. The equation will then be written  $s_3 = 0$ . The intertemporal budgetary constraint of the median expressed in the present values will be:

$$x_{m1} + T_1 b_{m1} + \frac{x_{m2} + T_2 b_{m2}}{1 + r_1} + \frac{x_{m3} + T_3 b_{m3}}{(1 + r_1)(1 + r_2)} = y_{m1} + \frac{y_{m2}}{(1 + r_1)} + \frac{y_{m3}}{(1 + r_1)(1 + r_2)} \quad (7)$$

From that point of view, the present value of the median public and privates consumer expenses match the current value of the future incomes.

But, supplying local public utilities ( LPU), to the users needs to produce them be for. Also, the median is confronted to a technical constraint by the production function.

### 2.1.1. Production function of the LPU

It's distinguished by a coefficient of capital  $v$ , and a coefficient  $u$  associated to the repeating costs of intermediary consumers (IC) and salaries (S). By hypothesis, the production is made at constant factor. Then, a combination of production is described by the input, postulating a wasteless production :

$$Z_t = K_t^\Theta \quad (8)$$

$\Theta$  indicates the production scale output that can be constant ( $\Theta=1$ ), decreasing ( $\Theta<1$ ) or increasing ( $\Theta>1$ ). Within simplified calculations, the outputs are constant.

### 2.1.2. Dynamic of development costs

The production of LPU creates an annual total cost that can be broken down into an annual variable cost (intermediary consumers and salaries) and an annual permanent cost ( hiring gross price of fixed assets).

In the frame of an efficient production of collective utilities, the variable cost in volume correspond to a determined proportion of the capital ( $v_t$ ):

$$CV_t = v_t K_t \quad (9)$$

As for the annual permanent cost, if we take into account the hiring gross price fixed assets is made of the economic profit and the depreciation provision on full year ( $K_t/m_t$ ,  $m_t$  certain duration of use). If the asset evaluation by the local community by the flow ( economic profit rate) he makes in one year, we get the recurrent permanent cost :

$$CF_t = \left( r_t^e + \frac{1}{m_t} \right) K_t \quad (10)$$

$r_t^e$  indicates the profit rate of the local community total asset. Then, it comes from the permanent total cost :

$$CT_t = \left( v_t + r_t^e + \frac{1}{m_t} \right) K_t \quad (11)$$

From that point of view, in addition to the necessary financial debt to finance the local collective investments, the concept of permanent expense points out the obligation for the local community to provide future amounts to assure the continuity and the maintenance of the local public utilities. They can be analysed as a technical debt. So we have a double dynamic of development permanent charges and an induction dynamic of financial charges.

De facto, the local community budgetary constraint can be done by the accounting links coming from internal mechanisms of the budget operation : connection of the operation and investment sections.

### 2.1.3. Accounting balance of the operation section

First and foremost, the balance of the operation section is secured when the operation section is secured when the operation receipts match the operation expenses :

$$T_t B_t + G_t = CT_t \Leftrightarrow T_t B_t + G_t = \left( v_t + r_t^e + \frac{1}{m_t} \right) K_t \quad (12)$$

If the difference is positive, the local community redeems a gross saving ( $EB_t$ ) which, on an accounting level, is made of the depreciation provision ( $DAP_t$ ) and profit or loss for the financial year ( $RES_t$ ) :

$$EB_t = DAP_t + RES_t \quad (13)$$

However, the equation doesn't help to overview the other dynamic described at the previous paragraph, i.e. the dynamic of financial debt. To put it right, an help to a decomposition of the economic profit rate is done. On the one hand, the interest rate of the debt and the other hand the financial profit rate. That difference of profit rate refers to the financial gearing by M-M (1959).

Indeed, the structure of the local community asset ( $K_t$ ) written at the liabilities is made of debt stock, the public facilities subventions and the net saving or self financing.

Supposing that the long-term capital cover & employment stable” (gross values of capital assets), it’s now :  $K_t = K_t^p + D_t$  (14)

With,  $K_t^p$  for Am stockholders’ equity.

Flow-stock induction of the permanent financial charges helps to link every part of financial sheet to a flow.

As it is, at the credit of the financial sheet, the local community asset is associated to the economic result that results from the profit or loss for the financial year and the financial costs. To the liabilities the debt stock is associated to financial charges flow ( $FF_t$ ). We successively obtain :

- The median interest rate :

$$i_t = \frac{FF_t}{D_t} \quad (15)$$

- The financial profit rate :

$$r_t^f = \frac{RES_t}{K_t^p} \quad (16)$$

- The economic profit rate :

$$r_t^e = \frac{RES_t + FF_t}{K_t} \quad (17)$$

By the hypothesis of financial markets efficiency, we deduce the equation of financial gearing:

$$r_t^f = r_t^e + (r_t^e - i_t) \frac{D_t}{K_t^p} \quad (18)$$

From the equation (12), (14) and (18), the accounting balance constraint is as such :

$$T_t B_t + G_t = \left( v_t + r_t^f + \frac{1}{m_t} \right) K_t + (i_t - r_t^f) D_t \Leftrightarrow T_t B_t + G_t = v_t K_t + i_t D_t + \frac{K_t}{m_t} + r_t^f (K_t - D_t) \quad (19)$$

$$T_t B_t + G_t = v_t K_t + i_t D_t + \frac{K_t}{m_t} + r_t^f (K_t - D_t) \quad (20)$$

$$\Rightarrow EB_t = \frac{K_t}{m_t} + r_t^f (K_t - D_t) \quad (21)$$

#### 2.1.4. Account balance of the investment section

Then, the balance of the investment section is made when :

$$EB_t + E_t + S_K K_t = RK_t + I_t \quad (22)$$

$E_t$  corresponds to the debt flow of the current period;  $S_K K_t$  corresponds to the public facilities subventions received from the Government  $RK_t$  corresponds to the financial amortization of the current period. The introduction of the investment ( $I_t$ ) helps the precise expression of the balance constraint. But that specificity needs two more hypothesis. Indeed, the investment made along the period  $t$  ( $I_t$ ) generates a modification of the local public utilities at the end of the period. So that investment decomposes of replacement investment ( $IR_t$ ) and development investment ( $ID_t$ ). The latter increases the equipment stock, so it's characterised by a variation of the local public utilities stock :

$$ID_t = \Delta K_t \quad (23)$$

The replacement investment permits to fill a local public utilities loss occurred during the previous period. By hypothesis, the investment covers exactly the capital assets fall in value:

$$IR_t = \frac{K_{t-1}}{m_{t-1}} \quad (24)$$

$$\text{i.e. } I_t = K_t - \left(1 - \frac{1}{m_{t-1}}\right) K_{t-1} \quad (25)$$

Moreover, the amortization of the financial debt is lineary made connected to the median residual duration ( $n_t$ ) of borrowing portfolio :

$$RK_t = \frac{D_t}{n_t} \quad (26)$$

Rewriting the balance constraint of the investment section from the equations (21) and (26), it comes:

$$\left(r_t^f - \frac{\Delta K_t}{K_t}\right) K_t = \left(r_t^f - \frac{\Delta D_t}{D_t}\right) D_t + S_K K_t \quad (27)$$

With,  $\Delta D_t = E_t - RK_t$ , the debt annual instalment. Supposing that the financial profit rate of own assets is nil and neglecting the endowed facilities subventions, the variation of the debt balances exactly the development investment.

## 2.2. Budgetary balance

From accounting balance of operation and investment section, global balance of community obtained in the structural model form :

$$\begin{cases} T_t B_t + G_t = CV_t + FF_t + EB_t \\ EB_t + E_t + S_K K_t = I_t + R_t \end{cases} \Rightarrow \text{Structural model form} \quad (28)$$

The verification of the existence and the solution uniqueness is easy because the model is linear. The entry of a reduced form give the possibility to specify the global imposition of the municipal financial stability via the unstable gross saving which is shared by the two equation. Writing of a reduced form permit to specify the global constraint of accounting balance of community via the gross saving who is the common variable to aboth equation :

$$T_t B_t + G_t + E_t + S_K K_t = RK_t + I_t + CV_t + FF_t \quad (29)$$

However, this imposition goes against the golden rules of the real stability of the local budget which obliges the local government to affect mainly the loan by the single funding of the investment and the gross saving at the amortisation of capital. This obligation ( $EB_t > RK_t$ ) involves a positive or null net saving ( $EN_t : EB_t - RK_t \geq 0$ ). From this equation (21) and after the simplifying, we obtain:

$$EN_t : r_t^f K_t^p + \left(\frac{K_t}{m_t} - \frac{D_t}{n_t}\right) \geq 0 \quad (30)$$

If the hypothesis of a profit or loss for the financial year result is null

$$EN_t : \left( \frac{K_t}{m_t} - \frac{D_t}{n_t} \right) \geq 0 \quad (31)$$

In that case the depreciation provision is superior or equal to the funding amortization. However, this inequality in connection with the budgetary imposition does not enable to entry correctly the synthetical financial imposition of the municipality. In the case of a strict budgetary, the net saving is null. The consequence is that the specification of the indebtedness conduct is necessary. This specification is obtained from the relation between the debt stock and the public stock facilities after entering and simplifying the expression of the net saving: amortization allocation becomes greater or equal than financial amortization allocation. On the other hand, this disparity tied to budgetary constraint doesn't allow to write correctly the global constraint for the municipality. In this case of strict budgetary balance, net saving is equal to zero. As a result, characterization of behaviour debt is necessary. The latter obtained from the relation between the debt stock and public facilities after reducing net saving expression :

$$D_t = \left( \frac{r_t^f + \frac{1}{m_{t-1}}}{r_t^f + \frac{1}{n_t}} \right) K_{t-1} \quad (32)$$

If the profit or loss for the financial year is null, the indebtedness conduct with the imposition of the budgetary stability is written:

$$D_t = \left( \frac{n_t}{m_{t-1}} \right) K_{t-1} \quad (33)$$

Finally we obtain global balance with strict stability per addition of (19) and (32) :

$$T_t B_t + G_t + S_K K_t = \left[ \left( v_t + \frac{1}{m_{t-1}} \right) + i_t \left( \frac{r_t^f + \frac{1}{m_{t-1}}}{r_t^f + \frac{1}{n_t}} \right) + r_t^f \left( \frac{\frac{1}{n_t} + \frac{1}{m_{t-1}}}{r_t^f + \frac{1}{n_t}} \right) \right] K_{t-1} \quad (34)$$

Finally the budgetary constraint obtained involving a financial profit rate null is:

$$T_t B_t + G_t = \left( v_t + \frac{1+i_t n_t}{m_{t-1}} \right) K_{t-1} \quad (35)$$

$$\text{where: } T_t = \frac{v_t + \left( 1 + \frac{i_t n_t}{m_{t-1}} \right) K_{t-1} - G_t}{B_t} \quad (36)$$

Here's what occurs to the median intertemporal global constraint:

$$\begin{aligned} & x_{m_1} + \frac{x_{m_2}}{1+r_1} + \frac{x_{m_3}}{(1+r_1)(1+r_2)} + \left[ \left( v_1 + \frac{1+i_1 n_1}{m_0} \right) k_0 N_0^y \right] \frac{b_{m_1}}{b_1} + \left[ \left( \frac{v_2 + \frac{1+i_2 n_2}{m_1}}{1+r_1} \right) k_1 N_1^y \right] \frac{b_{m_2}}{b_2} + \left[ \left( \frac{v_3 + \frac{1+i_3 n_3}{m_2}}{(1+r_1)(1+r_2)} \right) k_2 N_2^y \right] \frac{b_{m_3}}{b_3} \\ & = y_{m_1} + G_1 + \frac{y_{m_2} + G_2}{1+r_1} + \frac{y_{m_3} + G_3}{(1+r_1)(1+r_2)} \end{aligned} \quad (37)$$

The current value of the public and private consolidated consumer covers the current value of the private and public resources.

From which the following intertemporal optimisation program:

$$\text{Max}_{x_{m_1}, x_{m_2}, x_{m_3}, k_0, k_1, k_2} U = u_m(x_{m_1}, x_{m_2}, x_{m_3}, k_0, k_1, k_2)$$

$$\begin{aligned}
& x_{m_1} + \frac{x_{m_2}}{1+r_1} + \frac{x_{m_3}}{(1+r_1)(1+r_2)} + \left[ \left( v_1 + \frac{1+i_1 n_1}{m_0} \right) k_0 N_0^\gamma \right] \frac{b_{m_1}}{b_1} + \left[ \left( v_2 + \frac{1+i_2 n_2}{m_1} \right) \frac{1}{1+r_1} \right] k_1 N_1^\gamma \frac{b_{m_2}}{b_2} + \left[ \left( v_3 + \frac{1+i_3 n_3}{m_2} \right) \frac{1}{(1+r_1)(1+r_2)} \right] k_2 N_2^\gamma \frac{b_{m_3}}{b_3} \\
& = y_{m_1} + G_1 + \frac{y_{m_2} + G_2}{1+r_1} + \frac{y_{m_3} + G_3}{(1+r_1)(1+r_2)} \tag{38}
\end{aligned}$$

We make the hypothesis of a Cobb-Douglas utility function :

$$U(x_{m_t}, x_{m_{t+1}}, x_{m_{t+2}}, k_t, k_{t+1}, k_{t+2}) = \prod_{t=1}^3 \left( x_{m_t} \cdot k_{t-1} \right)^{\frac{1-a}{3}} \frac{1}{(1+\rho)^\gamma} \tag{39}$$

With  $\rho$  represents the subjectif interest rate, we obtain the demand functions for locals private and publics goods :

$$x_{m_1}^* = \frac{a(1+\rho)}{2+\rho} \cdot (y_{m_1} + G_1) \tag{40}$$

$$x_{m_2}^* = \frac{a(1+\rho)}{2+\rho} \cdot \frac{y_{m_2} + G_2}{1+r_1} \tag{41}$$

$$x_{m_3}^* = \frac{a(1+\rho)}{2+\rho} \cdot \frac{y_{m_3} + G_3}{(1+r_1)(1+r_2)} \tag{42}$$

$$k_0^* = \frac{(1-a)(1+\rho)}{2+\rho} \cdot \frac{y_{m_0} + G_0}{\left[ \left( v_1 + \frac{1+i_1 n_1}{m_0} \right) N_0^\gamma \right] \frac{b_{m_1}}{b_1}} \tag{43}$$

$$k_1^* = \frac{(1-a)(1+\rho)}{2+\rho} \cdot \frac{y_{m_1} + G_1}{\left[ \left( v_2 + \frac{1+i_2 n_2}{m_1} \right) N_1^\gamma \right] \frac{b_{m_2}}{b_2}} \tag{44}$$

$$k_2^* = \frac{(1-a)(1+\rho)}{2+\rho} \cdot \frac{y_{m_2} + G_2}{\left[ \left( v_3 + \frac{1+i_3 n_3}{m_2} \right) N_2^\gamma \right] \frac{b_{m_3}}{b_3}} \quad (45)$$

The demand functions for local public goods depends effectively of recurrent cost, financial fees, depreciation rate and the fiscal ratios. The private revenue of median voter, is one variables that determines the local public demand for the municipality.

If private price is equal to zero, fiscal price of local public goods for median voter are :

$$p_{m_0} = \left[ v_1 + \left( \frac{1+i_1 n_1}{m_0} \right) \right] \frac{b_{m_1}}{b_1} \quad (46)$$

$$p_{m_1} = \left[ v_2 + \left( \frac{1+i_2 n_2}{m_1} \right) \frac{1}{(1+r_1)} \right] \frac{b_{m_2}}{b_2} \quad (47)$$

$$p_{m_2} = \left[ v_3 + \left( \frac{1+i_3 n_3}{m_2} \right) \frac{1}{(1+r_1)(1+r_2)} \right] \frac{b_{m_3}}{b_3} \quad (48)$$

i.e :

$$p_{m_i} = \left[ \frac{\left( v_{r+1} + \frac{1+i_{r+1} n_{r+1}}{m_r} \right) N_r^\gamma}{\prod_{i=1}^r (1+r_i)} \right] \frac{b_{m_i}}{b_i} \quad (49)$$

The fiscal price expression insert fiscal return on investment by tax base growth (base effect). In practical terms, this effect will be in favour of municipality if the economic profit rate expected from public development is

greater or equal than debt cost. The debt allow to make net saving by Euro invested greater than credit cost by Euro debt.

In other words, more debt weight compared with Am stockholder's equity is high, better will be financial profit. Conversely, if the economic yield rate expected become lower than credit cost, the growth of debt compared with Am stockholder's equity will damage the financial profit. So the municipality will be forced to diminish his debt.

In addition, the marginal cost use is :

$$p_t = \frac{C'(k_{t-1} N_{t-1}^\gamma) N_{t-1}^\gamma}{R_t} = \frac{N_t^\gamma \left( v_{t+1} + \frac{1+i_{t+1} n_{t+1}}{m_t} \right)}{R_{t+1}} \quad (50)$$

The short term cost function is defined as minimum production cost when we adjust only the variables productions factor. The expression of variables cost was defined by equation (9). But, the production cost of local public goods in static was :

$$C(Z) = p \times Z \quad (51)$$

$p$  is use cost for local public goods :

$$p = \frac{C_z N^\gamma}{R} \quad (52)$$

By identification :

$$C(Z) \equiv C(Z)_v \quad (53)$$

It results a function  $v$  defined by the usage cost of locals public goods :

$$v = \frac{C(k N^\gamma)}{R} \quad (54)$$

$$v'_k = \frac{\partial}{\partial k} \left[ \frac{C(kN^\gamma)}{R} \right] = \frac{N^\gamma}{R} C'_k \quad (55)$$

The variables marginal recurrent cost expressed in term of stock per capita is similar to marginal use cost of local public goods in static.

In order to write the expense function per capita, we deduce the dynamic marginal use of local public goods to  $t+1$  order terms :

$$p_t = \frac{N_t^\gamma \left( C'_k + \frac{1+i_{t+1} n_{t+1}}{m_t} \right)}{R_{t+1}} \quad (56)$$

i.e. :

$$p_{m_t} = \left[ \frac{\left( C'_{k_t} \frac{1+i_{t+1} n_{t+1}}{m_t} \right) N_t^\gamma}{\prod_{i=1}^t (1+r_i)} \right] \frac{b_{m_t}}{b_t} \quad (57)$$

The public facilities function is :

$$d_t = k_0 (p_{m_t} \times p_t)^\alpha \times y_{m_t} \beta_2 \times G_t \beta_1 \times E_t \beta_3 \quad (58)$$

With  $\alpha$  price effect and  $\beta$  revenue effect. The intertemporal expense function per capita is :

$$\frac{1}{\prod_{i=1}^t (1+r_i)} \times \frac{d_t}{R_t} = \left[ \frac{\left( C'_k + \frac{FF_{t+1}/RK_{t+1}}{m_t} \right) N_t^\gamma}{\prod_{i=1}^t (1+r_i) R_{t+1}} \right]^{\alpha+1} \left( \frac{b_{m_{t+1}}}{\prod_{i=1}^t (1+r_i) b_{t+1}} \right)^{\alpha+\beta_1} \left( \frac{y_{m_t}}{\prod_{i=1}^t (1+r_i)} \right)^{\beta_2} \left( \frac{G_t}{\prod_{i=1}^t (1+r_i)} \right)^{\beta_1} \left( \frac{E_t}{\prod_{i=1}^t (1+r_i)} \right)^{\beta_3} \quad (59)$$

The originality of this paper compared to median voter static model is the first term of right . That's say the synthetic measure of number of users.

Indeed, in front of durable public goods, the congestion increased according to traditional parameters ( length of road, resident population ) but also according four news induction parameters : financial fees, repayment amortization, depreciation and marginal cost use.

Indeed, as we are rigidity public facilities, diminution of users of local public goods don't signify the reduction of burden. Because of fixed cost higher and variables cost resulting from capital accumulation.

In this case, reducing of resident population doesn't lied a diminution of expenses but contrary an increase of expenses per capita.

In the case of durable public goods, fixed cost are so important that local adjustment period almost infinite.

### **3. Conclusion**

This paper attempted to build a partial balance model of local financial behaviors, characterizing municipality financial choice as resulting of capital accumulation. This accumulation generates firstly internals risks tied either expenses (recurrent expenses operates et financial fie futur), or incomes (locals situation and tax bases mobility)

Now, it might be instructive to validate this theoretical model with an econometric approach.

## **Abstract**

*As the name suggests, a Special-Purpose Vehicles is an entity created to engage in a specific transaction, most commonly for asset acquisition, leasing, securitization and insurance. SPVs or SPEs (Special Purpose Entity) have been used for several decades as a preferred form to raise financing for large international projects and other projects with well-defined cash flows and risk characteristics. This paper analyzes some aspects concerning SPV and analyzes the securitization. SPVs are carefully designed to avoid bankruptcy. Finally, the paper insists on juridical aspects on SPV in Romania and their impact in our economy.*

**Keywords:** *special purpose vehicles, securitization, bankruptcy*

## 1. Introduction

The word "special purpose vehicle" or "special purpose entity" is a buzzword in structured finance and can be potentially confusing. Specially, after the Enron collapse, the word SPE has acquired an unpleasant connotation in public mind.

The word "vehicle" is a marketplace equivalent of "entity". Therefore SPV and SPE mean the same thing. As opposed to a general purpose vehicle or a trading corporation, a Special Purpose Vehicle, as the name suggests, is formed for a special purpose: therefore its powers are limited to what might be required to attain that purpose and its life is destined to end when the purpose is attained.

An SPE is either a Trust or a Company. SPEs can be either on shore or offshore. Special purpose corporations are used for a variety of legitimate purposes, including structured risk management solutions. In securitizations, the SPE houses the asset risk either through the purchase of the assets or in synthetic form.

When a corporation, call it the sponsor of the SPV, wants to achieve a particular purpose, for example, funding, by isolating an activity, asset or operation from the rest of the sponsor's business, it hives off such asset, activity or operation into the vehicle by forming it as a special purpose vehicle. This isolation is important for external investors whose interest is backed by such hived-off assets, etc., but who are not affected by the generic business risks of the entity of the originating entity. Thus SPVs are housing devices - they house the assets transferred by the originating entity in a legal outfit, which is legally distanced from the originator.

By its very nature, an SPV must be distanced from the sponsor both in terms of management and ownership, because if the SPV were to be owned or controlled by the sponsor, there is no difference between a subsidiary and an SPV.

Being an independent, an SPV is responsible for its own funding, risk capital and management decisions. Most SPVs, for example, securitization SPVs, run on a pre-punched program and do not have to take any management decision: they are almost "brain dead".

Apart from securitizations, SPVs are often used for many purposes. One common purpose is to use them for what is known as "synthetic leases" - a device by which assets are acquired under an off balance sheet lease from the vehicle that funds them with debt. After the Enron collapse, the public

has come to know for the first time the all kinds of obscure SPVs floated by US companies.

## **2. What are special Purpose Vehicles?**

A SPV, or a special purpose entity (SPE), is a legal entity created by a firm (known as the sponsor or originator) by transferring assets to the SPV, to carry out some specific purpose, or circumscribed activity, or a series of such transactions. SPVs have no purpose other than the transaction(s) for which they were created, and they can make no substantive decisions; the rules governing them are set down in advance and carefully circumscribe their activities. Indeed, no one works at an SPV and it has no physical location.<sup>1</sup>

Special purpose entities (SPE) are usually created for a single, well-defined and narrow purpose. An SPE does not have a single defining characteristic but is generally identified by the single purpose nature and a number of common features. The SPE may have any one of a number of legal forms: corporation, partnership, trust, unincorporated entity or a multi-user structure such as a protected cell company.

The common features that identify an SPE are:

1. Auto-pilot arrangements that restrict the decision-making capacity of the governing board or management;
2. Use of professional directors, trustees or partners;
3. Thin capitalization, the proportion of 'real' equity is too small to support the SPE's overall activities;
4. Absence of an apparent profit-making motive, such that the SPE is engineered to pay out all profits in the form of interest or fees;
5. Domiciled in 'offshore' capital havens;
6. Have a specified life;
7. Exist for financial engineering purposes;

---

<sup>1</sup> Gary Gorton, Nicholas S. Souleles, 2005, Special Purpose Vehicles and Securitization, National Bureau of Economic Research, Cambridge, March 2005, <http://www.nber.org/papers/w11190>

8. The creator or sponsor may transfer assets to the SPE, often as part of a derecognizing transaction involving financial assets.

An essential feature of an SPV is that it be “bankruptcy remote,” that is, that the SPV never be able to become legally bankrupt. The most straightforward way to achieve this would be for the SPV to waive its right to file a voluntary bankruptcy petition, but this is legally unenforceable<sup>2</sup>.

The only way to completely eliminate the risk of either voluntary or involuntary bankruptcy is to create the SPV in a legal form that is ineligible to be a debtor under the U.S. Bankruptcy Code. The SPV can be structured to achieve this result. As described by Klee and Butler (2002): “The use of SPVs is simply a disguised form of bankruptcy waiver” (p. 34).

To make the SPV as bankruptcy remote as possible, its activities can be restricted, for instance it can be restricted from issuing debt beyond a stated limit. The SPV can also obtain agreements from its creditors that they will not file involuntary petitions for bankruptcy. Depending on the legal form of the SPV, it may require more structure to insure effective bankruptcy remoteness.

There is also the risk that if the sponsor of the SPV goes bankrupt that the bankruptcy judge will recharacterize the “true sale” of assets to the SPV as a secured financing, which would bring the assets back onto the bankrupt sponsor’s balance sheet. Or the court may consolidate the assets of the sponsor and the SPV. As a result of this risk, most structured financings have a two-tiered structure involving two SPVs. Often times the sponsor retains a residual interest in the SPV that provides a form of credit enhancement, but the residual interest may preclude a “true sale.” Consequently, the residual interest is held by another SPV, not the sponsor. The “true sale” occurs with respect to this second vehicle.

The presence of any of the features identified above does not automatically make an entity an SPE, nor does the absence of a feature or features mean that it is not an SPE. The decision about whether an entity is an SPE, and subsequently who controls it, is one of professional judgment requiring careful consideration of all relevant facts. Pension plans and equity compensation plans are not SPEs.

### 3. The legal form of SPV

A SPV can take the form of a *corporation, trust, partnership, or a limited liability company*. SPEs often are created with legal arrangements that impose strict and some times permanent limits on the decision-making powers of their governing board, trustee or management over the operations of the SPE. Frequently, these provisions specify that the policy guiding the ongoing activities of the SPE cannot be modified other than perhaps its creator or sponsor.

The sponsor (or entity on whose behalf the SPE was created) frequently transfers assets to the SPE, obtains the right to use assets held by the SPE or performs services for the SPE, while other parties (capital providers) may provide the founding to the SPE. An entity that engages in transactions with an SPE (frequently the creator or sponsor) may in substance control the SPE.

A beneficial interest in a SPE may take form for example of a debt instrument, an equity instrument, a participation right, a residual interest or a lease. Some beneficial interests may simply provide the holder with a fixed or stated rate of return, while others give the holder rights or access to other future economic benefits of the SPE's activities. In most cases, the creator retains a significant beneficial interest in SPE's activities, even though it may own little or none of the SPE's equity.

SPV may be a subsidiary of the sponsoring firm, or it may be an "orphan" SPV, one that is not consolidated with the sponsoring firm for tax, accounting, or legal purposes (or may be consolidated for some purposes but not others).<sup>3</sup>

Most commonly in securitization, the SPV takes the legal form of a **trust**. Traditionally, a **trust** is "*a fiduciary relationship with respect to property, arising as a result of a manifestation of an intention to create that relationship and subjecting the person who holds title to the property (the trustee) to duties with it for the benefit of third party beneficiaries*". Often the SPV is a charitable or purpose trust. Traditional gratuitous or charitable trusts have been transformed into a vehicle with a different economic substance than perhaps contemplated by the law.

---

<sup>3</sup> Gary Gorton, Nicholas S. Souleles, 2005, Special Purpose Vehicles and Securitization, National Bureau of Economic Research, Cambridge, March 2005, <http://www.nber.org/papers/w11190>

A purpose trust (called a STAR trust in the Cayman Islands) is a trust set up to fulfill specific purposes rather than for beneficiaries. A charitable trust has charities as the beneficiaries. For many transactions there are benefits if the SPV is domiciled offshore, usually in Bermuda, the Cayman Islands, or the British Virgin Islands.

#### **4. Taxation of the SPV**

There are two tax issues. First, how is the SPV taxed? Second, what are the tax implications of the SPV's debt for the sponsoring firm?

The first question is easier to answer. SPVs are usually structured so as to be tax neutral, that is, so that their profits are not taxed. The failure to achieve tax neutrality would usually result in taxes being imposed once on the income of the sponsor and once again on the distributions from the SPV. This "double tax" would most likely make SPVs unprofitable for the sponsor. There are a number of ways to design the SPV to achieve tax neutrality. Many SPVs are incorporated in a *tax haven jurisdiction*, such as the Cayman Islands, where they are treated as "exempted companies."

An exempted company is not permitted to conduct business in, for example, the Cayman Islands, and in return is awarded a total tax holiday for twenty years, with the possibility of a ten year extension. Because such entities are not organized or created in the U.S., they are not subject to U.S. federal income tax, except to the extent that their income arises from doing business in the U.S.

An investment trust that issues pass-through certificates is tax neutral, that is, the trust is ignored for tax purposes – there is no taxation at the trust level – and the certificate owners are subject to tax. Pass-through certificates represent pro rata interests in the underlying pool. It is important for maintaining this tax neutral tax status that the SPV not be reclassified as a corporation. To avoid this it is necessary that the trustee have no power to vary the investments in the asset pool and activities must be limited to conserving and protecting the assets for the benefit of the beneficiaries of the trust.<sup>4</sup>

More common than pass-through structures are pay-through structures. Pay-through bonds are issued by SPVs that are corporations or owner trusts. In these structures the SPVs issue bonds, but this requires that there be a party that holds the residual risk, an equity holder. If the SPV is a corporation, then the pay-through bonds have minimal tax at the corporate

---

<sup>4</sup> Kramer, Andrea (2003), *Financial Products: Taxation, Regulation and Design*, 3 volumes (Aspen Publishers; New York City).

level because the SPV's taxable income or loss is the difference between the yields on its assets and the coupons on its pay-through bonds. Typically these are matched as closely as possible.

The second question is more complicated. Some SPVs achieve off-balance sheet status for accounting purposes but not for tax purposes. Securitizations can fit into this category because they can be treated as secured financing for tax purposes.

There is no easy answer to the question: "Where is the best place to set up an SPE?" It depends on the structured finance application among other considerations. SPEs are currently set up in a variety of tax friendly venues including Delaware (in the United States), New York, Luxembourg, the Caymans, Ireland, Jersey, Guernsey, and Gibraltar.

While SPEs in the United States are often, but not always, set up as trusts for tax reasons, in non-U.S. venues, the special purpose corporation is a common structure. Venues can be chosen wherever an SPE structure is allowable, but as a rule, only tax friendly venues for the specific structured finance application are chosen.

While choice of venue usually revolves around tax issues, other considerations can be important. For example, many investors in Germany will buy notes issued by SPEs, but often require an OECD issuer. Therefore, the SPE must be set up in an OECD country. Among the OECD countries, the Netherlands, Luxembourg, and Ireland are currently the most commonly used tax-friendly venues.<sup>5</sup>

In tax terms, we want the SPE to pay zero tax on payments flowing in and flowing out. We want to avoid corporate income tax at the venue of the SPE and the bank sponsor.

There are two withholding tax issues: 1) withholding tax at the source, the venue of the incorporation of the SPE, on EMTNs issued by the SPEs; and 2) withholding tax imposed on the underlying assets purchased by the SPEs by the country in which the assets were originated. The goal is that neither interest nor dividends paid by the SPEs is subject to withholding tax, so an ideal venue does not impose this tax.

If we choose a venue such as the Cayman Islands that does not have tax treaties in place with most jurisdictions, there is no mechanism for reclaiming tax withheld (if any) on the underlying asset income from the

---

<sup>5</sup> Janet M. Tavakoli, 2005, SPECIAL PURPOSE ENTITIES: USES AND ABUSES  
Presentation to the International Monetary Fund

country of origination. The SPE will purchase assets that are not subject to withholding at the country of the assets' origination so that investors will not suffer a reduced return.

If instead we choose a venue with tax treaties in place, assets that suffer withholding tax may specifically be chosen so the withholding tax can be reclaimed. This is a legitimate use of an SPE. Tax evasion is illegal; tax avoidance is legal.

We do not want to suffer tax on the SPEs income. In Europe, we also want to avoid value added tax (VAT) and stamp duties. The goal is to have zero tax leakage, if possible. Venues such as the Caymans, Jersey, and Guernsey offer this advantage, but may not enjoy ready investor acceptability.

Other venues such as the Netherlands, Luxembourg, and Ireland, also offer several tax advantages. There is no withholding tax on note interest. There is no stamp duty. There may be a very small value added tax (VAT) on servicing and administration for the SPE. There is no withholding tax on deposits. Among these three venues, there are other considerations that may affect the final choice, however. The Netherlands seems to take several weeks longer to provide tax rulings for SPEs compared to Ireland and Luxembourg. In the Netherlands, there seems to be a turf war between Amsterdam versus Rotterdam, and most SPEs are set up in Amsterdam. For speed, one might choose Ireland or Luxembourg. In Ireland, the SPE must fit within the Irish tax securitization code. This may drive up the cost slightly relative to Luxembourg. U.K. based deal arrangers might find it more convenient to deal with Ireland, since Ireland uses an English law based system. Lately, Ireland has been the fastest of the three venues in actual set-up time; usually two to three weeks once the paperwork is in order.

## **5. SPV usage**

SPEs have been used to legitimately move assets off of a balance sheet and monetize them through repackaging combined with sales to investors. SPEs have also been used for embezzlement, money laundering, to mischaracterize revenues and losses, to perpetrate fraud on unwitting fund investors, to move money offshore for tax evasion, to channel funds to terrorist operations, and to disguise the source of money for illegal arms sales.

All of the following are examples of SPEs: Special Purpose Corporations (SPCs) which may or may not be Special Purpose Subsidiaries or captives; Master Trusts; Owners Trusts; Grantor Trusts; Real Estate Mortgage

Investment Conduits (REMICs); Financial Asset Securitization Investment Trust (FASIT); Multiseller Conduits; Single Seller Conduits.<sup>6</sup>

The SPE is formed concurrently with or immediately prior to the subject transaction, that is unlikely to become insolvent as result of its own activities and that is adequately insulated from the consequences of any related party's insolvency. The SPE is generally utilized in one of three different types of transactions:<sup>7</sup>

- the property-specific or large loan transaction;
- the pool transaction;
- the credit lease transaction.

#### ***Property-specific or large loan transaction***

Many property-specific transactions include, as part of their structure a deposit of one or more mortgage loans into a trust. As a result, in a property-specific transaction, multiple SPE's may be appropriate. In addition to each borrower being an SPE, the depositor and/or the holder of any securities or interests in mortgage loan received or retained in connection with a transfer of a loan or loans should be an SPE if the transfer of the loan or loans by the originator to the depositor, or by the depositor to a trust, could not otherwise be characterized properly as a "true sale".

#### ***Pool transaction***

In a traditional pool transaction, one or more mortgage loan sellers will transfer a portfolio of mortgage loans to the depositors which, in turn, will transfer a such mortgage loans to a trust. The trust will issues the rated securities, which are backed by the mortgage loans, to investors in exchange for the proceeds from the sale of securities.

In situations where a transfer cannot be characterized properly as true sale, the transferor generally should be an SPE. In addition, any securities or interests in the transferred mortgage loans received or retained by a loan originator in connection with such transfer generally should be held in an SPE.

The purpose of creating a SPE in this situations is to create an entity that should not become subject to a bankruptcy proceeding. The use of an SPE entity is designed to reduce the risk of the transferor becoming

insolvent, filing a bankruptcy petition, and claiming that the transfer of the mortgage loans and other collateral to the depositor or the securization trust was not a true sale.

### ***Credit lease transaction***

In a credit lease transaction, the borrower, as landlord and owner of the fee interest in an income producing real property, obtains a loan that is secured by a “triple net” bondable lease to a rated tenant.

Special purpose entities are often classified as either ***passthrough*** or ***paythrough structures***.

***Passthrough structures*** pass through all of the principal and interest payments of assets to the investors. Passthrough structures are therefore generally passive tax vehicles and do not attract tax at the entity level.

***Paythrough structures*** allow for reinvestment of cash flows, restructuring of cash flows, and purchase of additional assets. For example, credit card receivable transactions use paythrough structures to allow reinvestment in new receivables so bonds of a longer average life can be issued.

For securitization of cash assets, the key focus is on non-recourse (non-recourse to the originator/seller) financing. The structures are bankruptcy remote so that the possible bankruptcy or insolvency of an originator does not affect the investors’ right to the cash flows of the vehicle’s assets. The originator is concerned about accounting issues, especially that the structure meets requirements for off-balance sheet treatment of the assets, and that the assets will not be consolidated on the originator/seller’s balance sheet for accounting purposes. For bankruptcy and accounting purposes, the structure should be considered a sale.

This is represented in the documentation as a true sale at law opinion. The structure should be a debt financing for tax purposes also known as a debt-for-tax structure. Tax treatment is independent of the accounting treatment and bankruptcy treatment. An originator selling assets to an SPE will want to ensure that the sale of assets does not constitute a taxable event for the originator. The securitization should be treated as a financing for tax purposes i.e., treated as debt of the originator for tax purposes. This is represented in the documentation in the form of a tax opinion.

The structured solution to the bankruptcy, true sale, and debt-for-tax issues varies by venue.

Synthetic securitizations do not get true sale treatment for accounting purposes, since no asset has been sold. This is true whether the vehicle is an

SPE or a credit-linked note. The motive behind these structures is to reduce regulatory capital according to regulatory accounting principles. Funding is a non-consideration or a minor consideration. These are usually balance sheet deals for bank regulatory capital relief. Partial funding is feasible with a hybrid structure. A corollary motive is to get credit risk relief.

Repackaging is another legitimate use of SPEs. U.S. banks often set up multi-issuance vehicles (MIEs) in the Cayman's or other tax friendly venues. These are Qualifying Special Purpose Entities (QSPEs) for Financial Accounting Standards Board (FASB) purposes. By definition, they are off balance sheet, bankruptcy remote entities. The assets are put presumptively beyond the reach of the bank transferor's creditors through a true sale. Furthermore, the bank is not obligated to repurchase the transferred assets. Setting up the SPE in this way insulates the customers from the bank's credit risk, and ensures the assets don't re-emerge on the bank's balance sheet, even though the SPE may often purchase assets from the bank sponsor's books.

The MIE issues notes that reference only the underlying collateral specific to each note (unlike the structure in which the collateral for all the EMTNs is a reference pool of assets). The noteholders do not have a claim to any other asset owned by the SPE. Each set of assets is funded separately with its own EMTN tranche combining the risk characteristics of the underlying assets and/or derivatives. The derivatives may be hedges or may actually be an underlying asset, such as a credit derivative.

In a typical vanilla repackaging, the SPE purchases assets. The assets are pre-funded from proceeds of an EMTN issued by the SPE and underwritten or sold by the bank arranger's (bank sponsor's) capital markets group. The SPE pays the asset cash flows to the bank arrangers swap desk as one leg of a swap payment. The bank arranger provides the structured coupons due to the investors under the EMTN issue.

The flexibility and privacy of offshore SPEs in particular makes them very powerful financial tools for legitimate securitizations, but also makes them attractive tools for illegal financial dealings. The key issue seems to be disclosure of the true ownership of the SPE. Legitimate businesses voluntarily disclose minority ownership interests in offshore SPEs as equity on their balance sheet. Offshore subsidiaries are also disclosed.

While SPEs are ideal for securitizing assets, they are also ideal for hiding assets. Many offshore venues do not divulge ownership of SPEs, and to complicate matters, the owner may be one or more SPEs in different venues. There is no easy answer to this dilemma, since any legitimate means can be exploited for illegitimate gain.

## **6. Juridical aspects concerning the SPV in Romania**

In this year has been issued the law of securitization in Romania which provides the general framework for obtaining financing through securitization, and also the rights and obligations of the participants at the securitization transaction.

The object of securitization:

- ❖ credit contracts;
- ❖ lease contracts;
- ❖ commercial contracts with the payment price in term, as well as commercial contracts with the payment rate;
- ❖ financial instruments, issued according to the law.

According to this law the SPV is defined as an entity with or without juridical personality, which has the single objective to issue securitized financial instruments.

The transfer as it is defined by the present law is exempted by the value added tax. The SPV is an entity set up as securitization fund, based on contracts of limited company or corporation. The SPV must be approved by CNMV (National Committee of Securities).

## **7. Conclusion**

The overall issue, however, is how do regulators wish to react to any illegal financial activity, including the abuse of SPEs. What is the best course of action for entities such as the International Monetary Fund that are in a position to distribute funds? One could suggest that each country must introduce rule of law and financial accountability before debt is forgiven or before new funds are lent. Even in strong financial venues like the United States, it is difficult to curtail abuse. In disadvantaged countries, especially venues in which corruption is suspected, it may be even more difficult to curtail financial abuse, and the issues are more difficult. There are broader humanitarian issues such as the effect of withholding funds on the general population and whether funds provided aren't diverted to special interests instead of employed as intended.

## **Abstract**

*Various empirical studies regarding the bankruptcy risk were conducted using financial analysis of companies, with or without financial difficulties. The variables (mainly accounting variables) which influence the risk were determined. In this article, we propose a short overview which emphasizes the efficiencies of different methods of classification used so far. We describe the available techniques, compare their performances and underline various modalities of empirical applications. We also perform an empirical study on a set of Romanian companies. We are using two alternative models: Binary Logit and Binary Probit. Their performance is evaluated based on econometric criteria as well as a criterion of accuracy of predictions: receiver Operating Characteristic Curve.*

**Keywords:** *bankruptcy risk, logit, probit, ROC curve*

## 1. Introduction

The purpose of this paper is to present synthetically the evolution and the present state of research concerning the bankruptcy risk and to propose a modality of application on the Romanian market, where the chosen model is based on a prediction criterion, not on econometric criteria. The first part of the study displays the common methodology of the research concerned, as well as the various modalities of the empirical applications, the construction of the sample, the choice of the explanatory variables and the method to validate the results.

## 2. The construction of the sample

The elaboration of the sample is very important for the quality of the proposed prediction. The defining of the states of the endogenous variable and the choice of the prediction level play an essential part, because they determine the objective of the constructed indicator, and the selection of the units which form the given sample. The choice of the variables characterizing the selected units is also very important because these variables condition the homogeneousness and the representativeness of the sample, hence they influence the quality of the prediction.

**The explanatory variables:** the representativeness and the homogeneousness of the sample. For the binary models, the construction of two sub-samples raises the problem of how representative and homogeneous the two sub-samples are. For instance, in the case of a model of financial scoring related to the enterprise bankruptcy risk, the full sample must be representative for the economy: from the point of view of the sectors of activity, of the size of the enterprises, but also of the relation between the number of bankrupt enterprises and non-bankrupt enterprises. However, this representativeness creates a heterogeneousness which might generate a statistical displacement: explanatory factors could be rendered under the aspect of sectorial or size effects. In order to reconcile the two exigencies, several solutions have been found.

Recent studies have resorted to enlarged samples: over 1000 enterprises (Lennox,1999) and more than 40000 for the Bank of France score (Bardos,1998). If the number of the supervised enterprises (belonging to the given sample) is large enough, we have a good representativeness. However, the representativeness must be verified by comparing the characteristics of the sample with the characteristics of the global population. Another way of rendering a good representativeness is to limit the research to an economic

field or to a size interval (Trieschmann and Pinches, 1973; Calia and Ganuci, 1997). This particular method has the advantage of reconciling the representativeness and the homogeneousness.

### **3. Date analysis models and binary econometric models**

These techniques were used mainly in the enterprise bankruptcy analysis and the bankruptcy risk estimation, starting from a series of book-keeping data characteristic for the given enterprise, namely economic and financial indicators. The studies that propose or make use of such models generally fall into three classes, according to the classifying methods which are being used. The most frequent classifying methods are the parametric statistical methods: the discriminant-linear models analysis (Altman, 1968) or the square analysis (Lachenbruch et al., 1973)- and the techniques of the qualitative variables econometric (Ohlson, 1980; Zmijewski, 1984). Other studies resort to non-parametric statistical methods, such as: the recursive partition (Frydman et al, 1985) and the nucleus estimators (Calia and Ganuci, 1997). At the same time, more recently, there have been performed analysis concerning the artificial intelligence, such as the neuronal networks (Altman et al, 1994; Bardos and Zhu, 1997) and the genetic algorithms (Varetto, 1998). In the following lines, we are going to explain briefly the techniques mentioned above, resorting to the founding studies, as well as to the various improvements later suggested.

#### **The parametric methods of statistical classification**

The parametric methods of statistical classification establish a functional relation between the explanatory variables (the law of variable distribution is supposed to be known in this case) and the variable explained, the form of this relation being given a priori. Three types of such methods have been identified:

The one-dimensional methodology founded by Beaver (1966)

The discriminant analysis (liniary and non-liniary)

The regressions with qualitative variables

##### *a. Beaver's one-dimensional methodology (1966)*

Beaver (1966) elaborated a one-dimensional dichotomic classification, namely a classification based on a single book-keeping indicator: the most discriminant (in relation to which the sample is more heterogeneous). In a first sub-sample, he groups the enterprises according to the value given by a specific indicator. Next, a critical limit is being chosen, and all the enterprises that have an installment inferior to this limit are considered bankrupt, while the enterprises that have an indicator value superior to the limit are non-

bankrupt. This critical limit is determined by maximizing the percentage of the well-classified enterprises belonging to the first sample. A second sub-sample is further elaborated, starting from the critical limit previously established, and the percentage of the well-classified enterprises is calculated once again. This percentage lies at the basis of the final selection of the most discriminant book-keeping instalment. Although the method proposed by Beaver could supply an easy and efficient indicator for the characterization of the financial health of various enterprises, the shortcomings of the method related to the unicity of the book-keeping instalment, as well as the advantages provided by the multidimensional methods applied to the description of the state of the enterprise, drastically restrict the area of application of Beaver's methodology.

*b. Prediction models based on the discriminant analysis*

In 1968, Altman pointed out that the one-dimensional analysis does not take into account the complexity of the bankruptcy process. He was the first one to use simultaneously in his research several book-keeping instalments by means of a multidimensional linear analysis. In order to classify an enterprise as bankrupt or non-bankrupt, Altman (1968) uses the simple decision law, which refers to the inclusion of an enterprise in the group to which this particular enterprise is the closest. Accordingly, he resorts to the the discriminant analysis proposed by Fisher, based on a metrical criterion. Essentially, a function named **score** is being constructed, a linear combination of the explanatory variables given; the realization of this function suggests the risk level of the enterprise.

A number of  $k$  book-keeping indicators will be selected, the ones which are most likely to justify the bankruptcy. At the same time, the model maintains the indicators which limit the problem of the exogenous variables multicollinearity and provide the greatest power of discrimination between the enterprises. The sum of the enterprises could be represented in a  $\mathfrak{R}^k$  space. The purpose of the discriminant analysis is to divide this space into two sub-spaces: the bankrupt enterprises sub-space and the non-bankrupt enterprises space. This separation is made by determining the hyper plan  $H^*$  which separates most adequately the two groups of enterprises.  $H^*$  must be calculated so that on the one hand, the number of bankrupt enterprises related to the sub-space of the non-bankrupt enterprises should be minimum, while on the other hand, the number of the non-bankrupt enterprises included in the sub-space of the bankrupt enterprises should also be minimum. The enterprise whose bankruptcy risk will be estimated belongs to the group corresponding to the sub-space in which the enterprise is situated according to its coordinates. If  $A$  is an enterprise whose bankruptcy risk we intend to estimate, and  $x_A$  its coordinates, a value of the distance to a group will be

established. Thus, the distance to a group represents the distance to the middle point of the group, using a particular system of measure. If  $S(x)=0$  is the equation of the hyperplan  $H^*$  in the  $\mathfrak{R}^k$  space,  $S$  is a linear combination of the two  $k$  book-keeping installments we have in view. The value taken by the function  $S(\cdot)$  in the point  $x_A$  determines the classification of the enterprise  $A$  into one or another of the two sub-groups:

if  $S(x_A)>0$ , enterprise  $A$  belongs to the non-bankrupt enterprises

if  $S(x_A)<0$ , enterprise  $A$  belongs to the bankrupt enterprises

if  $S(x_A)=0$ , enterprise  $A$  cannot be classified.

There are, however, some disadvantages in the use of the linear discriminant analysis. Such disadvantages refer to a series of difficulties concerning the linearity of the the score-function constructed by Fisher's discriminant analysis, as well as to the necessity to satisfy some strict statistical conditions (the exogenous variables of the model must submit to a normal law, while their variation/co-variation matrix must be the same for the sub-sample of the bankrupt enterprises and for the sample of the non-bankrupt enterprises). The method was thus modified to some extent, although it had represented for 30 years the main technique used in predicting bankruptcy in several countries. A series of studies from the 80's and the 90's which confront the linear discriminant analysis with other techniques of classification (Collins, 1980; Rose and Giroux, 1984; Altman et al, 1994; Calia and Ganuci, 1997; Kira et al, 1997; Bardos and Zhu, 1997; Varetto, 1998) generally proves the superiority of the linear discriminant analysis.

*c. Models based on regressions upon the qualitative variables*

These methods imply the estimation of some qualitative variable regressions (at least the endogenous variable), based either on a logistical distribution of the errors (Logit), or on a normal distribution of the errors (Probit). The Logit regression was applied in predicting the bankruptcy risk by Ohlson (1980), Mensah (1984), Aziz et al (1988), Bardos (1989), Burgstahler et al (1989), Flagg et al (1991), Platt and Platt (1991), Weiss (1996), Bardos and Zhu (1997), Mossman et al (1998). The Probit model was used to a smaller extent (Zmijewski, 1984; Gentry et al, 1985; Lennox, 1999). According to the two models, the endogenous variable  $y$  is a qualitative variable, dichotomic, in the given case:  $y$  takes the values 0 or 1 if the enterprise is bankrupt, respectively- non-bankrupt. The  $x$  vector of exogenous variables includes a series of  $k$  economic and financial indicators, used in the operation according to their discriminant quality and their weak interdependence. The model requires that between the chosen indicators and

the bankruptcy risk there be a linear relation. The estimated model is expressed as follows:

$$y_i = 1 \text{ if } \beta x_i + \varepsilon_i > 0 \quad (1)$$

$$y_i = 0 \text{ if, } \beta x_i + \varepsilon_i \leq 0 \quad (2)$$

where  $\varepsilon$  is the error associated to enterprise  $I$ , while  $\beta$  is the coefficient vector. The a posteriori likelihood for the enterprise to be bankrupt is expressed as follows:

$$P\{y_i = 0\} = P\{\beta x_i + \varepsilon_i \leq 0\} = P\{\varepsilon_i \leq -\beta x_i\} = F(-\beta x_i) \quad (3)$$

where  $F$  is the function of  $\varepsilon$  error repartition. The a posteriori likelihood for enterprise  $I$  to be non-bankrupt is expressed as follows:

$$P\{y_i = 1\} = P\{\beta x_i + \varepsilon_i > 0\} = P\{\varepsilon_i > -\beta x_i\} = 1 - P\{\varepsilon_i \leq -\beta x_i\} = F(\beta x_i) \quad (4)$$

$$\text{See : } P\{y_i = 1\} = F(\beta x_i) \quad (5)$$

$$P\{y_i = 0\} = 1 - F(\beta x_i) = F(-\beta x_i) \quad (6)$$

The Logit model requires that the errors submit to a logistical law which has the following repartition function:

$$F(x) = (1 + e^{-x})^{-1} \quad (7)$$

In this case, the a posteriori likelihood for enterprise  $I$  to be bankrupt is expressed as follows:

$$P\{y_i = 0\} = (1 + e^{\beta x_i})^{-1} \quad (8)$$

According to the Probit model, the errors submit to a normal law, which has the following repartition function:

$$F(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt \quad (9)$$

As a consequence, the a posteriori likelihood for enterprise  $I$  to be bankrupt is expressed as follows:

$$P\{y_i = 0\} = \int_{-\infty}^{-\beta x_i} \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt \quad (10)$$

Similarly to the previous case, the a posteriori likelihoods are of great help in taking the decision: they allow us to construct a series of risk classes. If we intend to classify a specific enterprise,  $A$ , into one of the two groups of enterprises (bankrupt or non-bankrupt) starting from the bankruptcy likelihood, we could determine a critical limit according to which we may take a decision. We note this critical likelihood with  $P$ . The judgment that

brings us to the decision is the following: if the bankruptcy likelihood estimated for enterprise  $A$  is higher than in the case of  $P$ , then enterprise  $A$  is considered bankrupt; in the opposite case,  $A$  is considered non-bankrupt. The  $P$  likelihood is chosen in such a manner as to maximize the quality of the classification operation. The predictions performed by several researchers on the basis of Probit and Logit models are of a very good quality (Platt and Platt, 1991; Mossman et al, 1998) and they are generally superior to the discriminant analysis (Kira et al, 1997; Lennox, 1999).

#### 4. Application

We start from a sample consisting of 25 commercial enterprises competing on the Romanian market. In order to form the sample, we have used a simple aleatory test. By observing the sample units, we came to the conclusion that 13 of the supervised enterprises were bankrupt, while the other 12 remained in the competitive economy. Consequently, we associate to the observation of the event  $y_i = 0$  in the case of the bankrupt enterprises, respectively  $y_i = 1$  in the case of the surviving enterprises, where  $y_i$  is the endogenous variable standing for the bankruptcy risk. The variables  $x_i$  are associated to the observation of the event  $y_i$ , where  $x_i$  with the value of  $i = \overline{1,5}$  represents the variables expressing accurately the economic and financial situation of the enterprises, as follows (Altman, 1968):

$X_1 = \text{Working capital/Total assets}$

$X_2 = \text{Retained Earnings/Total assets}$

$X_3 = \text{Earnings before interest and taxes/Total assets}$

$X_4 = \text{Market value equity/Book value of total debt}$

$X_5 = \text{Sales/Total assets}$

We have calculated these variables with the help of the data from the Balance-Sheet and the Profit and Loss Account for each enterprise. We have processed the data on the basis of the econometry soft LIMDEP 7.0.

d. The Probit binary estimation model

**Table 1. The estimation of the Probit binary model parameters**

*Binomial Probit Model*

*Maximum Likelihood Estimates*

*Log likelihood function -11.22305*

<i>Variable</i>	<i>Coefficien t</i>	<i>Standard Dev.of b</i>	<i>t=b/st.dev.</i>	<i>P[ Z &gt;z]</i>
<i>Constant</i>	-1.372	0.861	-1.594	0.111
<i>X1</i>	8.894	6.319	1.408	0.153
<i>X2</i>	1.008	8.194	0.123	0.902
<i>X3</i>	1.835	5.409	0.339	0.733
<i>X4</i>	0.288	0.274	1.053	0.292
<i>X5</i>	0.433	0.413	1.048	0.294

e. The Logit binary estimation model

**Table 2 The estimation of the Logit binary model parameters**

*Binomial Logit Model*

*Maximum Likelihood Estimates*

*Log likelihood function -11.29708*

<i>Variable</i>	<i>Coefficien t</i>	<i>Standard Dev.of b</i>	<i>t=b/st.dev.</i>	<i>P[ Z &gt;z]</i>
<i>Constant</i>	-2.292	1.431	-1.603	0.109
<i>X1</i>	14.92	10.32	1.447	0.148
<i>X2</i>	1.605	14.13	0.114	0.909
<i>X3</i>	3.144	8.849	0.355	0.722
<i>X4</i>	0.483	0.458	1.056	0.291
<i>X5</i>	0.721	0.673	1.070	0.284

Although the parameter estimators are very different for each of the two models, their representativeness is practically the same. We estimate for each enterprise the bankruptcy likelihood by using both models.

**Table 3 The estimation of the bankruptcy likelihood, Probit and Logit 1 models**

<i>Observ.</i>	<i>Observed Y</i>	<i>Predicted Y</i>	<i>Prob[Y=1] (probit)</i>	<i>Prob[Y=1] (logit)</i>
1	.000	.000	.3289	.3244
2	.000	.000	.0002	.0025
3	.000	.000	.0000	.0004
4	.000	.000	.0008	.0051
5	.000	.000	.2780	.2756
6	.000	1.00	.6702	.6772
.....				
20	1.00	1.00	.7203	.7244
21	1.00	1.00	.5264	.5256
22	1.00	1.00	.5797	.5864
23	1.00	1.00	.9957	.9880
24	1.00	.000	.3235	.3184
25	1.00	.000	.2699	.2661

The likelihoods are very similar and, as a consequence, the two models are equivalent, from an econometric point of view (the parameter representativeness), as well as from the point of view of the likelihood. The parameters of the models with all the explanatory variables might be however less representative due to the correlations between the X1-X5 variables. We might even think about obtaining superior results by eliminating some variables. We make the estimation for models from which we gradually eliminate one variable or another (Logit 2- Logit 6).

**Table 4. The estimation of the reduced models parameters : Logit 2- Logit 6**

	<i>Logit 2</i>		<i>Logit 3</i>		<i>Logit 4</i>		<i>Logit 5</i>		<i>Logit 6</i>	
	<i>Coe f.</i>	<i>Pro b.<sup>1</sup></i>	<i>Coe f.</i>	<i>Pro b.<sup>1</sup></i>	<i>Coe f.</i>	<i>Pro b.<sup>1</sup></i>	<i>Coe f.</i>	<i>Pro b.<sup>1</sup></i>	<i>Coe f.</i>	<i>Pro b.<sup>1</sup></i>
<i>Constant</i>	- 2.23	0.05	-2.28	0.11	- 2.15	0.10	- 1.47	0.19	- 1.47	0.15
<i>X 1</i>	-	-	15.2	0.13	13.6	0.12	17.0	0.08	13.2	0.12
<i>X 2</i>	6.15	0.61	-	-	5.71	0.48	- 7.09	0.54	4.65	0.73
<i>X 3</i>	0.054	0.99	3.97	0.42	-	-	6.73	0.37	1.03	0.89
<i>X 4</i>	0.83	0.42	0.46	0.28	0.51	0.24	-	-	0.33	0.34
<i>X 5</i>	0.85	0.18	0.73	0.66	0.67	0.30	0.52	0.39	-	-

<sup>(1)</sup>Prob=P[|Z|>z]

Here we notice that none of the models has a good parameter representativeness. According to this criterion it is difficult to choose between the models. We will thus focus on each one's prediction capacity.

**Table 6 The bankruptcy likelihood estimation, models : Logit 2- Logit 6**

<i>Observation</i>	<i>Logit 2 Prob[Y= 1]</i>	<i>Logit 3 Prob[Y= 1]</i>	<i>Logit 4 Prob[Y= 1]</i>	<i>Logit 5 Prob[Y= 1]</i>	<i>Logit 6 Prob[Y= 1]</i>
<i>1</i>	0.1378	0.3302	0.3336	0.5104	0.4651
<i>2</i>	0.1640	0.0023	0.0042	0.0023	0.0071
<i>3</i>	0.1677	0.0003	0.0007	0.0003	0.0013
<i>4</i>	0.3255	0.0044	0.0086	0.0029	0.0127
.....	.....	.....	.....	.....	.....
<i>22</i>	0.4269	0.5936	0.5771	0.5928	0.6422
<i>23</i>	0.7992	0.9884	0.9832	0.9836	0.9763
<i>24</i>	0.3696	0.2961	0.3546	0.2763	0.4784
<i>25</i>	0.1807	0.2826	0.2253	0.4709	0.3326

The likelihoods vary in a significantly in the case of each model. Therefore, in order to be able to choose the best model, we need an efficient criterion to evaluate the prediction capacity of each model. Such a criterion is the Receiver Operating Characteristics Curve.

*f. Receiver Operating Characteristic Curve*

We use the following symbols:

$y_i$  is the noticed value of the endogenous variable

$y_i = 1$  if enterprise  $I$  survives

$y_i = 0$  if enterprise  $I$  does not survive

$$\hat{y}_i = \begin{cases} 1 & \text{si } \text{Prob}(y_i = 1) \geq c \\ 0 & \text{sinon} \end{cases}$$

$c \in [0;1]$  is a cut-off

In most of the applications, cut-off  $c$  can be chosen by the user. For each value of  $c$  we may draw a cross-figure:

$\hat{y}_i$ $y_i$	<b><i>I</i></b>	<b><i>0</i></b>	<b><i>Total</i></b>
<b><i>I</i></b>	$N_{11}$	$N_{10}$	$N_{1T}$
<b><i>0</i></b>	$N_{01}$	$N_{00}$	$N_{0T}$
<b><i>Total</i></b>	$N_{T1}$	$N_{T0}$	$N$

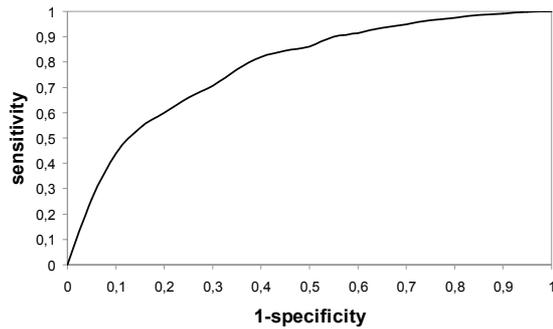

We note the relations as:

$\frac{N_{11}}{N_{1T}} = \textit{sensitivity}$  = the relative frequency of the correct predictions for the individuals for whom  $y_i = 1$

$\frac{N_{00}}{N_{0T}} = \textit{specificity}$  = the relative frequency of the correct predictions for the individuals for whom  $y_i = 0$

By changing the value of  $c$ , we obtain different values for *sensitivity* and *specificity*, which allows us to trace the R.O.C. *curve*.

**Figure 1 R.O.C. curve**

If  $c=1$ ,  $\hat{y}_i = 0 \quad \forall i = \overline{1, N}$  (for all enterprises)  $\Rightarrow$  *specificity* = 1 et *sensitivity* = 0 and the curve reaches the coordinates (0 ;0). If  $c=0$ ,  $\hat{y}_i = 1 \quad \forall i = \overline{1, N}$  (for all the individuals)  $\Rightarrow$  *specificity* = 0 and *sensitivity* = 1 and the curve is situated at the (1;1) coordinates. The ideal model curve traverses the abscissa and ordinate axis, passing trough the (0;1) coordinates, where *specificity*=1 and *sensitivity*=1, so there are 100% correct predictions for enterprises with  $y_i = 0$ , and 100% correct predictions for enterprises with  $y_i = 1$ . Consequently, the closer is the curve to (0;1) coordinates, the more efficient is the model in terms of likelihood. The value indicating the competitiveness of a particular model is the surface of the sub-diagram determined by the R.O.C. curve.

## 5. Conclusions

The academic research concerning the methods of bankruptcy prediction is still up-to-date, while they become more widely used. The linear discriminant analysis, after its probing phase from the 70's, is the most widely used operational method, providing trustworthy predictions. The score function provides many useful applications to the practitioners, and makes possible the calculation of *a posteriori* likelihoods or the construction of risk classes. Other methods, such as the square discriminant analysis, the regressions upon qualitative variables or the non-parametric techniques were also developed, with the view of avoiding the statistical compulsions imposed by the linear discrimination. Recent techniques borrowed from the artificial intelligence, such as the neuronal networks or the genetic algorithms are more and more popular in the academic medium. They allow us to obtain good predictions and, in addition to that, they have the advantage of not imposing statistical limitations.

As for the application, it proves that it is difficult to choose between the different possible models, even if they belong to the same class. We may

get to several competing models, which could be compared from the point of view of their quality, on econometric criteria. We could make the choice using a criterion of prediction efficiency (for instance: R.O.C. Curve), which is however preferred by the practitioners, a fact which stimulates the applications.

## Abstract

*The Romanian banking system comprises private banks mainly and has the following bank risk management structures:*

- 1. The Bank Risk Bureau - (BRB) is a structure specialized in collecting, storing and centralising information on the exposure of each crediting institution in the Romanian banking system to those debtors who were granted loans and/or have commitments that totalize more than the reporting threshold or the payments overdue more than 30 days, regardless the amount, of the natural persons against whom crediting institutions exposures are of approximately 5.700 Euro, as well as information on card frauds committed by the card holders;*
- 2. The Payment Incidents Bureau (PIB) is an intermediation centre that manages information specific to payment incidents both from the bank's point of view (overdraft), as well as from a social point of view (stolen). Information is sent to the PIB through the Interbank Communication Network which links the head office of the National Bank of Romania to the head offices of all banks;*
- 3. The Bank Deposit Guarantee Fund has the purpose of repaying natural persons' deposits according to the terms and conditions imposed by law..*

**Keywords:** *structure; risk; deposits; credit; debtors.*

---

<sup>1</sup> The data presented in this paper are taken from the National Bank of Romania site.

## **1. Introduction**

Romania prepares to adhere to the EU, the countdown to January 1<sup>st</sup> 2007 having begun. Although the negotiations closed, the economic reform is still in development. The banking system, essential in developing the Romanian economy, improved, important progress in privatisation and aligning to the EU surveillance standards being made. The investments in infrastructure and in improving the financial indicators made by banks led to creating a banking system able to face the international standards after the adherence to the EU. On the whole, the banking system has improved from the point of view of monitoring the credit risk, very important being the regulations of the National Bank of Romania as well as of the risk management structures created by the banking authority.

## **2. Bank Risk Management Structures**

### ***2.1 The Bank Risk Bureau (CIB)***

This is a structure specialized in collecting, storing and centralising information on the exposure of each crediting institution in the Romanian banking system to those debtors who were granted loans and/or have commitments that totalize more than the reporting threshold or the payments overdue more than 30 days, regardless the amount, of the natural persons against whom crediting institutions exposures are of approximately 5.700Euro, as well as information on card frauds committed by the card holders.

The database of the Bank Risk Bureau is organized into:

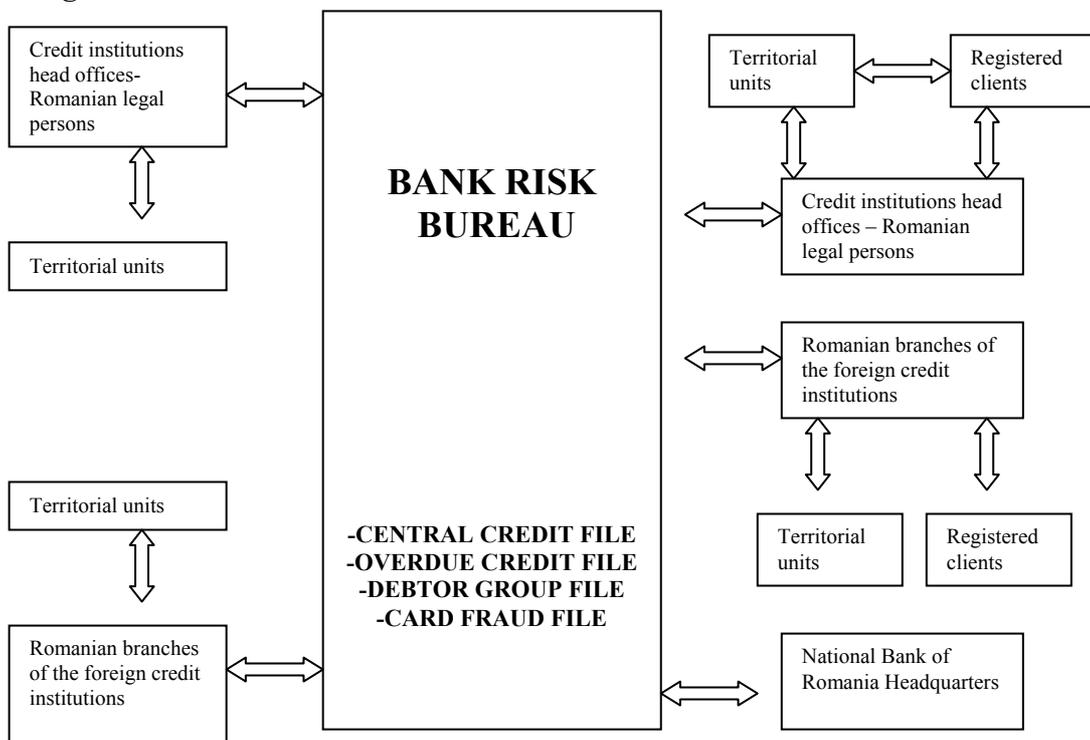

- ▶ The Central Credit File (CCF) which contains information on the bank risk reported by credit institutions and is updated monthly.
- ▶ Overdue Debt File (ODF) which contains credit risk information on delays at the repayment schedules over the past seven years at most and is updated monthly from the Central Credit File.
- ▶ The Debtor Group File (DGF) which contains information on groups of natural persons or/and legal persons representing one debtor and is updated monthly from the Central Credit File.
- ▶ The Card Fraud File (CFF) which contains information on card frauds made by the card holders as reported by the credit institutions and is updated on-line.

The users of the information from the data base of the Bank Risk Bureau are the reporting entities and the National Bank of Romania. The reporting entities are the credit institutions and the companies that deal with loans on mortgage and which are organised according to existing law.

The exchange of information on bank risk is done electronically through the Interbank Communication Network. The reports contain the following information:

- The identification data of the debtors against whom the credit institution has an exposure equal to or higher than the reporting threshold;
- Information on all loans and commitments of the debtor: the type of the loan, maturity, type of warranty, debt service, granting date and maturity date, amount granted, used and unused amounts, overdue loans;
- Information on the natural persons who do not fulfill the conditions imposed by the reporting threshold and are overdue more than 30;
- Information on the groups of natural or/and legal persons representing one debtor: the name of the group, the code of the group, the members of the group.
- Information on card frauds committed by the cardholders: the identification data of the cardholder, type of card, the currency, the date when the fraud was noticed, the amount of fraud.

**Figure 1 Bank Risk Bureau Information Flow**

Source: [www.bnro.ro/legislatie](http://www.bnro.ro/legislatie)

The information is disseminated by the Bank Risk Bureau in two ways:

1. Monthly reports containing information on all the debtors reported that month, all the information available at the Bank Risk Bureau, regarding the loans and commitments of the debtor from all the credit institutions, without mentioning the identity of those institutions (the overall risk situation).

2. In reply to the on-line queries in which the reporting entities may request two types of information: the overall risk situation and the overdue loan situation (on a 7 year period).

It must be underlined that the information is given unconditionally for the reported debtors, while for clients as possible debtors, the access of the reporting entities to the information is conditioned by having that client's approval

Similar credit information management systems are successful in EU countries with a high degree of financial intermediation such as: Austria, Belgium, France, Germany, Italy, Portugal, Spain, etc.

## ***2.2 The Payment Incidents Bureau (PIB)***

Is an intermediation centre that manages information specific to payment incidents both from the bank's point of view(overdraft), as well as from a social point of view(stolen).

Information is sent to the PIB through the Interbank Communication Network which links the head office of the National Bank of Romania to the head offices of all banks.

The database of the PIB is organised in two files:

1. The Payment Incidents National File (PINF) having the following structure:

- Cheques National File (CNF);
- Bills of Exchange National File (BNF);
- Promissory Notes File (PNF)

2. Risky Persons National File (RPNF), which is automatically fed from PINF.

Risky Persons National File is a permanent database. Information on major payment incidents (overdrafts, cheques issued without the approval of the drawee, cheques bearing a false date or lacking a compulsory specification, circular ceques and traveller cheques issued as bearer cheques, cheques issued by a drawer under ban on banking operations, bills of exchange discounted without a claim being assigned upon transfer) registered in the name of a natural/legal person can not be erased from the database unless they are cancelled by the same reporting persons who has previously submitted them to the PIB, on their own initiative, or following a court order.

Ban on banking operations is imposed by a bank on an account holder who is not allowed to issue cheques for a period of one year since the recording to the PIB of a major payment incident, in order to prevent the occurrence of further payment incidents as well as to sanction the account holders who generate them in the banking system.

On the basis of the information received by PIB from the reporting persons, it must:

- send a *Report on the ban* to issue cheques to all bank head offices that will disseminate this information in their own interbank system;

- send a *Report on the loss/theft/destruction/cancellation* of payment instruments to the remitting bank in order to prevent settlement of such cheques, bills of exchange or promissory notes, in case they are presented for settlement by a malevolent person.

The bank head office or the territorial branch, the account of the natural or the legal person is opened with, must recoup not filled-in or faulty filled-in cheques, except those used for cash withdrawal. In case they fail to recoup all the not filled-in or faulty filled-in cheques, they must cancel them and notify it to the PIB within 15 days from the PIB's Report on imposing the ban.

The information stored in the PINF and RPNF will be used:

- a) compulsory by banks and the National Bank of Romania, when remitting chequebooks to account holders

- b) on its own initiative by the PIB, in order to defend public interest, by sending the information to the Prosecutor's Office attached to the Supreme Court and to the Ministry of Interior with their territorial units, from its own evidence or by publishing the information in the mass-media.

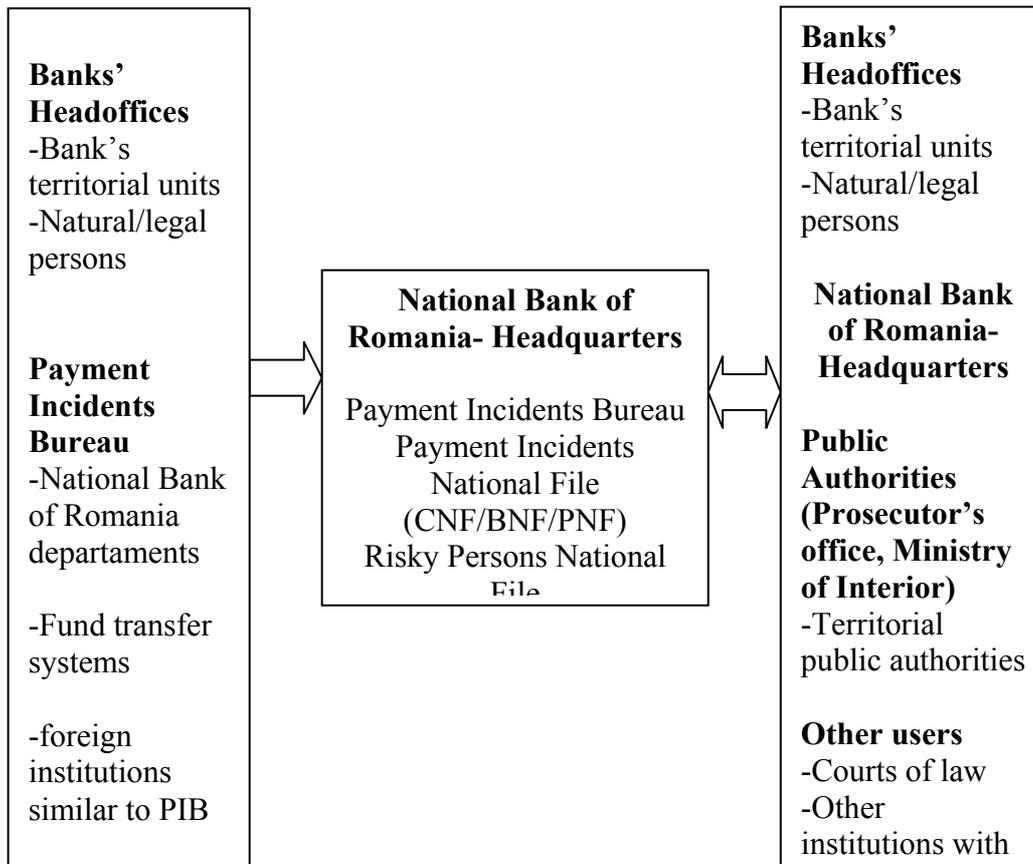

- c) by court, the institutions under letter b), other supervision and control institutions of the state, as well as mass-media based on the data required from the PIB;

- d) by natural or legal persons, other than those under letters a) – c), through banks;

- e) by foreign institutions similar to PIB, on the ground of data concerning payment incidents supplied by the PIB on its own initiative or at the request of these institutions.

Before signing a contract with a partner, a company may consult, through a bank, the PIB's database to verify if the partner is registered as having payment incidents with cheques, bills of exchange or promissory notes. According to the information received from the PIB, the company will be in the position to decide on continuing or ceasing the collaboration with that partner.

**Figure 2 Payment Incidents Information Flow**

Source: [www.bnro.ro/legislatie](http://www.bnro.ro/legislatie)

The database may be accessed by a trader, through a bank, before receiving a cheque from a partner, in exchange for the sold goods. In this case, the trader is able to find out whether the series and number of the cheque, he is going to receive, is part of the payment instruments approved by the NBR, or the cheque was previously declared to the PIB as lost/stolen/damaged or withdrawn.

When issuing a bill of exchange, the beneficiary may access the PIB's database, in order to get information on the drawee. The beneficiary may grant a commercial loan to the drawer if by the issue date of the bill of exchange the drawee (the person indicated to pay for the drawer) hasn't had any payment incidents with other credit incidents. The same prudent

behaviour may be shown by the beneficiary of a promissory note towards the underwriter as the beneficiary of a cheque towards the drawer.

The information stored in the RPNF on a natural or legal person and the specific analysis done by banks may contribute to making the decision of granting a loan or opening an account for a new client.

### ***2.3 The Bank Deposit Guarantee Fund***

The Bank Deposit Guarantee Fund, legal entity subject to public law, has the purpose of repaying natural persons' deposits according to the terms and conditions imposed by law. The Fund guarantees deposits held both by residents and non-residents in domestic or foreign currency.

In case of a bank insolvency, the Fund guarantees the payment in Lei of deposits, irrespective of the currency or the number and size of deposits, within the guarantee ceiling, updated half-yearly with the consumer price index. The guarantee ceiling includes interest on the respective deposits until the date they became unavailable.

The total amount of financial obligation of a bank towards a depositor is established by totalizing all the deposits held by the depositor, including due but not paid interest at the date the deposits became unavailable and by deducting the financial obligations of the depositor to the respective bank.

The Fund pays the compensation within 3 months from issuing the court order for commencement of bankruptcy proceedings, but not later than 3 years from beginning of compensation payments.

### ***2.4. The Credit Information Bureau***

In 2004 granting of loans for natural entities increased. Although they do not have money people buy more and more goods, especially household items. Loans can be obtained easily, sometimes an ID being enough, and within a short period of time, in two hours, without an endorser. An instalment could be under 10 Euro making the loan accessible to almost anyone. Due to the granting conditions crediting has increased alarmingly, as the whole banking system and mainly the National Bank of Romania noticed. A lot of Romanian citizens got loans from more than one bank, being unable afterwards to repay. It is eloquent the case of a person who had loans at no less than 10 banks, the total amount of granted money being of 168,000 USD. Creating an institution specialised in managing bank risk was necessary. This

was the point when the Credit Information Bureau, an institution that manages credit risk information, was set up.

Created at the initiative of the Romanian banking system, the Credit Information Bureau has the role to support the credit institutions, forwarding reliable, actualised and consistent information on natural entities who were granted loans by banks or other financial institutions, bought something through leasing, were insured against payment risk or are subscribed users of the mobile or national telecommunication companies.

The Credit Information Bureau began its existence on August 16<sup>th</sup> 2004 and at present manages positive and negative data received from banks or non-banking institutions.

The activity of the CIB refers to:

- Collecting/processing data regarding the clients- natural entities portfolio of the participants;
- Information/analyses offered to the participants so that they can:
  - Identify and estimate the credit risk;
  - Increase the credits quality;
  - Diminishing the fraud risk and protecting the granters;
- Establishing the scoring criteria;
- Financial and banking counselling;
- Confidentiality;
- Impartiality and correctness;
- Efficiency.

The CIB system develops in three phases:

*In the first phase*, begun in 16<sup>th</sup> 2004, the participants submit, daily, in electronic format, information on:

- ✓ Debtors whose payments are overdue more than 30 days
- ✓ Fraudsters – persons who committed a banking fraud
- ✓ Inaccurate or incomplete application forms

During *the second phase* of the system development, the so called “positive phase”, operational from July 11<sup>th</sup> 2005, the information received from the institutions mentioned above, on all crediting and insurance instruments for natural persons will be processed.

The CIB, through CREDIT – IT system, forwards the information to the participants, on-line, when the information is required. The information is sent within seconds in form of the Credit Report. Also, the CIB forwards at

request, once a year, the registered entities, information that comprises the name of the participant(s) where the registered entities have payment that are overdue.

*The third phase* is dedicated to developing the scoring, a product that will offer a synthetical image of the debtor, making the crediting decision easier. The calendar of this phase hasn't been established yet. The CIB is an efficient and secure source of information for the participants. This information adds to that the participants have from own sources or other external ones in order to decide whether to start or not a financial relationship with the person.

Similar institutions have proved their efficiency in many countries all over the world. Statistics prove that credit bureaus facilitate access to loans and also helps to reducing payment overdue in the financial and banking system.

### **3. Conclusion**

As a result of the activity of those structures, the expanding crediting process in the Romanian economy hasn't affected the quality of the loans portfolio, the insecure and overdue loans remaining constant.

Although the measures taken by the National Bank of Romania may be considered as 'drastical', they led to cleaning the loans portfolio, to granting performant loans and, the most important, to forming a banking culture.

## **Abstract**

*To expand foreign-trade relations and exports in particular states developed integrated national systems of export promotion. States – either in co-operation or without co-operation with the private sector – create organizations focused on the functional support to exporting companies (incl. information, advertising and education) and separately organizations for the financial promotion of exports, so called Export Credit Agencies. The Export-Import Bank of the Slovak Republic (Eximbank), representing the latter type of these specialized institutions, offers to the Slovak exporters a wide range of export-financing and insurance products. The article deals with the place of the Eximbank within the Slovak export-promoting system and provides an overview of offered products and the bank's activities in 2004.*

**Keywords:** *export promotion, financial instruments*

## 1. Introduction

While executing foreign-trade operations, exporting companies have to face a wide range of political, commercial and other risks. In response, a large number of states have established a national export-promoting system in order to eliminate or at least minimize these risks. Financial and informational promotion is a key element of these systems.

The establishment of first export-promoting policies is usually dated to the beginning of the 20<sup>th</sup> century.<sup>[1]</sup> This was closely connected with the creation of Export Credit Agencies (ECAs) that constitute up to this day the basis of the national systems of export promotion. At the end of the 19<sup>th</sup> century was the international exchange of goods realized through cash payments or through bills of exchange. Taking into account the political and commercial risks, the only considerable risk was that one of the purchaser's failure to pay. The political stability of the contemporary international environment resulting from the balance of powers significantly contributed to the development of the international trade at the end of the 19<sup>th</sup> century. The World War I represented – as any other military conflict – an enormous source of risks for exporting companies and for economic stability in general. The Great War led to the increase of disbelief among commercial partners, which together with the abolishment of the gold standard resulted in a breakdown of the international exchange of goods.

The economic development after the World War I directly supported the ideas of increasing state interventionism in the area of economic policy.<sup>[2]</sup> In relation to export-promoting policies this led to the establishment of ECAs with the objective to cover the risks resulting from the international exchange of goods and services. The need for such institutions appeared for the first time in states whose economies were characterized by a high dependence on international trade. One of the most important moments was the rising awareness of the linkage between exports (or foreign trade) and the domestic economy.

### Box 1: Main Establishment Waves of ECAs

Phase	Term	Description
1 <sup>st</sup> wave	1918 – end of the 1920s	Establishment of first ECAs in developed industrial countries, which were prevalingly dependent on foreign trade, (e.g. Great Britain – 1919, Belgium – 1921, Germany – 1926, etc.) as a direct consequence of the World War I.
2 <sup>nd</sup> wave	The 1930s	In the aftermath of the 1930s Depression were ECAs founded in other developed economies (e.g., Japan – 1930, Sweden – 1933, USA and Switzerland – 1934, etc.). Export promotion philosophy of this period can be perceived as a result of the prevailing tendency towards state interventionism and protectionism.
3 <sup>rd</sup> wave	After 1945	This period after the end of the World War II is characterized by a dramatic expansion of ECAs. Their establishment was motivated by the necessity to promote the overall reconstruction of by war-destroyed Europe inter alia through mutual trade exchange. The economies of the increasingly liberalizing world started to benefit again from international trade as a source of economic growth.
4 <sup>th</sup> wave	From the beginning of the 1990s	Establishment of specialized institutions for export promotion in the countries of Central and Eastern Europe as a consequence of economic transformation. The main incentive behind was the effort to enable the exporting companies to act in at least comparable conditions as enjoy competing businesses abroad.

*Source: author*

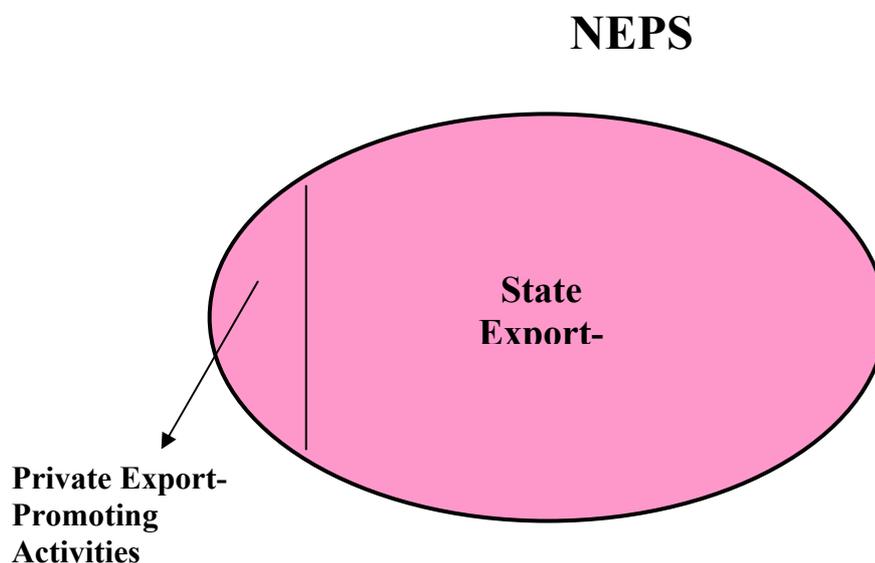

A positive impact on economic performance and employment provided theoretical and practical arguments that allowed the creation of national systems of export promotion. Britain's Export Credit Guarantee Department founded in 1919 in order to provide the companies exporting to risky East-European markets with short-term cash advance was the first in the long line of ECAs in public, private or combined ownership that were established almost in all states in the course of the 20<sup>th</sup> century. The whole history of national systems of export promotion could be characterized

through four major stages in the context of the 20<sup>th</sup> century's main political and economic events as it is described in *Box 1*.

## 2. National System of Export Promotion and Export-Promoting Policy

As we have already indicated, the above-mentioned development lead to the establishment of specialized institutional structures focused on the promotion of exports. State and private activities export-promoting activities together form in every state the national export-promoting system (see Figure 1). Thus it can be defined as a complex of institutions, activities, instruments and measures established and applied with the aim to increase exports.

**Figure 1: National Export-Promoting System (NEPS)**

*Source: author*

State activities are within the NEPS defined through the Export-Promoting Policy. It is possible to state in this regard, that every NEPS is a highly unique complex with particular parameters in every country. This special combination of its characteristics is a reflection of a unique economic

and political development in the particular state, its general economic development, economic structure and level of participation in the international division of labour. A distinctive impact has the development level of the private banking and insurance sector, which provides exporting companies with necessary financial services. Its strength usually defines its share within the NEPS. In a country with a weak or underdeveloped financial system it is the state that has to overtake the responsibility for providing these services to the exporting companies. Thus in many countries, including those in Central Europe, the export-promoting policy constitutes the dominant part of the NESP.

But the critical question always is, what actually the export-promoting policy is and how should it be defined. To give an answer we have to begin from a different point. From the viewpoint of the economic theory, all foreign trade theories are consistent in declaring the impacts of the international exchange of goods and services for contributing to the economic growth and welfare. Concerning the active participation of an economy in the international division of labour, certain differences could be observed. While the clear liberal theory is based on the strict application of the laissez-faire principle, other theories accept or even enforce state interventions. Meant are the first of all Keynesian or neo-Keynesian theories and also some neo-liberal theories (e.g., the Theory of the Social Market Economy) that were developed in the 1930s and after 1945. Efforts to succeed on foreign markets request co-ordination of many areas of the economic life. Economic policy is then called to create such strategies and economic conditions that would allow the achievement of a sufficient competitive advantage of the domestic production and its persistent or at least long-term tenability.

The level of economic development and differences in comparative advantages between economies determine the initial position of the national economy in the process of participation in the international division of labour. Modern (export oriented) economic policy is aimed at creating a competitive advantage by means of structural changes in favour of the most promising sectors. The nature of the process of creation of a competitive advantage allows the execution of such development strategies that do not need to be derived from areas in which the economy enjoys, or enjoyed, internal comparative advantages. The promotion of economic development and creation of an optimal economic environment with emphasis on its long-term tenability and competitiveness are also subsequently projected to the areas of the foreign trade policy and of the results in foreign trade.<sup>[3]</sup> Furthermore, the state has the opportunity to affect the success of its

---

<sup>[3]</sup> *Baláž, P. et al., Medzinárodné podnikanie, Sprint, Bratislava, 1997, p. 261*

domestic legal entities in the competition with foreign rivals. Additional support can in particular emanate from measures implemented within the fiscal, monetary and financial, social or foreign policies.

Foreign-trade policy, as a part of the economic policy, represents a complex of principles and appropriate means through which the state centrally, directly, wittingly affects the stimulation or weakening of certain development tendencies in the foreign trade.<sup>[4]</sup> The application of the foreign-trade policy means and measures leads essentially to the regulation of import or to an increase of the volume of exported goods and services. If the result of the application of such means leads to a growth of export performance or to creation of more favourable conditions for realization of the domestic production on foreign markets, we speak about the export-promoting policy. The policy means that are used for this purpose are called active means of the foreign-trade policy.

Concerning the mutual relation of the export-promoting policy and the foreign-trade policy it is necessary to notice that while the foreign-trade policy affects both the development of the export and import sides of the foreign trade, the export-promoting policy is focused only on positive affection of export. However, by achieving this objective, the export-promoting policy uses not only the instruments of the trade policy but also a number of political instruments, means and measures that wittingly, directly and also indirectly lead to an increase of the volume of exported goods and services.

If all the measures that directly or potentially lead to a growth of the volume of exported goods (and services) should be understood as instruments of the export-promoting policy, it is clear that the traditional approach to the policy is widely exceeded. Export performance could be stimulated through a wide scale of policies, from which, for example, monetary policy, industrial policy, structural policy, regional policy, educational policy, state policy on the field of research and development, etc. can be considered as the most important. Traditional export policy realized by means of fiscal (subsidies), financial, informational and promotional instruments could be then understood as a consequent and necessary form of export promotion.

From the number of possibilities how to categorize the means and instruments of the export-promoting policy we can mention the most usual one – the division of all relevant instrument into:

- Financial
- Functional

---

<sup>[4]</sup> *Lipková, L.*, Medzinárodné hospodárske vzťahy, Sprint, Bratislava, 2000, p. 95

Financial instruments usually include export financing instruments (export credits incl. refinancing credits) and insurance instruments (export credit insurance against risks in foreign trade, reinsurance and sometimes also state guarantees). States (when speaking about the official export promotion) establish either one or two (or even more) specialized financial institutions to offer these services. i.e. we can find one institution covering both financing and insurance services within the NEPS or two different institutions covering these two types of financial instruments separately.

Due to the relatively strong regulation of export promotion in form of financial instruments through international agreements (e.g., GATT, Consensus OECD, etc.), informational and promotional support – or the functional services – to exporters enjoys an increasing degree of importance. At the same time an increasing involvement of the state – through a network of official commercial representations – could be observed, too. Economic diplomacy (sometimes also called commercial or trade diplomacy, diplomacy in the marketplace, etc.<sup>[5]</sup>) represents, as an organic and inseparable element of the whole diplomatic activity of the state, a specific performance of relevant national institutions for international commercial relations and their representatives in relation to foreign subjects and is aimed at the realization of objectives and tasks of the official foreign-trade policy.<sup>[6]</sup> Since export promotion belongs to traditional objectives of the foreign-trade policy, economic diplomacy is according to the above-mentioned definition an important instrument of the export-promoting policy.<sup>[7]</sup>

### 3. Slovak National System of Export-Promotion

The system of export promotion in the Slovak Republic is a direct successor of the former federal system of export promotion that was established at the beginning of the 1990s in Czechoslovakia. The process of economic transformation towards a market economy was accompanied by the establishment of an institutional framework with the objective to execute the tasks of the state export-promoting policy. In charge of the issues related to foreign trade was the Federal Ministry of Foreign Trade that co-ordinated activities falling under economic diplomacy. In order to provide exporting companies with advanced financing possibilities, the Export Guarantee and

Insurance Company was founded. This institution was focused on export credit insurance against territorial and commercial risks. After the establishment of two independent successors in 1993 this company remained in the ownership of the Czech Republic and a new company was immediately founded in Slovakia – the Slovak Export Credit Insurance Company (SPE).

Great attention was given to foreign trade issues during the following years. Foreign trade policy of the newly independent state counted from beginning with a developed institutional framework for the promotion of the expansion to foreign markets. Ministry of Economy that was and still is in charge of foreign trade affairs in the Slovak Republic established a network of Trade and Economic Departments at diplomatic missions. In 1996 was the Foreign Trade Promotion Fund (FPZO) established with the objective to make the export promotion more effective with its linkage to business circles. The Fund was funded both from the state budget and from contributions of exporting companies. A parallel network of official commercial representations was created under its guidance. The idea behind was the application of solidarity principle among exporting companies when big exporters helped to promote internationalisation of small companies. Fund's sources were used mainly for activities that required higher costs at once.

In 1997 started its activities the Export-Import Bank of the Slovak Republic replacing the former SPE. It seemed then that the export-promoting policy as a part of the state's foreign-trade policy has the appropriate institutional framework for the realization of its extensive objectives. Although limited through the shortage of resources that characterizes all economies in transition, the export-promoting policy enjoyed the free space without any significant regulation, e.g. from Brussels. Unfortunately, it has come again to some systemic changes. From 1999 to 2002 were priorities in the area of export promotion set by the "Complex Programme of Export Promotion" adopted by the government in 1999.<sup>[8]</sup> Main activities were divided into three areas of financial, monetary and price policies, regional policy and of institutional organization with annual actualisation with reference to the development of foreign trade.

The Programme counted with the establishment of a new agency that would cover both areas of export and investment promotion. In consequence, the Slovak Investment and Trade Development Agency (SARIO) was founded and the activities of the Fund were damped at the same time starting

---

<sup>[8]</sup> Government of the Slovak Republic, Government Decree No. 499/1999

with the dissolution of its representation network abroad.<sup>[9]</sup> This represented a serious weakening of the existing informational and promotional system, as economic departments at diplomatic missions consisted in the majority of cases of one diplomat and the new agency was established without any institutional network abroad. This problem was formally eliminated in the following years after the heads of Trade and Economic Departments were appointed as representatives of SARIO, but the network of official commercial representations remained understaffed. The lack of budgetary resources became the strongest argument against any major personal consolidation of the official representation network and the few cases were in general compensated by the termination of diplomatic missions in some territories. In comparison with extensive plans of the Complex Programme 1999-2002 it might seem to be an at least contradictory decision.

The Complex Programme of Export Promotion was in the time of its implementation more than a simple export promotion “action plan”. As implies the above-mentioned scope of main activities, its expected impact was considerably wider. It also included activities in the areas of foreign investment promotion and tourism, which naturally exceed the export-promoting policy. Despite their indisputable impact on balance of payments, their inclusion into one partial economic policy makes this harder to manage and thereby less effective. The need to coordinate the development of all economic sectors related to international exchange of goods and services prevailed over the necessity to define the export-promoting policy in a way that would allow its effective management. The development after parliamentary elections in 2002 led to a less extensive definition of the export-promoting policy, but the previous merger of export- and investment-promoting systems resulted in favour of the latter with the decision to put a higher priority on the attraction of foreign direct investments.

#### **4. Eximbank within the Slovak NEPS**

The Export-Import Bank of the Slovak Republic (Eximbank) is a part of the state system of pro-export policy. Pursuant to Act No 80/1977 Coll. on the Export-Import Bank of the Slovak Republic it is charged with supporting the export and import activities of domestic importers and exporters by financing export credit, insurance of export credit with the aim of supporting the growth of foreign trade and increasing the competitiveness of domestic

---

[9] For more on SARIO see e.g. *Grešš, M.*, SARIO. In: Almanach 2002. Bratislava: Ekonóm 2003, pp. 18-25

products. It means that Eximbank is a type of specialized institution that covers both main areas of financial export promotion – export financing (or banking) and insurance services – under one roof. Performance of the Slovak export support function means that as regards the activity of Eximbank the primary criterion is not profit maximization, but the maximum volume of supported export with the concurrent ensuring of a return of funds by minimizing risks resulting from credit, financial and insurance activities.

Eximbank in its activity fully respects rules of the OECD Consensus, concerning state-supported export credits, and complies with the principles of the World Trade Organization. It complies with the rules ensuing to Slovakia from its membership in the EU and participates in the preparation of regulatory rules. It also respects regulations focused on evaluating the impact of the supported export on the environment in the importer's country, as well as directives related to the fight against corruption.

The role of the Eximbank includes as follows:

**A. Banking Activities**

- Refinancing Loans

- current interest rate 5.0% p.a. (+max. 3% p.a. margin from a commercial bank)
- maximum 1 year repayment schedule

- Direct Loans

- Bill of exchange and promissory note-based loans
- Discounting of exporters short-term accounts receivable
- Guarantees and bonds

- contract bonds
- counter guarantees
- payment guarantees

- **Support of Small and Medium Enterprises (SME's)**

- Bill of Exchange and promissory note based loans for the support of SME's

- lower interest rates (5.0% +max. 3% a commercial bank margin)
- bill of exchange based loans up to 1 mil. USD for a period not exceeding 12 months
- for a short term loan of 3-6 months it is possible to finance a specific contract up to the limit on the receivable for that contract

- Discounting of exporters short-term accounts receivable
  - minimum value of the discounted receivables is 10 000 USD
  - repayment period is 30 to 180 days

### **B. Insurance products**

- Insurance of short term export credits
  - against commercial risk
  - against political risk
  - against combined risk
  - insurance of production risk
- Insurance of export guarantees
- Insurance of a confirmed irrevocable export documentary letter of credit
- Insurance of medium and long term export credits
  - insurance of suppliers credit against political and commercial risk
  - insurance of buyers credit against political and commercial risk
  - insurance of production risk
- Insurance of the foreign investments of Slovak legal entities abroad

## **5. Eximbank in 2004**

Eximbank in 2004, through its banking and insurance activities, supported exports worth 66.9 billion SKK, where this figure exceeded budgeted expectations (60.5 billion SKK) by 10.62%.<sup>[10]</sup> Banking activities contributed to this volume in the amount of SKK 48.2 billion, where the figure for insurance activities was 18.7 billion SKK. In comparison with 2003, export support for Slovak businesses by Eximbank grew by 12.3 billion SKK (22.51%). According to preliminary data from the Statistics Office of the SR, Eximbank supported 7.5% of the total export of the Slovak Republic. Eximbank's priority in 2004 was again to endeavor to provide a maximum volume of export support, with a concurrent improvement in the efficiency of its own operation.

---

<sup>[10]</sup> Annual Report 2004. Bratislava: Eximbanka SR 2005.

Direct financing of clients of Eximbank accounted, as at 31.12.2004, for SKK 454 776 thousand, and comprised discount loans to clients. Besides credit activities, Eximbank supported exports also by means of guarantees issued, achieving at the end of 2004 the level of SKK 2 106 227 thousand. Against the preceding year this figure represents an increase of SKK 1 081 838 thousand (105.61%), which was connected with the replacement of a part of discount loans by guarantees issued.

In 2004 Eximbank operated primarily on its own funds, which according to the Act on Eximbank comprise registered capital, funds and retained profit, totaling 4 588 275 SKK thousand, and entrusted funds in the amount of 1 694 236 000 SKK. Compared to 2003 the volume of own funds grew by 2 106 000 SKK, the balance of entrusted funds did not change. Likewise as in 2003, in 2004 Eximbank again succeeded in acquiring external funds on the money market, the balance of which at the end of the year reached 268 901 000 SKK. These resources were used exclusively for financing export-supporting loans.

**Table 1: Overview of Eximbank's Selected Indicators**

	2002	2003	2004	Index 2003/2002	Index 2004/2003
Export supported by EXIMBANKA SR (in mill. SKK)	53 899	54 628	66 881	101,3	122,4
of which: – by banking activities	35 392	40 531	48 211	114,5	118,9
– by insurance activities	18 507	14 097	18 716	76,2	132,8
Registered capital (in mill. SKK)	3 000	3 000	3 000	100,0	100,0
Balance value (in mill. SKK)	7 920	7 187	7 368	90,7	102,5
Total volume of credit in nominal value * (in mill. SKK)	4 470	5 735	5 402	128,3	94,2
Total volume of guarantees issued (in mill. SKK)	1 612	1 024	2 106	63,5	205,7
Level of insurance risk underwritten by EXIMBANKA SR (in mill. SKK)	11 290	11 664	13 906	103,3	119,9
Number of employees	104	88	80	84,6	90,9
General operating costs (in mill. SKK)	142	124	115	87,3	92,7
Profit after taxation (in mill. SKK)	138	96	50	69,6	52,1
Capital adequacy (in %)	97,78	167,65	124,97	171,5	74,5

*Source: Eximbank's Annual Report 2004*

In 2004 Eximbank supported exports worth 67 billion SKK, representing a 22.51% increase on 2003 through its banking and insurance activities. This value comprised export support via banking operations in the volume of 48 billion SKK (an increase of 18.95%) and insurance activities in the volume of 19 billion SKK (an increase of 32.77%).

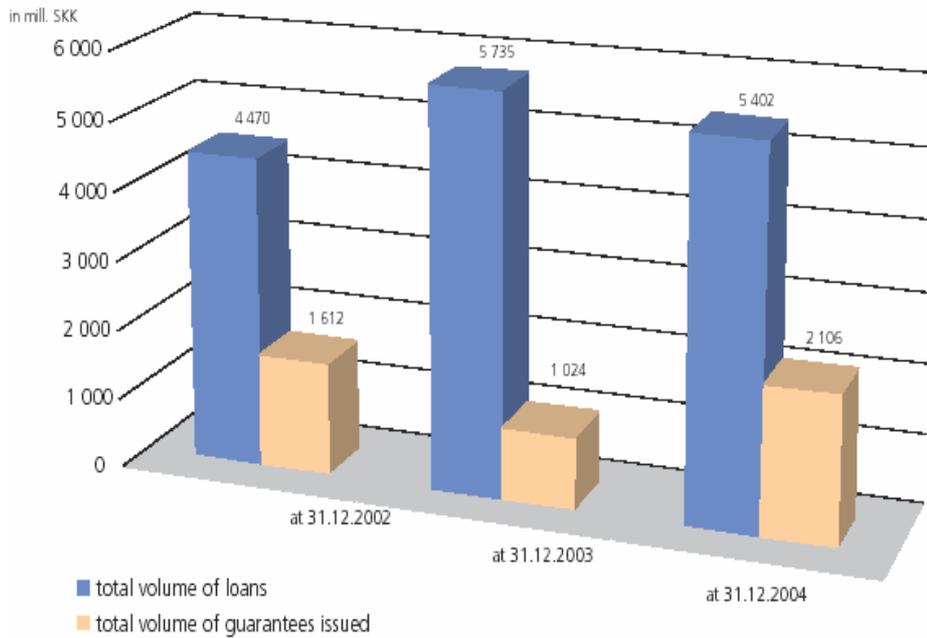

The total volume of credit activities as at the end of 2004 reached 5 402 million SKK, which represents a decrease of 333 million SKK on 2003, i.e. 5.8%. A fall in the total volume of loans was connected mainly with a decline in the balance of discount credit to clients, when a part of discount credit was replaced by guarantees issued. The total volume of guarantees issued to clients as at 31.12.2004 was 2 106 million SKK, representing a year-on-year increase of 1 082 000 SKK, i.e. of 105.61%.

**Figure 2: Export Supported by the Eximbank in 2002-2004 (in mil. SKK)**

Source: Eximbank's Annual Report 2004

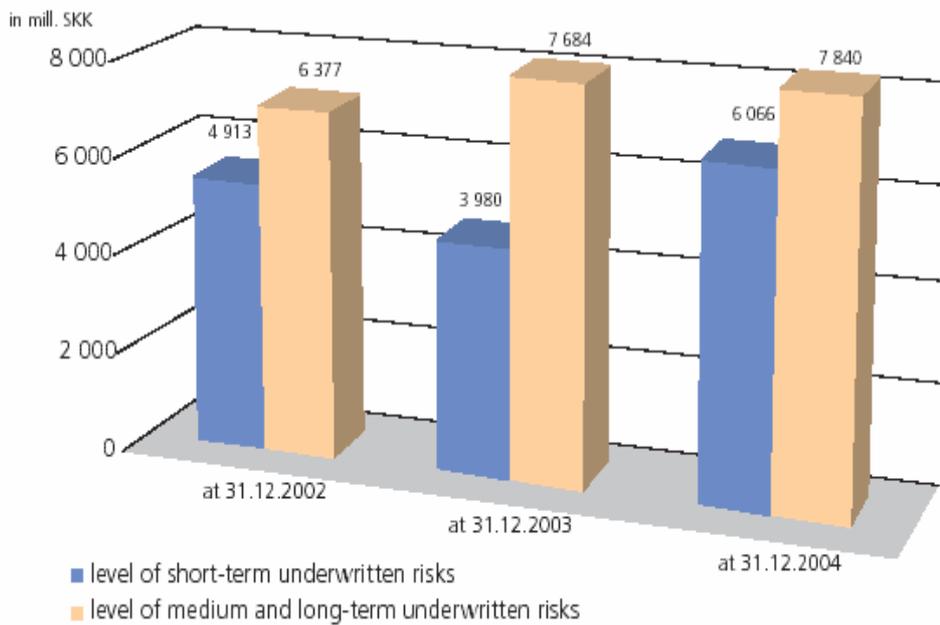

**Figure 3: Total value of credits and guarantees granted in 2002-2004**

*Source: Eximbank's Annual Report 2004*

The total amount of short-term underwritten risks at the end of 2004 totaled 6 066 million SKK. This is a 2 086 million SKK growth on 2003, i.e. an increase of 52.41%. The share of underwritten risks in the insurance of medium and long-term risks represented 7 840 million SKK, which is a year-on-year increase of 156 million SKK, i.e. an increase of 2.03%.

**Figure 4: Underwritten risks 2002-2004**

Source: Eximbank's Annual Report 2004

In looking at the results for the past year it may be said that the year 2004 saw further development in the field of banking products supporting Slovak exports. The amendment to the Act on Eximbank allowed a more flexible adaptation of the Bank's products to market conditions, in particular where this concerns the especially price of financing made more advantageous and the regulation of credit and guarantee conditions. The SR's membership in world economic groupings created opportunity for cooperation with foreign credit and insurance agencies (ECAs), as well as the acceptance of the institution on some foreign financial and capital markets.

The main product, with a continually growing trend in 2004, continued to be refinancing loans. Favorable development was recorded not only in the case of corporate clients, but also in the SME segment, in the provision of discount loans, in the field of approved and provided guarantees, where guarantees are from the long-term aspect becoming a core product of Eximbank. As regards loan products, Eximbank focused mostly on refinancing loans, i.e. short-term refinancing of operating capital of up to one year, transacted via commercial banks by means of a tripartite contractual credit agreement between the client, the commercial bank and Eximbank. By means of discount loans we supported exports worth 2 572 million SKK of which approx. 400 million was formed by the SME segment by way of

repurchasing receivables. Export support by insurance activities of Eximbank in 2004 amounted to 18.7 billion SKK, of which 93% represents export support from insuring marketable risk and 7% from insuring non-marketable risk. In 2004 the Eximbank insured export credits to 52 countries.

## 6. Conclusion

The Eximbank showed in 2004 the ability to adapt to new circumstances related to the accession of the Slovak Republic to the EU and also to the trends and requirements of the business sector. For the closest future, further capital strengthening is necessary. This can enable the Eximbank to reach the desired level of supported exports, what is in our opinion necessary especially with regard to the small and middle enterprises sector. Another proposal for the future activities of the Slovak Eximbank might be the establishment of consulting services as one of the major activities alongside the banking and insurance services to exporters. Unfortunately, this kind of services are suppressed in the competent institution – SARIO – as this is focusing almost completely on investment promotion and attracting foreign direct investments and thus there is no complex package of services for exporting companies. Eximbank, with its competence in financial services and having the analytical basis anyway, might then cross over to the functional export promotion.

## **Abstract**

*The development of financial markets is to an increasing extent currently characterized by their interior and exterior integration, internationalization, evolution of a number of new highly sophisticated financial instruments, especially in the segment of financial derivatives, increasing securitization and creation of very complex international financial structures and financial flows within their framework. At the same time the necessity of restoring free market competition, growing volatility of monetary and financial quantities, institutionalization and intellectualization is more and more intensively discussed. Understandably, both regulation and supervision of the markets have to adapt to these objectively existing trends, including the growing call for increasing the efficiency of all activities. The integration of relations and processes carried out in financial markets requires a similar integration of relations and processes in the sphere of their regulation and supervision. However, there are a number of features of "lower level objectivity" or specific subjectivity and other characteristics functioning in this sphere which modify the implementation of the above mentioned trend, both in terms of depth and width of its intention and especially in terms of its concrete shape. The level of accepted specifics should never impair the very substance of the integration trend. That is the problem dealt with in the presented contribution.*

**Keywords:** *Financial markets; Integration tendency; Regulation and supervision; Specifics of integration of regulation and supervision*

<sup>1</sup> The contribution has been made within the grant project: "Theoretical and methodological bases for the analyses of the systems of regulation and supervision of financial markets", for which the author has got a grant from the Grant Agency of the Czech Republic.

## 1. Introduction

Recent research in the field of regulation and supervision of the financial market is aimed at finding and defining theoretical and methodological bases for analysing existing systems and basic relations between the development stage of this market and corresponding system of regulation and supervision, so as to ensure the optimum and efficient range of these activities while respecting acceptable costs, and lastly to define quality and quantity criteria for efficient operating of the systems of regulation and supervision of the financial market, and to define theoretically the optimum organizational structure of the systems using the above mentioned criteria.

It is necessary for the effort and the possibility of their realization to be based and consequently elaborated respecting deep and valid knowledge of objectively working trends, which objectively define the content and scale of relations and processes, subjects and objects which should exist and work in this sphere, but also their form and ways of their realisation and selfrealisation. It is essential, in accordance with these efforts, chosen starting points and model forms of relations, processes, subjects and objects created on their base, to compare their identity with or differences from the forms of their real, practical and mainly subjective application. The possibility of such comparison and the level of its application is of course directly connected with the level of the knowledge of reality, with the feasibility of settled objectives and last but not least with the possibility of suggesting changes within the existing form and, in case of consensus with their principle and form, of their subsequent realization. Regarding the enormous complexity, relevance and expensiveness of everything hapenning in the mentioned sphere it is very difficult to come to such consensus and therefore it is essential to pursue with maximum prudence and coordination all partial steps which must unconditionally be taken to achieve more complex solutions. Activities such as the “Big Bang” are possible only exceptionally and such operations are mostly both factually difficult and time demanding. The factual, in complex meaning, and time demands are significantly increasing at present and characterised by globalization, internationalization, integration, intellectualization, institutionalization and who knows what else. Existing dimensions are becoming almost automatically totally different, and misunderstanding or even neglect of the fact is, in my opinion, unacceptable and could result in serious problems.

Another partial issue, though in my opinion a very relevant one, to be solved today within the studied area is the issue, or better to say the problem

of integration of the regulation and supervision of the financial market, maybe better to say markets. Objective changes in market economies unconditionally necessitate corresponding changes in the system of regulation and supervision of financial markets. Such changes have already been implemented in a lot of countries with more advanced financial markets than those in the Czech Republic, and here I mean especially EU member countries. In our country such changes are in preparation. It is impossible not to point out that it is the preparation, namely a significant change of its course and results which took place a few weeks ago, that made me accelerate the elaboration of my views on it. I am convinced that it is not positive change, but on the contrary that there are a lot of risks which can have negative impacts. The effort to avoid them or at least to explain them is thus one of basic reasons why I have prepared this contribution.

## **2. Systems of regulation and supervision and efforts of their optimization**

The contribution dealing with the issue of integration of the regulation and supervision of financial markets cannot be complete without at least a very brief remark<sup>2</sup> concerning its systems, their classification, main types and the effort to optimize them and thus ensure the most efficient meeting of their basic objectives and tasks.

The existing development of the regulation and supervision is connected with a vast set of specific systems, proving a lot of differences and diversities. The differences reflect the functioning of a lot of factors, e.g. different historical development in individual countries, different structures of financial systems, different political systems and their traditions and last but not least the size of areas of individual countries and that of their financial sectors. Besides the above mentioned differences, different systems have as well a lot of identical and general characteristics, e.g. the basic objective of regulation and supervision, which can be understood as the preservation of the integrity of the financial market, namely the protection of investors, in its concrete forms, together with retaining its maximum functionality and efficiency.

However, the individual systems differ in many specific items, especially in what they regulate, whether they regulate subjects acting in certain subsegments of the financial market, or the subjects activities in the same or different subsegments, what is the extent and depth of the regulation and

---

<sup>2</sup> V. Pavlát, A. Kubiček: Regulation and Supervision of Capital Markets, pp. 12 - 40

supervision, whether the regulation and supervision are executed by one or more subjects, what are the powers of this subject or subjects, etc. Some of the mentioned items are of qualitative character, others of quantitative one, and it is also possible to encounter their combination.

### ***2.1 Classification of the systems of regulation and supervision***

The systems of regulation and supervision are partly based on legal standards approved by legislative bodies according to a proposal of an authorized subject (sometimes we meet such terms as the top regulator or the regulator of higher grade) and brought to perfection in implementing provisions issued by the regulatory body (usually called the regulator), and partly on the ways and forms of controlling activities (control, monitoring, supervision) carried out by supervision bodies, which can either make part of the regulator or be independent. Numerous classifications have been created for an easier orientation in individual systems according to specific items which constitute these systems. As an example I would like to give a classification used in the above mentioned publication.<sup>3</sup>

1. The subject of regulation – institutional or functional systems
2. The extent of regulation – universal (general, all-embracing, or so-called mega-systems) or specialized systems
3. The number of regulators of the financial sphere – systems with one or several regulators
4. The position of the regulator in the system of state institutions - centralized or decentralized systems, or a combination of both
5. The powers of the regulator – autonomous or subordinate systems
6. The democratic nature of the regulator's functioning – systems of the state regulation and supervision or systems with the elements of self-regulation of the regulated organizations or their craft associations
7. The way the regulator's activity is financed – either systems fully financed by the means of the regulated organisations or the systems fully financed by the means of the
8. national budget, or systems financed in a combined way
9. The way the regulation and supervision are exercised by the regulator – systems which use more formal and bureaucratic approach to solve the problems of regulation and supervision, or systems which lay the primary emphasis on the content (factual) side of a problem.

The above mentioned characteristics, which are intentionally given here as contradictions, however, do not occur in their absolute form in practice.

---

<sup>3</sup> V. Pavlát, A. Kubiček: The Regulation and Supervision of Capital Markets, p. 13

Every concrete system of regulation and supervision is mostly a combination of individual elements while the importance of some of them is predominant. It is necessary and very difficult at the same time, while creating this real “mixture”, to keep a proper rate of combination, and that of compatible elements only. Although a generally acceptable optimal model is in practice almost unreachable, there is a theoretical possibility to create it by a combination of compatible elements. As an example we might possibly mention an autonomous functional system containing the elements of self-regulation, financed by the means of regulated subjects, which is factual, transparent and flexible, and it is necessary to add: relatively inexpensive and efficient. And it is, of course, possible to formulate quite easily an idea of the opposite to the optimal system defined that way. The created classification is an essential basis for a practical comparison of real systems existing in individual national economies, as well as for the creation of models of their further possible development. Similarly it creates the basis for the typology of these real systems and their possible future forms.

## ***2.2 Current main types of regulation and supervision of the financial market***

There are three main types of the regulation and supervision of financial markets in the contemporary world:

- a. **A mega-system**, in which the only one universal regulator of the whole financial sphere ensures the regulation and supervision of the whole financial administration realized in a given national economy. I am going to deal with this type in greater detail in the following part of my contribution because I consider it to be generally the most progressive;
- b. a system based on the existence of a **pair of regulators**, each of them being in charge of administration related to the regulation and supervision of the financial market;
- c. a system of regulation and supervision which is carried out by **one or more specialized regulators**.

As an example of the first type it is possible to mention the systems introduced quite recently in Great Britain, the Federal Republic Germany and Austria, which in my opinion represent one of the best possible forms

of a reaction to the trends in the development of financial markets; the second type, which is also called “a twin”, is currently used in Australia, and the third one exists for example in Italy, where the regulation and supervision of the capital market as a segment of the financial market is vested in one specialized institution, other segments being regulated by one or more specialized regulatory institutions.

Before any further deeper analysis of the mega-system it is necessary to say already here that it is usually internally differentiated. However, within this all-embracing system there are usually parts which fulfil the functions previously performed by independent regulatory subjects, and focused on the regulation and supervision of a certain group of institutions – banks, insurance companies, subjects of collective investing, securities dealers, etc., in an institutional system, or to certain sets of activities – securities dealing, collective investing, supplementary pension insurance, etc., in a functional system of regulation and supervision.

In the patterns used until now, the main types of systems of regulation were divided in such a way to see clearly the prevailing trend of development leading to uniting separate systems of regulation and supervision of individual segments of the financial market into a sole, universal and all-embracing entity – a mega-system or, in other words, **an integrated homogenous system**. However, this point of view is not only a view expressing an intention of the author, it is in the first place the necessity to emphasize the objectivity of the relationship between the development trends of the regulation and supervision, and the elementary development trend of the current financial market as a complex, internally differentiated system which moreover –with growing internationalization and globalization – will in future undoubtedly head for even more complex forms and ways of integration of the regulation and supervision of financial markets.

### ***2.3 Optimization of regulation and supervision of financial markets and its possible methods***

In any period of the current as well as the future development of the financial market, the views on the level and range of regulation differ considerably. The only thing they have in common is that the regulation has never been optimal. According to the views you may encounter on the level of individual subjects of the financial market, it is usually too severe and costly, not efficient enough, even unnecessary, etc. Under certain conditions

of the financial market situation, such assessment and the like can be agreed upon even by those subjects that under different conditions have different views resulting from their different interests. Such situation is usually called overregulation, which is mostly a considerable simplification. Under different conditions that can be associated, in a simplified way, with another stage of the business cycle and its usual excesses aimed at maintaining the so far achieved profit rate, the same subjects can consider the regulation too low, toothless, rigid, unable to predict future development, etc. but again too expensive and not efficient enough. This state is usually called, in a very simplified way, under regulation. Besides those two extremes there is also a third state, in my opinion more frequent, in which the views on regulation and supervision differ according to the interests of individual groups of subjects operating on financial markets represented by investors on the one hand and financial services provided.

The above mentioned facts and a whole range of other opinions result, both in theory and practice, in a permanent effort to optimize the regulation. Generally, it can be stated that this effort is carried out mostly in two levels, first in understanding the substance of optimization and its defining and consequently in realization of the defined. In any case, the third level of this effort, the level of permanent improvement of the result achieved in the previous two levels, cannot be neglected.

As far as the understanding or definition of an optimum system of regulation and supervision of the financial market is concerned, this issue was mentioned, though very briefly, in subchapter **2.1**, so now I am going to be more specific about the above mentioned and to show some possible ways how to achieve the required.

First, let us raise the question what is "required" of financial markets regulation and supervision. Because I neither can nor want to deal with all the pleiad of possible answers and their analysis and assessment now, I will help myself out of it by something more or less agreed upon by the majority of theorists and practitioners, by an example of the definition of the role and objectives of the Securities Commission in Article 2 Section 2 of the Act no.15/1998 of the Collection of Laws, as amended: "The role of the Commission is to strengthen investors' and issuers' confidence in the capital market. The objective of the Commission is to contribute to the protection of investors and the development of the capital market and to support education in this area." We may encounter similar definitions, some brief, others florid, not only in legislation but also in numerous publications of various nature published almost anywhere in the world in the past, at present and, undoubtedly, in the future, too. At the International Conference on

Regulation and Supervision, organized by VSFS in 2003, I defined the basic objective of the regulation and supervision as follows: "maintenance and further development of a fully functioning financial market, namely in all its particular forms and shapes, to enable it to fulfill its basic purpose . . ." <sup>4</sup> At the same time, it is necessary to emphasize that besides these basic, general, irrefutable, strategic objectives it is always necessary to define also the objectives and tasks concerning the changes in the financial system which took place in the past or are showing in outline as probable trends of development. In a modern dynamically developing economy, regulation and supervision must not lag behind the dynamism of financial markets development bringing new problems all the time, whose positive solution - in favour of investors - the existing regulation and supervision should contribute to.

If we consider an optimum system of regulation and supervision, then these considerations must unambiguously result in the premise of its **maximum flexibility**, which would not only secure a fast reaction to current problems by means of repressive measures (negative regulation) but also anticipate potential negative situations and apply the complex of its preventive measures in advance (positive regulation). Unfortunately, most of the currently used systems of regulation and supervision meet the prerequisite of flexibility and combination of suppression and prevention only partially.

When solving the optimization of the system of regulation and supervision, it is impossible to avoid the problem of efficiency of the institutions running the system. The efficiency of the whole system cannot depend on an optimum combination of its compatible elements only. As far as the costs are concerned, changes in the system are mostly connected with relatively high, but more or less nonrecurring costs, whereas the operation of executive bodies of regulation and supervision claims permanent supply of financial means. From this point of view, it is very important to define a set of materialized quantitative as well as qualitative indicators of results (positive or even negative) achieved by these bodies and compare them with the costs incurred. The procession of such a set of indicators is unfortunately still nascent and any complex agreement does not seem impending. There are still such extreme views as "the most effective regulation is no regulation at all". The elaboration of these issues will be the objective of our research team in the near future.

---

<sup>4</sup> In: Regulation and supervision of financial markets. Proceedings of International Conference, VSFS, Prague, June 24 – 25, 2003, p. 28

### **3. Basic trends of the future development of financial markets and system of their regulation and supervision**

I have already mentioned some basic trends of the future development of financial markets, such as internationalisation, globalisation, integration, intellectualisation, etc. Now, I would like to deal with two concrete forms of applying those trends, and than also with the reflection of those changes in required and partly also accomplished modifications of the system of regulation and supervision.

#### ***3.1. Financial conglomerates***

The establishment of conglomerates, i.e. simply said economic subjects formed by joining units of various fields in the only one large complex, has been a momentous manifestation of trends in the economy since the last century. This phenomenon is quite new in the financial sphere mostly because the possibilities of free movement among individual segments of the financial market, at national and international scale, were until recently relatively considerably restricted due to the elements built in the existing regulatory systems. We can mention, for example, the strict separation, in force until recently in many countries, of commercial banking from securities dealing, as well as the separation of insurance activities from other fields of financial dealing. The gradual development of conglomerates, even in the financial sphere, could have occurred only at the moment of weakening of the field principle of regulation, and more generally at the moment when, as an important part of objective trends gaining ground in the field of financial market regulation, the principles of deregulation and harmonization were recognised by political will and projected into the relevant legal norms. It is also important to mention, and I will deal with this issue in greater detail in the following chapter, that this step has not been until now and cannot be very penetrative, and it is just because not everything is clear and solved down to the last detail and we do not wish for any unpleasant surprise.

Financial conglomerates are usually defined as: ‘a group of companies under common control whose exclusive or prevailing activities are based on services provision in at least two financial sectors (i.e. banking, securities, and insurance)<sup>5</sup>

---

<sup>5</sup> The supervision of financial conglomerates. A report by the Tripartite Group of Banks, Securities and Insurance Regulators, July 1995, p. 13

There are not only financial conglomerates but also mixed conglomerates in the financial sphere which are mainly focused on trading or other industrial activities, but at least one regulated financial unit functioning within the framework of their overall structure must be included.

We may distinguish five types of financial conglomerates according to the form of their internal structure:

1. groups in which individual companies mutually own significant stakes in other companies within the given group
2. groups which are headed by a licensed holding group superior to other companies which are members of the group
3. groups which are headed by a non-licensed holding group superior to other members of the group
4. groups with highly integrated companies
5. groups with a different structure

The above mentioned types are, on the basis of their historical development, more or less connected with the individual national economies and, on top of that, they are regulated by legal regulations which are far from being fully compatible mostly because this is a new and not quite known issue, and various political and professional groups perceive it differently and their worries are different too. That is why these financial conglomerates regulated it with different intensity and by means of different instruments.

### **3.2 *Financial derivatives***

By financial derivatives we mean, for example for the purpose of our law of capital market dealings:

- a) options and investment instruments stipulated by this law,
- b) financial forward contracts (namely futures, forwards and swaps) concerning investment instruments stipulated by this law,
- c) difference contracts and similar instruments for the transfer of interest rate or exchange rate risks,
- d) instruments enabling transfer of credit risks,
- e) other instruments which result in the right to financial compensation, and the value of which is derived primarily from the investment securities rate, index, interest rate, exchange rate or the commodity price<sup>6</sup>.

---

<sup>6</sup> Article 33 Section 3 of the Act no. 256/2004 of the Collection of Laws, dealing with business activities in capital markets

In addition to the above mentioned financial derivatives there exist a lot of others which our legislative has not accepted and our practice has not managed to term yet. They represent the most dynamically developing and at the same time, from the viewpoint of the possibility of their rational and effective regulation and supervision, also the most problematic objects of the financial market. A few weeks ago, not only me but also the members of the International Conference about the Situation on Financial Markets could listen to the opinion of one of our most erudite specialists saying that these investment instruments and insufficient regulation of trade (or maybe better quasi-trade) represent a significant threat not only for the development but even for the existence of national financial markets (an organized market with these instruments in the Czech Republic has not, luckily, come into existence yet), but also for international financial markets and not only for them. One of the most important regulation principles, in my opinion, was breached on derivatives markets, namely the ability to enter the market was offered only to such investment instruments which are by their nature transparent, clear and controllable and such is also their trading, including their content and aims.

The popularity of financial derivatives originates in the possibility to use them in two ways: on the one hand they successfully hedge securities dealings against possible risks and, on the other hand they are suitable for speculations. While the first way results in the risk reduction, which is an important factor of investor protection, the second way is connected with substantial risk increase, i.e. threat to investors, which could, together with a considerable institutionalisation growth in this segment, have fatal consequences.

Taking into consideration what has been said and the fact that not only the volume of derivatives trading but also the volatility on capital markets have considerably increased, it is quite understandable that the regulators have paid, in the last few years, a great attention to the speculative use of derivatives. Their effort – to elaborate and further develop methods of regulation and supervision of the activities of financial market institutions which deal with derivatives – is hampered by their unfinished integration at national as well as international levels, while integration and globalisation of derivatives trading is already in a more advanced stage. Since the mid 90s of the last century, it has particularly been the Committee for Technological Issues of IOSCO<sup>7</sup>, which,

---

<sup>7</sup> International Organisation of Securities Commissions

in cooperation with the Basel Committee for Bank Supervision operating with the Bank for International Payments in Basel, has been dealing with the issue of regulation and supervision in the field of financial derivatives trading on financial markets.

### ***3.3 Main issues concerning regulation and supervision over financial conglomerates and business with financial derivatives***

As an attentive reader must know a number of issues of regulation and supervision have been already mentioned above, in addition to that they are mutually connected or sometimes even identical.

The key problem of regulation and supervision over financial conglomerates is the fact that these subjects represent heterogeneous group of companies with different kinds of business in individual segments of financial system. Some of these activities are subject to regulation and supervision but some not according to in which countries the companies are located.

Supervision over financial conglomerates deals with relatively wide range of phenomena and processes -the most important is examining of capital adequacy i.e. finding out if the capital of given financial conglomerate is sufficient for covering his business risk, and then a number of other specific problems as e.g. risk resulting from financial relationships inside the conglomerate, danger of so-called infection, examining of transparency of legislation and management etc. Traditional feature of supervision over performance of individual structural components is a practice where each supervisory body monitors only one type of regulated companies without sufficiently developed contacts with other regulators. This practice is not suitable and sufficient for supervision over financial conglomerates because only individual parts of the whole are being monitored and analyzed. It is almost impossible to get an overall overview on business risks concerning financial conglomerates without mutual co-ordination of activities of individual specialized regulators.

Gradual integration of regulation and supervision on national and also supranational level is, in my opinion, one of the most crucial way which is important to be followed in order to minimize if not totally eliminate consequences of this issue.

If we talk about regulation and supervision in the area of financial derivatives the cardinal problem is to define and create proper information

basis. One of the results of activities of international organizations that I have mentioned in preceding sub-section is recommendation to apply so-called minimal standard at supervision over firms doing business on supranational level, especially in such cases when the scope of transactions of regulated companies is significant. Elaborating these standards supposes initial compilation of list of items (information) that are considered to be essential for risk monitoring related to using of derivatives – loan risk, risk of liquidity, market risk connected with business of derivatives. Another step is compiling of these items into catalogue containing compact file of information being considered as a minimal standard.

The aim of supervisory bodies is to pursue a scope using of derivatives i.e. monitor volume of businesses being concluded by regulated companies and to identify trends of their use. This information must be sorted out according to individual types of derivatives i.e. for swaps, financial futures, forwards a options and simultaneously according to if it concerns stock exchange or out of stock exchange transactions i.e. to monitor the risks really connected with them. It is also important to follow if the regulated companies with shown derivatives get on doing business themselves and use them for securing their transactions. Qualitative information is information on organizational structure of regulated companies, on systems of their internal control, on their policy and practice related to measuring and managing of risks relevant to derivatives. Supervisory bodies can get this information from various reports being prepared by relevant departments of regulated companies for management of the company e.g. report on internal audit etc.

Without saying that doing business with derivatives is connected solely with financial conglomerates of supranational provenience, this connection cannot be ignored and objective requirement of integration of regulation and supervision over financial markets is being strengthened. Another significant relevant aspect is using of derivatives by subjects from all segments of financial market, wide scale of markets where transactions with them are being made and also technological integration of complex implementation of these deals beginning from supply and finished with their settlement. In my opinion, everything calls for gradual, thoughtful, multilaterally secured but urgent initiation of integration- first of all where it has not been instituted and where the reached level even requires it.

#### **4. Integration of regulation and supervision over financial markets and its Czech distinctiveness**

I have already mentioned two of three basic trends specifying development of financial market –i.e. deregulation and harmonization. I dare say some notes on this issue. Supporters of liberal conceptions that mind any regulations are quite benevolent about regulation of financial market but if they hear about integration they are usually very critical. I would like to assure them of the fact that for most theorists and practitioners of regulation of the financial market tendency for deregulation is fundamental and that integration can be understood as removing of overlap and useless requiring of unimportant information, bureaucracy and petrification of unneeded and obsolete matters but also as objectively essential step enabling deeper knowledge of substance of regulated, faster reaction to new subjects, objects, processes and relations and problems connected with this origin, higher level of accepted solutions, larger share of positive regulation and increasing its effectiveness.

As for the trend of harmonization, it is, in my opinion, the crucial one for understanding of objectiveness of integration of regulation and supervision as a form of its harmonization with objective developing trends of financial markets having been mentioned above. Integration, internationalization and globalization of financial markets requires the same level of regulation and supervision. The most important thing is that this simple relation -that is not simple from the perspective of its practical implementation, must be understood by relevant state authorities and first of all politicians and enable its realization.

##### ***4.1. Existing procedures of integration used in selected countries***

The contents of this paper cannot serve as an entire description of all existing procedures and changes in organization of regulation and supervision in individual national economies nor detailed specification of one of those. It would be beyond capabilities of this conference as well. Therefore I refer my readers to relevant parts of publication<sup>8</sup> having been issued before and draw our attention to several of given countries.

At present, working classical mega-regulators are to be found in Great Britain, Germany, and Austria. Institutions like FSA, BAFin and FMA are well-known to specialists.

---

<sup>8</sup> V. Pavlát, A. Kubiček: The Regulation and Supervision of Capital Markets, str. 67 - 100

In Great Britain where the process of integration was finished as of December 1<sup>st</sup>, 2001 there was a change in responsibilities of Bank of England that saved its responsibility in the area of stability of financial system but responsibility concerning supervision over financial market has been transferred to FSA. Co-ordination of activity among the central bank, FSA and ministry of finance has been agreed on the basis of accepted memorandum. All the three institutions meet regularly on Permanent Committee discussing all system problems.

In Germany, an increasing significance of integrated financial strategies and financial conglomerates was clearly defined reason for origin of BAFin. A reform of German system of regulation and supervision was supported by novella of the main legal norms related to financial sphere: Act on Banks, Act on Supervision over Insurance Companies, Act on Security Transactions and Act on Stock Exchange of Securities. As for the relation between BAFin and Bundesbank in Germany exists so-called dual system. According to this system Bundesbank participates in bank supervision in co-operation with Bundesinstitution for supervision over financial services. “By comparison with some ideas existing in CR, the Bundesbank does not perform key function of banking supervision it is done by BAFin because only it is authorized by executive functions.”<sup>9</sup>

In Austria there has been the sole regulator – FMA since April 2002. Austrian federal ministry of finance transferred all responsibilities in the area of banking supervision, supervision over security market, insurance companies and pension funds. Responsibilities and rights of this institution have been stated in Act on Supervision over Financial Market.

#### ***4.2 Specifics of integrating the regulation and supervision of the financial market in CR***

The first official and generally valid document, in which the intention of creating a certain level of an integrated relationship among individual organs of the regulation and supervision of the Czech financial market was simply formulated, was represented by the 15/1998C/L Law about The Commission for Securities and changes and completion of special laws, especially its Part 6 “The Cooperation with Other Institutions and Administrative Bodies”, which defines in §§ 16 – 20 the basis and forms of

---

<sup>9</sup> Peter Baier: Šance a rizika při vytváření integrovaného finančního dozoru v ČR, Pojistný obzor 9/2004, příloha

mutual cooperation of KCP (Commission for Securities), ČNB (Czech National Bank) and MF ČR (Ministry of Finance CR) and is more specific about it in the relation of KCP to individual above mentioned partners and in addition to The Chamber of Auditors of The Czech Republic and to relevant administrative bodies and institutions of other states with the competence in the area of the capital market regulation. It is also necessary to mention a completion of the Law about The Czech National Bank with § 60a worded this way: “The Czech National Bank in cooperation with the Ministry of Finance and the Commission for Securities will create a system of mutual cooperation in the capital market area at the latest in three months since the operation of a special statute ( 1 April 1998, AK remark). No substantial changes were done in the mentioned provisions of the 15/1998C/L Law with the exception of § 20 – International cooperation, which was cancelled and with a substantially wider extent included into § 26 – The Duty of Discretion and International Cooperation.

While preparing new laws compatible with EU Laws which came into force on 1 May 2004, the problems of integrating the regulation and supervision were already discussed but it was underlined in the government proposal of the law about the entrepreneurial activities on the capital market that: “The problems of double supervision will be solved only in the new conception of a consistent national supervision of the financial market.”<sup>10</sup>

Then because of the above mentioned fact there was a surprising contribution of the deputy minister of finance of that period, Ing Jaroslav Šulc, CSc, at an international conference held by the College of Finance and Administration with the subject “The Regulation and Supervision of the Financial Markets” on 24 – 25<sup>th</sup> June 2003, where he gave to the surprise of other supervision bodies – ČNB (Czech National Bank), KCP (Commission for Securities), The Office for Supervision of Cooperative Savings Banks and other participants, too an integral proposal of the integrating of the regulation and supervision of the financial market in CR with enough arguments, though not fully detailed.<sup>11</sup> A contribution of doc. Ing Jan Frait, CSc, the senior director and a member of bankers’ board ČNB was not so surprising. The contribution was called “The bank supervision and the stability of financial system” and was presented at the conference held by VŠB-TU (Mining University) Ostrava 3 September 2003 with the subject “The Financial Management of Firms and Financial Institutions”, from which I would like to give at least a quotation that in my opinion is possible to be taken as a

---

<sup>10</sup> The government proposal of the law about the entrepreneurial activities on the capital market, pg 122, [www.sec.cz](http://www.sec.cz)

<sup>11</sup> The regulation and supervision of financial markets, The international conference file, pg 40-46

perfect prediction of contemporary stage in this area:”Countries which decided to create an integrated supervision institution as a more or less autonomous part of the central bank chose this way a solution which uses natural preferences of the central bank it smartly eliminates potencial conflicts and risks at the same time.”<sup>12</sup>It is possible to characterize the end of the year 2003 from the point of view of the development of oppinions in the problems in question by a quotation from the daily papers Právo: “ The financial market in the Czech republic will be supervised from 2009 – 2010 only by one institution instead of current four ones. The supervision of cooperative savings banks and banks should be united in two years, the control of insurance companies and pension funds will be amalgamated with the supervision of the capital market at first, in 2006.The two risen institutions should be united at least before the acceptance of euro.”<sup>13</sup>

During the remaining part of the year 2003 and the beginning of 2004 the Ministry of Finance CR was taking care especially to the activities related to accepting, publishing and ensuring a without-problem operation of new laws related to regulating capital market, which came into force on 1 May 2004 – the Law of trading on the capital market, the Law of group investments, the Law of bonds and so called Law of changes, and at the same time the problems of the integration and supervision were taken more care.

The result of all negotiations, which took part in that time, was in my oppinion a very serious decision which accepted the objectivity of the proces of integrating the regulation and supervision of the financial market and at the same time it took into consideration the real stage of the development of this market in CR, too, it estimated correctly the possibilities and the time horizon of its future development at last but not at least the deepness and the extent of all existing risks and necessary preparing and realizing steps ensuring the implementation of this objective trend into the Czech economic system without – of course while continuously monitoring, analyzing, evaluating and eventual correcting realized steps - redundant and its substance devaluating consequences. This determination was adopted by the Czech government valid decision on 12 May 2004 nr 452 and besides others individual phases of integrating and organizational steps related to their realization were determined here. In correspondence with the above mentioned decision the Ministry of Finance prepared a government law proposal, the aim of which was the realization of the first period of the integration – uniting the supervision of the capital market (KCP) and the supervision of insurance companies for pension additional insurance (MF)

---

<sup>12</sup> [www.cnb.cz](http://www.cnb.cz)

<sup>13</sup> Právo, 25/11 2003

into the new originated Commission for the financial market and transferring the supervision of cooperative savings banks to ČNB. This proposal was adopted by the government in the decision nr 611 on 21 June 2005. First reading took place at 45<sup>th</sup> meeting of the Parliament and the proposal was commanded to be dealt with by the budget committee and by the permanent commission for banking, which has not been done yet.

On the basis of the above mentioned assessment, I must state that I was very surprised by the government resolution no.1079 from August 24, 2005 on the change in the intention to integrate the state supervision of financial market into a single institution<sup>14</sup> and by the reasons for that change as mentioned in part III of the document ref.no.1338/05 that was prepared by the Ministry of Finance and served as a basis for government proceedings.<sup>15</sup>

The essence of the proposed change is a significant shortening of the integration process - it should be fully completed in 2008 - and with effect from April 1, 2006 all the supervision should become an organizational part of the Czech National Bank.

I can agree, though with some reservations, with the views of the Securities Commission in its press release from August 11, 2005 and especially in the following materials: "Institutional arrangement of supervision - key factors" and "Alternatives to integrated supervision arrangement in the CR"<sup>16</sup>, prepared by the Securities Commission.

Now let me mention a few of my own comments and doubts about the proposed change, which, I hope, the Parliament won't pass. I have formulated them as questions for the authors of the material for government proceedings. "Are you sure that

- the current level of development of the Czech financial market really requires acceleration of the integration process of its regulation and supervision?
- it is really the best solution to transfer all the secondary regulation and all the supervision to an institution whose main mission lies somewhere else and where regulation and supervision will always be on the second place at the

---

<sup>14</sup> [www.vlada.cz](http://www.vlada.cz)

<sup>15</sup> [www.mfcr.cz](http://www.mfcr.cz)

<sup>16</sup> [www.sec.cz](http://www.sec.cz)

best, although

a similar solution has already proved inappropriate?

- this transfer is sufficiently justified by the current importance of banking institutions

on the Czech financial market or even by the possibility of higher level salaries in

the Czech National Bank?

- passing the legislation enabling the integration represents a sufficient legislative

basis for such a performance of regulation and supervision that would enable

an efficient fulfillment of the objective mission, targets and tasks and also

the development of regulation and supervision?

- it is correct to speak exclusively about the integration of supervision if supervision

is mainly "an operational and feedback institute" for primary and secondary

regulation and the material mentions only primary and secondary legislation, maybe

for fear of the requirement to include primary regulation in the integrated system?

- it would not be really better to establish a relatively new and independent institution

of secondary regulation and supervision, on the right foundations and at the right

time, entitled with all the necessary rights and obligations which would enable it

to fulfill the tasks concerning its mission and target?

Understandably, there would be a lot more other questions, comments and topics, but let's wait for the answers to the questions raised so far before we decide to formulate others. In that way the other questions will be of higher quality.

# THE ROMANIAN CAPITAL MARKET IN THE CONTEXT OF EUROPEAN INTEGRATION

**Angela Maria Filip**

telephone: +04 0788461070

## **Abstract**

*This paper tries to identify the perspective of the romanian capital market in the context of european integration. The romanian capital market is an emergent market very attractive to foreign investors seeking international diversification and high profits. The major problem that investors have to face is political risk by which we refer to changes in tax policy and changes in the business climate of the country. The romanian capital market needs to provide a more stable environment for foreign investors in the near future. Even if before 2000, the activity of the stock exchange was very weak, after that year, the capital market registered a sustained growth. This denotes investors' interest on romanian securities which have evolved to meet the changing and complex needs of the participants in the financial system.*

**Keywords:** : emergent market, european integration

## 1. Introduction

The transitional countries of Central and Eastern need an inflow of foreign capital. The economies need high rates of investments and there is not enough domestic capital. The transition was accompanied by a strong decrease of the saving rate, caused by the liberalization of the markets, by the increased supply of goods and the real depreciation of the savings by the upcoming inflation. The need of investments being at a higher level than the economic possibilities of the countries the solution is the resort to foreign capital either by direct capital investments<sup>1</sup> (participation to the incorporation or development of an enterprise, in any of the legal form set by law, the acquisition of shares of the different types of companies, except for portfolio investments, the setting up or development of a branch by a foreign corporation) or by portfolio investments (the acquisition of securities on the organized and regulated capital markets). The foreign direct investments can substitute the national saving, soften the problems of the capital markets and sustain economic growth.

## 2. Considerations regarding emergent markets

In these days of high stock market volatility, the question of how to reduce risk is fore-most in portfolio manager's minds. Since Solnik<sup>2</sup> (1974) it is known that international diversification is one way of the best ways to achieve this goal.

There is a reduction in risk for a portfolio that includes foreign stocks, so rational investors should invest across borders. Adding international to national investments enhances the power of portfolio diversification. Even individuals can easily invest internationally. Many mutual funds cater to the demand for international diversification. There are separate index funds for Europe, the Pacific Basin and emergent markets.

Having too many choices, marketers face the challenge of determining which international markets to enter and which are the appropriate marketing strategies in the countries they are planning to penetrate in order to diversify their portfolios.

Like other transition countries, Romania is considered an emergent market.

---

<sup>1</sup> According to the Government Emergency Ordinance no. 92/1997 in Romania

<sup>2</sup> Solnik B., 1974, Why Not Diversifying Internationally Rather than Domestically?, Financial Analyst Journal, July-August

Broadly defined, an emergent market is a country making an effort to change and improve its economy with the goal of raising its performance to that of the world's more advanced nations. These countries try to make their economies strong and more open to international investors, and more competitive in global markets but they face lots of problems in order to achieve these goals. Anyway, most nations have something of value for international trade in terms of natural resources, labor, technology, location or culture.

Emergent markets are an increasing part of today's investment opportunities but so far have been taken into account primarily by global institutional players, who having the opportunity to make sizable allocations have selectively invested early in the most promising sectors to obtain high returns in very short time even if the risk is also high.

Investors are attracted by above average returns but many of them remain hesitant to participate due to a lack of understanding of the market, restricted access to research, minimal corporate information, risks associated with yet under-developed market-economies and the need for liquidity. Still some international investors favor emergent market stocks and bonds because of the potential high return in a relatively short period of time. There is a great deal of risk involved in these investments because by definition emergent markets are in a state of transition and subject to unexpected political and economic upheavals. The value of their stocks, bonds, and currency change drastically and without notice.

Some of the more common risks of investing in emergent markets include:

- Political risk: The process of modernizing the economies and systems of emergent markets does not represent a steady or predictable process.
- Legal and regulatory transparency: Every country has a system for governing development. It goes without saying that an improper appreciation for how these systems work within a specific country could have a severe impact on investment returns and the problem is that frequently there is a lack of such transparency.
- Liquidity concerns: Lack of central databases as well as public records of transactions means that there is a deficiency of market pricing information to make comparisons as well as drive transactions. Reduced market transparency also means that transactions take longer to close. Word of mouth selling methods because of a lack of a database driven listing service impedes

transactions and liquidity. This is a serious problem that undeveloped market have to face.

- Infrastructure
- Currency Risks
- Imperfect fundamental data and research information
- Possible enforcement difficulties.

### **3. The Romanian Capital Market**

#### ***3.1 Legal framework***

Capital market organization in Romania is based on principals of investor protection, administrative supervision, and self - regulatory organizations, and principals of specialization of activities performed and limited contractual freedom.

The design and implementation of the regulatory framework of the capital markets in Romania began in 1994. Ten years ago, the Romanian capital market had a widely dispersed shareholder structure, an insufficiently regulated over-the-counter (OTC) market, and six significant players (the State Ownership Fund and five Private Ownership Funds) on the Bucharest Stock Exchange and on RASDAQ. The National Securities Commission (CNVM) had been created to administer and control compliance with the Securities and Stock Exchanges Act (Law 52 / 1994), as an autonomous administrative authority which is directly subordinated to the Romanian Parliament.

#### **The main laws that regulate Romanian capital markets are:**

- Law 52/1994 on the securities and stock exchanges;
- Government Ordinance 24/1993 on regulation for the establishment and operation of open investment funds, financial investment companies, depository companies, and investment administration companies;
- Government Ordinance 19/1993 regarding the over-the-counter transactions of securities and organisation of brokerage institutions;
- Government Ordinance 20/1996 regarding venture capital funds;
- From the 9 of April 2002, a new package of Emergency Government Ordinances are regulating the Romanian capital

market (Emergency Government Ordinances No.25 - 28/13.03.2002).

- On July 29, 2004, a new consolidated Romanian Capital Markets Law (Law no 297/2004, “the Law”<sup>3</sup>) became effective. It implements the directives of the European Union in creating and developing a capital market for transactions of modern financial instruments.

**The institution building process consisted in:**

- ✓ Establishment of the legal framework (Law no. 52 and Law no. 83) and capital market regulations which was a extremely large and difficult process started in 1992 and not finished even today even if important steps were made;
- ✓ Establishment of the competent authority, Romanian National Securities Commission (N.S.C.) as the autonomous administrative authority, which is as we mentioned above directly subordinated to the Romanian Parliament:
  - ◆ The National Securities Commission (NSC) is the market’s main rule maker and supervisor;
  - ◆ NSC is responsible for the all operation on the Romanian securities markets, the protection of investors against unfair, abusive, and fraudulent practices, the circulation of information regarding securities, holders and issuers, and the establishment of a legal framework for brokerage activities;

---

<sup>3</sup> The Law respects Romania’s obligations regarding the negotiation of chapters on the free movement of services, the free movement of capital and the Economic and monetary union. The law encompasses the requirements of Council directive 93/22/EEC on investment services, Directive 97/9/EC of the European Parliament and of the Council on investor-compensation schemes, Council Directive 85/611/EEC on the coordination of laws, regulations and administrative provisions relating to undertakings for collective investment in transferable securities (UCITS), Directive 98/26/CEE of the European Parliament and of the Council on settlement finality in payment and securities settlement systems, Directive 2003/71/CEE of the European Parliament and of the Council on the prospectus to be published when securities are offered to the public or admitted to trading, Directive 2001/34/EC of the European Parliament and of the Council on the admission of securities to official stock exchange listing and on information to be published on those securities, Directive 2003/6/CEE of the European Parliament and of the Council on insider dealing and market abuse, Directive 2002/65/EC of the European Parliament and of the Council concerning the distance marketing of consumer financial services, and Council Directive 1993/6/EEC on the capital adequacy of investment firms and credit institutions.

- ◆ NSC set up the size of guarantee funds on both primary and secondary markets against failure of payment.
- ✓ The market's institutions, as follows:
  - Bucharest Stock Exchange (BSE);
  - RASDAQ (the OTC market, created to accommodate the trading of shares from the mass-privatization process; quote-driven market);
  - National Corporation for Clearing, Settlement and Depository (the clearing-settlement corporation for the trades executed on RASDAQ);
  - Independent Registrars;
  - The National Union of the Collective Schemes Organizations ( i.e. Union of Mutual Funds ).

The **National Bank of Romania's** main involvement in the functioning of the capital markets refer to authorisation of clearing and custodian banks, in co-operation with the NSC and cash settlement banks for both equity markets.

The **Bucharest Stock Exchange (BSE)** was initially established in 1882, but closed in 1948 following the nationalization of the private property.

BSE was reopened on **1995**. BSE is a legal entity, a self – regulated body. Trading is carried out through authorised securities companies that are members of the Stock Exchange Association-SEA. The executive body is the Exchange Committee (EC) elected by SEA. The Exchange Committee and the General manager of BSE are approved by NSC that designates a General Commissioner who acts as an observer at the Exchange Committee's Meetings but can propose the cancellation of any decision issued by EC.

The BSE has three listing sectors: corporate securities, public securities and international. The corporate sector of BSE is organised into two \* qualitative\* levels, namely First Tier and Base Tier, with different listing requirements. All listed are required to report quarter and annual financial results. The Bucharest Exchange Trading-BET index launched on September, 1998 monitors first-tier's ten listed stocks, while the BET-C (composite) index, launched on April, 1998 follows the performance of the entire market.

**RASDAQ- The Romanian Association of Securities Dealers Quotation or Romanian over-the counter- OTC – market** is the second segment of secondary capital market which tends today to merge with the **Bucharest Stock Exchange (BSE)**. The Romanian OTC market was

established on September 1996 along the lines of US NASDAQ. The official index of the RASDAQ called RASDAQ Composite was launched on July 1998. It is a market capitalization index, monitoring all the stocks listed on the OTC market.

In December 1994 the **Sibiu Monetary-Financial & Commodities Exchange (SMFCE)** is a very important Romanian exchange which was founded and in July 1997 it became the first financial futures and options exchange in Romania.

**Other structures and institutions acting on Romanian Capital Market:**

- ✎ Open Investment Funds established through a civil partnership contract;
- ✎ Risk Capital Funds set up as civil partnerships without legal personality or as investment joint-stock companies
- ✎ Investment administration companies organised as joint-stock companies for the administration of the open investment funds or investment companies
- ✎ Depositing companies, joint-stock companies that perform depositing activities for investment funds and companies
- ✎ Collective securities investment companies, organised as joint-stock companies, that gather financial resources and invest them in securities
- ✎ Authorised independent registers and independent private register companies

All these structures are authorised and supervised by NCS.

### ***3.2 The evolution of the Romanian Capital Market***

#### **3.2.1 The effect of privatization on the Capital Market**

Romania's capital market was mostly influenced by the way in which privatization was conceived and implemented. The first stage of the privatization process in Romania consisted of the conversion of state-owned companies into commercial companies. As part of the so-called institutionalizing process, six new entities were founded to smooth the progress of the privatization process: the State Ownership Fund (SOF), and five regional Private Ownership Funds (POFs). The SOF retained a 70 percent stake in these companies administering them on behalf of the

Romanian State. The remaining 30 percent stake in the newly created companies was distributed to the POFs under regional and sectoral criteria, which meant that their portfolios consisted of shares in both big and small companies. The POFs acted as administrators of the interests that were distributed to the citizenry.

In the second stage of the privatization process, in August 1992, tradable Certificates of Ownership were distributed to Romanian citizens (15.5 million). The Certificates of Ownership were freely tradable, although no organized market for them existed – similar to the situation on Wall Street before the Buttonwood Tree Agreement of 1792. The Certificates could also be exchanged for shares but only through either a MEBO privatization (in which the employees became owners in the company) or an issuance in an initial public offering (IPO). Statistics show that the MEBO method was used extensively since its start in 1994, with around 1,500 companies having been sold to associations of employees and management for Certificates of Ownership and/or cash from the POFs, and for cash from SOF. In March 1995, 113 IPO's were launched. The first listed stocks on the Bucharest Stock Exchange came from among those companies. In the same period, other companies were sold directly to strategic investors.

The scarcity of domestic capital, the inability to attract foreign investments, and the bureaucracy resulted in a disappointingly low participation in privatization efforts. As a result, in June 1995, a new Mass Privatization Program was commenced. This time, 49 percent to 60 percent of the shares in 3,905 companies were on offer. These companies were the remaining ones from the initial 6,280. Another 800 companies were retained by the SOF to be sold directly to foreign and local strategic investors. New, nominative, non-tradable vouchers with ROL 975,000 nominal value were allocated to 17 million citizens.

In the third stage, new vouchers were issued which, together with the Certificates of Ownership, could be exchanged with the shares of companies or shares in POFs. Each citizen had the right to exchange their vouchers in ROL 1.0m (approximately US\$290 at that time) worth of stock. The number of shares that could have been exchanged by one individual was limited in order to avoid the accumulation of Certificates of Ownership. In March 1996, when the subscription period came to an end, 95 percent of Romania's citizen holders had changed their vouchers for company shares.

The Mass Privatization Program created a widely dispersed shareholder structure for the privatized companies. This created problems for the newly-privatized companies that sought out methods to avoid decisional deadlock stemming from the difficulty in organizing and moderating

shareholder meetings due to the large number of participants, their divergent perceptions, and their total ignorance of economics, law, and the specific industry of the issuer. Meanwhile, portfolio investors gathered vouchers dispersed through the privatization process in order to pass them on to large institutional investors and ultimate acquisition of these packages by majority shareholders. This retail business was conducted by a considerable number of small brokerage firms, pooling the otherwise insignificant stakes of individuals. This process created a sort of boom in the brokerage business, but once it was over many brokerage firms went out of business.

Direct investments were made by purchasing the majority of shares from the SOF. This was followed by acquisitions of minority packages through brokerage firms that had collected shares from individuals. A third stage occurred in some instances in which an offer to the public to purchase all of the shares in a company was made with a view to changing the status of the company from a public to a closed one.

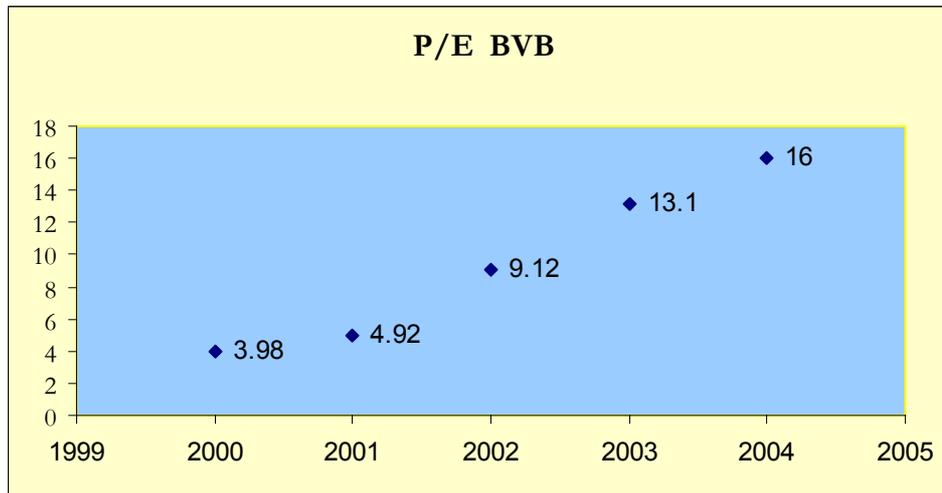

The SOF had to dissolve itself within seven years from its creation by selling 10 percent of its initial stake each year but it developed into a durable institution. In 2000, it was renamed the Authority for Privatization and Management of State Ownership, and merged in 2004 with the Authority for Recovery of Banking Assets under the name of the Authority for Recovery of State Assets. The five POFs were transformed in 1996 by Law 133/1996, drafted by Herzfeld & Ruben, P.C., into Financial Investment Companies (SIFs). Holding in their portfolios significant stakes in various companies, the five SIFs were able to nominate members to the boards of administrators of the companies, which allowed for a concentration of decision-making. Although in some cases the decisions imposed by SIF representatives in the boards of administrators were short sighted, or lacked coherence, the overall effect of their presence on the background of an otherwise widely dispersed shareholder structure was beneficial. Today all five SIFs are listed on the Bucharest Stock Exchange.

### **3.2.2 The Romanian Capital Market today**

The good results registered in 2005 come as a continuation of those seen in 2004, considered to be the best year the Bucharest stock exchange has had since its foundation in 1995. The total value of the transactions in 2004 stood at 600 million euros, with capitalization exceeding 9 billion euros, while the BET index rose by more than 100 percent.

It is interesting to underline the main reason for the increase of the stocks prices. Figure 1 illustrates the evolution of the price/equity index and we can observe that the increase was due to the adjustment of the Romanian index to those of other countries. Between 1979-1999 Romanian stocks were highly under-evaluated.

**Figure 1 Price per equity on BVB between 2000-2004**

*Source: www.kmarket.ro*

After a long recess, the year 2004 saw the listing of new issuers on the Bucharest Stock Exchange; these companies had their shares listed here, but they also listed their bonds. Another major event in 2004 was the broadening of a market niche consisting of instruments generating fixed returns. Many people voiced skepticism about the consolidation of this sector, shortly after its establishment in 2001, when a small decline was registered. However, a big step towards the consolidation of this sector was made in 2004, when important banks, such as BRD - Societe General, quoted significant amounts of corporate bonds on the Stock Exchange.

Under the consolidated capital market law, issued in 2004, the Bucharest Stock Exchange was turned from a state owned institution into a joint-stock company. The law also provides for the establishment of a new institution, namely the Investors' Compensation Fund, and enables banks to play the role of middlemen on the capital market, together with financial investment companies. In 2007, any broker from the EU space will be granted access to the Romanian stock exchange.

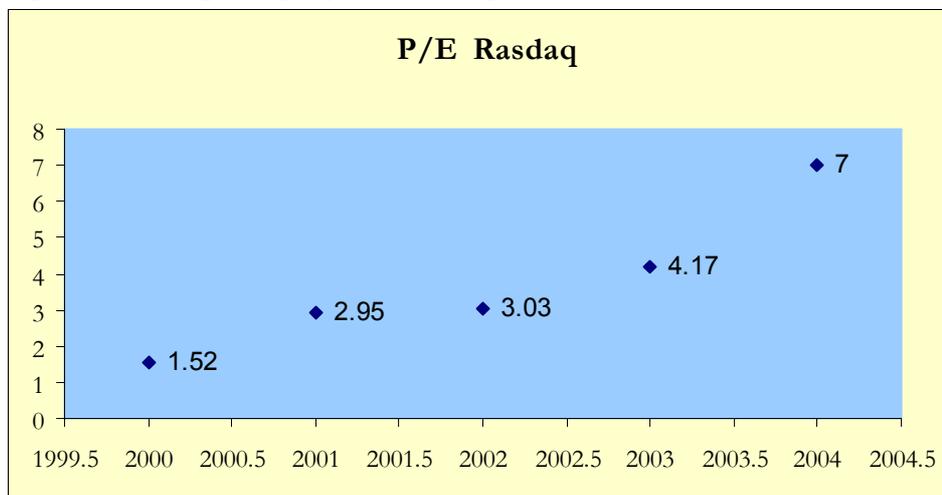

The electronic stock-exchange, RASDAQ, established in 1996 along the lines of the US NASDAQ, also behaved well in 2004. The composite

index witnessed an increase of almost 40%; however, the most important upturn was seen in the Category I and Category II indexes, 60% and 72% respectively.

Also, the stock exchange capital increased to almost 2 billion Euros. The shares of 11 companies are listed in the RASDAQ's Category I; 17 companies can be found in Category II, and the basic category consists of more than 3900 companies. Preparations for a merger with the Bucharest Stock Exchange started last year.

Figure 2 illustrates the evolution of P/E index for stocks listed on Rasdaq and we can observe that the values are appreciatively half of those encountered on BVB.

**Figure 2 Price per equity on Rasdaq between 2000-2004**

*Source:www.kmarket.ro*

A very promising market in our country is that of mutual funds. By the types of investment instrument that these investment companies acquire we distinguish<sup>4</sup>:

- Money market funds – are investment companies that acquire high-quality, short-term investment (money market investment). Individuals tend to use money market funds as alternatives to bank savings accounts because they are generally quite safe (although they are not insured, they typically limit their

<sup>4</sup> Reilly F., Brown K., 2000, Investment Analysis and Portfolio Management, The Dryden Press, USA, p.87

investments to high-quality, short-term investments), they provide yields above what is available on most savings accounts, and the funds are readily available.

- Bond funds – generally invest in various long-term government, corporate or municipal bonds. They differ by the type and quality of the bonds included in the portfolio as assessed by various rating services. Specifically, the bond funds range from those that invest only in risk-free government bonds included in the portfolio as assessed by various rating services. Specifically, the bond funds range from those that invest only in risk-free government bonds and high-grade corporate bonds to those that concentrate in lower-rated corporate and municipal bonds, called high-yield bonds or junk bonds. The expected rate of return from various bond funds will differ, with the low risk government bond funds paying the lowest returns and the high-yield bond funds expected to pay the highest returns.
- Common stock funds – invest to achieve stated investment objectives, which can include aggressive growth, income, and international stocks. Such funds offer smaller investors the benefit of diversification and professional management. They include different investment styles, such as growth or value, and concentrate in alternative-sized firms, including small-cap, mid-cap, and large-capitalization stocks. To meet the diverse needs of investors, funds are being created that concentrate in one industry or sector of the economy, such as chemicals, electric utilities, health, housing and technology. These funds are diversified within a sector or an industry, but are not diversified across the total market. Investors who participate in a sector or an industry fund bear more risk than investors in a total market fund because the sector funds will tend to fluctuate more than an aggregate market fund that is diversified across all sectors.
- Balanced funds – invest in a combination of bonds and stocks of various sorts depending on their stated objectives.

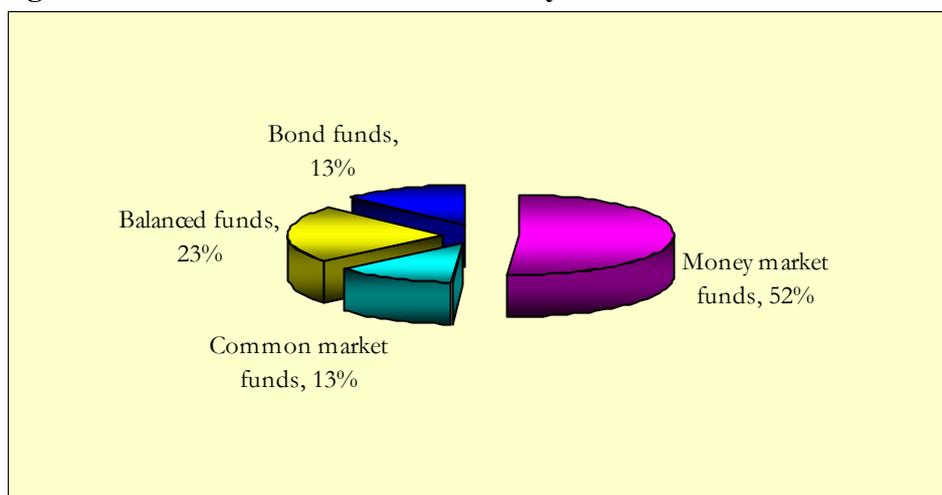

It isn't natural to compare the performances of a money market fund with those of a balanced fund or to compare the risk level of a bond fund with that of a common stock fund. They respond to different needs, the risk level is different and so is the return.

The Romanian Capital Markets Law (Law no 297/2004) defines intermediaries as investment firms authorized by the CNVM, credit institutions authorized by the National Bank of Romania according to

relevant banking laws, and any other such entities authorized in Member or non-Member states to carry out investment services. The financial instruments which are the object of such investment services are: transferable securities, units in collective undertakings, financial market instruments including governmental bonds with a less than 1 year maturity period and deposit certificates, financial futures contracts, forward interest rate agreements, options, derivatives on commodities, and any other instrument admitted to trading on a regulated market in a Member State or for which a request for admission to trading on such a market has been made. In addition, the new Law waives the obligation of SSIFs to get prior authorization for each market. Intermediaries can apply for authorization, granted by the CNVM, permitting the provision of one or more core or non-core services. The minimal capital requirement for these entities ranges from Euro 50,000 to Euro 730,000 depending on the services intended to be provided. The law provides for a gradual schedule until September 30, 2006 for these entities to augment their capital. Supervision of minimal net capital requirements is made through the monthly financial reports that assess the risk of investments in the different categories of financial instruments.

In the figure bellow are presented the market quotas of each type of Romanian fund in march 2005 and we can observe that money market funds were the majority.

**Figure 3 Funds Market Structure in may 2005**

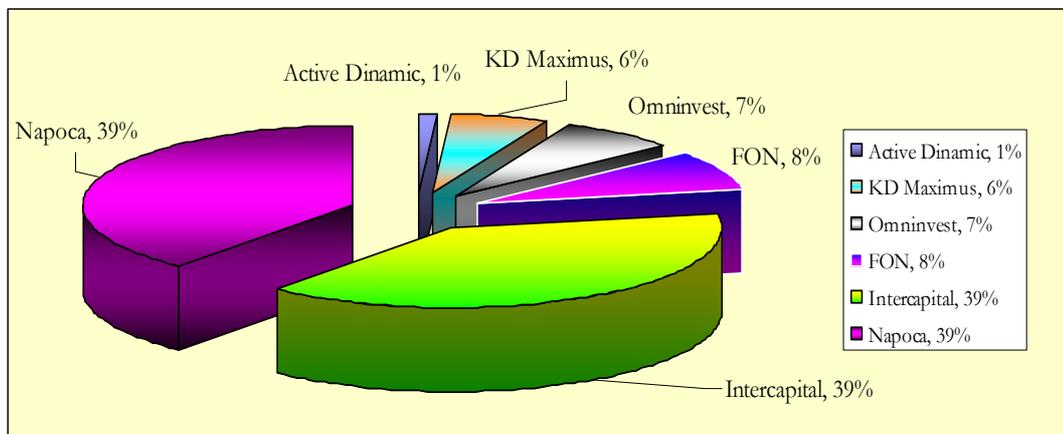

Anyway, the development of financial instruments on the Romanian capital market, the growing liquidity at the stock exchange determine a better

flexibility of investment funds with regard to the investments they are able to perform.

In consequence, these are able to diversify or to specialize on certain type of financial investment in order to offer the investors optimum rates of return in the risk parameters that they choose, and the market quotas the funds detain are likely to change.

Considering the stock exchange growth in the last years, common stock funds have offered high returns, several times higher than the interest offered by banks. The risk level of such funds is indeed big and their performance depends on the general evolution of the stock exchange. In 2004 the best results were achieved by two funds Napoca and Intercapital witch hold together 80% of the Romanian common stock funds market.

**Figure 4 Common stock funds market structure**

Anyway, even the other common stock funds have offered very good returns during 2005 and have good chances to become a strong sector in the conditions in which investors have matured and they prefer to offer their money to a fund administrator rather than to deposit at a bank or to invest directly at the stock exchange.

The administrators of Romanian common stock funds are very optimists and consider that in a short time these funds will become a majority on the market. This will signify an approach to the situation in UE, where the majority of investment funds invest on the stock exchange and create well diversified stock portfolios.

In the first eight months of the current year, balanced funds and common stock funds have attained benefits of over 14%, the bonds funds of

7.6% and the money market funds have offered to investors benefits of only 5%, below the interest rate which was of 5.2%. The interest for these common stock funds is very high and it is expected to appear more common stock funds with bigger levels of risk than the present ones as it seems that Romanian investors do not consider risk when investing, they only expect good returns.

#### **4. Conclusion**

With EU accession set for 2007, Romania represents an attractive emergent market for institutional investors. With a capital market that has flourished in the past years far beyond most expectations, Romania promises generous returns to investors willing to overcome the difficulties of doing business in an emergent market. A comparison of international trends with Romania's legal regime shows that only certain investment techniques and instruments are available in Romania and some new legislation is still necessary to nurture the interest of foreign investors in the local market.

An important step towards the harmonization of Romanian legislation in view of the country's accession to the EU was taken in July 2004 with new securities and capital markets legislation. The adoption of a consolidated law on capital markets, which aims at further alignment with the *acquis* on investment services, market abuse and undertaking for collective investments in transferable securities (UCITS) was a major step for the investment services and securities markets in Romania.

The Law provides for the possibility of the providers of investment services to operate on the markets of member countries upon authorizations granted in the country of origin. There are minimal requirements to be met regarding the Investment firms (SSIFs) and the Management companies (SAI) that will grant them the right to provide services in the member states of the European Union.

In Romania, it is upon the authorization of the CNVM. These requirements include the sufficiency of the financial resources for the proposed line of business, the standard of professional expertise and ethics of the administrative/executive personnel. Detailed provisions are set forth regarding the capital adequacy, the membership in the Investor Compensation Fund (for the SSIF) and prudential rules for the fund administrating firms (in accordance with Directive 85/611/CEE regarding undertakings for collective investment in transferable securities). The "Single Passport Principle" on issuers makes it possible for publicly held companies

to attract capital from the European market as a whole, and once the prospectus for a public offering is authorized in the country of origin, it will be valid for public offerings and/or admission to trading on any regulated market with the EU.

The consolidated version of the Law improves the supervision and the competitiveness of Romania's capital markets. It establishes a solid framework for the development of the Romanian market and its interconnection with European trading and clearing-settlements systems. It is, of course, just that – a framework. Much more will have to happen before the transition can succeed. Indeed, analysts consider that the hardest part is yet to come for CNVM but fortunately, the CNVM has been one of Romania's better-run agencies and there is every reason to believe that its members will live up to the challenge.

## **Abstract**

*Compared with the United States, bonds long played a minor role as a financing instrument for European enterprises. However, during the past few years this market segment has undergone a sharp expansion and has become more important in corporate financing. The aim of this paper is to explain the transformation in this market and the factors influencing it. The analysis of the corporate bond markets in the individual "old" EU-countries shows dynamic development of the debt market since the introduction of the euro. It provides the evidence that the growing importance of the euro as an international currency has led to the integration of the national markets for corporate bonds and has made the market for euro-denominated issues more attractive for both issuers and investors. The current broadening and deepening of the corporate bond markets in the "old" EU-countries has the positive implications for the development of the debt securities markets in the "new" EU- members.*

**Keywords:** *corporate bonds, bond markets*

## **1. Introduction**

An important feature of a well-developed financial system is the existence of a robust corporate bond market working alongside a sound banking system. The existence of a mature corporate bond market including a deep high-yield bond segment has the positive implications for economic development. It allows corporations to raise funds more quickly and on more flexible terms. The existence of the corporate bond markets complementary to bank and equity finance is particularly beneficial for economies with a large number of small and medium sized firms. The introduction of the euro has opened the possibility for the development of the more integrated European capital market. The single currency, by eliminating exchange – rate risk, has removed the main barriers to integration of the debt markets. Before the European Monetary Union (EMU), the government and private bonds issued in different currencies were imperfect substitutes and traded at different prices. The EMU has eliminated this source of market segmentation.

It is now time, after six and a half years of the existence of the single currency, to give some assessment concerning the impact of the euro on the bond market. The aim of this paper is to show the major trends in the European corporate bond market after the introduction of the euro and to explain the transformation in this market.

The paper is structured into five parts. Section 2 provides an overview of developments in the corporate debt sector in Europe before and after introduction of the euro. Section 3 discusses the issues relating to the impact of the single currency on the supply and demand side of the corporate bond market. The problem of the integration of the European corporate bond market and its prospects is covered in section 4 followed by concluding remarks in section 5.

## **2. Overview of the corporate bond markets in Europe**

### ***2.1 Brief history of the European corporate bond market before EMU***

The corporate bonds are debt obligations, issued by private corporations. The companies use the funds from selling of the bonds for a variety of purposes, from building facilities to purchasing equipment and expanding the business. The issuers of the corporate bonds represent various sectors: public utilities, transportation companies, industrial corporations, financial services companies and conglomerates.

The early 20th century was a time of active corporate bond issuance in Europe. Industrialisation, the rapid diffusion and adoption of new

technologies and the development of capital markets to fund economic growth resulted in both supply- and demand-driven bond issuance. The worldwide depression of the 1930s and the Second World War effectively shut the European corporate bond market for nearly 50 years, though domestic credit markets continued to operate over that period. Since 1985, the bond market began to develop and the European corporate bond issuance has increased in relative as well as in nominal terms.

Before the introduction of the single currency, European bond markets were largely domestic and significantly smaller than those in the United States. In 1998 the value of the total bonds outstanding in the euro area was only 56 per cent of the value in the USA. This size differential existed for both the private and the public bond market. In addition, the volume of the domestic issues of corporate bonds in 1995 was low compared with other developed markets: for example USD 0.1 billion in Germany and USD 6.4 billion in France, compared with USD 20.7 billion in the United Kingdom, USD 77.2 billion in Japan, and USD 154.3 billion in the United States (Prati and Schinasi 1997).

In the late 1990s there was sustained growth in the issuance of bonds worldwide, and Europe shared in this growth of the market especially with much increased corporate bond issuance, representing the second most-active bond market in the world. It is interesting to note that the relatively small corporate bond market in Europe until the late 1990s was mirrored by the greater importance of bank lending. While in the USA bank loans play a negligible role in the financing of large companies, they have been traditionally the dominant source of debt financing for European companies. This feature of European corporate finance began to erode just in the second half of the 1990s.

## ***2.2. Issuing activity in the corporate bond segment after the introduction of the euro***

The euro area corporate bond market is the sector in which impressive changes have taken place following the launch of the single currency. In particular, this segment saw the strongest growth in the three years following the introduction of the euro. The size of the long-term bond markets in euro area is presented in Table 1.

**Table 1 Gross issues of long-term debt securities by euro area residents by sector from 1998 to 2004** (EUR billions, issues during the year)

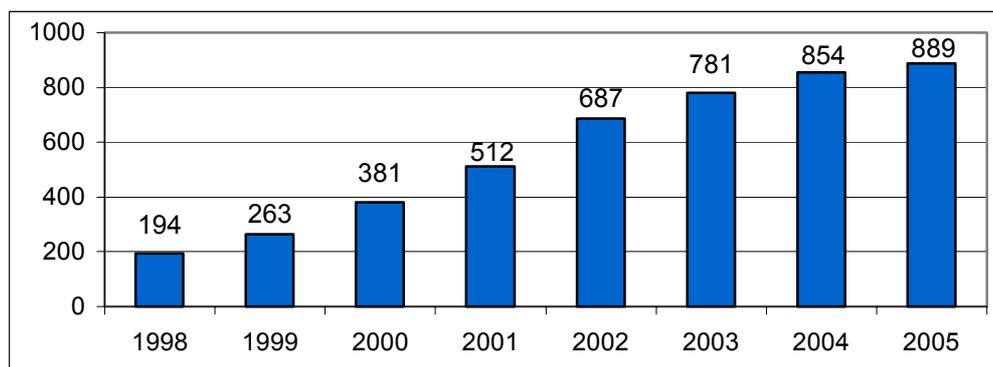

Item	1998	1999		2000	2001		2002	2003	2004	
		EUR	%		EUR	%			EUR	%
(MFIs)	460.4	608.6	43.0	599.1	647.2	40.8	949.5	787.5	866.3	46.8
Non-monetary financial corp.	57.0	141.7	10.0	188.5	242.4	15.3	208.2	203.5	178.3	9.6
<b>Non-financial corporations</b>	<b>33.7</b>	<b>63.4</b>	<b>4.5</b>	<b>94.6</b>	<b>137.1</b>	<b>8.6</b>	<b>79.8</b>	<b>113.6</b>	<b>96.9</b>	<b>5.2</b>

TOTAL	1,160.2	1,416.1	100.0	1,399.2	1,585.4	100.0	1,881.9	1,815.7	1,849.4	100.0

Source: ECB (2005d)

As shown, the corporate bond market in the euro area experienced a major change in 1999, when gross issuing volume increased from EUR 33.7 billion in 1998 to EUR 63.4 billion, by almost 90 per cent. The issuance of corporate bonds by euro area residents in 2004 was EUR 96.9 billion. It is slightly below the EUR 137.1 billion recorded in 2001 but significantly above the levels recorded in earlier years. The gross issuance of euro area non-financial corporations tripled since 1998, compared with a growth rate of only 88 per cent in the case of bank bonds. The share of corporate bonds in the European bond market increased from 4.5 per cent to 8.6 per cent between 1999 and 2001. In 2004 the issuance declined to a share of 5 per cent and reflects the higher issuance activity of the monetary financial institutions (MFIs).

The impressive development of the corporate bond market in the euro area is illustrated by Figure 1. From 1999 to 2005 the outstanding amount of the bonds issued by non-financial corporations rose from EUR 250 billion to around EUR 900 billion. Despite this exceptional growth, the gap between the euro area and the United States is still large. The outstanding volume of the bonds issued by the corporations in the US is now around EUR 2.4 trillion (European Commission 2005).

**Figure 1 Euro area corporate bond market – outstanding amount (EUR billions)**

Source: ECB

According to Rajan and Zingales (2003) the introduction of the euro had a positive effect on the amount of net debt issues. Namely, the amount of debt issues almost tripled after the introduction of the euro. Before the adoption of the single currency the euro area countries had average total net debt issues of almost zero, while the non-euro countries had an average of 1 per cent of GDP. After the introduction of the euro, the non-euro countries remained at the level, while the euro countries jumped to the net issues of 2 per cent of GDP per year.

### ***2.3 Developments in the corporate bond segment in the euro area countries***

The greatest issuers of the corporate bonds among the eurozone countries are: France, Germany and Italy. In France during the 1990s, bond market development reflected the increasing importance of the market-oriented financing. In particular, the debt securities segment has been marked by a considerable growth since its creation in 1985, on account of a liberalization policy and the increase in the number of new debt securities. Moreover, the liberalization of the conditions of the issue in 1999 and a contingent rise in the number of foreign holders led to a higher growth (ECB 2002).

**Table 2 Amounts outstanding of the euro denominated long-term debt securities by euro area country** (EUR billions, at the end of June 2005)

Country	Total	General government	Monetary financial institutions	Non-monetary financial corporations	Non-financial corporations
Euro area	8,244	4,109	2,946	753	437
Belgium	304	231	48	3	22
Germany	2,524	999	1,453	0	71
Greece	171	168	0	1	2
Spain	671	302	171	189	9
France	1,456	838	364	31	222
Ireland	103	31	71	-	-
Italy	1736	1,090	464	141	42
Luxembourg	36	0	36	-	-
Netherlands	807	211	185	377	34
Austria	264	124	119	5	17
Portugal	98	64	21	5	8
Finland	71	49	13	1	8

*Source: ECB securities issues statistics*

The number of the debt securities issued by non-financial corporations in France expanded considerably over the second half of the 1990s. While non-financial corporations accounted for 15 per cent of the total issuance at the end of 1994, by 2000 this proportion has increased to 18.8 per cent, (or EUR 235.1 billion). The bond issuance strengthened significantly between 1998 and 2000 (by about 100%), in connection with the sharp increase in the need for financing arising in particular from the mergers and acquisitions (M&A) activity. At the end of June 2005 the issuance of long-term bonds accounted for a half of the total issue in the eurozone (Table 2).

The German financial system was, and still is, essentially bank-based, which implies that most corporations are largely dependent on bank financing. However, after the introduction of the euro and the integration of the national bond markets, the non-financial corporations have obtained an increasing amount of their funding through the issuance of corporate bonds. Since the launch of the monetary union, there has been a sixfold increase in

the German corporate sector's volume of debt securities outstanding in the euro area. Among the larger European economies, this dynamic growth has been outplaced only by Italy (Table 3).

Although German enterprises' outstanding amount of bonds has increased to 6 per cent in relation to GDP, it is considerably lower than in the US and the UK or France where bonds have long played a significant role in corporate financing. The American, English and French non-financial enterprises' outstanding volume of bonds and money market instrument was equivalent to around one-quarter of their GDP.

**Table 3 Corporate bonds outstanding – an international comparison, September 2003**

Item	Non-financial corporations domiciled in				
	Germany	France	Italy	UK	US
Outstanding amount as %-age of GDP	6	23	12	26	26
Percentage market growth since 1993	907	280	1,522	524	63
Percentage market growth since 1998	613	144	1,119	139	22

*Source: Deutsche Bank (2004).*

In Germany the issuance of corporate bonds is concentrated on a small number of industries. In the first place is the car and air transport industry (28 per cent of the overall volume), followed by telecommunications and IT enterprises (23 per cent) and the energy sector (12 per cent). The average outstanding volume per bond issue in the telecommunications and IT sector amounts to about EUR 1 billion, while the issues of enterprises in the car and air transport sector are on average less than half as large (around EUR 400 million).

The issues consist very largely of papers which the rating agencies classify as "investment grade". Just under two-thirds carry a rating in the highest category (Aaa to A3). These are primarily the bonds of car, air transport and energy enterprises. Telecommunications and IT enterprises are mostly rated lower, however, with a B rating being dominant. The higher-risk "high yield bonds" accounted for 5 per cent of the bonds outstanding.

### **3. Impact of the euro on the development of the corporate bond market**

#### ***3.1 Consequences for the supply side of the market***

The introduction of the euro has been an important catalyst for European issuance over the past six years. Although the member states of the eurozone did not formally adopt the single currency until 1999, the euro-denominated issuance commenced two years earlier, in 1997. From an issuer's perspective, the introduction of the euro has provided access to a larger pool of potential investors and has facilitated the comparison of returns offered by various international issuers. Furthermore, the introduction of the euro enhanced the corporate bond market. For example, in the period 2000-2001, the volume of euro issues in the corporate sector increased by more than 100 per cent. In addition, during the late 1990s many European corporations engaged in the mergers and acquisitions and euro bonds provided a means of their financing. The euro bonds were also the attractive sources of funding for corporations because of the low interest rates.

According to Rajan and Zingales (2003) the boom of the corporate bond market after the introduction of the euro was indeed stronger in the euro area than outside. The authors have conducted a simple panel data analysis for a sample of European countries since 1990 and find that the net private debt issues have become significantly larger for countries that adopted the euro. This suggests that the introduction of the euro had a causal impact on the development of the corporate bond market in Europe.

#### **3.1.1 Changes in the issue size, number of issues and the maturities**

The national currencies were the main cause of the corporate bond market segmenting in Europe. On the one hand, firms were reluctant to issue large number of bonds denominated in foreign currencies, because of the exchange risk involved in repayments. On the other hand, the demand for bonds denominated in national currencies was limited because institutional investors, such as pension funds, had to face exchange risk as well. In consequence of the euro adoption the average size of new bond issues rose considerably, as the number of very large issues, of EUR 1 billion or more, grew significantly. In the period 1999-2005 the average size of corporate issues has almost tripled. In January 1999, the average size of a corporate bond issue in the euro area was EUR 0.3 billion, but by June 2005 it increased to EUR 0.8 billion. That is 60 per cent larger than the average issue size in the US-market.

Although in general the issue sizes in Europe have increased significantly since 1999, with issues above EUR 1 billion becoming more and more frequent, the institutional investors in particular stay away from the private bond market because of a relative lack of liquidity. While the government bonds issued by the large EU-countries tend to amount to EUR 15 billion to EUR 20 billion per line, the standard size of a corporate bond is only one – tenth of the amount or even less. Nevertheless, some progress has been made: among the corporate bonds the proportion of smaller issues below EUR 500 million decreased considerably from about 40 per cent of total issuance in 1999 to well below 20 per cent in 2003. At the same time, the percentage of issues above EUR 2 billion, which was more than 30 per cent in 2001, also decreased to less than 10 per cent in 2003. These changes show that the newly created euro-denominated bond market, because of its size and high degree of openness, is more able to absorb very large issues than the individual bond markets of the predecessor currencies of the euro. (European Commission 2003).

The number of outstanding corporate issues has also slightly decreased, namely by one-third since the creation of the euro. In January 1999, there were more than 1,600 issues outstanding whereas in June 2005 there were 1,077. This decrease is a global trend not confined to Europe. Over the same period, the number of corporate issues outstanding in the US market decreased by 44 per cent.

Concerning the bond maturities, while the government bonds provide nearly the complete range of maturities from 1 to 30 years, the corporates dominate in the short – and medium – term segments. The proportion of longer maturities of the newly issued bonds rose distinctly during the period from 2001 to 2004. In the first half of 2004 there were also a lot of buybacks and bond exchanges in the corporate bond market. In most cases the aim of these activities was to issue bonds with even longer maturities in order to lock in the low interest rates. In the early 2005 Telecom Italia opened the 50-year segment in the euro corporate bond market, just several weeks after the French Treasury had done so in the government bond market (ECB 2005b).

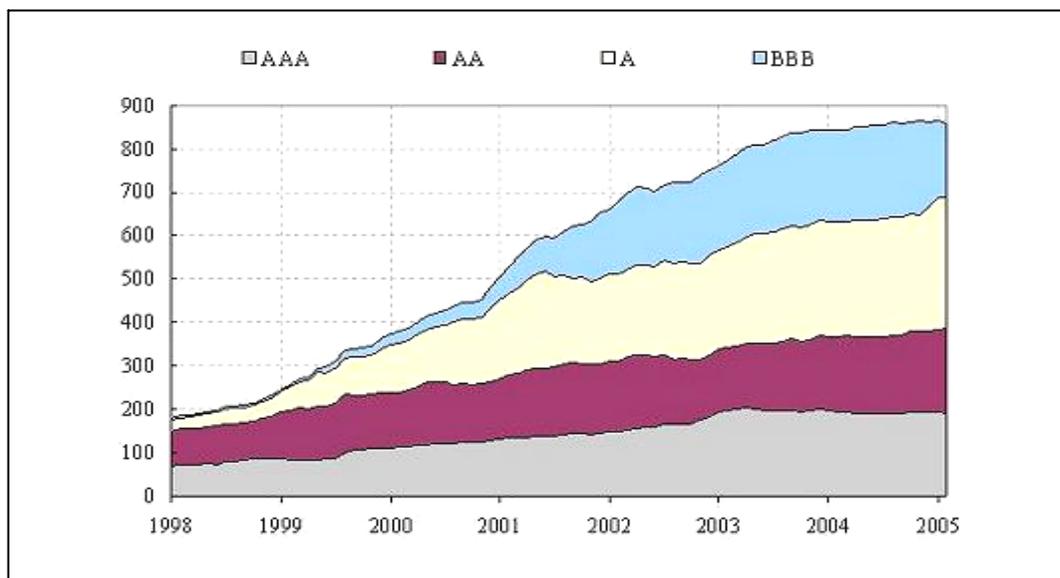

The long maturity market is well developed only in the UK, with the euro market lagging behind. Only 4 per cent of the euro area corporate bond market has maturity over 10 years compared with 50 per cent in the UK-market. A notable feature of 2003 and 2004 was the willingness of euro investors to support the very long-dated issues that had previously only been seen in the UK-market. This highlighted not only the continuing development of the European market at the long end of the maturity spectrum but also demand for lower credit quality at that longer maturity.

### 3.1.2 Decrease in the credit ratings profile and the development of the high-yield bonds

The corporates have a wide range of credit rating and fall into two broad credit classifications: the investment-grade and the speculative grade bonds. The speculative – grade bonds are issued by the companies perceived to have a lower level of credit quality compared with the more highly rated investment – grade companies. The speculative – grade bonds tend to be issued by the companies that have troubling fundamentals. While a speculative-grade credit rating indicates a higher default probability, the higher risk of these bonds is often compensated for by higher interest payments or yields.

As the corporate bond issuance in Europe has expanded, the ratings profile of issues has also undergone a change. In particular, the average credit rating has fallen significantly since the EMU. Prior to the launch of the monetary union, the majority of the bonds were classified as AAA and AA issues. After the adoption of the euro, 50 per cent of all corporate bonds issued in 1999 received a single A credit rating and BBB (Luengnaruemitchai and Ong 2005). Since then, the corporate bonds tend to have the lowest credit ratings in the bond market (Figure 2)..

**Figure 2 Euro area corporate bond market – outstanding amount per rating category**  
(EUR billions)

Source: ECB

As Table 4 shows, roughly just under 90 per cent of the corporate bonds outstanding in Europe were classified as investment grade. However, the shift in the distribution away from Aaa ratings has been marked, falling from 22 per cent in 1985 to 7 per cent in 2001. At the same time, the share of issuers in the Aa rating category has grown to 28 per cent. The percentage of rated issuers in the lowest investment-grade and lowest speculative-grade categories has also increased. The speculative-grade ratings have grown from 11 per cent of the total to 14 per cent. The distribution of ratings shows a much higher proportion of B and Caa-rated issuers than in 1985. Nonetheless, the average A2 credit rating of Europe's corporate debt market still remains higher than the average Baa2 rating of its US counterpart. The changes in the credit ratings distribution since 1985 reflects a new issuance in the lower rating categories rather than credit deterioration by existing issuers.

**Table 4 Distribution of European corporate ratings, 1985-2001 (per cent)**

Rating	1985	1990	1995	2001
Aaa	22.2	29.5	12.3	6.6
Aa	5.6	38.8	33.2	27.9
A	50.0	27.3	41.6	36.3
Baa	11.1	1.4	7.3	15.1
Ba	5.6	2.2	3.1	3.8
B	5.6	0.7	2.1	8.2
Caa-C	0.0	0.0	0.3	2.1
Investment-Grade	88.9	97.1	94.5	85.9
Speculative-Grade	11.1	2.9	5.5	14.1
Total Number of Issuers Outstanding	18	139	382	918

*Source: Moody's (2002).*

As mentioned above, the corporate bonds tend to have the lowest credit ratings in the bond market and are therefore the most strongly affected by economic downturns. This was reconfirmed after the 2001 economic slump, when many prominent companies (among them British Airways, ABB, Ericsson and Ahold) became "fallen angels", that is they were downgraded from investment grade to non-investment grade (Moody's 2002).

Although the growth of the speculative-grade segment of the European bond market over the last years has been an important feature in the market's development, the speculative-grade segment still represents a relatively small proportion of debt issues. In the euro area, these make up only around 15 per cent of the corporate bond market, compared to around 40 per cent in the USA. However, if one includes the fact that market capitalisation in the euro area is relatively low compared to the USA, Europe may be said to be an emerging market for the high-yield bonds i.e. below the investment-grade rated.

The high-yield bonds form an interesting segment of the financial market for the following reasons:

Firstly, these bonds provide a larger degree of flexibility than the bank loans, which are subject of more strict conditions. In consequence, a high-yield bond market can provide funds complementary to bank-based debt or equity.

Secondly, financing via high-yield bonds can encourage a reallocation of funds from economically declining sectors, to fast-growing sectors with urgent needs of funds. Consequently, a well-developed financial sector, in which the bonds are either rated below the investment grade or unrated, should facilitate the transition of medium-sized firms into large enterprises.

Thirdly, the market pricing of speculative-grade bonds takes place by the interplay of market participants. In this way a financial system with a well-developed high-yield bond market provides discipline for lower credit quality of the corporations.

Finally, the high-yield segment of the corporate bond market can be a useful source of information on the future economic activity and on the current credit conditions in the economy. (Bondt and Marques 2004).

Unlike in the US, where the high yield bond market developed in the early 1980s, in Europe the high-yield segment of the corporate bond market is a phenomenon of the late 1990s. The European high-yield bond market had shown the first signs of developing in 1997 and began to grow in the run of the introduction of the euro. The European high-yield bond market was established finally after significant issuances to fund the telecom market in late 1999 and is constantly evolving. In 2003 the issuances reached the record levels of 1999 when the market took-off. In the United Kingdom, the high-yield segment of the corporate bond market grew quicker than in the euro area, benefiting from having a more market-based financial structure. Another determinant of the high-yield bonds issuance are mergers and

acquisitions. During the 1990s there was an increase in the amount of M&A which peaked in 2000.

The high yield bond market has become an increasingly important source of capital for European corporations. At the end of 2003 the share of these bonds accounted for 7 per cent of the total corporate bond market. The size of transactions has increased alongside the greater liquidity in this market (notably with Heidelberg Cement EUR 700 million, Vivendi Universal EUR 325 million and USD 935 million, EMI EUR 425 million and Eircom EUR 835 million and USD 250 million). The performance of high yield bonds has significantly benefited from the general improving credit environment and has been demonstrated by both high returns for investors and European spreads breaking the 400 basis point barrier (the traditional minimum spread seen for a non-investment grade credit (KPMG 2004).

The European high yield market has maintained a very important diversification trend. In terms of the industry structure, the telecommunication sector was initially the dominant force in this field. At the end of 1999, it held a roughly 50 per cent share of the European market for high-yield bonds. However, in 2003, only 10 per cent of the issuances were telecom related and 61 per cent were the issuers of other industries.

In terms of ratings, in the period 1999-2005 the quality of issued high-yield bonds in Europe has declined. In June 2005, the percentage of B-rated bonds amounted to 33.5 per cent, BB-rated 49 per cent and CCC-rated 12%. The current composition of the euro high yield market is more reflective of a mature market.

<sup>1</sup> European default rates refer to EU-15 countries

Source: *Standard & Poor's (2005)*.

In 2003, the distressed and defaulted debt represented 32 per cent of the total high-yield market in Europe. This was down considerably from 58 per cent of the market at the end of 2002 due to defaults in the

telecommunications, technology and energy industries and down from almost 100 per cent at the end of 2001. This decline follows the global trend in default rates. As presented in Table 5, the default rates for global speculative grade fall from 4.89 per cent in 2003 to 1.83 per cent in 2004, with the comparative fall in Europe from 3.42 per cent to 1.23 per cent. It is interesting to note that at the end of 2004, the American and European default rates were similar, with the European default rate of 1.23 per cent and the American one at 2.30 per cent.

The European defaults, similar to those in the US, were concentrated in the media and telecommunication industry. For example, telecom and media issuers accounted for over 88 per cent of total defaults in 2002. In 2003 however, defaults were much more diversified. In fact, the share of telecom and media defaults dropped to less than 10 per cent. In 2003, although the defaults were somewhat fairly distributed across the industry categories, the consumer products industry was responsible for over 50 per cent of the total European default volume. Among the EU-15 countries Italy had in 2003 the largest total number of defaulting issuers (5) and volume (EUR 5.9 billion) due entirely to the default of Parmalat and its subsidiaries.

### ***3.2. Consequences for the demand side of the market***

#### **3.2.1. Corporates as the new investment opportunity**

On the demand side, the introduction of the euro opened up some new investment opportunities especially for internationally operating institutional investors such as investment funds and insurance companies. Namely, the launch of the euro meant the abolition of legal investment restrictions for many institutional investors which were previously not allowed to invest in foreign currencies. In addition to such structurally higher demand other factors have also helped to make corporate bonds more attractive. One factor was that life insurance companies and pension funds switched from equities to bonds, leading to great demand for such securities.

Since the creation of the euro, bond market investors have no longer been concerned by intra-euro exchange rate risks. As a result of a lower foreign exchange risk and an environment of low inflationary expectations, the credit risk has gained more importance in the pricing of financial instruments and the investment decisions of investors. Moreover, the decline in yields in the market for the government bonds encouraged investment in more risky corporate bonds.

After the creation of the euro and the increase in the supply of the euro area bonds, on the demand side a geographical diversification increased strongly in euro area bond portfolios. While until 1998 bond distribution in

the euro area for the largest firms was almost exclusively domestic, the larger bond issues in 1999 were sold on the European scale. A typical example was the EUR 1 billion issue of the French telecom firm Alcatel, in February 1999, 28 per cent of which was placed with Italian and more than 20 per cent with German investors. In addition, the adoption of the euro was associated with a large increase in the asset share of internationally investing bond funds in Austria, Finland, France, and Germany. The euro area unweighted average of the share of assets invested in bonds funds with a Europe-wide strategy rose from 17 per cent in 1998 to 60 per cent in 2002. A similar shift occurred also in the investment policies of pension funds and life-insurance companies. (Pagano, Thadden 2004).

### **3.2.2. Liquidity in the corporate bond market**

A study by Paul Harrison in 2001 stressed the importance of liquidity for the composition of the corporate bond market. If liquidity is restricted, investors emphasise the size and “familiarity” of issues, and so for the smaller and less prominent companies market access becomes difficult.

The expansion in the euro-denominated corporate bonds market has coincided with the other major trend in the bond market, namely the declining supply of treasury bonds. This development is a consequence of the consolidation of central government finances in the euro countries. In addition, at the same time, the introduction of the euro has led to increased competition. Previously, the governments were alone in their domestic markets. Today, they are doing battle for loans from the same source of financing. This competition has led to a number of changes to increase liquidity on the secondary market for treasury bonds. For instance, the average size of the issues has increased. The editions have also become increasingly standardised.

There is a key interrelation between the liquidity of a market and the existence of hedging opportunities. Without the possibility to hedge positions, the tendency to invest in this market remains subdued. The most commonly used instruments for the hedging of bond positions are bond futures. These are typically developed on the basis of government bonds. When these futures are used to hedge corporate bonds, major basis risks are incurred. In case of financial turmoil the prices of government and corporate bonds move in opposite directions. For this reason, the development of indices in non-government bonds and the introduction of futures and exchange-traded funds based on these indices may be a possible answer to these problems. Another possible solution to the liquidity problem could be to increase the issue size or to issue bonds fungible with previous bonds with a limited set of maturities. One of the main problems of the demand side

development is also the transparency of the private bond market, that can be improved by quotations on electronic trading systems (ECB 2004).

### **3.2.3. Development level of the secondary market**

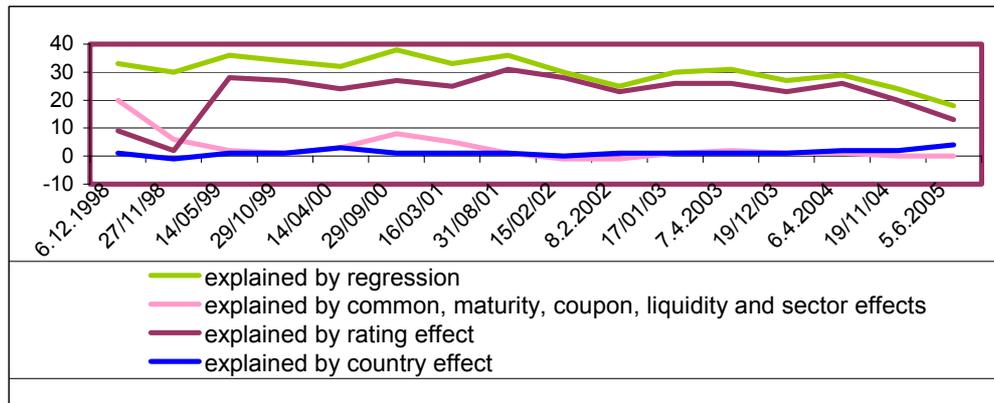

The secondary corporate bond market is fragmented. Most of this fragmentation is due to the fragmentation of clearing and settlements systems in Europe. Although the problem has been well known since the late 1990s, progress has been slow. Securities settlement in the euro area is still dominated by national players, whose number had only come down from 23 to 14 by 2003, compared to two in the USA, and hampered by national rules that restrict cross-border activities of settlement houses.

According to the study of Santos and Tsatsaronis (2003), the introduction of the euro reduced the cost of underwriting services for issuers in the single currency to levels similar to those prevailing in the US dollar – denominated segment of the market. The average gross fees in the euro-denominated segment of the bond market halved in the year the euro was introduced, dropping from 1.7 per cent in 1998 to 0.8 per cent in 1999, and remained at the average level of 0.6 per cent in the 1999-2001 period exactly the same figure as in the USD-denominated segment. It should be noted, that the reduction in underwriting fees was largely due to a greater competition of the investment banks in the post-EMU European market and connected to the rapid penetration of the market by the US investment banks. The European corporate issuers moved away from their home bankers towards the larger US investment houses.

## **4. Integration of the European corporate bond market**

The yield differential between corporate bonds depends on a number of factors, such as the credit rating, time-to-maturity and liquidity. Under full integration, the impact of these specific factors should be totally independent of the country of issuance. Using the same set of factors, it is possible to obtain measures of corporate bond market integration by investigating whether or not risk-adjusted the yield spreads have a systematic country component. In an integrated market, the proportion of the total yield spread variance that is explained by country effects should be close to zero. Following this approach the indicator shows that the euro area corporate bond market is fairly well integrated. Country effects are seen to explain only a very small proportion of the cross-sectional variance of corporate bond yield spreads (Figure 3).

**Figure 3 Proportion of cross-sectional variance of corporate bond yield spreads, explained by various factors (percentages).**

Source: ECB (2005c).

It should be concluded, that the bond-market integration does not require complete convergence of bond yields. Even in an integrated market, differentials may persist because they are a reflection of the various bonds' different risk, maturity, or cash-flow characteristics, rather than stemming from trading costs, taxes, clearing and settlements costs, or other institutional barriers to trade.

## 5. Conclusion

The euro area corporate bond market has grown considerably after the introduction of the euro. The evidence for the first 6 years of the euro suggests that the single currency has had a sizeable direct impact on bonds issued by non-financial corporations. Issuance of corporate bonds has taken off on an unprecedented scale in euro area. In this process, both investors and issuers have reaped the considerable benefits afforded by greater competition in the underwriting of private bonds and by the greater breadth and liquidity of secondary markets. The benefits have been very important for European companies, which have acquired cheaper access to a market. The single currency also appears to be a catalyst for restructuring the European corporate sector and for the emergence of new companies.

The euro area corporate bond market has not only remarkably grown in quantitative terms, but also its qualitative nature has changed. The euro area corporate bond market is nowadays characterised by large issues with all possible investment and speculative grade ratings from all types of economic sectors and typically low underwriting fees. As a consequence,

bond markets are gaining importance as means of obtaining corporate finance. The indicators for the corporate bond market, which has grown considerably since the adoption of the single currency suggests that this market is already fairly integrated in the sense that the country of issuance is only of marginal importance in explaining yield differentials.

Based on the findings in this paper it should be concluded, the following trends will play a major role in the improvement of the European corporate bond market in the future: convergence of structures towards the US style debt. This will lead to increased transparency; diversification of issues; growing debt issuance will attract more investors and will increase a competition. The challenge is to overcome the persistent fragmentation of clearing and settlement systems in the euro-area bond market, which prevents a full integration of the market for private sector bonds.

## **Abstract**

*In general, there are available many ways to detect the value of financial derivatives. Very useful approach is Monte Carlo simulation, mainly in case of complicated payoff functions or complex underlying processes. Unfortunately, the plain Monte Carlo simulation needs a very high number of independent paths to get reliable results. Fortunately, there exists many ways to decrease the number of paths via application of the variance reduction methods. In this paper we present some of them. First, we generate (i)  $\mathcal{N}[0;1]$  and (ii)  $\mathcal{VG}\{\theta, \vartheta, \nu\}$  random numbers. The second one was chosen as an example of a complex model which results in complicated applications. On the other hand it allows us to model the underlying distribution more reliably. Later we apply each of the methods to estimate the value of the European call option and barrier up-and-out call option within both settings – the Black and Scholes (1973) and the Variance gamma model (Madan et al., 1998).*

**Keywords:** *option pricing, MC simulation, VG process, variance reduction method*

## 1. Introduction

The essential condition of functional financial markets is the knowledge of methods to determine the prices of secondary financial assets (financial derivatives). It is regularly supposed that markets are efficient, prices of primary assets are given by the interaction of demand and supply, and there are no models to determine the price of primary assets more or at least such precisely as the market do.

However, the definition of a financial derivative says that its price is derived from the price of particular underlying asset. Therefore, there should exist some way to get the fair price of any financial derivative with respect to the price of the underlying asset. Simultaneously, this price must correspond with the market view. Otherwise the arbitrage opportunity will arise.

A very interesting type of financial derivatives is an option, since the payoff function is non-linear. It causes the risk resulting from short positions to be (almost) unlimited. It implies the requirement on efficient risk management of options. Of course, it also requires to know the ways to pricing and hedging.

By an option we generally mean a non-linear financial derivative that gives its owner (*long position*) the right to buy (*call options*) or the right to sell (*put options*) the underlying asset under predefined conditions. Simultaneously, the seller of the option has an obligation to meet the right of the owner (hence *the short position*). The predefined conditions concern, for example, the underlying amount of assets, the maturity time or the exercise price. Sometimes also other non-standard conditions are defined (average price, barrier level, etc.) and such options are referred to as exotic options.

Usually, there is a plenty of methods to price, and subsequently hedge, any option, to name some of them: solving of PDE (partial differential equation) or PIDE (partial integro-differential equations) if jumps occur, or applying the notion of martingales, the expectation operator with useful probability density functions to get analytical formula. It is naturale, that each method must lead to the same result, respecting the same inputs.

However, in some cases we can only run numerical procedures, such as binomial or multinomial lattice models, apply FDM (finite difference method), solve PDE and PIDE numerically or apply Monte Carlo simulation. For example, it is the case of options with complicated payoff functions, multifactor models or complex processes.

Some complex processes allow us to model higher moments of the distribution of asset returns. Although the non-normality of asset returns is

documented starting by Fama (1965), models incorporating skewness and kurtosis of asset returns were provided relatively recently, see e.g. Variance Gamma model (VG model) (Madan and Seneta (1990) for the symmetric case and Madan and Milne (1991) and Madan *et al.* (1998) for the asymmetric case), Normal Inverse Gaussian (NIG) model (Barndorff-Nielsen (1995)) and its generalization Hyperbolic Model by Eberlein and Keller (1995), Meixner model introduced by Schoutens (2001) or CGMY model (according to Carr, Geman, Madan and Yor (2003)) which further generalized VG model. In this paper we will suppose the VG model which can be regarded as a Brownian motion subordinated by a gamma time or, alternatively, as a difference between two gamma processes.

The task of this paper is to present the application of Monte Carlo simulation in case of estimating the price of financial derivatives. We describe and apply several approaches aiming on improvement of plain Monte Carlo simulation.

All such methods are applied in order to: (i) generate random numbers from standard normal distribution; (ii) random numbers from variance gamma process; (iii) estimate the price of vanilla call under BS model; (iv) estimate the price of vanilla call under VG model; (v) estimate the price of barrier call under VG model.

The next section is devoted to basic stochastic processes. Subsequently we describe the Monte Carlo approach in option pricing. In this section we also provide the most important variance reduction techniques (the general ones). Finally, we proceed to running the simulation in order to price the vanilla call and the barrier call option.

## 2. Stochastic processes

In this section we briefly define all processes related to this paper. The simplest building blocks of almost all process applicable in modelling of asset prices are the Poisson process (or closely related ones as a gamma process) and the Wiener process, which provides ingredients for construction of almost all processes with diffusion part.

The Wiener process  $w_{dt}$  can be defined as  $w_{dt} = \tilde{\varepsilon}_1 \cdot \sqrt{dt}$ , where random number  $\tilde{\varepsilon}_1$  belongs to the standard normal distribution, thus  $\tilde{\varepsilon}_1 \in \mathcal{N}[0;1]$ , and  $dt$  describes the (infinitesimal) time increment. Hence, the Wiener process is a martingale, its expected increment is zero at any time and the variance is closely related to the time change.

We can, besides others, build on the basis of Wiener process *the geometric Brownian motion* (GBM). It is the process which was supposed to be the one followed by stock prices in Black and Scholes (1973).<sup>2</sup> The typical property is the normal distribution of asset returns and logarithms of prices – which is equivalent to lognormal distribution of prices. Two key facts are that the financial assets gains return continuously and that their prices cannot be negative. Both ideas are supported by GBM, since the price is given by an exponential formula.

It is assumed that the price dynamic can be described by the following stochastic differential equation

$$dS = \mu \cdot S \cdot dt + \sigma \cdot S \cdot w_{dt}, \quad (1)$$

where  $dS$  is the price change over time interval  $dt$ ,  $\mu$  is the (continuous-time) expected return and  $\sigma$  is its volatility, both  $\mu$  and  $\sigma$  are supposed to be deterministic constants. The solution to stochastic differential equation (1) is according to Itô's lemma:

$$S_{t+dt} = S_t \cdot \exp\left[\left(\mu - \frac{\sigma^2}{2}\right) \cdot dt + \sigma \cdot w_{dt}\right] \quad (2)$$

Note also, that in the risk neutral setting the preceding formulation changes by  $\mu \rightarrow r$  to ensure that the asset gains riskless return  $r$ .

Since the volatility of asset returns is very difficult to measure and forecast, some slightly more realistic models suppose its stochastic feature. However, a candidate to model the volatility must respect the empirical fact that it regularly reverts back to its long run equilibrium. Besides others, it is the case of *Hull and White (HW) model* (1987). Hull and White supposed the volatility to put into (2) can be modelled by

$$d\sigma = a \cdot \sigma \cdot (b - \sigma) \cdot dt + s \cdot \sigma \cdot w_{dt}. \quad (3)$$

Here,  $a$  describes the tendency of mean-reversion,  $b$  is the long-run mean (equilibrium) and  $s$  is the volatility of the volatility. The Wiener process of HW (3) which drives the volatility is usually supposed to be independent to the one of the GBM (1).

## 2.1 Lévy models

Under a family of Lévy processes, in honour of Paul Lévy, are generally understood such processes that are of independent and stationary

---

<sup>2</sup> Although it is known at least starting from the Fama's work (1965), that the financial returns are not-normally distributed, the geometric Brownian motion has been the most commonly applied process to model asset prices and to price financial derivatives.

increments. These processes are also typical by the stochastic continuity – the probability of jump occurrence for given time  $t$  is zero. The Lévy process can be, besides others, decomposed into a diffusion part and a jump part. Clearly, not all parts must be present.

The modelling of financial prices is usually restricted to exponential Lévy models. The price dynamic is given by an exponential of a Lévy process  $\mathcal{X}_t$  and some (deterministic) drift  $\mu$

$$S_{t+dt} = S_t \cdot \exp[\mu \cdot dt + \mathcal{X}_{dt} - \varpi \cdot dt] \quad (4)$$

Moreover, we must deduce the term  $\varpi = -\frac{1}{v} \cdot \ln(1 - \theta \cdot v - \frac{1}{2} \cdot g^2)$  to ensure that  $E[S_{t+dt}] = S_t \cdot e^{\mu \cdot dt}$ . In fact, it is equivalent to deducing  $\frac{1}{2} \cdot \sigma^2 \cdot dt$  in case of geometric Brownian motion. We can therefore interpret  $\varpi$  as a mean correcting parameter to the exponential of the Lévy process  $\mathcal{X}_t$ .

The classical works incorporating jumps in price returns were based on jump-diffusion models such as the Merton model (1976). These models were typical by a finite number of jumps in any time interval. However, the modern models of financial returns are of infinite activity – thus, the jumps, although small in scale, occur infinitely many times in any time interval. In fact these models do not need to be constructed of diffusion components, since the infinite activity allows us to describe the true feature (either jumps or skewness and kurtosis in the distribution of returns) well enough. In addition, the terminal price can be produced by simulation within one step.

Many Lévy models are regarded as subordinated Brownian motions. If  $w(t)$  denotes a Wiener process in time  $t$ , we can define the subordinated Brownian motion  $\mathcal{X}_t$  with drift  $\mu$  and volatility  $\sigma$  by subordinating with another Lévy process  $g(t)$  just replacing  $t$  by  $g(t)$ . Thus

$$\mathcal{X}_t = \mu \cdot g(t) + \sigma \cdot w(g(t)) \quad (5)$$

Hence, the subordinated process  $\mathcal{X}_t(g(t); \mu, \sigma)$  is driven by another process  $g(t)$  which is referred to as the subordinator. In such case we need to imagine “an internal time” given by process  $g(t)$ . Of course, the process still evolves in time  $t$ . However, so called internal time give us very nice economic interpretation of subordinated processes – the (geometric) Brownian motion given in a random business time, which is stipulated by the

economic activity, the mass of information etc.<sup>3</sup> In other words, “the time increments” are not constant but stochastic. This feature allows us to model also other parameters of the distribution.

The very popular subordinators are *the Gamma process* resulting into *Variance gamma model* (the name is since the variance of the primary component is not given by the classical time but by the “gamma-time”) and the *Inverse Gaussian process* which results into *Normal Inverse Gaussian model* (see e.g. Barndorff-Nielsen, 1995).

In this paper we apply the Variance gamma (VG) model<sup>4</sup> (for more details see e.g. Madan and Seneta (1990), Madan and Milne (1991) or Madan *et al.* (1998)). Consider the VG process  $\mathcal{VG}(g(t; \nu); \theta, \vartheta)$ , where  $g(t; \nu)$  is the (random, but strictly increasing) gamma time from gamma distribution  $G[1; \nu]$ , (here  $\nu$  describes its variance and allows us to control the kurtosis),  $\theta$  is the drift (by which we can control the symmetry), and  $\vartheta$  describes the volatility. Hence the asset price dynamics can be expressed as<sup>5</sup>

$$S_{t+dt} = S_t \cdot \exp[\mu \cdot t + \mathcal{VG}_t - \varpi \cdot dt] = S_t \cdot \exp[\mu \cdot t + \theta \cdot g_t + \vartheta \cdot w(g_t) - \varpi \cdot dt]. \quad (6)$$

One step further is to incorporate the notion of stochastic environment into Lévy models. Although many Lévy models allow fitting well the empirical structure of returns including skewness and kurtosis, the calibrated parameters in general do not stay the same over time. Besides the stochastic volatility approach of Hull and White (1987) or Heston (1993), it can be done either by applying of Lévy-driven Ornstein-Uhlenbeck processes to model volatility (this direction was developed mainly by Barndorff-Nielsen and Shephard) or time changed Lévy processes (which was suggested by Carr *et al.*, 2003). A brief review of all approaches is provided e.g. by Cont and Tankov (2004) or Schoutens (2003).

Here, we proceed according to the approach of Carr *et al.* (2003), in which it is according to Brownian scaling property supposed that the change in volatility can be captured by the (random) change in time. Thus, although the VG model is given by time changed Brownian motion (by gamma time), it is further extended by introducing a stochastic time  $Y(t)$  given by mean-reverting CIR square-root process (Cox, Ingersoll and Ross, 1985):

---

<sup>3</sup> For example, if the economic activity is above average, the internal time grows rapidly comparing with the classical time. And vice versa.

<sup>4</sup> VG model can be alternatively defined as a difference between two increasing gamma processes, one for positive increments in the price, the other for negative ones.

<sup>5</sup> Note, that this is the true (statistical) evolution of the price. However, to price a financial derivative we need to change the drift to be risk-neutral and, probably, also change other parameters of the VG process.

$$dy = \kappa \cdot (\eta - y) \cdot dt + \lambda \cdot \sqrt{y} \cdot w_{dt} \quad (7)$$

with long run time change  $\eta$ , the rate of mean reversion  $\kappa$  and time volatility  $\lambda$ .<sup>6</sup> Thus, the  $\mathcal{VG}(g(t; \nu); \theta, \mathcal{G})$  model can be reformulated into  $\mathcal{VG}(g(y(t; \kappa, \lambda); \nu); \theta, \mathcal{G})$ . Note, that (7) describes the dynamics of the *time rate*  $y$  – the change of  $\mathcal{Y}$ -time over the interval  $dt$ . Thus,  $y_{t+dt} = y_t + dy$  and the alternate time describing the stochastic environment is given by

$$\mathcal{Y}_t = \int_0^t y_u du. \quad (8)$$

As before to get the asset price dynamic in either true or risk-neutral setting, we must incorporate the mean correcting parameter. For example, in the risk-neutral setting we need to get  $E[S_{t+dt}] = S_t \cdot e^{r \cdot dt}$ . And therefore

$$S_{t+dt} = S_t \frac{\exp[r \cdot dt + \mathcal{VG}(\mathcal{Y}(dt))]}{\mathcal{E}[\exp[\mathcal{VG}(\mathcal{Y}(dt))]]}. \quad (9)$$

## 2.2 Option pricing within Lévy models

Lévy models must be usually regarded as incomplete ones. Standard Black and Scholes arguments (replication with the underlying) cannot be used since there are more sources of risk. Alternative risk-neutral approach is also problematic since there do not exist unique martingale probability which is equivalent to the original space of true market probabilities. The pricing problem can be solved by incorporating of mean correcting parameter, introducing of characteristics functions or applying of suitable transform techniques. Some interesting questions of martingale measures of Lévy processes are examined e.g. by Fujiwara and Miyahara (2003).

For illustrative reasons, we will now state the European call option pricing formula within VG model  $\mathcal{V}^{\mathcal{VG}}(S, \mathcal{G}; \tau)$ , which is probably the only one available in the “user-friendly” expression:

$$\mathcal{V}^{\mathcal{VG}}(S, \mathcal{G}; \tau) = \int_0^\infty g(t) \mathcal{V}^{\mathcal{BS}} \left( S \cdot \exp \left( \theta g + \frac{1}{2} \mathcal{G}^2 g - \omega \tau \right), \mathcal{G} \sqrt{\frac{g}{t}}; \tau \right) dg. \quad (10)$$

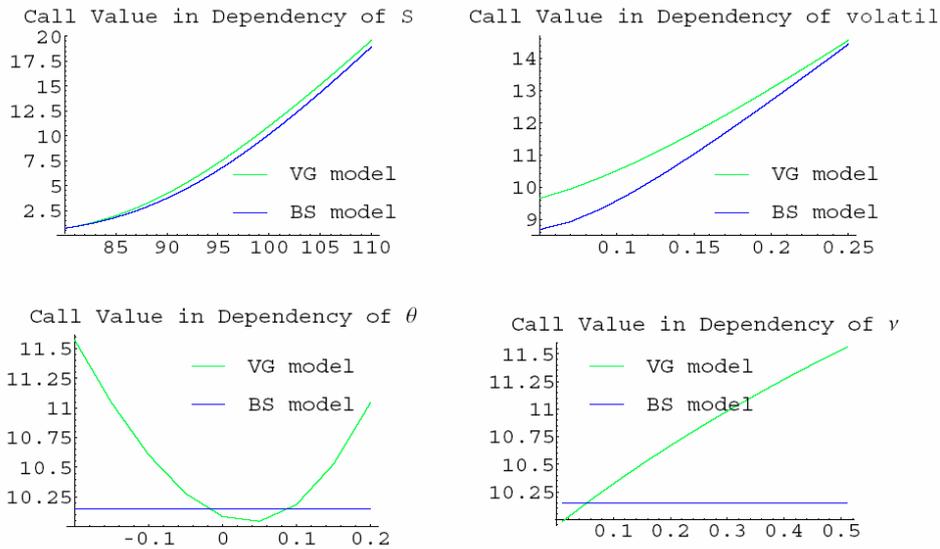

As before,  $S$  is the underlying asset price,  $\mathcal{G}$  is the volatility,  $\theta$  is the drift,  $\tau$  is the time to maturity,  $\omega$  is the mean correcting parameter,  $\mathcal{V}^{\mathcal{BS}}(\cdot)$  is the Black and Scholes pricing formula and  $g(t)$  denotes the probability density function of the gamma distribution.

---

<sup>6</sup> The CIR model should lead to positive values only if  $2 \cdot \kappa \cdot \eta \geq \lambda^2$ .

Following Figure 1 illustrates the effect of particular parameters to the VG model on the vanilla option price ( $S = 100$ ,  $K = 101$ ,  $\tau = 1$ ,  $\theta = 0.1436$ ,  $\rho = 0.12136$ ,  $\nu = 0.3$ ). Clearly, there is no significant difference to BS model considering various levels of  $S$ . The effect of volatility is much more considerable. Finally, we can see how  $\theta$  and  $\nu$ , not included into the BS model, influence the option price within VG model.

**Figure 1 – The effect of VG process parameters on vanilla call option price**

### 3. Monte Carlo simulation in option pricing

The application of Monte Carlo simulation in pricing of options was firstly analyzed by Boyle (1977) and complexly treated in Boyle *et al.* (1997). Suppose first a European plain vanilla call. The word "European" means that the option can be exercised just at the maturity time. "Plain vanilla call" indicates that the payoff function is following:

$$\Psi_{\mathcal{T}} = (S_{\mathcal{T}} - K)^+ \equiv \max(S_{\mathcal{T}} - K; 0). \quad (11)$$

Here,  $\mathcal{T}$  denotes the maturity time,  $S_{\mathcal{T}}$  is the price of the underlying asset at maturity, and  $K$  is the exercise price. Depict the value of an option  $f$ , whose payoff function  $\Psi_{\mathcal{T}}$  is defined by equation (11), at time  $t$  by  $\mathcal{V}_t$ . Now, define

the set of risk-neutral (martingale) probabilities  $\mathcal{Q}$  – such probabilities of future states under which the (risky) stochastic process  $\mathcal{S}(t)$  behave as it would be martingale. Hence, if

$$\dot{\mathcal{S}}(t) = \mathcal{S}(t) \cdot e^{-r(t)} \quad (12)$$

we get

$$\mathbb{E}_0^{\mathcal{Q}}[\dot{\mathcal{S}}_t] = \dot{\mathcal{S}}_0 \quad \forall t \geq 0. \quad (13)$$

In this case, we can define the value of an option  $f$  as its payoff expected at maturity and discounted at the riskless rate  $r$  up to the beginning:

$$\mathcal{V}_t = e^{-r\tau} \cdot \mathbb{E}_0^{\mathcal{Q}}[\Psi_{\tau}], \quad (14)$$

where  $\tau = \mathcal{T} - t$ .

Suppose also that  $\omega$  depicts future states of the world,  $\Omega$  is the set of all such states,  $\omega \in \Omega$ , and the option payoff at maturity is uniquely determined by  $\omega$ ,  $\Psi_{\tau}(\omega)$ . Thus, we can rewrite (4) in more details as follows

$$\mathcal{V}_t = e^{-r\tau} \cdot \mathbb{E}_0^{\mathcal{Q}}[\Psi_{\tau}(\omega)] = e^{-r\tau} \cdot \int \Psi_{\tau}(\omega) d\mathcal{Q}. \quad (15)$$

Hence, due to (15) it is clear that to get an estimate of the option value  $\hat{\mathcal{V}}_t$  it is sufficient to generate (simulate) enough relevant future states  $\omega$ . Note, that relevant states are all states which can affect the option payoff – the future evolution of stock prices, interest rates, volatility, dividend yields, foreign exchange rates, etc. However, if we study the plain vanilla European call option – the only relevant state is the underlying asset price at the maturity time,  $\omega^{(n)} \cong \mathcal{S}_{\tau}^{(n)}$ .

Denote by  $N$  the number of generated future states  $\omega$  – or random scenarios of the underlying asset price evolution. Then it holds that

$$\mathcal{V}_t \approx \hat{\mathcal{V}}_t = e^{-r\tau} \cdot \frac{1}{N} \sum_{n=1}^N \Psi_{\tau}^{(Q)}(\omega^{(n)}). \quad (16)$$

Obviously, in order to get an estimate of the price we first determine the option payoff for each relevant (risk neutral) state  $\omega$  (price of the underlying asset at the maturity time  $\mathcal{S}_{\tau}$ ). Subsequently, we have to calculate an average payoff and discount its value to the beginning. Note, that to get reliable estimate we must realize sufficiently high number of different future paths.

Suppose once again, that the underlying asset price follows geometric Brownian motion given by equation (1). Clearly, if we want to realize a random evolution of an asset  $\mathcal{S}$  in order to price an option, we must change

its statistical (risky) drift  $\mu$  into the risk neutral one – the riskless rate  $r$ . Moreover, we are interested only in the price at time  $\mathcal{T}$ . Hence, an  $n$ -th risk neutral estimate of the future price is

$$\mathcal{S}_{\mathcal{T}}^{(n)} = \mathcal{S}_t \cdot \exp(\Delta \mathcal{S}_{\mathcal{T}}^{(n)}) = \mathcal{S}_t \cdot \exp\left[\left(r - \frac{\sigma^2}{2}\right) \cdot \tau + \sigma \cdot \tilde{\varepsilon}^{(n)} \cdot \sqrt{\tau}\right] \quad n = 1, \dots, N. \quad (17)$$

From (17) it is evident that the only source of uncertainty is  $\tilde{\varepsilon}$ . Therefore, the optimal  $N$  is such which ensure target probability distribution (unit variance and zero mean, skewness and excess kurtosis) of the random element with minimal time cost.

The second model on which we concern here more particularly is the Variance gamma process. The model is determined by three parameters. It can be defined either as a subordinated Brownian motion  $\mathcal{VG}(g(t; \nu); \theta, \vartheta)$  or as a difference between two gamma processes. In both cases it consists of two independent processes which results into requirements of efficient simulation techniques.

### 3.1 Variance reduction methods

In this subsection we describe few techniques required to increase the efficiency of option pricing. In order to get reliable estimate of the price we should realize huge number of (independent) paths – usually we need  $N$  at least 100 000. Although it can be very time consuming to produce such huge number of paths, the result still need not be reliable. It is the reason why efficient improvements to plain Monte Carlo simulation (PMC) are still developed. These techniques are commonly referred to as *variance reduction techniques*, since applying them we aim on reduction of the variance (error term).

Brief review of most important methods is included for example in Charnes (2000) or Hull (2002). More complete and rigorous treatment with many applications is provided by Boyle *et al.* (1997) and Glasserman (2004).

The simplest technique, both from the theoretical and application point of view, is commonly called the *Antithetic variate method* (AVM, AMC). The method was firstly applied in option pricing by Boyle (1977). The key idea is, that if  $\tilde{\varepsilon} \in \mathcal{N}[0;1]$  then the same must be true also for  $-\tilde{\varepsilon} \in \mathcal{N}[0;1]$ . The perfectly negative correlation of these two samples substantially reduces the error in estimating the price.

The improvement is presented in two aspects. First, if we set the target number of independent paths to be  $N$  then we have to generate only  $M = N/2$  paths. Hence, applying the method we can significantly decrease the

time cost. Second, since  $(\tilde{\varepsilon}_m - \tilde{\varepsilon}_m)/2 = 0$ , the method will also have positive effect on all symmetry measures (mean, skewness), whose values will be exactly as we need. The shortcoming of this approach is that it can be applied primarily for symmetric distributions.

The *Moment matching method* (MM), which aims on matching the selected moment of the underlying distribution, can be regarded as an alternative. Of course, an inevitable condition is to know the right value to be matched. Basic applications of this method are presented e.g. by Barraquand (1995), Boyle *et al.* (1997) and Duan and Simonato (1998). Very similar is the *Control variate method* (CVM), see Boyle (1977). However, the application aims more on particular problems, such as pricing of geometric Asian options by virtue of arithmetic solutions, see Kemma and Vorst (1990).

More sophisticated method is the *Stratified sampling* (SS, SMC). In general, there exist two approaches to SS. The first way is direct. It consists of stratifying the interval of admissible values into equiprobable strata, that is with equal probabilities. Suppose random number from standard normal distribution:  $\tilde{\varepsilon} \in \mathcal{N}[0;1]$ . Therefore, the interval of admissible values is  $\tilde{\varepsilon} \in (-\infty; +\infty)$ . The next step is to divide this interval into  $M$  subintervals in such a way that

$$\Pr\{\tilde{\varepsilon} \in (\varepsilon_m; \varepsilon_{m+1}]\} = p_m, \quad p_m = \frac{1}{M}, \quad m = 1, \dots, M, \quad (18)$$

and for example

$$\varepsilon_1 = -\infty, \quad \varepsilon_{M+1} \rightarrow +\infty.$$

Subsequently, we need to generate  $M$  random numbers uniformly distributed between zero and one:  $\tilde{\mathcal{U}} \in \mathcal{R}[0;1]$ . Finally, we can generate random numbers from target distribution as follows:

$$\tilde{\varepsilon} = \varepsilon_m + \tilde{\mathcal{U}} \cdot (\varepsilon_{m+1} - \varepsilon_m). \quad (19)$$

Clearly, if  $M = N$ , then we take just one number from each equiprobable interval. Similarly, if  $M = N/5$  we have to generate five random values from each interval.

However, sometimes it is difficult to handle with plus or minus infinity. In this case, we can prefer indirect stratification. Applying this procedure, we generate (stratify) 'probabilities', first. Hence, we stratify the unit interval into  $M$  subintervals of equal length. Next we produce uniformly distributed random numbers from these subintervals:

$$\tilde{u}_m = \frac{m-1}{M} + \frac{\tilde{\mathcal{U}}}{M}. \quad (20)$$

Finally, we transform each  $\tilde{u}$  into its related value of the target distribution by inverse transform. For example, considering normal distribution:

$$\mathcal{N}^{-1}(\tilde{u}_m).$$

Another very interesting approach, which extends the application of SMC also for more dimensions, is *Latin hypercube sampling* (LHS). This approach was firstly introduced by McKay *et al.* (1979) and later analyzed by Stein (1987).

Suppose that we need to generate two-dimensional random processes. An obvious way for one dimension would be stratified sampling. However, here we need to get two independent coordinates for each random state. Hence, we cannot stratify the interval since results obtained in this way were not strictly independent.

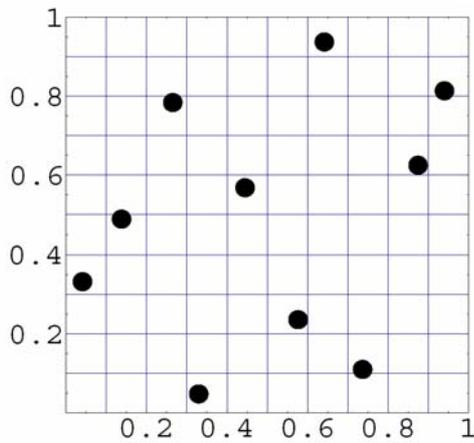

Fortunately, the solution is easy. We can put randomly the subintervals of both dimensions together. Suppose that  $M = N = 10$  and denote the coordinates by  $\{x, y\}$ . The first step is to stratify the unit interval into ten equiprobable subintervals. Next we randomly permute these subintervals. Subsequently, we can generate both coordinates for each  $N$  applying the indirect SS method. That is, we first get values of the inverse distribution function for both coordinates, where  $x$  is based on the origin subintervals and  $y$  on theirs permutation, and finally we transform them into target two-dimensional random numbers. For example, for  $n = 1$  we get  $x \in [0, 0.1)$  and  $y \in [0.3, 0.4)$  and therefore  $\{x, y\} \in \{0.043, 0.314\}$ . Figure 2 illustrates location of all coordinates within stratified subintervals.

It is clear that the method of stratified sampling (as well as its LHS extension) can be used only to price plain vanilla options with European payoff – since here only the price of the underlying asset at the maturity play role.

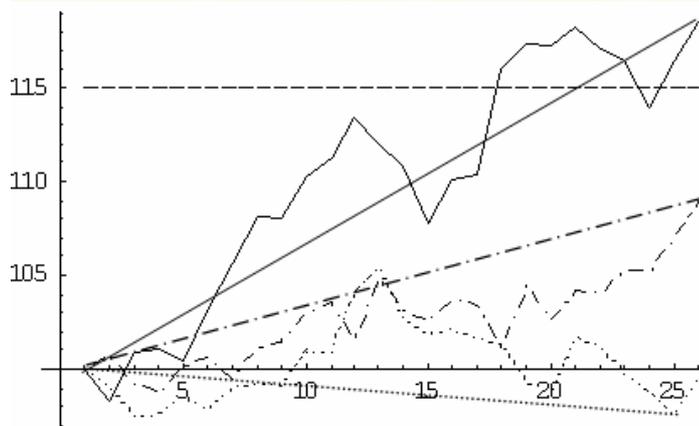

Figure 3 illustrates this effect. We present three distinct paths of asset price evolution (vertical axe) in time (horizontal axe). The initial price is 100. The method of stratification allows us to get directly the price at the terminal time,  $\mathcal{T} = 25$ . However, if we want to price some option whose payoff depends on the historical path (e.g. barrier

option) we must create other extension – *the bridge sampling* – since we need to recover the intermediate prices.

**Figure 2 - The technique of Latin Hypercube Sampling for two dimensions**

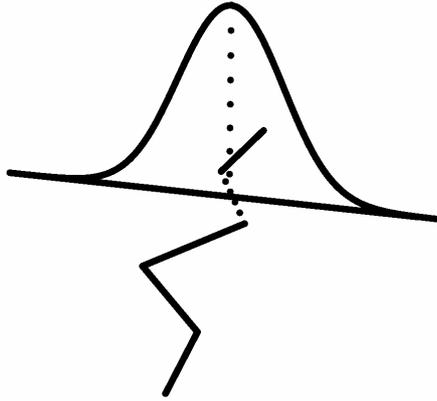

**Figure 3 – Stratifying the terminal price**

Thus, the technique of bridge sampling allows us to model whole part of the price trajectory via stratification. Knowing the value at time zero and the value at final time we can easy apply the bridge sampling to generate the value also for any intermediate time (depending on the conditional distribution), see Figure 4 for the case of Wiener process.

**Figure 4 – Wiener bridge sample**

The thin black line illustrates the random evolution of the process in discrete time. We know the endpoints. Denote the midpoint in time as  $t$ . Then we denote the endpoint values as  $w(t - \Delta t)$  and  $w(t + \Delta t)$ . Although the unconditional distribution of  $w(t)$  is  $\mathcal{N}(0; 1)$ , the conditional mean, for example, is given by linear interpolating of  $w(t - \Delta t)$  and  $w(t + \Delta t)$ . Hence, the intermediate value can be recovered by

$$w(t) = \frac{w(t + \Delta t) + w(t - \Delta t)}{2} + \sqrt{\frac{\Delta t}{2}} \cdot \tilde{\varepsilon}, \quad (21)$$

Very similar is the application of bridge sampling in the VG model, see e.g. Ribeiro and Webber (2003) for VG bridge or Avramidis *et al.* (2003) for double gamma bridge. Conditional VG-random numbers can be obtained by incorporating of related *Beta distribution*,  $\tilde{\beta} \in \text{Beta}(\frac{\alpha}{\nu}; \frac{\alpha}{\nu})$ . Thus

$$\begin{aligned} \mathcal{V}\mathcal{G}(t) &= \theta g_t + \mathcal{G}\sqrt{g_t} \varepsilon \\ &= \tilde{\beta}[\mathcal{V}\mathcal{G}(t + \Delta t) - \mathcal{V}\mathcal{G}(t - \Delta t)] + \mathcal{V}\mathcal{G}(t - \Delta t) + \mathcal{G}\sqrt{\tilde{\beta}[g(t + \Delta t) - g(t)]} \tilde{\varepsilon}, \end{aligned} \quad (22)$$

where  $g(t)$  can be stratified in this way:

$$g(t) = \tilde{\beta}[g(t + \Delta t) - g(t - \Delta t)] + g(t - \Delta t). \quad (23)$$

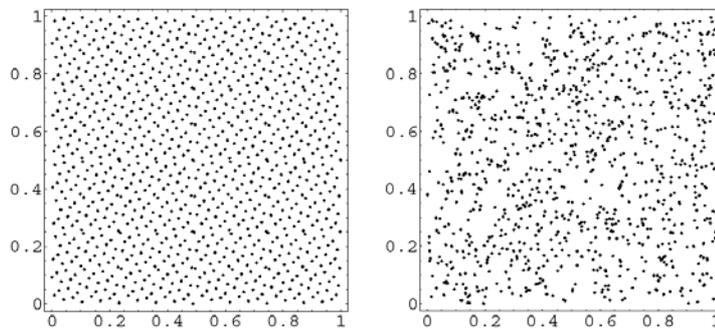

The double gamma bridge can be implemented on the basis similar to (23), since in this

case, the VG process is interpreted as a difference of two increasing (and independent)

gamma process,  $\mathcal{G}_u - \mathcal{G}_d$ .

All methods described above can be regarded as special cases of Monte Carlo simulation. However, it is not the case of the Quasi Monte Carlo simulation. While applying Monte Carlo simulation we primary need to generate pseudorandom numbers uniformly distributed on the unit interval and fulfilling prespecified tests of randomness, applying Quasi Monte Carlo simulation we proceed according to the chosen algorithm and generate quasirandom numbers in deterministic rather than random sequence. The review of basic approaches has been provided e.g. by Niederreiter (1992) or Glasserman (2004). Figure 2 shows the difference between pseudorandom and quasirandom numbers in two-dimensional cube for  $N=1000$ . In order to produce quasirandom numbers we have proceed according to Woźniakowski (1991).

**Figure 5 – Comparison of quasirandom numbers and pseudorandom**

## 4. Numerical study

In this chapter we compare chosen approaches of Monte Carlo simulation. First, we will aim on two types of probability distribution –  $\mathcal{N}[0;1]$  and  $\mathcal{VG}(g(t;v);\theta,\vartheta)$ . Next, we apply these methods in order to obtain the price of (i) plain vanilla call option and (ii) up-and-out call option.

All computation is done in Mathematica® software (version 5.1) on 512 MB PC with Pentium 4 3.2 GHz HT processor. If not stated otherwise, all cases are studied for five different numbers of random (and “independent”) paths – more particularly  $N=100, 1\ 000, 10\ 000, 100\ 000$  and  $1\ 000\ 000$ .

### 4.1 Generating random numbers

The first step to analyze the efficiency of particular approaches to Monte Carlo simulation is to generate random numbers from selected probability distribution and subsequently examine whether their actual

characteristics are close to target values. More particularly, we will evaluate mean, variance, skewness, kurtosis, and time costs.

The selected probability distributions are standard normal distribution, specified by  $\mathcal{N}[0;1]$ , and variance gamma distribution – the case of parametric one, specified by  $\mathcal{VG}(g(t;v); \theta, \vartheta)$ .

First we summarize some results of random numbers generated from standard normal distribution. Target values are zero mean, unit variance, zero skewness and zero excess kurtosis.

With plain Monte Carlo (PMC) we are able to be close to these target values only with huge  $N$ . Significant improvement can be done by incorporating of antithetic variates technique (AVM). Clearly, if the method is applied in right manner, we must get target values of mean and skewness, although the number of paths  $N$  is low. Relevant time costs are approximately one half of time needed to execute PMC. Note, that e.g.  $N = 10$  indicates  $N/2$  of independent paths.

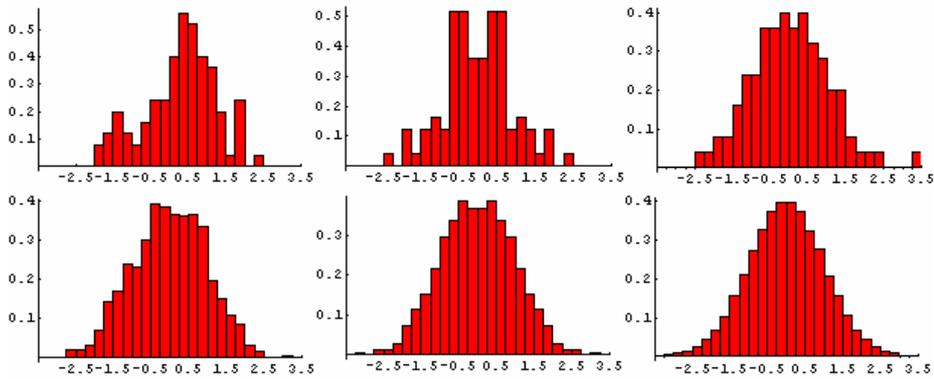

Next, we have evaluated stratification method (SS). In other words, we have stratified the interval of admissible values in order to get smoother curve of implied probability distribution even for low  $N$ . There is no surprise, that our expectations are fulfilled. However, respecting total time costs, there is no clear improvement against AVM. All observed results are included in Table 1.

**Table 1 Characteristics of random numbers from  $\mathcal{N}[0;1]$  for particular methods**

A Random numbers from $\square[0;1]$ – PMC						
Number of scenarios	Mean value	Standard deviation	Variance	Skewness	Kurtosis	CPU (seconds)
100	0.2954	0.9555	0.9130	-0.4117	2.7803	0.0000
1 000	-0.0049	0.9820	0.9643	-0.0177	2.8005	0.0310
10 000	-0.0038	1.0091	1.0183	0.0382	3.0018	0.0930
100 000	-0.0045	0.9998	0.9995	0.0094	3.0093	1.0470
1 000 000	0.0007	1.0001	1.0002	0.0012	3.0013	9.6720
B Random numbers from $\square[0;1]$ – AVM						
Number of scenarios	Mean value	Standard deviation	Variance	Skewness	Kurtosis	CPU (seconds)
100	0.0000	0.9047	0.8185	0.0000	3.2804	0.0000
1 000	0.0000	0.9738	0.9482	0.0000	3.0468	0.0160
10 000	0.0000	1.0036	1.0071	0.0000	2.9772	0.0620
100 000	0.0000	0.9996	0.9993	0.0000	3.0097	0.3910
1 000 000	0.0000	1.0000	0.9999	0.0000	3.0032	4.1250
C Random numbers from $\square[0;1]$ – SS						
Number of scenarios	Mean value	Standard deviation	Variance	Skewness	Kurtosis	CPU (seconds)
100	0.0120	1.0194	1.0392	0.2317	3.3918	0.1090
1 000	0.0010	1.0023	1.0046	0.0374	3.0942	0.3280
10 000	0.0000	0.9999	0.9998	0.0006	2.9932	3.0940
100 000	0.0000	1.0000	1.0000	0.0001	2.9992	31.7180
1 000 000	0.0000	1.0000	1.0000	0.0000	2.9998	322.8440

Furthermore, we include graphical presentation of some results – histograms of implied distribution for  $N = 100$  and  $N = 1\,000$ . There is no surprise, that results of PMC are very plain. Histograms of AVM exactly indicate the improvement of the method – it provides us with a distribution which is symmetric around mean. However, the histogram of SS indicates more smooth distribution, mainly around the mean and in tails.

**Figure 6 Histograms of random number from  $\mathcal{N}[0;1]$  PMC (left), AVM (middle) a SS MC (right)**

Last applied approach was simulation based on quasi random numbers (QMC) which give us similar results as SS MC for comparable  $N$ , but the time costs are significantly lower.

We have also tried to examine the results for the sum of two independent random numbers from  $\mathcal{N}[0;1]$ . Here, AVM does not provide clear improvement. Thus, the only possibility, how to get more reliable results is to apply Latin hypercube sampling (LHS). The results of LHS are better for the same  $N$ . However, if we compare these two methods for approximately same time costs, there is apparent only slight improvement. Of course, the convergence of LHS is better.

**Table 2 Characteristics of random numbers from  $\mathcal{V}\mathcal{G}((1;0.3);-0.14;0.12)$  for particular methods**

A Random numbers from $\mathcal{V}\mathcal{G}((1;0.3);-0.14;0.12)$ – PMC						
Number of scenarios	Mean value	Standard deviation	Variance	Skewness	Kurtosis	CPU (seconds)
100	-0.1023	0.1289	0.0166	-0.9190	4.1671	0.0150
1 000	-0.1424	0.1412	0.0199	-0.7940	3.8087	0.0470
10 000	-0.1435	0.1452	0.0211	-0.7590	4.2174	0.5160
100 000	-0.1441	0.1448	0.0210	-0.8063	4.3376	4.8440
1 000 000	-0.1435	0.1446	0.0209	-0.8095	4.3738	48.4060

B Random numbers from $\square\square((1;0.3);-0.14;0.12)$ – AVM						
Number of scenarios	Mean value	Standard deviation	Variance	Skewness	Kurtosis	CPU (seconds)
100	-0.1213	0.1330	0.0177	-0.1450	3.7442	0.1560
1 000	-0.1472	0.1487	0.0221	-0.8926	4.4165	0.0780

100 000	-0.1433	0.1441	0.0208	-0.7876	4.3085	5.6870
1 000 000	-0.1435	0.1445	0.0209	-0.8036	4.3570	57.1570

E Random numbers from $\square\square((1;0.3);-0.14;0.12)$ – LHS						
Number of scenarios	Mean value	Standard deviation	Variance	Skewness	Kurtosis	CPU (seconds)
100	-0.1423	0.1458	0.0213	-0.4828	4.0969	0.2340
1 000	-0.1443	0.1460	0.0213	-0.7755	4.3094	2.0470
10 000	-0.1437	0.1453	0.0211	-0.7843	4.1595	19.8280
100 000	-0.1436	0.1446	0.0209	-0.8214	4.4640	196.7660
1 000 000	-0.1436	0.1447	0.0209	-0.8046	4.3391	2197.5900

F Random numbers from $\square\square((1;0.3);-0.14;0.12)$ – QMC (LHS)						
Number of scenarios	Mean value	Standard deviation	Variance	Skewness	Kurtosis	CPU (seconds)
100	-0.1385	0.1323	0.0175	-0.9017	4.2937	0.2500
1 000	-0.1428	0.1430	0.0204	-0.7587	4.0679	2.2500
10 000	-0.1437	0.1454	0.0212	-0.8422	4.5940	20.4060
100 000	-0.1436	0.1444	0.0209	-0.8039	4.3717	255.1720
1 000 000	-0.1436	0.1445	0.0209	-0.8055	4.3619	2321.7200

The next step is to examine the efficiency of these approaches to Monte Carlo simulation in case of generating the complex Variance gamma process regarded as a combination of two independent random numbers – from standard normal distribution and from gamma distribution.

Here, we suppose following parameters  $\theta = -0.1436$ ,  $\vartheta = 0.12136$ ,  $\nu = 0.3$ , and  $\tau$  is one year, which imply *mean* = -0.1436, *standard deviation* = 0.1446, *skewness* = 0.8055, *kurtosis* = 4.1424.

In this case the results are summarized in Table 2. Since the problem is formulated as a generation of two independent processes, one of which is not symmetric, there is almost no effect of AVM, see Part B of the table.

Part E and F provided results obtained by LHS method either based on pseudorandom or quasi random numbers. Here, the method using quasirandom numbers takes about 10% much more time, while the results can be regarded as slightly better (except for low  $N$ ).

As before, if we are interested only in approximate results and respecting the time costs, it is suitable to apply simple method (PMC). However, if we need exact results, LHS should be applied.

#### 4.2 Vanilla call option valuation

Suppose a call option  $f$  with following parameters:  $r = 0.1$ ;  $\tau = 1$ ,  $S_0 = 100$ ,  $K = 101$ . We suppose two types of underlying distribution: GBM ( $\sigma = 21\%$ ) and VG (parameters as before). Results are included in Table 3: GBM/BS model (Black and Scholes, 1973) in Part A and VG model (Madan *et al.* 1998) in Part B.

As it is apparent from Part A, PMC is relatively far from theoretically true result even for huge  $N$ . AV MC does slightly better. Note, that there is almost no time improvement (time costs for generating random numbers are only a fraction of total time costs).

If we compare SS with PMC, we see that it provides very good results as early as  $N = 1\,000$ . Relating time costs are very low, so that there is no reason to apply simple methods (PMC, AV MC). Moreover, SS MC beats also QMC, although time costs of SS are approximately twice as much as of QMC for the same  $N$ .

Proceed now to the Part B. We can see that the complexness of the VG model plays big role. Although the simple methods (PMC, AV MC) can provide good result, the convergence is low and the error of estimated result is significant.

**Table 3 Approximating the value of plain vanilla call by simulation**

A Plain vanilla call in BS setting ( <i>GBM</i> )								true price = 13.0295	
method	PMC		AV MC		SS		QMC		
$N$	value	time (seconds)	value	time (seconds)	value	time (seconds)	value	time (seconds)	
100	17.7456	0.0000	11.8243	0.0000	12.9683	0.0780	13.0268	0.0160	
1 000	12.8686	0.0310	12.7975	0.0160	13.0265	0.3590	13.0766	0.0780	
10 000	13.0780	0.1560	13.0897	0.1250	13.0312	3.3440	13.0382	1.1560	
100 000	12.9633	1.3910	13.0267	1.0150	13.0295	32.4530	13.0305	13.7820	
1 000	13.0419	13.6090	13.0303	10.2190	13.0295	345.1410	13.0296	164.2960	

B Plain vanilla call in VG setting ( <i>Variance gamma process</i> )							true price = 10.9815	
method	PMC		AV MC		LHS		QMC (LHS)	
$N$	value	time (seconds)	value	time (seconds)	value	time (seconds)	value	time (seconds)
100	13.9800	0.0320	11.3148	0.0630	10.9701	0.3750	10.6830	0.2030
1 000	11.0006	0.0930	10.9513	0.0930	10.9302	2.1400	10.9353	2.0310
10 000	11.0352	0.5940	11.0041	0.6410	11.0210	24.0310	10.9800	21.9060
100 000	10.9509	5.8750	10.9800	5.8900	10.9751	198.3130	10.9986	211.4220
1 000	10.9845	57.9060	10.9762	58.7660	10.9840	1994.3600	10.9801	2249.1600

Thus, even if LHS based either on pseudorandom numbers or quasirandom numbers does not provide us with exactly the same value as the theoretically true price is (and time costs are huge), its error is acceptable. Notice, that LHS using quasirandom numbers gives us again slightly more interesting results (once again, except low number of scenarios).

Finally, we provide also some convergence results, see Appendix I for BS setting (PMC, AV MC and SS MC). When building the chart, we start with  $N = 5\,000$  and proceed up to  $N = 500\,000$ , the step is 500.

We can see that according the scenarios we have run the convergence of PMC is very pure. Although it can happen that the simulation will provide right number, we cannot be sure of that. By contrast, AV MC is very close to the line indicating the true price starting at  $N = 100\,000$ . Unfortunately, even if we increase the number of scenarios far behind  $N = 1\,000\,000$ , the estimated price will probably not be equal to the true value.

More importantly, the convergence of SS MC starts to be very good for  $N = 10\,000$  and with  $N = 150\,000$  there are almost no errors in price estimate. Thus, the improvement is clearly visible.

## 4.2 Up-and-out call option valuation

Suppose a call option  $f$  with barrier  $\mathcal{U}$  set initially above the price of an underlying asset  $S$  at time zero,  $S_0 = 100$ ,  $\mathcal{U} = 125$ . Other parameters are the same as before. For simplicity, we will suppose, that the price is monitored 16 times per option life (the intervals are of equal length).

Now, we will study only results for VG model executed with LHS

method.<sup>7</sup> Thus, as a first step we generate the terminal price of the underlying asset. Next we calculate the vanilla option payoff. At this moment, we can make a test – if the payoff is zero, also the payoff of barrier options must be zero and it is not useful to recover intermediate prices; if the terminal price is above the barrier, we know, that up-and-out option cannot be exercised and once again, there is no need to know intermediate prices; otherwise we must recover intermediate prices applying bridge sampling.

Results are apparent from Table 4. Since we monitor the underlying asset price at discrete times, we are not able to provide any theoretically true value. We can see that both approaches give us for higher  $N$  approximately same (and stable) results.

**Table 4 Approximating the values of call options under VG model**

B Plain vanilla call in VG setting (Variance gamma process)					True prices = {10.9815, ?, ?}		
method	LHS MC				QMC (LHS)		
$N$	vanilla value	up-and-in value	up-and-out value	time (seconds)	vanilla value	up-and-out value	time (seconds)
100	10.8154	4.8681	5.9473	0.391	10.4917	5.7820	0.422
1 000	10.9398	5.1459	5.7939	3.75	11.0262	6.1559	4.156

100	10.9828	5.0450	5.9378	377.078	10.9813	5.9353	432.032
500	10.9801	5.0503	5.9298	1919.67	10.9814	5.9246	1982.22

## 5. Conclusion

In this paper we have focused on basic ways to improve the efficiency of Monte Carlo simulation. We have described and applied the most important ones, which can be also regarded as a general – thus they are useful for general pricing problems.

We have examined the efficiency of selected approaches in case of (i) generating random numbers from prespecified distributions and (ii) option pricing. In the first case, we have seen that the effect (improvement) of these methods cannot be clear. However, when applied in pricing procedure the usefulness was clear.

Simultaneously, we have observed convergence of particular pricing problems. Relevant charts give us clear conclusion of efficiency of these methods. Note however, that pricing of barrier options is a complex problem

<sup>7</sup> Convergence of up-and-out as well as up-and-in call option under BS model is apparent from Appendix II and Appendix III.

through the (dis)continuous set of relevant prices. Therefore, it is much more important to examine whole family of variants – when to stratify, when to make the test, etc.

## **Abstract**

*This study examines the relationship between the market-to-book (M/B) ratio, size, and current returns of Icelandic stocks. The study uses monthly return data on stocks from the Iceland Stock Exchange from July 1997 to June 2003. The methodology applied in this research can be divided into two parts. First, the data from individual stocks are analyzed; portfolios are then formed and their returns examined. Analysis of the results of studying individual stocks reveals no relationship between size and returns, but a very significant one between M/B ratio and returns. However, there is no significant relationship between returns, M/B ratio, and size when the performance of portfolios is analyzed.*

**Keywords:** *Market efficiency, Icelandic stock market, Market-to-Book ratio, size*

## 1. Introduction

In this paper, empirical tests are performed to determine whether the Icelandic stock market shows clear signs of the market inefficiency that is apparent in other capital markets. Empirical tests are performed to study the relationship between market-to-book (M/B) ratios, i.e. the market value of common stocks divided by the book value of ordinary shareholders' funds, size, and returns of Icelandic stocks. This research is divided into two parts. First, data on returns, M/B ratios, and size of individual stocks are analyzed. Portfolios are then formed based on the variables examined and their performance compared. The findings are that there is no apparent relationship between the size measured by market value of common stocks and their returns. On the other hand, there is a statistically significant relationship between M/B ratios and returns when using data from individual stocks, but those results are not statistically significant when analyzing the performance of portfolios.

An efficient capital market is one in which stock prices fully reflect available information. The notion that stocks already reflect all available information is referred to as the efficient market hypothesis (EMH). A precondition for the strong version of the hypothesis is that information and trading costs, the costs of getting prices to reflect information, are always zero (Grossman and Stiglitz, 1980). A weaker and economically more sensible version of the efficiency hypothesis states that security prices reflect information to the point where the marginal benefits of acting on information, i.e., the profits to be made, do not exceed the marginal costs (Jensen, 1968). Therefore, according to the EMH, stock prices change in response to new and unpredictable information and they follow a random walk—i.e., they are random and unpredictable.

It is common to distinguish between three versions of the EMH: the weak, the semistrong, and the strong forms. The weak form of the hypothesis asserts that stock prices already reflect all information that can be derived by examining trading data. The semistrong form of the hypothesis states that all publicly available information regarding the prospects of a firm must already be reflected in the stock price. Finally, the strong version of the EMH states that stock prices reflect all information relevant to the firm, even information available only to company insiders.

The relationship between risk and returns is an important subject when studying capital market efficiency. It is obvious that investment in riskier assets such as stocks should generate higher return than investment in less risky assets. It was not until the Capital Asset Pricing Model (CAPM) was developed that academics were able to measure risk and its return.

CAPM is based on the assumption that asset returns are linearly related to their covariance with the market's return. The CAPM assumes that assets with higher systematic risk have a higher return than assets with lower systematic risk, and that assets with the same systematic risk should give the same return. Therefore, if investors own stock with the same systematic risk as the market, i.e., the beta coefficient is 1, then the expected return is the same as the market return. If the beta coefficient is 0 then the expected return is the same as the risk-free rate of return. The CAPM also implies there is no relationship between firm-specific risk and returns because, by diversification, specific risk can be eliminated.

Markowitz (1959) laid the groundwork for the CAPM. In that seminal research, he cast the investor's portfolio selection problem in terms of expected return and variance of return. He argued that investors would optimally hold a mean–variance-efficient portfolio—i.e., a portfolio with the highest expected return for a given level of variance. Sharpe (1964) and Lintner (1965a) built on Markowitz's work to develop economy-wide implications. They showed that if investors have homogeneous expectations and optimally hold mean–variance-efficient portfolios, then, in the absence of market friction, the portfolio of all invested wealth, or the market portfolio, is itself a mean–variance-efficient portfolio.

The Sharpe and Lintner derivations of the CAPM assume the existence of lending and borrowing at a risk-free rate of interest. Using this version of the CAPM, for the expected returns of asset  $i$  we have:

$$E[R_i] = R_f + \beta_{im}(E[R_m] - R_f) \quad (1)$$

$$\beta_{im} = \frac{\text{Cov}[R_i, R_m]}{\text{Var}[R_m]}, \quad (2)$$

where  $E[R_i]$  is the expected return of a security,  $R_f$  is the risk-free return, and  $E[R_m]$  is the return of a market index.

The purpose of this study is to examine whether there has been a relationship between the size of Icelandic stocks, their M/B ratios, and the returns. A significant relationship between these variables and returns might be interpreted as a violation of EMH. These two variables, M/B ratio and size, were chosen because previous research has shown significant relationship between returns and those variables on international stock markets.

## 2. Previous Research

Considerable research has been undertaken to test the CAPM. The main findings have been that the CAPM is not entirely valid as a model that explains stock returns, and that factors other than beta provide a better explanation. The Lintner (1965b) study of the American stock market from 1954 to 1963 found that the Security Market Line, i.e., the line that shows the relationship between systematic risk (beta) and returns, was too flat. Higher returns were not proportional to higher systematic risk. Later research where the CAPM was tested on the American stock market has shown that for periods, even for a decade, stocks with higher systematic risk do not give higher returns. Research by Black et al. (1972) and Fama and MacBeth (1973) showed that returns of high beta stocks were lower than the CAPM model would have predicted. In their seminal research, Fama and French (1992) found no relationship between returns and beta on the US stock market from 1963 to 1990, but a weak positive relationship between 1941 and 1990.

These findings have led to the development of multifactor models. These models are based on the classical CAPM with a factor additional to the return of the market included to explain returns. The Fama and French (1992) findings were that a multifactor model where stock returns were explained by their M/B ratio (market value/shareholder's equity), size (market value of common stocks), and the market's return was considerably better at explaining stock returns than the classical CAPM.

Reinganum (1992) analyzed the returns of New York Stock Exchange stocks ranked by size from 1926 to 1989. He found that small firms gave returns with a higher average arithmetic mean for that period. The returns of the small firms were superior even when accounting for risk. In a study of UK market data from April 1961 to March 1985, Levis (1989) found that small firms outperformed larger firms in that they gave excess returns when adjusted for risk.

Small stocks' out performance of large stocks has been related to the higher cost of trading. The bid/ask spread is generally much higher for small stocks, making the cost of trading much higher. Another explanation is that smaller firms have different sector or industry distributions than do larger firms.

In their extensive study, Haugen and Baker (1996) analyzed data for five countries from 1985 to 1993. They found that stocks with low M/B ratios gave excess returns in the US, Germany, France, the UK, and Japan. The excess return was statistically highly significant in all of these countries. In recent research, Chan and Lakonishok (2004) studied American stocks from 1979 to 2002. They found that stocks with low M/B ratios had

considerably higher average returns than other stocks and that they were less risky.

Low M/B ratio stocks' out performance of high M/B ratio stocks has been related to the tendency of investors to overestimate growth for high-growth companies and to underestimate growth for low-growth companies. High-growth companies often sell at high M/B ratios, whereas low-growth companies sell at low M/B ratios, with the result that the stocks with low M/B ratios outperform the others.

An extensive study by Gunnlaugsson and Jonsson (2004) on the Icelandic stock market from January 1993 to June 2003 they applied the methodology of forming portfolios based on the variable examined. They found that there was a significant relationship between the P/E ratio and return. There was also an indication of relationship between sizes, i.e., small stocks gave higher returns, but that was not statistically significant, and a low M/B ratio correlated with higher returns; that relationship also was not statistically significant.

This research is a continuation of Gunnlaugsson and Jonsson's study. Data on size and M/B ratios of individual stocks are examined and the relationship with returns analyzed. Portfolios are formed based on the variables examined and their performance and risk studied.

### 3. Data and Methodology

The purpose of this research is to examine whether there has been a significant relationship between the M/B ratios, size, and returns of Icelandic stocks. The period this study covers is from July 1997 to June 2003. To represent the Icelandic stock market, 34 stocks were randomly selected and their monthly returns, M/B ratios, and size, i.e., market value of common stocks, were measured every month of the period covered by this study.

Statistical tests were then performed to assess whether there was a significant relationship between returns, size, and M/B ratios by applying ordinary least squares (OLS) on the following regression:

$$R_i - R_f = \alpha + \beta(R_m - R_f) + \gamma(M/B) + \lambda(S) + u \quad (3)$$

where  $R_i$  is the return of individual stock,  $R_f$  is the risk-free return and, as a proxy, the monthly return of a three-month T-bill is used,  $\alpha$  is the intercept,  $\beta = \text{Covar}(R_i, R_m)/\sigma^2$  is the slope,  $R_m$  is the market return, and the ICEX-15 is used as a proxy for the market,  $M/B$  is the market to book ratio,  $S$  is the size of the stocks, i.e., their market value, and  $u$  is an error term. The

coefficients  $\gamma$  are  $\lambda$  key coefficients. They measure if there has been a significant relationship between returns, M/B ratio, and size, when controlling for the market return. If these coefficients are statistically significant, that might be an indication of market inefficiency.

In addition to the regression, using data on individual stocks, the previously mentioned portfolios were formed based on the variables examined, i.e., size and M/B ratios, and their performance was analyzed. For every month from July 1997 to June 2003, four portfolios were constructed based on the value of the variable examined. The stocks were equally weighted in the portfolios; i.e., the return of the portfolio was equal to the average return of the stocks. Then the returns of the stocks were measured and compared, and the returns of the extreme portfolios were tested to determine whether they were statistically different when accounting for systematic risk. As an example, when studying the relationship between size and returns, four portfolios were formed in the beginning of every month this research covered. Stocks were ranked according to their size into four portfolios. The smallest stocks were in Portfolio 1, and the largest in Portfolio 4. The performance (return) of the portfolios was then measured in the month. Each month this process was repeated and new portfolios were formed based on the market value of common stocks, and so on for the following months.

Statistical tests were then performed to examine whether there was a significant difference in return between the extreme Portfolios 1 and 4 when controlling for systematic risk. These statistical tests are based on an approach known as Jensen's alpha, which is one of many performance measures that are based on the classical CAPM. It is easily computed by finding the intercept,  $\alpha_p$  in the regression:

$$R_p - R_f = \alpha_p + \beta_p (R_m - R_f) + u_p \quad (4)$$

This method was introduced by Jensen (1968). The procedure allows the efficient estimation of  $\alpha_p$ , a measure of the monthly excess return after adjustment for portfolio risk. Assuming the CAPM holds, the alphas on passively managed portfolios are expected to be zero because all securities are expected to lie on the security market line. Therefore, a significantly positive alpha of a portfolio indicates an excess return.

The goal of this study is to compare the performance of portfolios by applying the methodology of Jahnke et al. (1987). Rather than estimating the previous equation for two extreme portfolios, the required performance is estimated by using OLS on the following regression:

$$R_{pt} - R_{ft} = \alpha_p + d_L D_{pt} + \beta_p (R_{mt} - R_{ft}) + s_L S_{pt} + u_{pt} \quad (5)$$

where  $R_{pt}$  is the return in month  $t$  ( $t = 1, \dots, 72$ ) earned by a portfolio purchased at the beginning of the month;  $\alpha_p$  is the intercept, which equals the monthly abnormal performance of the portfolio that is not represented by a dummy variable, i.e.,  $\alpha_H$ ;  $R_{ft}$  is the risk-free rate, i.e., the return of one-month Treasury bills in month  $t$ ;  $\beta_p$  is the slope, which equals the systematic risk of the portfolio  $\beta_H$ , which is not represented by a dummy;  $R_{mt}$  is the rate of return on the ISEX-15 index in month  $t$ ;  $D_{pt}$  is equal to zero for observations of the portfolio that are not represented by a dummy and one for all observations of the portfolio that are represented by a dummy variable; and  $u_{pt}$  is an error term assumed to have an expected value of zero and to be serially uncorrelated.  $S_{pt} = D_{pt}(R_{mt} - R_{ft})$  for all observations. The coefficient  $\alpha_p$  in the equation equals  $\alpha_H$ , i.e., the measure of monthly abnormal performance for the portfolio that is not represented by a dummy variable, which means that  $D_{pt} = 0$  for that portfolio. The coefficient  $d_L$  is a key parameter in this regression. It measures the difference between the excess returns of the portfolio that is not represented by a dummy variable and the portfolio that is represented by a dummy variable. It should be noted that  $\alpha_p + d_L$  is equal to the alpha of the portfolio, which is represented by a dummy variable. Thus, we may use a t-test to determine if  $d_L$  is significantly different from zero. If  $d_L$  is significant, then the returns of the portfolios are significantly different when differences in systematic risk are taken into account.  $\beta_p$  equals  $\beta_H$ , i.e., the systematic risk (beta) of the portfolio, which is not represented by a dummy variable. Finally,  $s_L$  provides an estimate of the difference in systematic risk between the portfolio that is represented by a dummy variable and the one that is not, with  $\beta_p + s_L$  being the systematic risk of the portfolio that is represented by a dummy variable,  $\beta_L$ .

## 4. Results

### 4.1 Individual stocks

In Table 1 the main results of the regression are from data used in regression applying Equation 3. The main finding is that there is a significant relationship between the M/B ratio and the return of Icelandic stocks. The coefficient  $\gamma$  is negative and statistically significant. This means that stocks with low M/B ratios had significantly higher average returns than stocks with high M/B ratios. The coefficient  $\lambda$  is not statistically significant so there was no significant relationship between the size and return of Icelandic stocks.

**Table 1. Result of the regression applying data on individual stocks**

	$\alpha$	$\beta$	$\gamma$	$\lambda$	$R^2$
Coefficient	0.0076	0.81	-0.0021	-0.045	0.15
t-statistics	(*2.82)	(*19.09)	(* -6.24)	(-0.21)	
p-statistics	0.0048	<0.0001	<0.0001	0.83	
Durbin W.	1.63			n = 2,181	

\*Significant at the 5% level.

### 4.2 Portfolios

Figure 1 shows the average return of portfolios formed according to the size of the stocks (market value). The figure shows that the portfolio with the smallest stocks had the highest average return, approximately 0.8% per month. The portfolio with the largest stocks had the second highest return, 0.7% per month. The portfolios of stocks of medium size, portfolios 2 and 3, had the lowest average returns.

**Figure 1. Returns of portfolios constructed according to firm size**

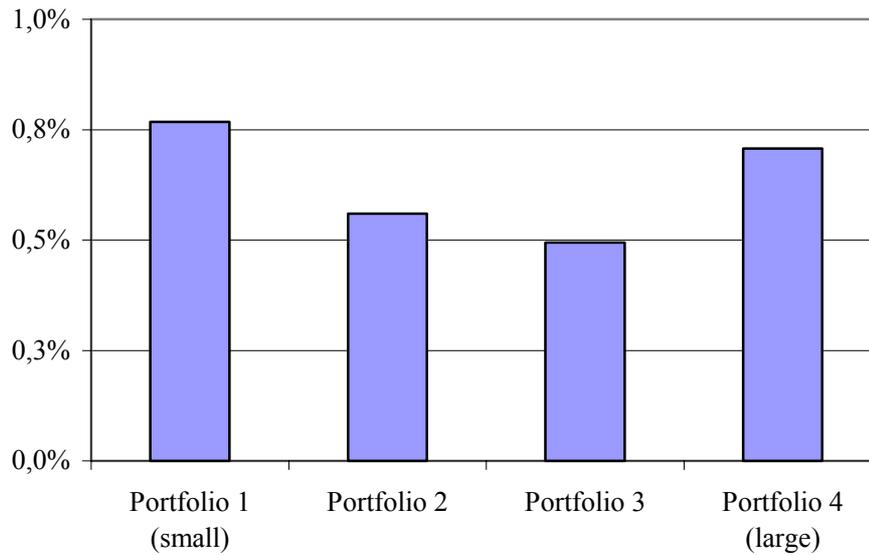

Table 2 shows the main result where the performances of Portfolios 1 and 4 are compared using regression applying Equation 5. Not surprisingly, the findings are that there is no difference in risk-adjusted returns between the portfolios as shown by the very insignificant  $d_L$  coefficient. The systematic risk (beta) of the portfolio formed from the smallest stocks is lower than the systematic risk of the largest stocks as indicated by the negative  $s_L$  coefficient. The difference in systematic risk is not statistically significant. These results clearly indicate that there was no relationship between the size and return of Icelandic stocks.

**Table 2. Results of the regression of portfolios constructed according to firm size**

	$\alpha_p$	$d_L$	$\beta_p$	$s_L$	$R^2$
Coefficient	0.0023	0.00019	0.94	-0.16	0.57
t-statistics	(0.59)	(0.03)	(*10.4)	(-1.22)	
p-statistics	0.56	0.97	<0.0001	0.22	
Durbin W.	1.99			n=144	

\* Significant at the 5% level.

Figure 2 shows the average return of portfolios constructed according to the M/B ratios. The figure shows that the return of Portfolio 4, i.e., the

portfolio with the stocks with the highest M/B ratio was lowest, at only 0.18% per month. Portfolio 2 had the highest average return or 1.03% per month. The figure indicates a possible relationship between M/B ratios and returns on the Icelandic stock market.

**Figure 2. Returns of portfolios constructed according to firms' M/B ratios**

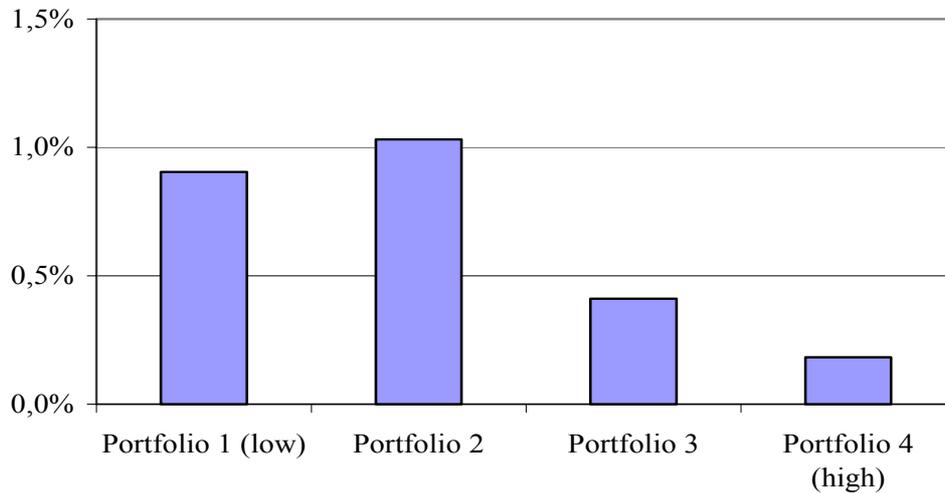

Table 3 shows the main result where the performances of Portfolios 1 and 4 are compared applying regression using Equation 5. The findings are that there is a difference in return between Portfolios 1 and 4 when adjusting for systematic risk as the coefficient  $d_L$  indicates. The coefficient is, however, not statistically significant, so the difference in return also is not statistically significant. Portfolio 1 has lower systematic risk than Portfolio 4 as the negative  $s_L$  indicates; however, the difference in systematic risk between the portfolios is not statistically significant.

**Table 3. Results of the regression of portfolios constructed according to M/B ratios**

	$\alpha_p$	$d_L$	$\beta_p$	$s_L$	$R^2$
Coefficient	-0.0027	0.0066	1.04	-0.23	0.47
t-statistics	(-0.51)	(0.91)	(*8.71)	(* -1.35)	
p-statistics	0.61	0.37	<0.0001	0.18	
Durbin W.	2.02			n=144	

\* Significant at the 5% level.

## 5 Conclusion

This paper reported empirical tests that were performed to determine whether the Icelandic stock market showed the clear signs of market inefficiency that have appeared on other capital markets. Empirical tests were performed to study the relationship between the M/B ratios, size, and returns of Icelandic stocks. This research was divided in two parts. First, data on returns, M/B ratios, and size of individual stocks were analyzed. Portfolios were then formed based on the variables examined and their performance was compared. The findings are that there is no apparent relationship between the size measured by market value of common stocks and returns. On the other hand, there was a statistically significant relationship between M/B ratios and returns when using data from individual stocks, but those results were not statistically significant when analyzing the performance of portfolios. The reason for that might be the number of data points, which are more than 15 times more numerous than when analyzing individual stocks rather than portfolios.

The finding that stocks with low M/B ratios provide high returns on the Icelandic stock market is consistent with findings on other stock markets. It is interesting that the small and underdeveloped Icelandic stock market shares the same signs of inefficiency that appear in larger and more developed stock markets.

## **Abstract**

*The paper builds on theoretical arguments suggesting that the debt-equity ratio is related to agency costs. Two predictions prevail. First, leverage aggravates agency conflicts between shareholders and bondholders. Frequently cited examples are (1) the direct wealth transfer problem, (2) the asset substitution problem and (3) the underinvestment problem. Second, leverage mitigates agency problems that arise from managerial behavior that conflicts with the interest of shareholders. Well-known example is the overinvestment problem. For analysis, we used questionnaire data of non-financial firms in Slovakia. The analysis itself uses structural equations modeling with confirmatory analysis. The structural equations model describes the relationships between the variables in the model and the endogenous variables are four agency problems mentioned above. Each of these four endogenous variables is potentially determined by a wide set of exogenous variables. The main result of the research is that direct relations between leverage and agency problems seem to be absent. This does not imply that the agency problems are irrelevant. However, other instruments than leverage affect agency problems.*

**Keywords:** *agency cost; leverage; capital structure*

## **1. Introduction**

In the paper we develop a model that helps to examine the presence of agency cost in financing decisions and capital structure decisions. For the purpose of this paper, we define agency cost as a direct and indirect cost caused by conflicts between stakeholders in the corporation. Many empirical studies provide tests of the relevance of agency problems in a capital structure setting. In these studies, it is assumed that direct relations between determinants of agency problems and leverage are caused by agency problems. The contribution of this paper is to apply and investigate potential influences of determinants of agency problems from these studies on decision making process in Slovak corporations.

## **2. Theories and hypothesis of agency problems and debt**

The pioneering work in the field of corporate capital structure is the paper of Modigliani and Miller (1958) about the irrelevance of financing choice between debt and equity. After this paper a vast and rapidly growing literature deals with potential relations between this choice and agency problems. We can briefly summarize the ideas behind the theories that we test in the present article. Additionally, we mention and discuss empirical studies and hypothesis used to test the theories.

### ***2.1 Shareholder – bondholder conflicts***

In the shareholder-bondholder conflicts shareholders make decisions transferring wealth from bondholders to shareholders. However, the bondholders are aware of the situations in which this wealth expropriation may occur. Therefore, they will demand a higher return on their bonds. Shareholders, foreseeing the bondholders' reaction, can mitigate the potential conflicts. Three potential conflicts can be distinguished: direct wealth transfer, asset substitution, and underinvestment. In the case of direct wealth transfer conflicts, dividends are increased or debt with higher priority is issued (Smith and Warner (1979)). In the case of asset substitution, the firm is substituting current projects for projects which have higher risk (Jensen and Meckling (1976)). As the bondholders are compensated given the risk of the current projects, wealth is transferred from bondholders to shareholders. In Myers' (1977) underinvestment problem, growth options will not be exercised because, due to the overhang of debt, the equity needed to finance these growth opportunities will not be provided by the shareholders. The shareholder-bondholder conflicts can be mitigated by adjusting the properties of the debt contract. This can take several forms. First, the contents of the debt contract can be adjusted by including covenants (Smith and Warner

(1979)). For example, a covenant can contain restrictions on the payment of dividends or the disposition of assets. Second, debt can be secured by collateralization of tangible assets in the debt contract. Third, convertible debt or debt with warrants can be issued (Jensen and Meckling (1976) and Green (1984)). Fourth, the maturity of debt can be shortened (Myers (1977)).

The empirical studies related to the shareholder-bondholder conflicts mainly focus on the degree to which a firm can secure its debt and the firm's growth opportunities, both in relation to the relative amount of debt. In Titman and Wessels (1988) the relative amount of fixed assets is used to approximate the relative amount of secured debt, which is a potential mitigating factor of wealth distribution and asset substitution. Titman and Wessels find no significant relationship for the expected positive relationship. However, it remains unclear whether this result is caused by agency problems or, for example, by decreasing bankruptcy costs. In Titman and Wessels (1988), Smith and Watts (1992), McConnell and Servaes (1995), and Lang, Ofek, and Stulz (1996) variables are used to approximate growth opportunities, which are hypothesized to aggravate underinvestment. The results are mixed, which is probably caused by the difficulty to measure growth opportunities from publicly available data. Titman and Wessels (1988) do not find the expected negative influence of proxies for growth opportunities on leverage, whereas Smith and Watts (1992) find the predicted effect. McConnell and Servaes (1995) and Lang, Ofek, and Stulz (1996) perform similar tests for a subsample of high-growth firms. The former study notices a significantly negative relationship between growth opportunities and leverage, while the latter finds no relationship. In these studies the properties of the debt contract that are mitigating factors of the underinvestment problem are not taken into account.

## ***2.2 The shareholder – management conflicts***

The conflicts between shareholders and management that stem from the separation of ownership and control are introduced by Jensen and Meckling (1976). The overinvestment problem of Jensen (1986) is a further elaboration of their theory. According to the overinvestment hypothesis, managers have incentives to cause their firm to grow beyond the optimal size and to accept projects with a negative value to the firm. Jensen argues that overinvestment is aggravated by more free cash flow and less growth opportunities. The overinvestment problem can be mitigated by issuing debt and Jensen refers to this nondiscretionary nature as the disciplining role of debt. Alternative mechanisms to control overinvestment exist. First, the managers' income can be made dependent upon the performance of the firm. This can be accomplished by means of managerial shareholdings or option plans, or by compensation schemes. Second, internal and external corporate

control mechanisms may mitigate overinvestment. The internal control mechanisms include monitoring by the board, large shareholders, or banks. An example of an external control mechanism is the market for corporate control, which is characterized by hostile takeovers.

Several empirical studies examine the overinvestment problem by analyzing the relationship between growth opportunities and free cash flow on the one hand, and leverage on the other. Smith and Watts (1992) do not differentiate between overinvestment and underinvestment and find the predicted negative relationship between debt and growth opportunities. McConnell and Servaes (1995) amend the test by examining the overinvestment hypothesis for a sample of low-growth firms, and include managerial shareholdings as a mitigating factor. They conclude that the results confirm the overinvestment hypothesis. In the study of Lang, Ofek, and Stulz (1996) the overinvestment hypothesis is also tested for a sample of low-growth firms, and a proxy for the availability of free cash flow is included. In line with the overinvestment hypothesis, a significantly negative relationship between debt and proxies for growth opportunities is found. Berger, Ofek, and Yermack (1997) test the influence of governance characteristics on leverage. Both studies find that alignment of interest, through managerial shareholdings and option plans, induces leverage. As a result of monitoring, the presence of large shareholders is found to increase leverage. Similarly, relationships with banks induce leverage.

### ***2.3 Summarization of the hypothesis***

In the following Table 1 we present theoretical relations (positive or negative) between four agency problems specified above and potential determinants of agency costs.

**Table 1 The endogenous relations between leverage and agency costs**  
**Theories and determinants** **Expected relationship**

<i>1. Shareholder vs. bondholder conflict</i>	
• direct wealth transfer problem	
○ leverage	positive
○ covenants	negative
○ secured debt	negative
○ convertible debt	negative
○ short-term debt	negative
• asset substitution problem	
○ leverage	positive
○ covenants	negative
○ secured debt	negative
○ convertible debt	negative
○ short-term debt	negative
• underinvestment	
○ leverage	positive
○ growth opportunities	positive
○ covenants	negative
○ secured debt	negative
○ convertible debt	negative
○ short-term debt	negative
<i>2. Shareholder vs. manager conflict</i>	
• overinvestment	
○ free cash flow	positive
○ growth opportunities	negative
○ managerial incentive structure	negative
○ control structure	negative

### **3 The empirical model and data**

The analysis is based upon results of questionnaires sent to the CFOs of over 100 non-financial firms. We received 46 usable questionnaires, what means the response rate of 45%. The questionnaire was completed anonymously. By means of questionnaire we asked financial managers for their opinion about firm characteristics. The reason for using questionnaire in opposite to accounting data was that we need specific information and the knowledge of the managers goes beyond publicly available data and includes internal information such as the presence of agency problems.

The data from questionnaires we included in the model. For model we used structural equations modeling with confirmatory analysis. The structural

equations model describes the relationships between the variables in the model. The endogenous variables are four agency problems – direct wealth transfer, asset substitution, underinvestment and overinvestment. Each of these variables is potentially determined by a wide set of exogenous variables and related to a subset of the other endogenous variables. The variables in the models are proxies of unobservable determinants that are derived from the theory. From the hypothesis in Table 1 we can derive a system of equations that describes the expected relationships. Summary of these relations in the structural equations model with both explained and explanatory variables is shown in the Table 2.

**Table 2 Structural model**

<i>Explained variable</i>	<i>Explanatory variables</i>
<i>Wealth transfer</i>	covenants, secured debt, convertible debt, short-term debt
<i>Asset substitution</i>	covenants, secured debt, convertible debt, short-term debt
<i>Underinvestment</i>	growth opportunities, covenants, secured debt, convertible debt, short-term debt
<i>Overinvestment</i>	free cash flow, growth opportunities, managerial incentive, structure, control structure

#### **4 Results and conclusions**

In the single-equation context we simplify each equation until all parameter estimates have absolute t-values that exceed a particular constant. Following suggestions in Haitovsky (1969), this is done by a series of estimations and t-tests, which we call the specification process. The first estimation model includes all variables. After the first estimation round the variable that has the lowest absolute t-value for its parameter estimate, is eliminated from the model. The resulting smaller model is re-estimated and a similar elimination procedure follows. The estimations and eliminations are stopped as soon as all t-values are larger in magnitude than the specified value. The constant in the model is, of course, never eliminated in this process. The single-equation method and the subsequent specification process lead to a relatively small system of equations than can be estimated by a full-information method. This estimation approach will lead to more efficient parameter estimates than those obtained in the single-equation context. The system includes among the explanatory variables the endogenous variables that are also present in the most general model and the exogenous variables that were not eliminated in the specification process.

Table 3 presents the OLS (Ordinary Least Squares) estimation results of the single equation models with stepwise deletion (in columns 2 – 4) of the variables reporting the lowest absolute t-value (t-value are in parentheses).

**Table 3 Determinants of the agency problems**

(1)	(2)	(3)	(4)

R <sup>2</sup>	0,9348	0,9352	-0,72 (-
			22,04)
			0,9311

Analyzing the wealth transfer, the remaining two variables in the model confirm the expected relationship and have negative influence on the agency costs. Asset substitution seems to be statistically irrelevant for the research. Underinvestment problem is central in many theoretical and empirical studies. Both remaining variables in this model confirm theoretical assumptions. Overinvestment is theoretically considered as a very important factor influencing the capital structure. Exogenous variables in the model – performance based income and market control threat are fully correspondent with expected relations. Nevertheless, the variable “market for corporate control threat” seems to be very interesting, because of absence of this market in Slovakia.

The main result from the Table 3 is that direct relations between leverage and agency problems seem to be absent. This does not imply that the agency problems are irrelevant. However, other instruments than leverage affect agency problems. As expected, a positive relation between some exogenous variables and agency problems determinants has been found in the model.

In developing a sensible approach to capital structure strategy, the CFOs should start by thinking about firm’s target capital structure, which is a ratio of debt to total capital, that can be expected to minimize taxes and contracting costs. In sum, to make a sensible decision about capital structure, CFOs must understand both the costs associated with deviating from the target capital structure and the costs of adjusting back toward the target. The next step forward in solving the capital structure problem is to involve a more formal weighing of these two sets of costs.

## **Abstract**

*Performance analysis in stock markets is an area of great interest in both academic and commercial circles. Many trading strategies have been proposed and practiced from the perspectives of technical analysis, market making, external data indication, etc. This paper finds out evidence of a performance search based on a strategic planning approach suggested by Eren (2002) as Mcnamee used (1984). The paper examines corporate values of shares on Istanbul Stock Exchange (ISE), the only securities exchange in Turkey which is a growing emerging market with an increasing number of publicly traded companies and foreign participation. It provides an alternative analysis of firms listed on the Istanbul Stock Exchange (ISE) to value their performance as a guidance for investors. The ratios of return on equity of the firms and the cost of an alternative investment are taken to attain their value matrix (v-matrix) results. The v-matrix results point out to the rational sectors to invest in ISE and the rational investment in Turkey.*

**Keywords:** *performance of stocks; return on equity; t-bills; value matrix*

## 1. Introduction

It is well-known that the majority of fund managers, financial planners, and investment advisors hold that investment in equity is the most appropriate way to build funds to meet major goals that are at least five to ten years off. This optimism about future stock returns has also become conventional wisdom for general investors. Many individual investors now expect not only that the stock market will outperform all other kinds of investments, but also that stock returns will exceed their long-run historical averages into the foreseeable future. It is equally well-known that these expectations are based largely on past experience rather than sound theory. In newspaper or journal articles, introductory textbooks, and news reports, and at professional meetings, the public is bombarded with data showing that in the long run no investment alternative comes close to stocks. In the last decade, for instance, the 15% average annual return on stocks was substantially higher than returns on other securities, as well as higher than the 10% average return on stocks over the previous 100 years.<sup>1</sup>

There are some market analysts like Pennar, Quinn and Zuckerman who do not believe that the current optimism about the future stock market is warranted. First of all, these skeptics believe that stock prices are too high relative to their fundamental value and anticipate a correction.<sup>2</sup> There are some critics that point to increased risk due to globalization, noting that as learned by various cases like that of US on October 27 in 1997, in a global economy, nobody is immune from shocks heard around the world.<sup>3</sup> Quinn notes that investors have forgotten or never knew that the stock market is a risky place.<sup>4</sup>

Studies of stock returns in emerging markets indicate that these markets are characterized by high volatility and abnormal returns. Investor interest in emerging markets exploded during the last decade as a result of the quest for higher returns. Yet little is known about the nature of stock in those markets. Variables like PAT/EQ (Profit After Taxes/Equity) ratios and dividend yields are reported to have some explanatory power for average market returns.<sup>5</sup> Like Bekaert et al., past empirical work of Basu (1983) and

Ball (1988) on asset pricing has identified a number of variables that help explain stock returns in addition to the market risk variable. P/E ratio is found to have significant indicator in asset pricing tests.<sup>6</sup>

Odean (1998) developed a theoretical model of financial markets where investors suffer from overconfidence. This overconfidence model predicts that investors will trade to their detriment.<sup>7</sup> Barber and Odean (2000) estimated the monthly time-series regression of the monthly return on t-bills and the monthly return on a value-weighted market index for testing net performance of individual investors.<sup>8</sup> Similar to that, Asness (2000) tested the expected bond returns and stock returns in a model pointing the equity risk premium in investments.<sup>9</sup>

The study is concentrated on Istanbul Stock Exchange providing information on investing in Turkey. Turkey is a country offering significant opportunities for foreign investors with its geographically perfect position to function as a gateway between Europe, Middle East and Central Asia. The opportunities exist not only in the dynamic domestic market, but also throughout the region.

Turkey has a developed market economy, with a rich history of private enterprise. The Turkish financial sector is well developed in both technology and legal procedures. It is primarily built upon universal banking system and related areas like insurance, leasing, factoring and stock brokerage. Banks operate in accordance with international rules and practices offering a wide variety of services.<sup>10</sup>

Before 1980's, political turmoil, economic instability and institutional underdevelopment have traditionally been powerful obstacles regarding Turkish Financial Markets. But recently, markets in Turkey have witnessed an economic and financial development -merely the case of deregulation and

<sup>10</sup> ISE, [www.ise.gov.tr](http://www.ise.gov.tr)

liberalization (financial openness). During 1990's, the accessibility to capital markets (especially the Istanbul Stock Exchange) has increased.

The Turkish economy and the stock market is characterized by high, sustained and variable inflation which is detrimental to an economy in terms of long-term growth, investments and operation of the financial system as a whole. Inflation is known to intensify all kinds of risk such as credit, capital, interest rate, investment, and liquidity risks in the financial system resulting in increased uncertainty. Inflationary effects on stock market result in puzzling-stock return behavior. Recently, Barnes et al., (1999) clearly put forward that high inflation rates lead not only to greater inflation variability, but to greater variability in other rates of return as well.<sup>11</sup>

This paper does not focus directly on the future possibilities of the ISE. Its contribution lies more in shedding additional light on the past experience of the market. In terms of a performance measure (PAT/EQ), we show that the performance of stocks compares much less favorably with that of treasury bills whereas Barber and Odean (2000) used as variables in another method they followed.

Accordingly, the paper is organized as follows: Section 2 gives information about ISE. Section 3 provides the data and the methodology in detail. Section 4 discusses the results, and Section 5 is devoted to the conclusions of the research.

## **2. Istanbul Stock Exchange (ISE)**

The financial markets in Turkey were highly inefficient and strictly regulated until 1980. Attempts for the liberalization of the country in general and financial markets started at the beginning of 1980s. Things changed then when the Capital Markets Board was set up as the main regulatory board, capital instruments were defined and laws governing the issuing of securities were drawn up. The establishment of the legal framework and regulatory agencies for the stock market was completed in 1982.

At the end of 1985 the Istanbul Stock Exchange in its current form was established and it started trading in 1986. The exchange has shown remarkable growth both in terms of trading volume and number of listed companies. Today market capitalization, trading volume and the number of

companies listed in ISE are above those in Eastern European exchanges. ISE now, is the eighth largest market in Europe.<sup>12</sup>

ISE is responsible for developing and maintaining the central securities market of Turkey, under the supervision of Capital Markets Board. The CMB is a member of the International Organization of Securities Commission (IOSCO), and has chaired the Emerging Markets Committee of IOSCO since May 2002. The CMB is also a member of the Capital Market Regulatory and Supervisory Consultative Group.

Along with the Istanbul Stock Exchange, the Istanbul Gold Exchange started operations in 1995. An ISE International Market was set up in 1996 and started trading in 1997 but volumes still remain minimal.

Although segmented, Turkish Capital Markets have recently shown interest in opening their borders and relaxing foreign ownership and capital repatriation restrictions. Turkey is more integrated with the world markets in its region. It seems to process information flows from global markets and act as conduits to other smaller markets.<sup>13</sup>

Turkish market is also characterized by high risk free rates, therefore market timing or appropriately switching between the fixed income securities and the equities might create higher returns for portfolio managers. ISE changes its basic characteristics quickly and carries additional risks due to the fact that it operates in a high and volatile inflation economy.<sup>14</sup>

The most important characteristics of capital market in Turkey is the predominance of the government securities. Because of tax burdens and availability of high income from government securities there is no encouragement for prospective issuers of corporate debt.<sup>15</sup>

Some other distinct characteristics of the Turkish Stock Market are the frequency and volume of stock dividends and right offerings. Stock dividends are declared from a revaluation fund, an equity account created as a result of inflation adjustment of fixed assets. Inflation in Turkey has decreased a great deal but still the problem with the revaluation fund remains and that leads to a change in balance sheets. Since 1983, corporations are permitted to adjust their financial statements for inflation by using revaluation method as a standard procedure. Revaluation, as exercised in Turkey, requires the increase of the book value of plant assets by a constant ratio, usually comparable to the inflation rate, announced by the Ministry of Finance. When the value of plant assets and related depreciation expenses are adjusted to inflation, an account called revaluation fund is credited and this account is listed under the equity. Corporations are also permitted to transfer the revaluation fund to paid-in capital by declaring stock dividends.<sup>16</sup>

### 3. Data and Methodology

The data used in this analysis contain the average yearly return (according to the latest year published- 2004) of the highest five and lowest five sectors traded in the ISE. After the initial sample selection and addressing the 10 sectors of ISE, the return on equity (PAT/EQ) of the firms listed on these sectors are calculated. The financial statement data were obtained from various ISE publications. In the second step, the yearly average compound rate of treasury bills (2004) is taken. The aim of comparison through the research as a whole was carried in another study whereas Gürsoy and Erzurumlu (2001) used returns of stocks and t-bills to be tested in another model.<sup>17</sup>

To facilitate the interaction between variables, we follow a methodology named as the Value Matrix used by McNamee (1984). The V-matrix suggested by Walsh and Mack is an alternative type of corporate planning. Walsh and Mack claimed that the cost of capital and the profitability of investments are crucial for business planning and portfolio analysis. It helps investors to quickly analyze past trends, assess their position and plan future strategic actions.<sup>18</sup> The aim of this research is to show the correct direction of investment in ISE for foreigners.

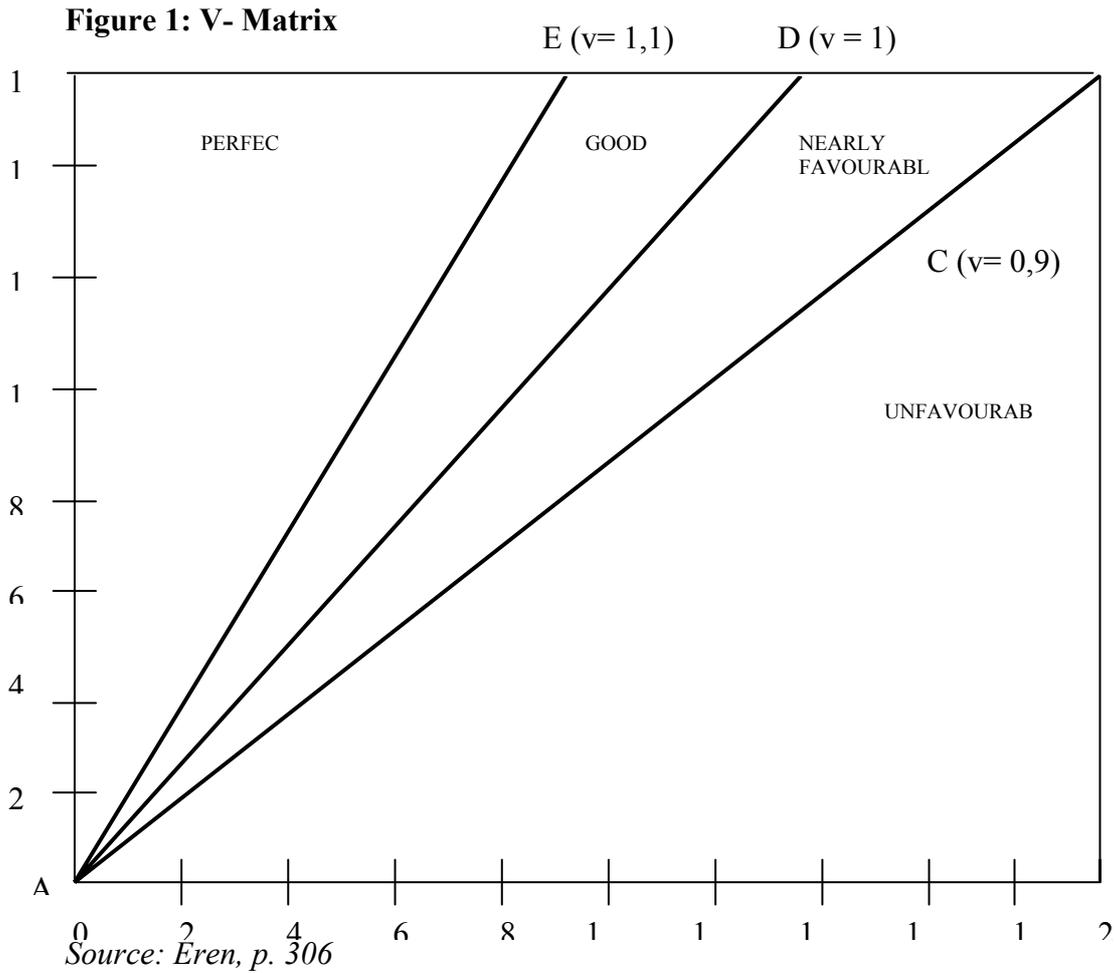

According to Walsh and Mack, the value matrix needs to be developed by the ratios of cost of capital and the profitability of investments. The cost of capital (representing t-bills in this research) based on current prices is on x-axis whereas the profitability (representing stocks in this research) of the business based on its investments is on y-axis. When the profitability of investments is equal to the cost of capital, it is shown with the AD diagonal. The value matrix -shown in Figure 1- is as follows: When the value of V is less than 1, the funds are invested unprofitably. On the other hand, when the value of V is 1, the funds are not profitable and when the value of V is greater than 1, the funds are invested to grow. The Strategic Business Units that are in the right below of the AD diagonal are unsuccessful whereas the SBUs that are in the left above of the AD diagonal are successful. The ADC triangle shows the area that is just below the equilibrium whereas the ADE triangle shows the area that is just above the equilibrium. The value matrix is used in the strategic planning of the companies. It is used to analyze the current situation and the annual trends. It

is also used to keep the strategic plan and fix the unsuccessful performance of the company. The value matrix is important to compare the company with its competitors.<sup>19</sup>

## 5. Research Findings

<sup>19</sup> Erol Eren, *Stratejik Yönetim ve İşletme Politikası*, Beta, 6. Baskı, 2002, pp. 305-306.

We computed the performance of ISE sectors and average t-bills in compound rate (Table 2). When we calculated for each year t-bills have a tendency to outperform. Just to show the results that resemble nearly the same in every year we chose 2004 to brief our study and Figure 2 represents the results of the v-matrix of the ISE's performance in 2004 compared with the performance of t-bills in 2004.

The results indicate that the ISE sectors do not show a satisfactory performance where they are unfavorable in v-matrix. One sector, *Defence* lays on over a little from t-bills where it is good in v-matrix. Two of the sectors, *Transportation* and *Manufacture Of Non-Metallic Mineral Products* are on the verge of growing and yet not profitable. Others are all unfavorable leading no growth. But more importantly, it was found that the best investment during the entire period is t-bills. The results of Gürsoy and Erzurumlu (2001) support our research that found t-bills to be the best investment rather than stocks over the entire analysis period in Turkey.

## *Turkey*

The case described above indicates two important points. Firstly, all the efforts of analyzing ISE to outperform market become highly questionable. This fact draws our attention to the second point, t-bills and their performance in Turkey, which interprets the results on ISE.

The results presented in Table 2 and Figure 2 show that t-bills are the best financial instruments merely helping to judge the ISE and its sectors' performance. The macroeconomic conditions under which the Turkish economy operates long before suggest a potential role for the results of our research. Turkish economy had and still has so many obstacles that investment incentives move towards financial instruments which are not risky. As a result of economical factors some risky investments alienate and their risk premium increases.

Despite the poor performance of ISE, we still can say that there are profitable stocks according to their good company profile. But sectors' performance is pushed down by companies that do not apply for the accepted company profile definition.

## **6. Conclusion**

According to the conventional wisdom, stock portfolios are the best investment vehicles for long-term investors. But once returns are adjusted for risk, whether the risk measured is total risk or systematic risk, the worst performer is the stock market, while the bond market outperforms the convertible bond market. Even in terms of mean returns, unadjusted for risk, the convertible bond market outperforms stocks.

Of course, historical returns cannot tell us much about future returns in ISE. But they should prompt us to ask several questions. First of all, in light of the above research and critiques, the question of how to make ISE more outperforming and efficient and in what ways the new legal regulations could be introduced to achieve such goals are possible areas for new studies. Secondly, can a fund manager continue to advise clients as before? Or is more caution required? Have we all forgotten that stock market is a risky place, and that expectations of continually higher returns from the stock market might be unrealistic?

Economical conditions of countries and the resistance power against expected and unexpected fluctuations would change homogeneity in specific situations. The nation is heterogeneous in the case of critical evaluations and

expectations. Because of that reason analytical consideration changes dramatically from country to country.

Treasury bills outperform stocks in Turkey and this is alright as there is a strong effect of macroeconomic obstacles prevailing in the country since the early 1980s. There has been (and still is to some extent) a substantial amount of inflation, volatility, and political and economic uncertainty in the Turkish economy. After 1990s, Turkey has made progress in improving the functioning of markets and in strengthening the institutional framework for a fully functioning market economy. However, macroeconomic stability and predictability has not yet been achieved to a sufficient degree. Inflationary pressures have not sufficiently declined to allow economic agents to conduct medium term planning. High real interest rates impede productive investment. The banking sector is channeling financial capital towards the private sector only to a limited degree and the sector's consolidation process is not yet completed. The considerable costs of servicing the huge public sector debt are a considerable burden, absorbing a large fraction of Turkey's economic potential. As a result of a narrow capital market and the crowding out of private investment by the public sector financing requirement, the investment incentives do alter. These conditions increase the risk premium demanded by investors and can reduce investment demand or change investment incentives to some other instruments having lower risk.

A broader discussions of these problems goes beyond the scope of our present data and therefore of this paper. However, facts assembled in this paper constitute a background for the design of investments in Turkey. Meanwhile, efforts to address those remaining issues must be maintained.

## **Abstract**

*The paper focuses on testing a weak form of market efficiency as regards capital markets in the Czech Republic, the Slovak Republic, Hungary, Poland and the United States. We have used a variance ratio test as a research method. Informational efficiency was tested using weekly and monthly values of relevant market indices in a period from 1993 until August 2004. We concluded that the US market reports the weak form of efficiency. Furthermore, the main results of our research concerning Central European markets show: (i) the weak form of the efficient market hypothesis could not be rejected for Central European capital markets, (ii) an improvement of market efficiency was observed over time on all the observed markets one can observe an improvement of market efficiency in these markets over time and (iii) the Central European capital markets converged to the U.S. capital market (in terms of the weak form of market efficiency).*

**Keywords:** market efficiency; hypothesis testing; market index; variance ratio test; PX-50;

<sup>1</sup> Note: This paper was supported by grant No. 402/05/2123 Efficiency of Financial Markets and New Basel Capital Accord (NBCA) awarded by The Grant Agency of the Czech Republic.

## 1. Introduction

The aim of the paper is to follow previous research (Hanousek [6], Vošvrda [13]) and to test a weak form of market efficiency of capital markets in the Czech Republic, the Slovak Republic, Hungary, Poland and in the United States. When using standard statistical methods, we want to answer following questions:

1. Can we observe any information efficiency in Central European capital markets?
2. Can we observe an improvement of information efficiency in these markets during time?
3. What gap is among Central European capital markets and the US (mature) capital market?

Based on our results we also want to address an issue if one can see any consolidation within Central European equity markets or any convergence to the U.S. market.

## 2. Informational efficiency of the capital market

Let us start with few definitions. An efficient capital market theory focuses on ability of a market to absorb new information and to react on it. A capital market is said to be efficient if fully and correctly reflects all relevant information in determining security prices. In other words, nobody can benefit from the information relevant to the stock prices that are not known to the other market participants.

Formally, the market is said to be efficient with respect to some information set if revealing that information does not affect security prices (Campbell [3]). Moreover, one cannot make economic profits by trading on the basis of that information set. Economists often define three levels of market efficiency, which are distinguished by the degree of information reflected in security prices.

A market would be described as being **weak-form efficient** if the security price reflects all information contained in the record of its past prices. In other words, this form of efficiency implies that relative changes of prices follow the random walk hypothesis and therefore price changes are unforecastable. Strategies used by technical analysts are failing in such a market.

**Semi-strong efficiency** of a market means that the information set includes both the history of prices and all publicly available information. Since publicly known information is incorporated in security prices, buying or selling recommendations from fundamental analysts are useless.

Finally, if market prices reflect all available information (both public and private), a market is said to be **strong-efficient**. In such a market, there is no such special information based on which an investor can make abnormal profits. In other words, insider information is valueless and therefore insiders do not post better trading results than other market participants (Filer [4]).

Formally, we can describe afore-mentioned definitions as follows:

$$E_t(P_{t+1} | \Phi_t) = P_t \quad (1)$$

Where:

$E_t$  = expected value operator

$P_{t+1}$  = price of security at time t+1

$P_t$  = price of security at time t

$\Phi_t$  = the set of information available to investors at time t

It follows from equation 1 that the best estimate for the future price of security is the current price of security.

### 3. Models of testing efficiency

Basic models, which are used by most methods mainly for testing the weak-form of efficiency, are based on various types of the random walk hypothesis including its generalization.

#### 3.1 The Random Walk – type 1 (RW1)

The simplest version of the random walk hypothesis assumes independent and identically distributed (IID) increments and is given by the following equation:

$$p_t = \mu + p_{t-1} + \varepsilon_t, \varepsilon_t \approx IID \quad (2)$$

Where:

$P_t$  = price of security at time t,  $P_{t-1}$  = price of security at time t-1

$p_t = \ln P_t, p_{t-1} = \ln P_{t-1}$

$\mu$  = the expected price change (drift)

$\varepsilon_t$  = independently and identically distributed value.

If we consider normality of  $\varepsilon_t$  (i.e. with the mean value 0 and variance  $\sigma^2$ ), we are talking about a Brownian motion. Such a distributional assumption implies that continuously compounded returns are IID varieties with mean  $\mu$  and variance  $\sigma^2$ .

### 3.2 *Random Walk – type 2 (RW2)*

However, the assumption of identically distributed increments of security prices is not fulfilled in the long-term run. The shift in the economic, social, technological, institutional, and regulatory environment affect security prices in the capital markets and therefore it changes the parameters of distribution of price increments over the long-term.

For reasons outlined above we relax the assumption of RW1 to include processes with independent but not identically distributed (IID) increments and we shall refer it to as the Random walk 2 (RW2). Clearly, RW1 is a special case of RW2. RW2 also allows modeling of more general price processes in the capital markets. For instance, the models with the time-variation volatility that assumes heteroscedasticity in the time series  $\{\varepsilon_t\}$  are the case.

### 3.3 *The Random Walk – type 3 (RW3)*

An even more general type of the random walk hypothesis is the one that relaxes the independence assumption of RW2 to include processes with dependent but uncorrelated increments. We shall call such a type the Random Walk model (RW3). It is clear that RW3 contains RW1 and RW2 as special cases.

For example, the following process satisfies assumptions of RW3 but not of RW1 or RW2 is any process for which:

$$Cov[\varepsilon_t, \varepsilon_{t-k}] = 0, \forall k \neq 0 \quad (3)$$

but where

$$\exists k \neq 0, Cov[\varepsilon_t^2, \varepsilon_{t-k}^2] \neq 0 \quad (4)$$

Such a process has uncorrelated increments, but is clearly not independent since its squared increments are correlated (Campbell [3]).

## 4. Methods of testing market efficiency

### 4.1 The break event point test

The Break event point test ranks to one of the most used nonparametric tests of the random walk hypothesis, i.e. of the tests being independent on particular distribution of increments. For more details see Campbell [3].

### 4.2 The runs test

The runs test is another test of RW1. This test investigates the number of sequences of consecutive positive and negative returns called *runs* in a particular sequence. More information about the runs test could be found in Levene [9] or Anděl [1]. Let us mention that the break event point test and the runs test are fully equivalent and differ only in a definition of a test statistic.

### 4.3 The variance ratio test

The variance ratio test (Ayadi [2] or Urrutia [12]) could be applied to all three types of the random walk hypothesis (if properly modified). The test follows the idea that if a time series of the natural logarithm of prices fulfills the random walk hypothesis, then variance of  $q$ -th derivations has to increase directly as a degree  $q$  of derivation increases. The variance ratio is defined as follows:

$$VR(q) = \frac{\sigma^2(q)}{\sigma^2(1)} \quad (5)$$

where  $\sigma^2(q)$  is variance of  $q$ -th derivations divided by  $q$  and  $\sigma^2(1)$  is variance of the first derivations (for more details see Lo[10]):

$$\sigma^2(q) = \frac{1}{m} \sum_{t=q}^{nq} (\ln P_t - \ln P_{t-q} - q\hat{\mu})^2 \quad (6)$$

$$\sigma^2(1) = \frac{1}{(nq - 1)} \sum_{t=1}^{nq} (\ln P_t - \ln P_{t-1} - \hat{\mu})^2 \quad (7)$$

whereas

$$m = q(nq - q + 1)\left(1 - \frac{q}{nq}\right)$$

$$\hat{\mu} = \frac{1}{nq}(\ln P_{nq} - \ln P_0)$$

and  $P_0, P_{nq}$  are the first and last values in times series of prices.

If the random walk hypothesis holds, the variance ratio  $VR(q)$  shall converge to 1. Then two test statistics  $z(q)$  and  $z'(q)$  could be derived in dependence on the fact if we assume for  $\varepsilon_t$  from equation (2) homoscedasticity (constant variance), which corresponds with RW1, or heteroscedasticity (variable variance), which corresponds with RW2 or RW3.

The formulas of the test statistics  $z(q)$  and  $z'(q)$ , which under RW1 shall converge to the standard normal distribution  $N(0,1)$ , are as follows:

$$z(q) = \frac{VR(q) - 1}{\sqrt{\Phi(q)}} \approx N(0,1) \quad (8)$$

where

$$\Phi(q) = \frac{2(2q-1)(q-1)}{3q(nq)}$$

$$z'(q) = \frac{VR(q) - 1}{\sqrt{\Phi'(q)}} \approx N(0,1) \quad (9)$$

where

$$\Phi'(q) = \sum_{j=1}^{q-1} \left[ \frac{2(q-j)}{q} \right]^2 \hat{\delta}(j)$$

and

$$\hat{\delta}(j) = \frac{\sum_{t=j+1}^{nq} (\ln P_t - \ln P_{t-1} - \hat{\mu})^2 (\ln P_{t-j} - \ln P_{t-j-1} - \hat{\mu})^2}{\sum_{t=1}^{nq} [(\ln P_t - \ln P_{t-1} - \hat{\mu})^2]^2}$$

Technically, if we reject the hypothesis for the reason that the variance ratio equals 1 (for any time lag), it is enough for rejection of the random walk hypothesis. Nevertheless, we can consider all time lags together and only one confidence interval (Stolin [11]) that can influence testing results. When using the test statistics  $z(q)$ , one shall not neglect that it is derived for RW1 and therefore it shall be tested if natural logarithms of price increments  $\varepsilon_t$  are IID. On the contrary, when using the test statistics  $z'(q)$  one shall test only independence or even the uncorrelation between the increments.

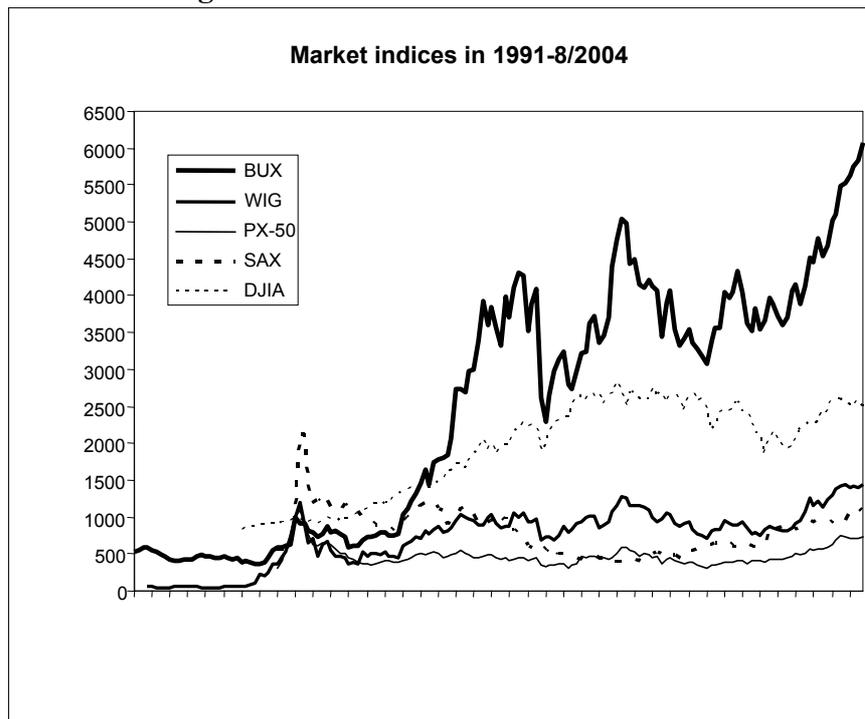

## **5. The results of testing market efficiency**

Regarding the scope of the paper and strength of the used tests we present only results of the variance ratio test, which has the highest predicative power.

### ***5.1 Data used***

When testing the market efficiency, we have used weekly and monthly data as regards capital markets in the Czech Republic, Poland, Hungary, Slovakia and in the United States. The US market is usually considered as highly effective and as a benchmark for other capital markets. This fact we have tried to prove or falsify. We have used the market indices of the particular markets as representatives of these markets: PX 50 for the Czech Republic, the Warsaw Stock Exchange Index (WIG) for Poland, the Budapest Stock Index (BUX) for Hungary, the Slovak Share Index for Slovakia and Dow-Jones-Industrial-Average (DJIA) for the US (see Figure 1):

**Figure 1 Development of stock market indices in the period from 1991 until August 2000**

*Source: Own calculations based on data of the stock exchanges*

Note: All indices were recalculated to the closing value of 1,000 as

Apart from the closing monthly and weekly values of market indices, end-of-month values recalculated to dollars were used. This fact can play an important role in the view of foreign investors that want to invest monies in the analyzed capital markets. Such obtained results can variegate the conducted research of market efficiency (under the assumption of no transaction costs occurred in relation to terms of trade).

### ***5.2 The variance ratio test***

In contrast to the break event point test and the runs test used by some authors (Ayadi [2] or Urrutia [12]), the variance ratio test considers drift  $\mu$  in the test statistics. On the other hand, a pitfall of the variance ratio test is its dependence on the parameters of data distribution respectively on data normality (at least in case of testing RW1).

Considering every lag being independent and homoscedasticity of the time series  $\varepsilon_t$  (see formula (2)), we concluded relatively clear results for the

weekly values in the period from September 1993 until August 2004 with the lags of 1, 2, 3 and 6 months (more precisely 4, 8, 13 and 26 weeks). While we reject the hypothesis in Central European markets, the US market seems to be effective under RW1. Technically, if we reject the hypothesis for the reason that the variance ratio equals 1 (for any time lag), it is sufficient for rejection of the random walk hypothesis. When thinking about a) all lags from the interval from 2 to 26 weeks together and b) the unique confidentiality interval of the maximum value of the test statistics for all time lags, we concluded the same result as mentioned above (i.e. we reject the hypothesis in Central European markets, but we do not disaffirm for the US market) – see Table 1.

Although we have found some statistical support for the weak-form efficiency in the US market, one shall investigate why RW1 was rejected in Central European markets. One of the reasons could be heteroscedasticity in the time series  $\varepsilon_t$  (from formula (2)) being explained by increasing market capitalization, a rise in trading activities and by nonsystematic interference in Central European markets (e.g. privatization deals - a direct sale of state-owned companies to an investor etc.). All these factors could lead to various-frequented stock price movements in the capital market per time unit and therefore a variable variance of  $\varepsilon_t$  (or heteroscedasticity) in time series could occur.

For reasons outlined above one shall study also the second test statistic  $z'(q)$ , which is resistant to heteroscedasticity in data and denoted in Table 1 in square brackets. As it follows from table 1, we do not reject RW1 in any analyzed market.

**Table 1: The variance ratio test (weekly data, local currencies, long period)**

Weekly returns September 1993 - August 2004 ( <i>z</i> – homoscedasticity assumption) [ <i>z'</i> – resistance against heteroscedasticity]					
Lag	Hungary	Poland	C R	SR	USA
<i>q</i> =4	1,33 (4,76)* [0,40]	1,28 (3,89)* [0,21]	1,62 (7,92)* [0,71]	1,71 (9,13)* [0,77]	0,94 (-0,85) [-0,07]
<i>q</i> =8	1,57 (5,14)* [0,46]	1,44 (3,95)* [0,23]	2,08 (8,74)* [0,87]	2,11 (8,95)* [0,87]	0,85 (-1,21) [-0,10]
<i>q</i> =13	1,59 (4,00)* [0,37]	1,70 (4,73)* [0,29]	2,18 (7,18)* [0,77]	2,26 (7,65)* [0,85]	0,80 (-1,29) [-0,11]
<i>q</i> =26	1,65 (3,05)* [0,30]	2,10 (5,06)* [0,33]	1,82 (3,43)* [0,39]	1,54 (2,25)* [0,29]	0,75 (-1,07) [-0,10]
<b>max <i>z</i>(<i>q</i>=2..26)</b>	(5,30)*	(5,06)*	(8,76)*	(9,13)*	(-1,87)
<b>max <i>z'</i>(<i>q</i>=2..26)</b>	[0,48]	[0,33]	[0,87]	[0,91]	[-0,14]

\* The variance ratio significantly differs from 1 on 5% significance level and therefore we reject RW1.

If we do similar calculations for weekly returns in local currencies in the shorter period from January 1998 until August 2004, we reject RW1 under homoscedasticity assumption only for the Czech market. If we suppose data heteroscedasticity, we do not reject RW1 in all markets.

**Table 2: The variance ratio test (weekly data, local currencies, short period)**

(Weekly returns January 1993 - August 2004 (z –homoscedasticity assumption) [z' – resistance against heteroscedasticity])					
Lag	Hungary	Poland	C R	SR	USA
<i>q=4</i>	1,15 (1,51) [0,18]	1,14 (1,35) [0,10]	1,33 (3,32)* [0,38]	1,01 (0,06) [0,01]	0,95 (-0,53) [-0,06]
<i>q=8</i>	1,31 (1,93) [0,24]	1,22 (1,41) [0,12]	1,47 (2,96)* [0,38]	1,05 (0,32) [0,04]	0,87 (-0,82) [-0,09]
<i>q=13</i>	1,15 (0,72) [0,10]	1,27 (1,29) [0,11]	1,42 (2,03)* [0,28]	1,12 (0,59) [0,08]	0,77 (-1,10) [-0,13]
<i>q=26</i>	0,98 (-0,05) [-0,01]	1,24 (0,78) [0,07]	1,43 (1,41) [0,21]	1,26 (0,85) [0,14]	0,67 (-1,07) [-0,13]
<b>max z(q=2..26)</b>	(2,10)	(1,41)	(3,32)	(0,85)	(-1,36)
<b>max z'(q=2..26)</b>	[0,26]	[0,12]	[0,40]	[0,14]	[-0,14]

\*The variance ratio significantly differs from 1 on 5% significance level and therefore we reject RW1.

The table 3 shows results of testing RW1 assuming foreign investments (monthly dollar market returns) in the period from September 1993 until August 2004.

**Table 3: The variance ratio test (monthly data, dollars, long period)**

Monthly returns September 1993 - August 2004 ( <i>z</i> – homoscedasticity assumption) [ <i>z'</i> – resistance against heteroscedasticity]					
Lag	Hungary	Poland	C R	SR	USA
<i>q</i> =3	0,93 (-0,51) [-0,13]	1,05 (0,35) [0,06]	1,27 (2,01)* [0,35]	1,43 (3,28)* [0,50]	0,92 (-0,67) [-0,11]
<i>q</i> =6	0,89 (-0,53) [-0,13]	0,95 (-0,22) [-0,03]	0,96 (-0,16) [-0,03]	0,92 (-0,39) [-0,07]	0,85 (-0,73) [-0,12]
<i>q</i> =9	0,97 (-0,11) [-0,03]	0,71 (-1,06) [-0,16]	1,00 (0,01) [0,00]	0,93 (-0,26) [-0,05]	0,88 (-0,44) [-0,07]
<i>q</i> =12	1,07 (0,22) [0,05]	0,64 (-1,10) [-0,17]	1,11 (0,34) [0,06]	1,04 (0,12) [0,03]	0,99 (-0,04) [-0,01]
<b>max <i>z</i>(<i>q</i>=3..12)</b>	(-0,78)	(-1,10)	(2,01)	(3,28)	(-0,76)
<b>max <i>z'</i>(<i>q</i>=3..12)</b>	[-0,19]	[-0,17]	[0,35]	[0,50]	[-0,12]

\*The variance ratio significantly differs from 1 on 5% significance level and therefore we reject RW1.

When comparing results in the Table 3 (monthly dollars returns) with the results for the same period for local currencies returns (this table is not concluded in the paper), we can see a movement in the Polish market, where we do not refuse under heteroscedasticity assumption, other changes did not occur. Assuming heteroscedasticity, we do not reject RW1 in any market in both periods.

However, the main pitfall of the variance ratio test is its sensitivity to normality of the time series  $\varepsilon_t$  (see formula (2)). In practice, this assumption is equivalent to normality of market returns and is to be tested. The table 4 shows the results of such testing on dollars market returns.

**Table 4: The data normality test (monthly data, dollars, both periods)**

Distribution of dollar returns on capital markets

<b>Standard deviation</b>	10,4%	<b>9,9%</b>	<b>12,5%</b>	<b>9,9%</b>	9,8%	<b>8,6%</b>	11,0%	<b>6,6%</b>	4,4%	<b>5,0%</b>
<b>Skewness</b>	-0,40	- <b>1,75*</b>	-0,34	- <b>1,17*</b>	0,48*	- <b>1,00*</b>	2,85*	<b>0,23</b>	- 0,75*	- <b>0,60*</b>
<b>Kurtosis</b>	4,92*	<b>6,57*</b>	2,39*	<b>4,04*</b>	4,03*	<b>3,23*</b>	20,18*	<b>0,72</b>	1,49*	<b>1,03</b>
<b>Max. return</b>	43,2	<b>20,5</b>	35,2	<b>20,6</b>	45,1	<b>20,7</b>	76,5	<b>21,9</b>	10,1	<b>10,1</b>
<b>Min. return</b>	-48,2	<b>-48,2</b>	-43,7	<b>-43,7</b>	-34,4	<b>-34,4</b>	-36,8	<b>-14,9</b>	-16,4	<b>-16,4</b>
<b>Student spread</b>	8,8**	<b>6,9**</b>	6,3**	<b>6,5**</b>	8,1**	<b>6,4**</b>	10,3*	<b>5,5</b>	6,0	<b>5,3</b>
<b>Number of observations</b>	134	<b>79</b>	134	<b>79</b>	131	<b>79</b>	130	<b>79</b>	139	<b>79</b>

Notes:

returns=100\*ln(P<sub>t</sub>/P<sub>t-1</sub>)

standard error (S.E.) skewness =  $[6/N]^{1/2}$

standard error (S.E) kurtosis =  $[24/N]^{1/2}$

N=number of observations

Student spread = (Max return – Min return)/ relative variance

\*It significantly differs from 1 on 5% significance level

\*\* If Student spread is greater than 6, we reject data normality on 5% significance level.

It follows from the Student spread results that monthly dollar returns in the period from September 1993 until August 2004 do not satisfy the normality assumption except for the US market, which therefore confirms its property of a benchmark of the capital market. We can see from the Table 4 an improvement of the vast majority of the test statistics for the shorter period from January 1998 until August 2004. As a result, the tests assuming heteroscedasticity reflect reality more precisely than the other ones. Such tests are not so sensitive to data normality and provide us relatively good statistical evidence for non-rejection of RW2 and RW3. Furthermore, the tests imply that not only the US market but also the Czech, Slovak, Polish and Hungarian ones post the weak-form of market efficiency.

### ***5.3 The results of testing***

1. Can we observe any information efficiency in Central European capital markets?

**We could not reject the weak form hypothesis of Central European capital markets – see the results in tables 1-3 (especially the results concerning heteroscedasticity).**

2. Can we observe an improvement of information efficiency in these markets during time?

**Yes, we do not reject RW1 in all markets in the shorter of period from January 1998 until August 2004 – compare results in tables 1 and 2 or with previous research (Hanousek [6], Vošvrda [13]).**

3. What gap is among Central European capital markets and the US (mature) capital market?

**Central European capital markets converge to the US one also through distribution characteristics (see Table 4).**

## **6. Conclusion**

The methods, calculations and obtained result proof the general statement that the U.S. market is mature and effective. We concluded that the US market reports the weak form of efficiency. On the other hand, we are aware of simplifications we made when using the U.S. market index (DJIA) as a representative of the market (the same simplification was made for other capital markets as well).

Despite the restrictive assumptions of some used test (e.g. data normality), we could not unambiguously reject the weak form of efficiency in any researched market. Concerning the results of the relatively robust variance ratio tests, we share the opinion that current stock prices in the analyzed markets reflect the past price movements. Therefore strategies used by technical analysts are useless and could not help investors to make abnormal returns. The same holds when assuming foreign portfolio investments. In other words, the examined markets effectively incorporate information about exchange rates movements of the local currencies against the world ones (in our case against the US dollar).

When analyzing the shorter period commencing in January 1998, one can see an improvement in the test statistics. For this reason, we claim that

stabilization (or an improvement in market efficiency) of Central European has been happening. The U.S. market still seems to be more effective compared to Central Europe, but the gap is getting smaller. The fact behind it could be an implementation of standard bourse rules, IT development, Internet and other manners that make informational flows quicker and more accurate.

In conclusion, our analysis answered three questions to be asked at the beginning of the paper. On the other hand, we know that our research is not comprehensive. Other topics are to be addresses to do our work more precise. These topics include using more robust tests as GARCH models, testing the semi-strong form of efficiency of Central European markets, testing efficiency not only on market indices but also on particular stocks and finally focus on intra-day stock trading etc.

## **Abstract**

*This extensive study examines the relationship between the price-to-earnings (P/E) ratio, the market-to-book (M/B) ratio, dividend yields, size, past returns, and current returns of Icelandic stocks. The study uses monthly return data on stocks from the Iceland Stock Exchange from January 1993 to June 2003. The model, which uses multiple regression analysis with dummy variables, is based on the classical Capital Asset Pricing Model, so the beta coefficient is the sole measure of risk. The findings are that the returns of stocks with a low P/E ratio are much higher than returns of other stocks, and that these returns are statistically significantly higher when differences in systematic risk are accounted for. The returns of small stocks and stocks with a low M/B ratio are higher than that of other stocks but the difference is not statistically significant. However, there is no relationship between current returns and historical returns, or between returns and dividend yields.*

**Keywords:** *Market efficiency, Icelandic stock market, P/E ratio*

## 1. Introduction

An efficient capital market is one in which stock prices fully reflect available information. The notion that stocks already reflect all available information is referred to as the efficient market hypothesis (EMH). A precondition for the strong version of the hypothesis is that information and trading costs, the costs of getting prices to reflect information, are always zero (Grossman and Stiglitz, 1980). A weaker and economically more sensible version of the efficiency hypothesis states that security prices reflect information to the point where the marginal benefits of acting on information, i.e., the profits to be made, do not exceed the marginal costs (Jensen, 1968). Therefore, according to the EMH, stock prices change in response to new and unpredictable information and they follow a random walk—that is, they are random and unpredictable.

It is common to distinguish between three versions of the EMH: the weak, the semistrong, and the strong forms. The weak form of the hypothesis asserts that stock prices already reflect all information that can be derived by examining market trading data. The semistrong form of the hypothesis states that all publicly available information regarding the prospects of a firm must already be reflected in the stock price. Finally, the strong version of the EMH states that stock prices reflect all information relevant to the firm, even information available only to company insiders.

Testing capital markets for signs of inefficiency is difficult because ambiguity about information and trading costs causes problems. The joint-hypothesis problem is even more serious. It states that we can only test whether information is properly reflected in prices in the context of a pricing model that defines the meaning of “properly”. Consequently, when we find anomalous evidence on the behavior of returns, we cannot be sure whether it is clear evidence of market inefficiency or if the model we use is ambiguous. Therefore, market efficiency *per se* is not testable (Fama, 1991).

Despite these problems, a great deal of research has been done on capital market efficiency. Most of the research supports the EMH, but some studies have found signs of capital market inefficiency. The most important signs are:

- Size. Small stocks, i.e., stocks with small market capitalization, have outperformed stocks with large market capitalization over long periods. The general belief is that small stocks give superior returns, even when accounting for risk (Fama and French, 1992).
- Temporal anomalies. Studies indicate that average stock returns have been higher in January than in other months. Across the days of the

week, average stock returns have been found to be lowest on Mondays (Berument and Kiymaz, 2001).

- Value vs. glamour. A number of studies have shown that stocks with low price-to-book ratios and/or low price-to-earnings (P/E) ratios, generally called value stocks, outperform stocks with high ratios, called glamour stocks (Fama and French, 1992).
- Reversals. Several studies have found that stocks that perform poorly in one time period have a strong tendency to experience sizeable reversals over the subsequent period. Likewise, the best performing stocks in a given period tend to perform poorly in the following period (De Bondt and Thaler, 1985).

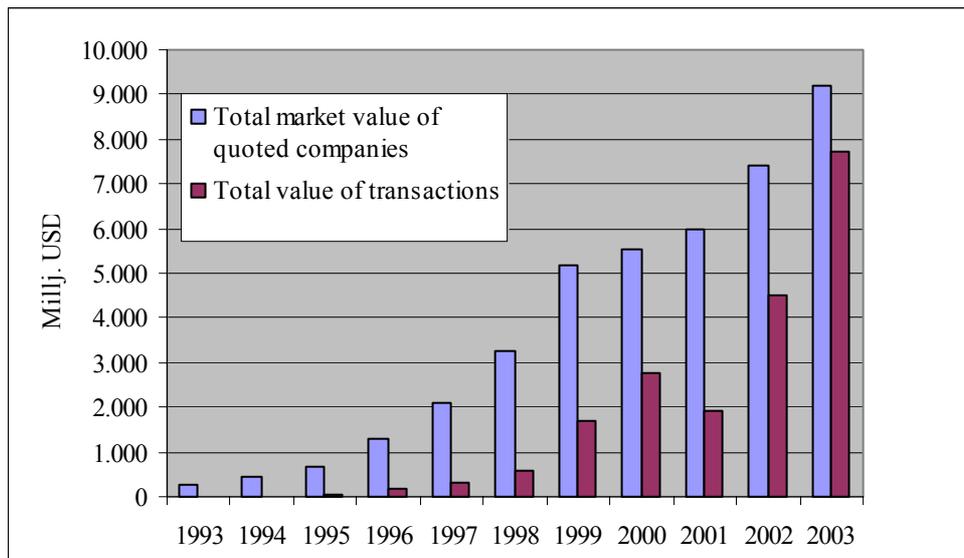

In this paper, empirical tests are undertaken to determine whether the Icelandic stock market shows signs of market inefficiency. The results of these tests are discussed in relation to the EMH and alternative theories that might explain the findings. The empirical tests search for the appearance of the abovementioned important signs of market inefficiency, which have been found on other capital markets. Therefore, the relationships between the P/E ratio, the market-to-book (M/B) ratio, size, historical returns, dividend yields, and returns on the Icelandic stock market are examined.

## **2. The Icelandic Stock Market**

### ***2.1 Size and Activity***

The total market value of quoted companies on the Icelandic stock market at the end of 2003 was approximately 9,200 million USD, or 82% of GDP. By contrast, in 1993, the total market value was only 270 million USD, which was then 4% of GDP. Figure 1 shows the total value of transactions of stocks on the Icelandic Stock Exchange (ICEX) and the total market value of quoted companies from 1993 to 2003. As the figure shows, the size of the market and its turnover has increased exponentially. In 1993, the total volume of stock trading on the ICEX was only 13 million USD but by 2003, it had grown to 7,750 million USD.

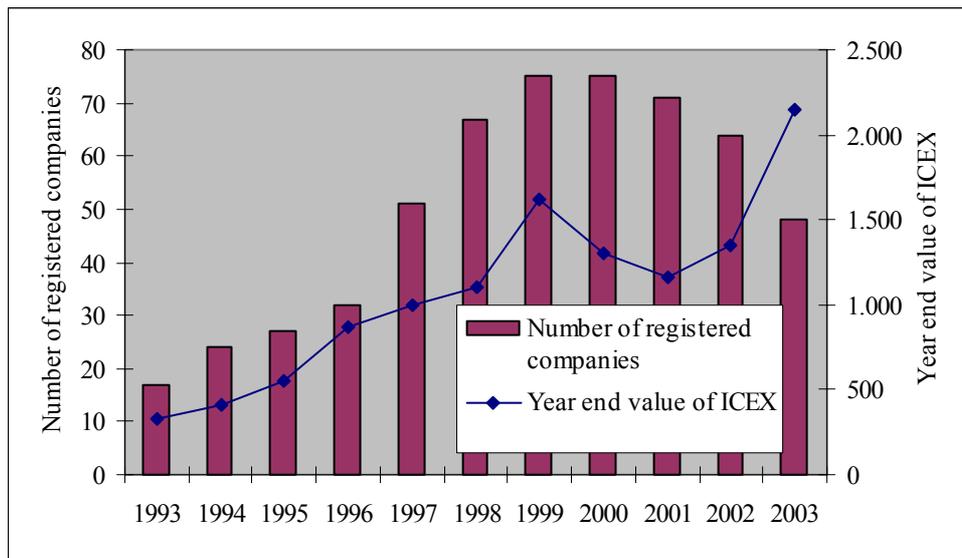

**Figure 1. Total market value of stocks and the total value of transactions, 1993–2003**

*Source: The Icelandic Stock Exchange.*

The number of registered companies reached a peak in 1999–2000, when 75 companies were trading on the exchange. Since then, the number has declined steadily, mainly because of mergers and acquisitions. Figure 2 shows the number of registered companies on ICEX and the year-end value of the ICEX-15 index. The ICEX-15 index is an index consisting of the 15 largest stocks quoted on the ICEX weighted by market capitalization. The figure shows clearly that the Icelandic stock market has been an excellent place in which to invest. The geometric mean annual return of the ICEX-15 index was 17.1% from the beginning of 1993 to the end of 2003. The return of the market was negative only in 2000 and 2001.

**Figure 2. Number of registered companies on ICEX and the year-end value of the ICEX-15.**

Source: The Icelandic Stock Exchange.

### 3. Data

This study uses monthly return data of ICEX stocks from January 1993 to June 2003. The data used to calculate monthly returns was obtained from the ICEX price database. End of the month prices were used to calculate monthly returns for every stock. Returns were adjusted for stock splits and dividends; i.e., dividends were included in returns. Data on earnings, dividends, stockholders' equity, and the total number of shares outstanding were obtained by examining each firm's financial reports for the period observed. To avoid the look-ahead bias, the previous years' figures were not used until they were made available to investors

The stocks used in this research were randomly selected. There are 20 stocks in the sample for 1993, with five in each portfolio during that year. For 1994, there are 24 stocks, with six in each portfolio, and for 1995 to June 30, 2003, there are 28 stocks in the sample, with seven in each portfolio.

## 4. Methodology

Finding a suitable methodology for this study was a problem. The limited number of stocks quoted and the short period of trading on the Icelandic stock market reduce the scope for a suitable methodology. The methodology used is almost identical to that used by Jahnke, Klaffke, and Oppenheimer (1987) to analyze the performance of low and high P/E portfolios. The main difference is that they constructed a portfolio and held it for the entire period. In this paper, new portfolios are constructed each month because new information regarding earnings, yield, etc., is published for some of the stocks almost every month. Therefore, by regrouping the portfolios every month, the new information is incorporated into the research sooner. In addition, the denominator of most of these factors changes every month because the prices of the stocks change.

The main fault in this methodology is that some of the variables examined here may be related. For example, it is likely that the size of firms may be related to their P/E ratios, i.e., the price per share divided by earnings per share. To overcome this problem, it would have been necessary to split the available sample into a number of portfolios that combine attributes in a controlled manner. Because of the limited number of stocks observed, this was impossible. The reader should bear these limitations in mind when interpreting the results.

This methodology is based on grouping procedures and the construction of portfolios. For every month from January 1993 to June 2003, four portfolios were constructed based on the value of the variable examined. The stocks were equally weighted in the portfolios; i.e., the return of the portfolio equals the average return of the stocks. Then the returns of the stocks were measured and compared, and the returns of the extreme portfolios were tested to determine whether they were statistically different when accounting for systematic risk.

Markowitz (1959) laid the groundwork for the Capital Asset Pricing Model (CAPM). In his seminal research, he cast the investor's portfolio selection problem in terms of expected return and variance of return. He argued that investors would optimally hold a mean-variance-efficient portfolio—that is, a portfolio with the highest expected return for a given level of variance. Sharpe (1964) and Lintner (1965) built on Markowitz's work to develop economy-wide implications. They showed that if investors have homogeneous expectations and optimally hold mean-variance-efficient portfolios, then, in the absence of market friction, the portfolio of all invested wealth, or the market portfolio, is itself a mean-variance-efficient portfolio.

The Sharpe and Lintner derivations of the CAPM assume the existence of lending and borrowing at a risk-free rate of interest. Using this version of the CAPM, for the expected return of asset  $i$  we have:

$$E[R_i] = R_f + \beta_{im}(E[R_m] - R_f) \quad (1)$$

$$\beta_{im} = \frac{\text{Cov}[R_i, R_m]}{\text{Var}[R_m]}, \quad (2)$$

where  $E[R_i]$  is the expected return of a security,  $R_f$  is the risk-free return, and  $E[R_m]$  is the return of a market index. An approach known as Jensen's alpha is one of many performance measures that are based on the classical CAPM. It is easily computed by finding the intercept,  $\alpha_p$ , in the regression:

$$R_p - R_f = \alpha_p + \beta_p(R_m - R_f) + u_p. \quad (3)$$

This method was introduced by Jensen (1968). The procedure allows the efficient estimation of  $\alpha_p$ , a measure of the monthly excess return after adjustment for portfolio risk. Assuming the CAPM holds, the alphas on passively managed portfolios are expected to be zero because all securities are expected to lie on the security market line. Therefore, a significantly positive alpha of a portfolio indicates an excess return.

The goal of this study is to compare the performance of portfolios by applying the methodology of Jahnke et al. (1987). Rather than estimating the previous equation for two extreme portfolios, the required performance is estimated by using ordinary least squares (OLS) on the following regression:

$$R_{pt} - R_{ft} = \alpha_p + d_L D_{pt} + \beta_p(R_{mt} - R_{ft}) + s_L S_{pt} + u_{pt}, \quad (4)$$

where:  $R_{pt}$ , is the return in month  $t$  ( $t = 1, \dots, 126$ ) earned by a portfolio purchased at the beginning of the month;  $\alpha_p$  is the intercept, which equals the monthly abnormal performance of the portfolio that is not represented by a dummy variable, i.e.,  $\alpha_H$ ;  $R_{ft}$  is the risk-free rate, i.e., the return of one-month Treasury bills in month  $t$ ;  $\beta_p$  is the slope, which equals the systematic risk of the portfolio  $\beta_H$ , which is not represented by a dummy;  $R_{mt}$  is the rate of return on the ICEX-15 index in month  $t$ ;  $D_{pt}$  is equal to zero for observations of the portfolio that are not represented by a dummy and one for all observations of the portfolio that are represented by a dummy variable; and  $u_{pt}$  is an error term assumed to have an expected value of zero and to be

serially uncorrelated.  $S_{pt} = D_{pt}(R_{mt} - R_{ft})$  for all observations. The coefficient  $\alpha_p$  in the equation equals  $\alpha_H$ , i.e., the measure of monthly abnormal performance for the portfolio that is not represented by a dummy variable, which means that  $D_{pt} = 0$  for that portfolio. The coefficient  $d_L$  is a key parameter in this regression. It measures the difference between the excess returns of the portfolio that is not represented by a dummy variable and the portfolio that is represented by a dummy variable. It should be noted that  $\alpha_p + d_L$  is equal to the alpha of the portfolio, which is represented by a dummy variable. Thus, we may use a t-test to determine if  $d_L$  is significantly different from zero. If  $d_L$  is significant, then the returns of the portfolios are significantly different when differences in systematic risk are taken into account.  $\beta_p$  equals  $\beta_H$ , i.e., the systematic risk (beta) of the portfolio, which is not represented by a dummy variable. Finally,  $s_L$  provides an estimate of the difference in systematic risk between the portfolio that is represented by a dummy variable and the one that is not, with  $\beta_p + s_L$  being the systematic risk of the portfolio that is represented by a dummy variable,  $\beta_L$ .

## 5. Performance According to Firm Size

### 5.1 Previous Research

The size of a company is normally measured by the market value of its ordinary shares. Over long periods, and in many countries—for example, Australia, Belgium, Canada, Finland, France, Japan, the Netherlands, the UK, the US, and former West Germany—small firms have produced higher returns than large firms (Lofthouse, 1994). In an extensive study, Fama and French (1992) analyzed data from the American stock market from 1963 to 1990. They constructed portfolios based on betas and the size of firms. They found that small firms outperformed large firms for both low- and high-beta stocks. Reinganum (1992) analyzed the returns of New York Stock Exchange (NYSE) stocks ranked by size from 1926 to 1989. He found that small firms gave returns with a higher average arithmetic mean for that period. The returns of the small firms were superior even when accounting for risk. In a study of UK market data from April 1961 to March 1985, Levis (1989) found that small firms outperformed larger firms in that they gave excess returns when adjusted for risk.

The reason that small stocks outperform large stocks has been related to the higher cost of trading. The bid/ask spread is generally much higher for

small stocks, making the cost of trading much higher. Another suggested reason is that smaller firms have different sector or industry distributions than do larger firms.

### 5.2 Study and Results

For every month covered by this study, four portfolios were constructed according to the market capitalization of common stocks. The returns of the portfolios were measured and the performance of the extreme portfolios (the smallest and largest stocks) was measured by using standard OLS to estimate the parameters in equation 4.

Figure 3 shows the geometric mean returns of the portfolios. The portfolio with the smallest stocks has the highest returns, whereas the portfolio with the largest stocks has the lowest returns.

**Figure 3. Returns of portfolios constructed according to firm size**

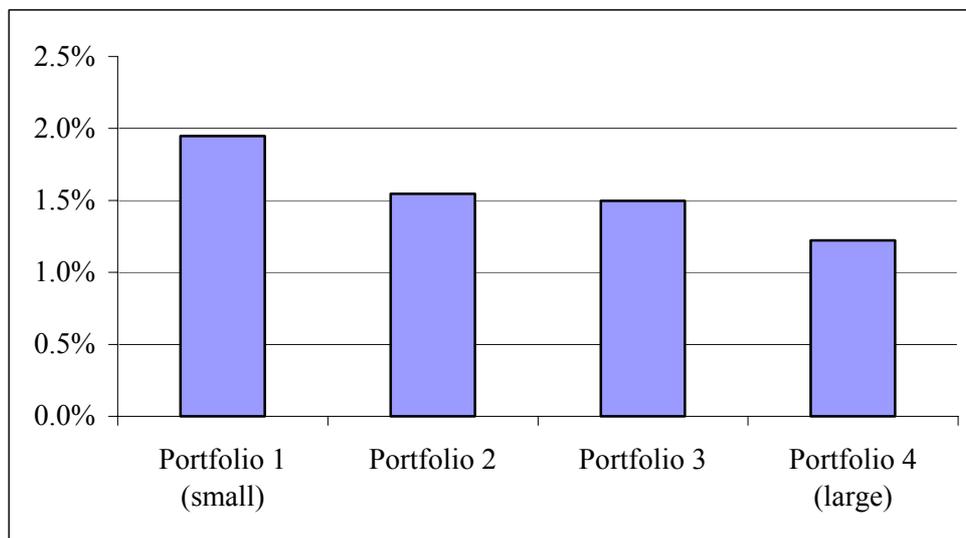

Table 1 gives the most important results of the regression when applying equation 4. The systematic risk (beta) is estimated to be 0.97 ( $\beta_p$  equals  $\beta_H$ ) and 0.76 ( $\beta_p + s_L$ ) for the highest and lowest market capitalization portfolios, respectively. The difference in systematic risk is statistically significant as the t-statistic of  $-2.13$  for ( $s_L$ ) indicates. The alphas of the higher and lower market capitalization portfolios are estimated to be 0.15% ( $\alpha_p$  equals  $\alpha_H$ ) and 1.04% ( $\alpha_p + d_L$ ), respectively. The difference is not statistically significant as the t-statistic of 1.93 for ( $d_L$ ) indicates. Therefore, the returns of portfolios 1 and 4 are not statistically different even

when the lower systematic risk of portfolio 1 is taken into account. The Durbin–Watson coefficient of 1.90 indicates that there is not a significant first-order autocorrelation.

**Table 1. Results of the regression of portfolios constructed according to firm size**

	$\alpha_p$	$d_L$	$\beta_p$	$s_L$	$R^2$
Coefficient	0.0015	0.0089	0.97	−0.21	0.56

p-statistics	0.65	0.054	<0.0001	0.034	
Durbin W.	1.90				

\* Significant at the 5% level.

## 6 Performance According to dividend yield

### 6.1 Previous Research

Dividend yield is defined as dividends per share divided by the market value of the share. There has been some debate as to whether high-yield stocks offer superior returns. There are many reasons for different findings. For instance, in many countries, income, including dividends, is taxed at a higher rate than are capital gains. Another reason may be that some clients prefer income and will buy high-yield stocks, whereas other investors may prefer capital gains.

Litzenberger and Ramaswamy (1979) examined the effects of taxes and dividend yields on returns. They used NYSE data from January 1936 to December 1997. They found that high returns and high yields went together and that high-yield stocks offered excess returns. In his investigation of the UK market, Levis (1989), studying data from April 1961 to March 1985, found that high-yield stocks gave excess returns. Levis tested many variables and found that yields affected returns for most of the variables tested. In a study analyzing NYSE data from January 1927 to December 1976, Elton, Gruber and Rentzler (1983) examined the effects of dividend yields on returns. They found that there was a persistent relationship between dividend yields and excess returns. In particular, except for those stocks that had

previously paid zero dividends, the higher the dividend yield was, the higher was the excess return.

### 6.2 Study and Results

For every month covered by this study, we constructed four portfolios according to the dividend yield of common stocks. Figure 4 shows the geometric mean returns of the portfolios. Portfolio 1, the portfolio with the lowest dividend yield, had the highest monthly return. The portfolio with the highest dividend yield had the second highest average return.

**Figure 4. Returns of portfolios constructed according to the dividend yields of firms**

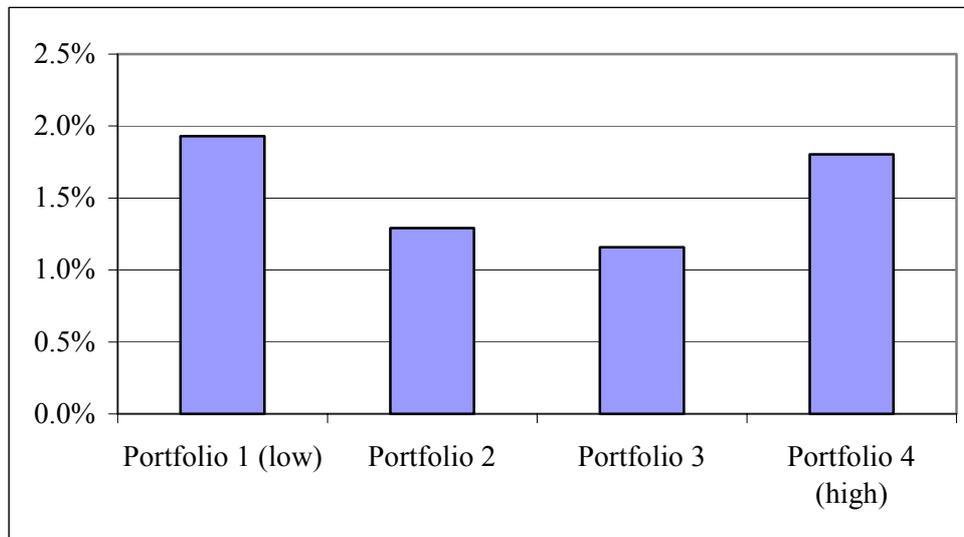

Table 2 shows that there is no statistically significant difference between the returns of portfolios 1 and 4 because the coefficient  $d_L$  is not statistically significant. Therefore, it is safe to conclude that there has not been a relationship between returns and dividend yields for Icelandic stocks.

**Table 2. Results of the regression of portfolios constructed according to dividend yields**

	$\alpha_p$	$d_L$	$\beta_p$	$s_L$	$R^2$
Coefficient	0.0083	0.0015	0.79	0.14	0.46

## 7 Performance According to P/E ratios

### 7.1 Previous Research

The performance of stocks based on P/E ratios is one of the most widely analyzed issues in relation to capital markets. Many US studies have shown that low P/E-ratio stocks outperform high P/E-ratio stocks over long periods. Studies of other markets have come to similar conclusions (Lofthouse, 1994). In an extensive study on the US, German, French, English, and Japanese equity markets, Haugen and Baker (1996) studied data from 1985 to 1993. They found that the ratio of earnings to price, that is, the reciprocal of the P/E ratio, affected returns in all these markets. In all countries studied, low P/E stocks gave excess returns during the period. The effect of the P/E ratio was highest in the US and France. Basu (1977) attempted to determine empirically whether the investment performance of stocks was related to their P/E ratio. He analyzed data from the NYSE between September 1956 and August 1971 and found that a low P/E portfolio gave, on average, a 13.5% return per year, whereas a high P/E portfolio gave a 9.5% return. This higher return was not associated with higher levels of systematic risk. Indeed, the systematic risk of the low P/E portfolio was lower than that of the high P/E portfolio. In an extensive study on the UK stock market from 1961 to 1985, Levis (1989) found that low P/E stocks gave excess returns during that period.

The reason for low P/E ratio stocks outperforming high P/E ratio stocks has been related to the tendency of investors to overestimate growth for high-growth companies and to underestimate growth for low-growth companies. High-growth companies normally sell at high P/E ratios, whereas low-growth companies sell at low P/E ratios, with the result that the stocks with low P/E ratios outperform the others.

### 7.2 Study and Results

In this study, earnings are defined as profits after tax plus exceptional and extraordinary items. To rank the stocks into portfolios and compare the

performance of high and low P/E portfolios, we used the E/P ratio (i.e., earnings divided by price) because companies with negative earnings are automatically ranked as having the lowest E/P ratio. For every month under study, we constructed four portfolios based on E/P ratios. The performance of the extreme portfolios, portfolios 1 and 4, was measured by estimating parameters in equation 4 using OLS.

**Figure 5. Returns of portfolios constructed according to the P/E ratios of stocks**

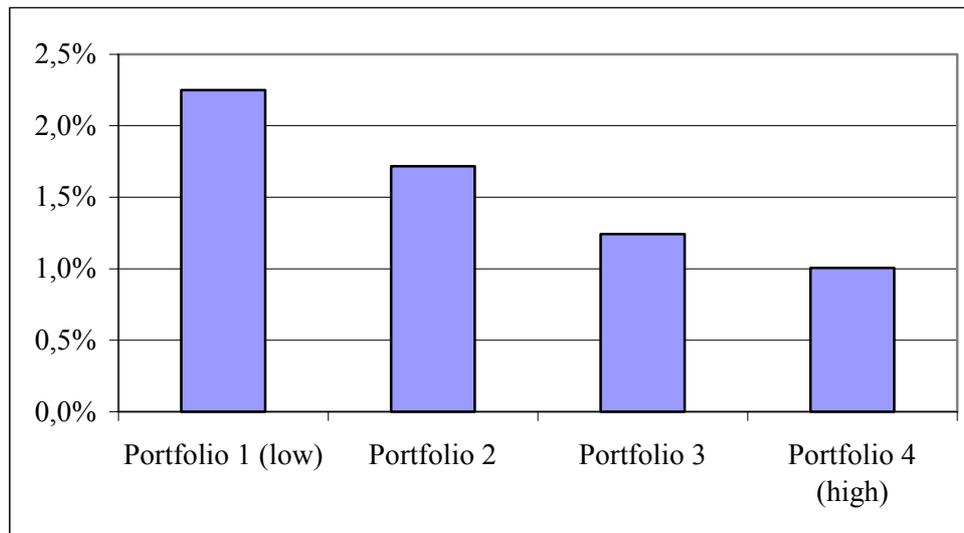

Figure 5 shows the average returns of the four portfolios. The returns of portfolio 1, which contained the stock with the lowest P/E ratios, were much higher than the returns of other portfolios. Portfolio 4's returns were the lowest. The figure indicates that a relationship between returns and P/E ratios might have existed.

Table 3 shows the results of the regression. The systematic risk (beta) is estimated to be 0.89 and 0.74 ( $\beta_p + s_L$ ) for the low and high P/E ratio portfolios, respectively. The alphas of the low and high P/E ratio portfolios are estimated to be 1.3% and 0.1% ( $\alpha_p + d_L$ ), respectively. The difference is statistically significant as the t-statistic of  $-2.06$  for ( $d_L$ ) indicates.

**Table 3. Results of the regression of the portfolios constructed according to P/E ratios**

	$\alpha_p$	$d_L$	$\beta p$	$s_L$	$R^2$
Coefficient	0.013	-0.012	0.89	-0.15	0.43
t-statistics	(*3.16)	(*−2.06)	(*10.03)	(−1.23)	
p-statistics	0.0018	0.041	<0.0001	0.22	
Durbin W.	1.82				

\* Significant at the 5% level.

Forming portfolios based on low P/E-ratio stocks provides considerably higher returns than portfolios based on high P/E-ratio stocks. Moreover, the difference in returns is statistically significant.

## 8 Performance According to M/B ratios

### 8.1 Previous Research

M/B ratios, also referred to as price-to-book ratios, express the market value of common stocks divided by the book value of ordinary shareholders' funds. Many studies have found that buying stocks with low M/B ratios has resulted in excess returns. Rosenberg, Reid and Lanstein (1985) analyzed the performance of a strategy of purchasing stocks with low price-to-book ratios using data from January 1973 to March 1980 from the COMPUSTAT database. The stocks analyzed were mainly NYSE stocks. The study was constructed as a hedge study, which means that stocks with low price-to-book ratios were bought and stocks with high price-to-book ratios were sold short. The study showed that this strategy gave excess returns; i.e., it resulted in a positive return of 0.32% per month. In their extensive study, Haugen and Baker (1996) analyzed data for five countries from 1985 to 1993. They found that stocks with low price-to-book ratios gave excess returns in the US, Germany, France, the UK, and Japan. The excess return was statistically highly significant in all of these countries. Capula, Rowley, and Sharpe (1993) analyzed the performance of stocks with low price-to-book ratios (called value stocks) and stocks with high price-to-book ratios (called growth stocks) from January 1981 to June 1992 in France, Germany, Switzerland, the UK, Japan, and the US. They found that the value stocks outperformed the growth stocks in all countries studied, as they gave higher average returns when adjusted for risk during the period under study.

## 8.2 Study and Results

For every month of the study, we constructed four portfolios according to the M/B ratios of the stocks in the sample. Figure 6 shows that portfolio 1, which consisted of the stocks with the lowest M/B ratios, had the highest average returns, whereas portfolio 4 provided the lowest average returns.

**Figure 6. Returns of portfolios constructed according to firms' M/B ratios**

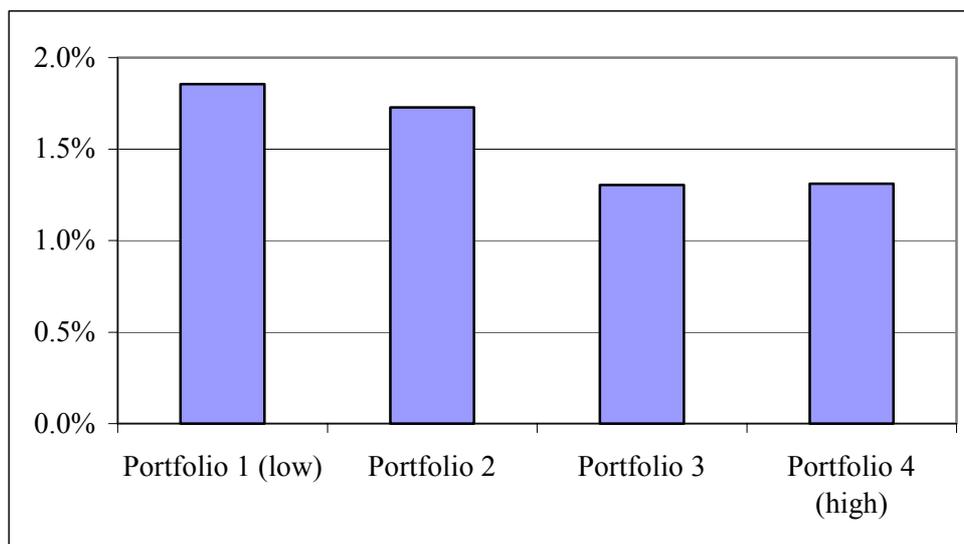

Table 4 shows that the systematic risk (beta) is 1.04 and 0.71 for the highest and lowest M/B portfolios, respectively. The difference in systematic risk between the portfolios is statistically significant as the t-statistic of  $-2.76$  for  $s_L$  indicates. The alpha is estimated to be 0.29% and 0.94% for the highest and lowest M/B portfolios, respectively. The difference between the alphas of the portfolios is not statistically significant. Therefore, there is not a statistically significant difference in returns between the two portfolios when accounting for risk.

**Table 4. Results of the regression of portfolios constructed according to M/B ratios**

	$\alpha_p$	$d_L$	$\beta p$	$s_L$	$R^2$
Coefficient	0.0029	0.00653	1.04	-0.33	0.47
t-statistics	(0.73)	(1.17)	(*12.22)	(* -2.76)	
p-statistics	0.46	0.245	<0.0001	0.006	
Durbin W.	2.07				

\* Significant at the 5% level.

A portfolio based on stocks with low M/B ratios provides a considerably higher return than does a portfolio with high M/B stocks. The risk (beta) of the low M/B portfolio is significantly lower than that of the high M/B portfolio. However, the difference in risk-adjusted returns between the portfolios is not statistically significant.

## 9 Performance According to Previous Returns

### 9.1 Previous Research

De Bondt and Thaler (1985) studied market behavior by analyzing monthly return data for NYSE common stocks from January 1936 to December 1982. They found that the market did overreact. They formed portfolios based on winners—i.e., stocks that had provided positive abnormal returns—and losers—i.e., stocks that had given negative risk-adjusted returns over the previous three years. Then they held the portfolios for 36 months. They found that, over this time, the portfolios of the 35 loser stocks outperformed the market by 19.6%, on average. In contrast, the winner portfolios performed about 5.0% below the market average. Thus, the difference in the cumulative average residual between the extreme portfolios equaled 24.6%. Jagadeesh (1990) studied the behavior of security returns using NYSE data for the period 1934 to 1987. He found that there was a negative first-order serial correlation in monthly stock returns and that it was statistically highly significant. This meant that high returns were followed by low returns. In addition, Jagadeesh found that there was significant positive serial correlation of longer lags, with the 12-month serial correlation being particularly strong. He found that the overreaction was most notable in January. Jagadeesh concluded that his research reliably rejected the hypotheses that stock prices follow a random walk. Haugen and Baker (1996)

studied data from the US, Germany, France, the UK, and Japan from 1985 to 1993. They found that, in all of these countries, stocks that had given excess returns relative to an index in the previous month underperformed the following month.

The reason for the overreaction of markets has been related to the overreaction of investors to new information. Investors observe each other and the market as a whole, and some investors chase trends. This makes the market excessively volatile, as trends persist for overly long periods and then reverse.

## 9.2 Study and Results

To compare the performance of winners and losers and to analyze the difference, we formed four portfolios for each month of the study according to the previous month's return.

**Figure 7. Returns of portfolios constructed according to previous returns**

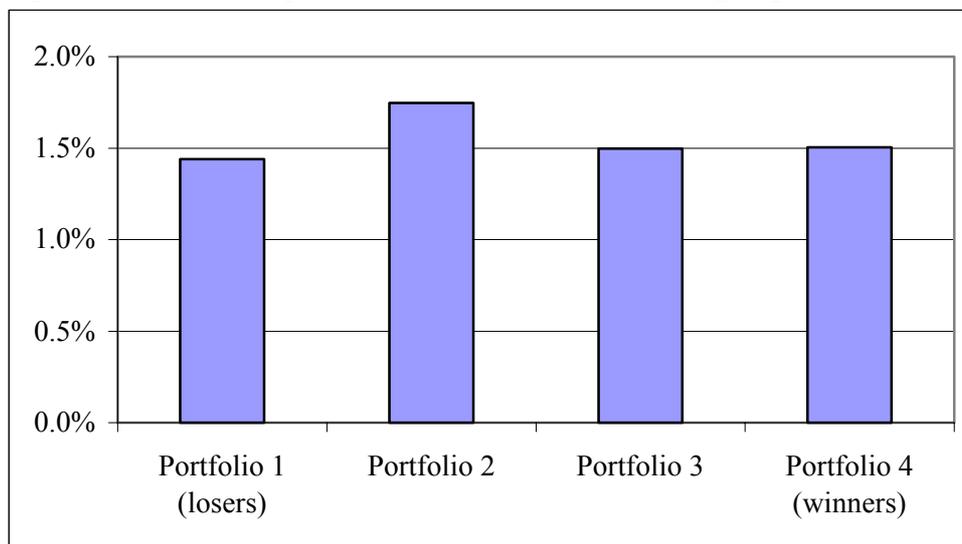

Table 5 shows the results of the regression, and figure 7 shows the returns of the portfolios. The average monthly returns are similar for all the portfolios: there is no statistically significant difference in returns. Therefore, there was no apparent relationship between the returns of Icelandic stocks and the previous returns.

**Table 5. Results of the regression of portfolios based on losers and winners**

	$\alpha_p$	$d_L$	$\beta p$	$s_L$	$R^2$
Coefficient	0.0051	-0.00001	0.87	-0.18	0.47
t-statistics	(1.45)	(-0.02)	(*11.56)	(-1,48)	
p-statistics	0.15	0.99	<0.0001	0.14	
Durbin W.	2.07				

\* Significant at the 5% level.

## 10 Conclusion

In this paper, empirical tests were performed to determine whether the Icelandic stock market showed clear signs of market inefficiency, which have appeared on other capital markets.

The performance of portfolios was measured and compared both in absolute terms and when accounting for systematic risk. The model applied in this research, which used multiple regression analysis with dummy variables, was based on the classical Capital Asset Pricing Model, so the beta coefficient was the sole measure of risk. The findings were that returns of stocks with low P/E ratios were much higher than returns of other stocks, and that the returns were statistically significantly higher than those of other stocks when accounting for differences in systematic risk. The returns of small stocks and stocks with low M/B ratios were higher than that of other stocks, but the difference was not statistically significant. However, there was no relationship between current returns and historical returns, or between returns and dividend yields.

The finding that stocks with low P/E and M/B ratios provide high returns on the Icelandic stock market is consistent with findings on other stock markets. It is interesting that the small and underdeveloped Icelandic stock market shares the same signs of inefficiency that appear in larger and more developed stock markets.

## **Abstract**

*The present paper examines the short and long run dynamics between the Romanian equity market and different stock markets from the European Union. By using the Johansen's cointegration test we find evidence to support cointegration between the nine European markets chosen. Our short run investigation is done within a VECM framework. We examine the impact of shocks to external equity markets on the Romanian market by using the Impulse Response and Variance Decomposition analyses. No evidence is found to support short run integration of the Romanian market with other stock markets from EU. We reveal that the most important Romanian index, BET, responds mostly to its own shocks. Our findings are consistent with the fact that foreign investors still choose to diversify their portfolios by buying stocks at the Bucharest Stock Exchange, which offers them the possibility to obtain very large speculative profits.*

## 1. Introduction

The last decades of the world history can be characterized by the process of globalization. As time goes by, the effects of this process are more widely and faster spread. Moreover, they penetrate a wide range of domains (the economic one, as well as the social, political and cultural ones).

In the economic field, the globalization process implies that cash flows between different national economies are bigger, faster and more and more frequent. This phenomenon has caused –over time- an increasing integration of national economies, especially of national capital markets. The integration of world capital markets has increased also due to a process of relaxation of restrictions on capital flows and exchange controls in many countries.

There is a lot of research regarding the integration of world capital markets. This interest of researchers towards this subject can be explained first of all by considering the impact of this phenomenon on portfolio international diversification, as well as on the arbitrage possibilities between different national stock exchanges. In addition, the fast propagation of the crises settled on different capital markets to other capital markets was another factor that gave a strong impulse to the research in this field.

This article investigates the cointegration between the Romanian Stock Exchange and other stock exchanges from the European Union. The selection criterion of the European stock exchanges regards the level of the economic relationships with Romania. We chose stock exchange indices from Austria, Belgium, France, Germany, Holland, Hungary, Italy and United Kingdom. We work with blue-chip indices: BET for Romania, ATX for Austria, BFX (BEL 20) for Belgium, CAC 40 for France, DAX for Germany, AEX for Holland, BUX for Hungary, MIB 30 for Italy and FTSE 100 for England. The analysis covers the period from the 1<sup>st</sup> of January, 2000 to the 22<sup>nd</sup> of June, 2005.

In section 2 we review the literature written in this field of research. Section 3 describes briefly the Romania's transition to a market economy after 1989, as well as the appearance and the development of a capital market. In Section 4 we present the data and the methodology we consider. We use the Johansen's cointegration test, as well as a VECM approach for the short-run analysis. Section 5 is a presentation of our results, while in section 6 we draw the conclusions.

## 2. Literature Review

Over time, researchers have had a strong interest in the linkages among international stock markets. The first studies in this area were done by Levy and Sarnat (1970), Ripley (1973), Lessard (1976) and Hillard (1979). They found low correlations between national stock markets.

Identifying the co movements of various stock markets became a constant preoccupation of specialists after the 1987 international market crash. Eun and Shim (1989) find evidence sustaining the existence of a co-movement between the US stock market and other world equity markets by using the VAR approach. Malliaris and Urrutia (1992) analyze “lead-lag relationships for six major stock market indexes” (from New-York, Tokyo, London, Hong Kong, Singapore and Australia) before, during and after the 1987 crisis. By using Granger causality methodology, they find no important causality relationships before and after the crisis. However, they detect uni-/bi-directional causalities for the month of the crash. Furstenberg and Jeon (1990), Lee and Kim (1994) find that the linkages between stock markets became stronger after the October 1987 crash.

Kasa (1992), Blackman et al. (1994), Jochum et al.(1999) examine the existence of a long run equilibrium for different mature as well as emerging equity markets and find evidence to sustain the cointegration of these markets. On the contrary, Richards (1999) finds no cointegration by using the small sample critical values proposed by Cheung and Lai (1993).

As during the last decade of the 20<sup>th</sup> century a wide range of emerging stock markets appeared and started to develop, a lot of research was done on the integration between these markets or between them and mature equity markets.

Studies like Gelos and Sahay (2000), Scheicher (2001), Gilmore and McManus (2002) investigate the extent to which the equity markets from Central Eastern Europe are integrated with the global markets and whether they are subject to global shocks. Linne (1998) tries to find whether the emerging Eastern European markets (Russia, Poland, Hungary, the Czech Republic and Slovak Republic) are cointegrated between themselves, as well as with mature markets (Germany, UK, France, Italy, Switzerland, US and Japan). The results show that among the emerging markets, Poland displays a common trend with the world portfolio proxied by MSCI-World Index. Russia doesn't display any linkages with any of the analyzed markets, while the Slovakian stock market is cointegrated with all mature stock markets.

Gelos and Sahay (2000), Hernandez and Valdes (2001), Dungey et al. (2003) investigate the repercussions of the Russian currency and debt crisis on other world stock markets.

Numerous studies aim to reflect the integration of emerging markets from South Asia, South Africa, South America or Middle East. Ratanapakorn and Sharma (2002) use the cointegration analysis and Granger causality test to analyze the short run and long run relationships between stock indices from the Middle East, US, Europe, Latin America and Eastern Europe. They find no long run relationship between the Middle East indices and the rest of the stock markets. Maysami et al. (2000) examines interactions between the Singapore equity market and the stock markets of the US and Japan, by using unit root tests and the VAR methodology. The same methodology is used by Phylaktis (1999) to determine the influence of the US and Japan markets on the markets from the Pacific Basin countries.

All the studies mentioned above represent only a small part of the vast literature written in this area. The Romanian stock market was not part of any research concerning the other emerging markets from CEE. This is probably due to the slow development of the capital market in Romania during the last decade of the 20<sup>th</sup> century, mostly as a result of the severe recessions that characterized the Romanian economy during that period.

### **3. The Romanian Capital Market –a mirror of the Romanian economy in transition**

The Romanian transition to a market economy after the collapse of the socialism has been more difficult than the transition of other former socialist countries, being characterized by a range of severe economic periods of recessions. The recession of the first years of transition was due mostly to more objective causes such as: the whole Romanian economy before 1989 was completely nationalized and centralized; its management was irrational and refused to take into account any signals from the real economy; there was no competition on any market of the national economy; after 1989, the politicians, but also the managers and entrepreneurs had no experience at all. Unlike this first period of recession, the severe depression between 1997 and 1999 was caused by the lack of continuity in the macroeconomic policies. This period was characterized by a fall of 12% in the GDP, high external deficits and a very high inflation rate. All these led to the “edge” of the crisis in 1999, when Romania was close to bankruptcy (cessation of payments).

Starting from 2000, several measures were adopted in order to stop the economic fall and achieve stabilization. The GDP grew in 2000 with

2.1% and this trend was continued afterwards. The last three years were characterized by deflation, due to the prudent monetary policy led by the National Bank, but also to the austerity Government policy concerning public expenditures. The foreign direct investments, as well as the Romanian exports increased.

The Romanian capital market followed the same trends as the national economy. The legal basis of the capital market was put in 1994. In 1995, after almost 50 years of interruption, the Bucharest Stock Exchange was refounded<sup>1</sup>. During 1995 and the 1<sup>st</sup> trimester of 1997 the stock exchange was characterized by a slow growth and lack of liquidity. During the second and the third trimesters of 1997, a boom in the transactions volume took place. This boom was mostly due to massive foreign investments, while only 5% of the transactions were done by residents. The cause of this phenomenon was the increasing trust in the Romanian economy, as a result of the politic shift in 1996 (from left wing to right wing) and the promising policies of the new government.

The Romanians didn't choose to invest at the stock exchange for several reasons:

- ✓ they lacked the education and the trust in such kind of investment;
- ✓ in this period, the state bonds offered very high interest rates (in general, higher than any other investment)
- ✓ the level of income in Romania was continuously depreciating.

However, the legislative hesitations of the new government, the slow rhythm of privatization, the high level of political instability, the resignation of the government in 1998 led to diminishing foreign investments at Bucharest Stock Exchange. Certainly, the period of economic recession between 1997 and 1999 left marks on the stock exchange activity.

However, the economic growth achieved beginning with 2000 was reflected in the stock exchange activity as well. The main stock exchange index, BET, grew from 814.85 points on the 5<sup>th</sup> of January 2000 to more than 5000 points in March 2005. The liquidity has improved and the transactions volumes has increased. The ratio between residents transactions and nonresidents transactions also grew. Nowadays, about 80% (in average per month) of the transactions are done by residents.

Apart from the Bucharest Stock Exchange, several other organized capital markets were founded:

---

<sup>1</sup> On the 23<sup>rd</sup> of June 1995 the Association of the Stock Exchange was founded.

- ✓ On the 1<sup>st</sup> of November 1996, the RASDAQ market (Romanian Association of Securities Dealers Automated Quotations) was founded. This is an OTC market where the companies that do not fulfill the requirements to be traded at BSE are negotiated.
- ✓ In 1994, The Sibiu Merchandise Stock Exchange was founded. In 1997, this institution became The Monetary – Financial and Merchandise Stock Exchange, and derivatives started to be negotiated (especially futures on currencies and indices).
- ✓ In November 1998, following the model of the stock exchange mentioned above, The Romanian Merchandise Exchange was founded. Futures on currencies, interest rates, as well as options on currency futures are traded here.

At the Bucharest Stock Exchange (BSE), the variations in stock prices are mostly reflected by three important indices.

The first one, BET, a blue chips index, was launched in September 1997. It measures the price variations of the top ten companies in terms of liquidity and market capitalization. It is a Laspeyres index, weighted with the market capitalization of the stocks.

BET-C (1998) reflects the global evolution of the market, while the third index, BET FI is a sectorial one. It measures the price variation of the five close investment funds listed at the Bucharest Stock Exchange.

#### **4. Data and Methodology**

We use the natural logarithms of weekly indices for the period from the 1<sup>st</sup> of January 2000 to the 22<sup>nd</sup> of June 2005. We chose to collect Wednesday prices in order to avoid any “day of the week” effects on data. All the indices are based on prices denominated in Euros. Adjustments were made for those indices denominated in other currencies.

Concerning our methodology, first of all, we determine the number of unit roots of each index series by using the Augmented Dickey Fuller Test and the Philips Perron Test.

Then, cointegration is tested by using Johansen’s cointegration test.

Finally, if the cointegration hypothesis is confirmed, we proceed to a short-run analysis, by using the VECM methodology, impulse response functions, as well as variance decomposition.

The data processing was made by using software packages like: Microsoft Excel, Fox Prow, EViews 3 and Stata 9.

### 4.1 Unit Root Tests

i. Dickey-Fuller (DF) and Augmented Dickey-Fuller (ADF)

The starting point in testing the presence of unit roots is an AR(1) model with one of the next three forms:

$$\Delta y_t = \gamma y_{t-1} + \varepsilon_t \quad (1)$$

or  $\Delta y_t = \mu + \gamma y_{t-1} + \varepsilon_t$  - a drift term is added (2)

or  $\Delta y_t = \mu + \beta t + \gamma y_{t-1} + \varepsilon_t$  - both a drift term and a linear time trend are added. (3)

In the above equations,  $\varepsilon_t$  is a white noise.

In all equations, we test whether the parameter  $\gamma=0$ , which is equivalent with testing the presence of a unit root.

The test described above is only valid when the series is an AR(1) process. In the case of higher order serial correlation, in order for  $\varepsilon_t$  to be a white noise, a correction must be made. The Augmented Dickey-Fuller method of solution to this problem was based on assuming that the  $y$  series follows an AR(p) process and adding lagged difference terms of the dependent variable  $y$  to the right-hand side of the regression:

$$\Delta y_t = \mu + \gamma y_{t-1} + \delta_1 \Delta y_{t-1} + \delta_2 \Delta y_{t-2} + \dots + \delta_{p-1} \Delta y_{t-p+1} + \varepsilon_t \quad (4)$$

The null hypothesis is the same as in Dickey Fuller test:  $H_0: \gamma = 0$ , while the alternative is:  $H_1: \gamma < 0$ .

The t-statistic under the null hypothesis of a unit root does not have the conventional t-distribution. The critical values for the t-test were first simulated by Dickey and Fuller (1979) and more recently by MacKinnon (1991).

#### 4.1.1 The Philips Perron Test (PP test)

The test regression for the PP test is the same as the one for the DF test. But, Philips and Perron (1988) propose a non-parametric correction for higher order correlation. An estimate of the spectrum of  $\varepsilon$  at frequency zero that is robust to heteroskedasticity and autocorrelation of unknown form is used. The Newey-West heteroskedasticity autocorrelation consistent estimate is:

$$\omega^2 = \gamma_0 + 2 \sum_{j=1}^q \left(1 - \frac{j}{q+1}\right) \gamma_j, \quad (5)$$

$$\gamma_j = \frac{1}{T} \sum_{t=j+1}^T \tilde{\varepsilon}_t \tilde{\varepsilon}_{t-j}, \quad (6)$$

where  $q$  is the truncation lag.

The PP t statistics is:

$$t_{PP} = \frac{\gamma_0^{1/2} t_\gamma}{\omega} - \frac{(\omega^2 - \gamma_0) TS_\gamma}{2\omega\tilde{\sigma}}, \quad (7)$$

where  $t_\gamma$  and  $S_\gamma$  are the t-statistic and standard error of  $\gamma$  and  $\tilde{\sigma}$  is the standard error of the test regression.

The PP statistics has the same asymptotic distribution as the DF or ADF statistics.

#### 4.1.2 The Johansen's cointegration test

The starting point for this test is a VAR(p) process:

$$y_t = A_1 y_{t-1} + A_2 y_{t-2} + \dots + A_p y_{t-p} + Bx_t + \varepsilon_t, \quad (8)$$

This can also be written:

$$\Delta y_t = \sum_{i=1}^{p-1} \Pi_i \Delta y_i + \Pi y_{t-p} + Bx_t + \varepsilon_t, \quad (9)$$

where  $y_t$  is a  $k$ -vector of non-stationary I(1) variables,  $x_t$  is a  $d$  vector of deterministic variables, and  $\varepsilon_t$  is a vector of innovations. Also,

$$\Pi = \sum_{i=1}^p A_i - I \quad \text{and} \quad \Pi_i = - \sum_{j=i+1}^p A_j.$$

If the series are cointegrated,  $\Pi$  has reduced rank  $r \leq k-1$  and can be factorized into  $\Pi = \alpha\beta'$ , where  $\alpha$  and  $\beta$  are two ( $k \times r$ ) matrices.  $\alpha$  represents the speed of adjustment to disequilibrium and  $\beta$  is a matrix of long run coefficients, such that  $\beta'y_{t-p}$  represents up to  $k-1$  cointegration relationships in the multivariate model.

Johansen (1988) obtains estimates of  $\alpha$  and  $\beta$  using the procedure known as reduced rank regression. He estimates the  $\Pi$  matrix without imposing any VECM restrictions, by calculating  $k$  eigenvalues<sup>2</sup> ( $\lambda_1, \dots, \lambda_k$ ). The  $r$  eigenvectors -  $\hat{V} = (\hat{v}_1, \dots, \hat{v}_r)$  - corresponding to the first  $r$  eigenvalues contain, in fact, the estimations of the elements of the  $\beta$  matrix. The combinations  $\hat{v}_i'y_t$ ,  $i=1 \dots r$ , are all stationary. The other  $k-r$  combinations obtained with the last  $k-r$  eigenvectors are nonstationary. In order for the series to be cointegrated (this implies that  $\beta'y_t$  is stationary), the last  $k-r$

---

<sup>2</sup> For more information, see Harris and Sollis (2003)

eigenvalues must be very small (zero). Therefore, Johansen proposes to test the null:

$$H_0 : \lambda_i = 0, \quad i=r+1, \dots, n \quad (10)$$

In order to test the null above, the so-called trace statistic is used:

$$\lambda_{trace} = -T \sum_{i=r+1}^k \log(1 - \hat{\lambda}_i), \quad r=0, 1, 2, \dots, k-1. \quad (11)$$

Asymptotic critical values for the trace statistics were provided by Johansen and Juselius (1990), Osterwald-Lenum (1992), Pesaran et al. (2000) and Doornik (1999)<sup>3</sup>. EViews 3, the statistical software we use, tabulates the critical values for the reduced rank test as given by Osterwald-Lenum (1992).

Johansen considered the following five possibilities of conducting the test<sup>4</sup>:

1. Series  $y$  have no deterministic trends and the cointegrating equations do not have intercepts;
2. Series  $y$  have no deterministic trends and the cointegrating equations have intercepts;
3. Series  $y$  have linear trends but the cointegrating equations have only intercepts;
4. Both series  $y$  and the cointegrating equations have linear trends;
5. Series  $y$  have quadratic trends and the cointegrating equations have linear trends.

#### **4.2 The short-run analysis**

If the index series are proved to be cointegrated, the short-run analysis must be done within a VECM framework. Therefore, after establishing the number of cointegration relationships, we need to estimate the short-run vector autoregression (VAR) in error-correction form with the cointegration relationships explicitly included:

$$\Delta y_t = \sum_{i=1}^{p-1} \Pi_i \Delta y_i + \Pi y_{t-p} + Bx_t + \varepsilon_t \quad (12)$$

---

<sup>3</sup> See Harris and Sollis (2003), pg 122

<sup>4</sup> see Johansen, 1995, p. 80–84 for details

Considering that all the components of the VECM are stationary  $I(0)$  variables, standard OLS regression and inference can be used in estimating the coefficients.

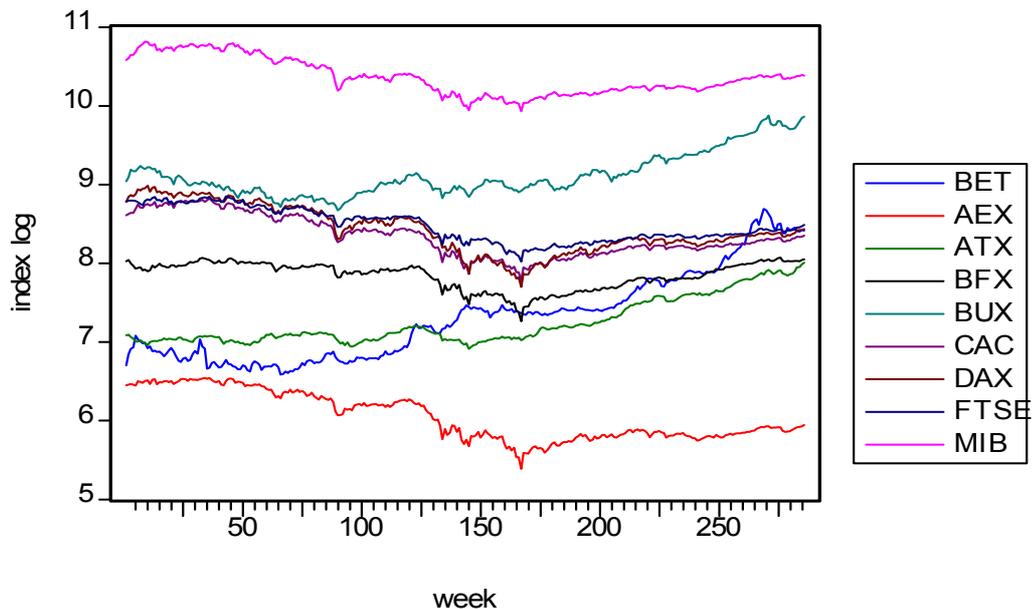

Our short-run approach also concerns the analysis of impulse-response functions and variance decomposition, which are estimated within a VECM framework as well. The impulse-response functions are meant to trace the impact of one standard deviation shock in the innovations on the endogenous variables of the VECM. Briefly, the impulse-response analysis involves that the errors are orthogonalized by a Cholesky decomposition so that the covariance matrix of the resulting innovations is diagonal.

The variance decomposition decomposes variation in an endogenous variable into the component shocks to the endogenous variables in the VAR. Such an analysis provides information on the relative importance of each random innovation to the variables in the VAR.

## 5. Results

Before running any tests, a chart was made, representing the variations of the logs of the nine series:

**Figure 1 The Variations of the Logs of the Index Series**

*Source: Author's calculation*

By analyzing the chart, we can observe that the line graphs representing the variations in the indices of most of the mature markets (MIB, DAX, FTSE, AEX, BFX, CAC) are quite parallel, suggesting a common trend. The line graphs of BET (the Romanian index) and BUX (the Hungarian index) seem to be parallel as well.

### 5.1 Unit Root Tests

We conducted the Augmented Dickey Fuller Test with a number of four lagged differences on the right hand of each equation tested. For the Philips Perron Test, we chose a truncation lag equal to five. This truncation lag was determined using the Newey-West method:

$$q = \text{floor}(4(T/100)^{2/9}),$$

where  $T$  is the total number of observations.

The results of the Augmented Dickey Fuller and Philips Perron tests can be summarized in the following tables:

1.1.1. Table 1 The ADF and PP statistics for the nine index series		
	<i>ADF STATISTIC</i>	<i>PP STATISTIC</i>
<i>AEX</i>	-0.972028	-1.111446
<i>ATX</i>	-0.421773	-0.732197
<i>BET</i>	-2.95374	-1.806125
<i>BFX</i>	-0.605546	-0.873784
<i>BUX</i>	-1.532198	-1.048656
<i>CAC</i>	-0.682541	-0.80589
<i>DAX</i>	-0.819667	-0.902629
<i>FTSE</i>	-0.346169	-0.588957
<i>MIB</i>	-0.77107	-0.972134

*Source: Author's calculation*

Table 2 MacKinnon critical values for rejection of hypothesis of a unit root.		
<i>for the ADF test</i>	1% Critical Value	-3.9941
	5% Critical Value	-3.4272
	10% Critical Value	-3.1366
<i>for the PP test</i>	1% Critical Value	-3.9937
	5% Critical Value	-3.427
	10% Critical Value	-3.1365

Comparing the test statistics in Table 1 with the critical values in the Table 2, we can conclude that in all the cases the null hypothesis of one unit root is accepted for all the significance levels considered (1%, 5%, 10%).

## 5.2 Johansen's Cointegration Test

In conducting Johansen's cointegration test, we encountered two kinds of problems.

The first one concerns the number of lags of the first differenced terms included in the right hand side of equation (1). In solving this problem, we used all information criteria available: the Hannan Quinn Information Criterion (HQ)<sup>5</sup>, the Akaike Information Criterion (AIC), the Schwarz criterion (SC). According to these criteria, we chose to perform the test with 1 lag in levels.

The second problem was selecting one of the five possibilities proposed by Johansen to run the test. We eliminated the first model (no deterministic components in the data or in the cointegration equations), especially because the intercept is needed to account for the units of measurement of the variables  $y_i$ <sup>6</sup>. In order to choose one of the models 2 to 5, we applied the so-called Pantula principle suggested by Johansen in an article written in 1992<sup>7</sup>. According to this principle, all models are estimated and the results are presented from the most restrictive model (2) to the least restrictive (5). "The test procedure is then to move from the most to the least restrictive model and at each stage to compare the trace statistic to its critical value and only stop the first time the null is not rejected."<sup>8</sup> Following this procedure for 1 lag in the differenced terms, the first time the null was not rejected was for the third model (series  $y$  have linear trends but the cointegrating equations have only intercepts) and for a rank  $r=1$ .

We didn't include in the test regression any other exogenous variables, such as dummies.

Table 3 presents the results of the Johansen's test performed in its third form and for 1 lag in levels:

---

<sup>5</sup> Johansen et al (2000) recommend using the HQ criterion in establishing the lag length of a VAR.

<sup>6</sup> The series means differ from zero. Therefore intercepts are needed in the cointegrating equations.

<sup>7</sup> For more information, see Harris and Sollis (2003), pages 134, 135

<sup>8</sup> Harris and Sollis (2003), page 134

<b>Table 3 The results of Johansen's cointegration test</b>				
<i>Eigenvalue</i>	<i>Likelihood Ratio</i>	<i>5 Percent Critical Value</i>	<i>1 Percent Critical Value</i>	<i>Hypothesized No. of CE(s)</i>

0.1359	151.0397	156	168.36	At most 1
0.1049	109.3944	124.24	133.57	At most 2
0.0874	77.8050	94.15	103.18	At most 3
0.0631	51.7547	68.52	76.07	At most 4
0.0453	33.1803	47.21	54.46	At most 5
0.0428	19.9756	29.68	35.65	At most 6
0.0222	7.5017	15.41	20.04	At most 7
0.0039	1.1118	3.76	6.65	At most 8

Source: Author's calculation

\*(\*\*) denotes rejection of the hypothesis at 5%(1%) significance level.

In the table above, L.R. test indicates one cointegration relationship at 5% significance level. The normalized coefficients of this cointegration

relationships are presented in the following table (Table 4):

<b>Table 4 Normalized Cointegrating Coefficients: 1 Cointegrating Equation</b>									
<i>BET</i>	<i>AEX</i>	<i>ATX</i>	<i>BFX</i>	<i>BUX</i>	<i>CAC</i>	<i>DAX</i>	<i>FTSE</i>	<i>MIB</i>	<i>Intercept</i>
1	22.96	-3.18	5.24	2.71	52.32	-13.96	-58.62	-18.75	183.37

Source: Author's calculation

The cointegration analysis suggests that the Romanian stock market is integrated in the long-run with other European stock markets. This is not in contradiction with the fact that at the Bucharest Stock Exchange, nonresidents are still able to obtain very large profits, performing every year about 20%<sup>9</sup> of the transactions. Such transactions are mainly speculative and capital flows have a transitory nature. There are large foreign capital flows during winter and spring, when the returns at BSE are very high. Such capitals are withdrawn in a few months. Therefore, while displaying a long-run equilibrium with EU stock markets, the Romanian market offers the possibility of large profits in the short run.

---

<sup>9</sup> In average, 24.96% in the first seven months of 2005 and 18.28% in 2004 (Source: www.bvb.ro).

### 5.3 The short-run analysis

As described in section 4, in the case of cointegration, the VECM methodology is required in the short-run analysis. Therefore, we estimated a restricted VAR containing one cointegrating relationship and 1 lag in levels. The results of our estimation can be seen in Table 5:

Table 5 The VECM estimation output					
	<i>Coef.</i>	<i>Std. Err.</i>	<i>t</i>	<i>P&gt; t </i>	<i>R-sq</i>
<b>D_bet</b>

<b>D_mib</b>					
<i>Coint Eq</i>	<b>-0.0036*</b>	0.0013	-2.8	0.005	0.0275
<i>Constant</i>	-0.0006	0.0017	-0.36	0.717	

Source: Author's calculation

In the above table, all the 5% statistically significant coefficients are marked with \*. The coefficients of the cointegration relationship denote the speed of adjustment to disequilibrium. Within these coefficients, only some of them are statistical significant: the ones for the AEX, BFX, BUX, CAC40,

DAX and MIB30 equations. For all the VECM equations, the  $R^2$  coefficients are very low, indicating a reduced degree of statistical significance of the models. Although the Romanian market represents for foreign investors an opportunity for obtaining speculative profits, it does not display short-run interdependences with other EU markets. We also believe that in the short-run, an analysis based on daily data would be more appropriate.

### **5.3.1 Impulse-Response functions**

As described in Section 4, the impulse response functions provide information on the expected response of each market to shocks affecting that market, as well as to shocks on other stock markets considered. The response of BET to one standard deviation shock in BET, AEX, ATX, BFX, BUX, CAC40, DAX, FTSE100 or MIB30 are presented within the figure in Annex 1. As expected, shocks on itself display a high and constant impact on BET. Shocks to ATX, BFX and BUX have an insignificant effect on the Romanian index, while shocks to AEX, DAX and MIB30 exert a small, but constant influence on BET. AEX has a negative impact on BET, while the German and the Italian indices have a positive influence. From all the EU stock indices, CAC40 and FTSE100 exhibit the largest, increasing in time effects on the Romanian index. The French index has a negative impact, while the British one displays a positive effect on BET.

### **5.3.2 Variance decomposition**

To further assess the relative importance of shocks in prices, we decompose the forecast error variance of BET into parts attributable to shocks to BET, as well as to the other indices considered. The variance decomposition of BET is graphed in Annex 2. Shocks from the Romanian market explain most of its own forecast uncertainty (about 98%). Within the possible external shocks, the ones from FTSE100 account for only 1% -2% of the forecast error variance of BET, as the forecast horizon increases.

Although the Romanian market displays a long-run equilibrium with the equity markets from the EU, in the short-run it does not react promptly to shocks emanating from EU markets. Both the impulse-response and the variance decomposition analyses show that the Romanian index, BET, responds, most of all, to its own shocks.

## **6. Conclusions**

This paper investigates to what extent the Bucharest Stock Exchange is integrated with eight European stock markets (Austria, Belgium, England, France, Germany, Holland, Hungary, Italy). First, we determine the order of

integration for each index series, by using unit root tests (ADF and PP). We find that every index series displays one unit root. Then, in order to identify a long run relationship between the nine markets, we apply Johansen's cointegration test. We find one cointegrating relationship between the nine equity markets. We can say that in the long run the Romanian stock exchange is integrated with the other European equity markets.

Our investigation in the short run implies the estimation of the VECM, as well as impulse-response functions and variance decomposition analyses. We find that responses of the Romanian stock market to external shocks are neither significant nor prompt. About 98% of the forecast error variance of the Romanian index, BET, is due to shocks of itself. Our findings are consistent with the fact that foreign investors still obtain very large speculative profits at the Bucharest Stock Exchange. We cannot speak of a short-run integration of the BSE with other stock markets from EU.

## **Abstract**

*Two easily measured variables, size and book-to-market equity, combine to capture the cross-sectional variation in average stock returns associated with market  $\beta$ , size, book-to-market equity, and earnings-price ratios for the Athens stock exchange for the period from 1997 to 2003. Creating portfolios on the basis of beta values produces no reliable relation between betas and average returns. Moreover, when portfolios are formed on size alone there is no relation between size and average return. When portfolios are formed on E/P alone there seems to be no evidence about any relation between E/P and average returns while when portfolios are formed on their estimated book-to market-equity no relation between average return and book-to-market equity can be derived. Variables like size, E/P and book-to-market equity are all scaled versions of a firm's stock price. They can be regarded as different ways of extracting information from stock prices about the cross-section of expected stock returns. Since all these variables are scaled versions of price, it is reasonable to expect that some of them are redundant for explaining average returns.*

**Keywords:** *Athens Stock Exchange, portfolio returns, beta, risk free rate, stocks*

## 1. Introduction

Investors and financial researchers have paid considerable attention during the last few years to the new equity markets that have emerged around the world. This new interest has undoubtedly been spurred by the large, and in some cases extraordinary, returns offered by these markets. Practitioners all over the world use a plethora of models in their portfolio selection process and in their attempt to assess the risk exposure to different assets.

One of the most important developments in modern capital theory is the capital asset pricing model (CAPM). The capital asset pricing model (CAPM) of William Sharpe [1964], John Lintner [1965] and Fischer Black [1972] marks the birth of asset pricing theory. Four decades later, the CAPM is still widely used in applications, such as estimating the cost of capital for firms and evaluating the performance of managed portfolios. The attraction of the CAPM is that it offers powerful and intuitively pleasing predictions about how to measure risk and the relation between expected return and risk. Unfortunately, the empirical record of the model is poor – poor enough to invalidate the way it is used in applications.

The efficiency of the market portfolio implies that a) expected returns on securities are a positive linear function of their market  $\beta$ s (the slope in the regression of a security's return on the market's return), and b) market  $\beta$ s suffice to describe the cross section of expected returns.

There are several empirical contradictions of the Sharpe-Lintner – Black (SLB) model. The most important is the size effect of Banz [1981]. He finds that market equity, ME (a stock's price times shares outstanding), adds to the explanation of the cross section of average returns provided by market  $\beta$ s. Average returns on small (low ME) stocks are too high given their  $\beta$  estimates, and average returns on large stocks are too low.

Another contradiction of the SLB model is the positive relation between leverage and average return documented by Bhandari [1988]. It is plausible that leverage is associated with risk and expected return, but in the SLB model leverage should be captured by market  $\beta$ .

Stattman [1980] and Rosenberg, Reid, and Lanstein [1985] find that average returns on U.S stocks are positively related to the ratio of a firm's book value of common equity, BE, to its market value, ME. Chan, Hamao and Lakonishok [1991] find that book to market equity, BE/ME, also has a strong role in explaining the cross section of average returns on Japanese stocks.

Finally, Basu [1983] shows that earnings-price ratios (E/P) help to explain the cross section of average returns on U.S stocks in tests that also include size and market  $\beta$ . Ball [1978] argues that E/P is a proxy for factors in expected returns. E/P is likely to be higher for stocks with higher risks and expected returns.

All the above variables can be regarded as different ways to scale stock prices, to extract information in prices about risk and expected returns. Moreover, since E/P, ME, leverage and BE/ME are all scaled versions of price, it is reasonable to expect that some of them are redundant for describing average returns. Initial goal of this paper is to evaluate the joint roles of market  $\beta$  size, E/P, and book-to-market equity in the cross section of average returns on the stocks of the Athens Stock Exchange.

Tests are conducted for a period of seven years (1997-2003), which is characterized by intense return volatility (covering historically high returns for the Greek Stock market as well as significant decrease in asset returns over the examined period). These market return characteristics make it possible to have an empirical investigation of the pricing model on differing financial conditions thus obtaining conclusions under varying stock return volatility.

Existing financial literature on the Athens stock exchange is rather scanty and it is the purpose of this study to widen the theoretical analysis of this market by using modern finance theory and to provide useful insights for future analysis of this market.

## **2. Empirical Appraisal of the model**

### ***2.1 Empirical Tests***

The theory itself has been criticized for more than 30 years and has created a great academic debate about its usefulness and validity. Tests of the CAPM are based on three implications of the relation between expected return and market beta implied by the model (Fama & French, [2003]). First, expected returns on all assets are linearly related to their betas, and no other variable has marginal explanatory power. Second, the beta premium is positive, meaning that the expected return on the market portfolio exceeds the expected return on assets whose returns are uncorrelated with the market return. Third, assets uncorrelated with the market have expected returns equal to the risk free interest rate, and the beta premium is the expected market

return minus the risk free rate. Most tests of these predictions use either cross-section or time-series regressions.

## 2.2 Tests on Risk Premiums

The early cross-section regression tests focus on the model's predictions about the intercept and slope in the relation between expected return and market beta. The approach is to regress a cross-section of average asset returns on estimates of asset betas. The model predicts that the intercept in these regressions is the risk free interest rate,  $R_f$ , and the coefficient on beta is the expected return on the market in excess of the risk free rate,  $E(R_M) - R_f$ .

Two problems in these tests quickly became apparent. First, estimates of beta for individual assets are imprecise, creating a measurement error problem when they are used to explain average returns. Second, the regression residuals have common sources of variation, such as industry effects in average returns. To improve the precision of estimated betas, researchers such as Blume [1970], Friend and Blume [1970], and Black, Jensen, and Scholes [1972] work with portfolios, rather than individual securities. Since expected returns and market betas combine in the same way in portfolios, if the CAPM explains security returns it also explains portfolio returns. Estimates of beta for diversified portfolios are more precise than estimates for individual securities. Thus, using portfolios in cross-section regressions of average returns on betas reduces the critical errors in variables problem. Grouping, however, shrinks the range of betas and reduces statistical power. To mitigate this problem, researchers sort securities on beta when forming portfolios; the first portfolio contains securities with the lowest betas, and so on, up to the last portfolio with the highest beta assets. This sorting procedure is now standard in empirical tests.

The model's relation between expected return and market beta also implies a time-series regression test. CAPM says that the average value of an asset's excess return (the asset's return minus the risk free interest rate,  $R_{it} - R_{ft}$ ) is completely explained by its average realized CAPM risk premium (its beta times the average value of  $(R_M - R_f)$ ).

Many tests reject the basic assumption of the CAPM model. There is a positive relation between beta and average return, but it is too "flat". The evidence that the relation between beta and average return is too flat is confirmed in time series tests, such as Friend and Blume [1970], Black, Jensen, and Scholes [1972], and Stambaugh [1982]. The returns on the low

beta portfolios are too high and the returns on the high beta portfolios are too low.

The model predicts that the intercept is the risk free rate and the coefficient on beta is the expected market return in excess of the risk free rate,  $(E(R_M) - R_f) - R_f$ . The regressions consistently find that the intercept is greater than the average risk free rate (typically proxied as the return on a one or three month Treasury bill), and the coefficient on beta is less than the average excess market return (proxied as the average return on a portfolio of stocks minus the Treasury bill rate). This is true in the early tests, such as Douglas [1968], Black, Jensen and Scholes [1972], Miller and Scholes [1972], Blume and Friend [1973], and Fama and MacBeth [1973], as well as in more recent cross-section regression tests, like Fama and French [1992].

### ***2.3 Testing Whether Market Betas Explain Expected Returns***

The model predicts that the market portfolio is mean-variance-efficient. This implies that differences in expected returns across securities and portfolios are entirely explained by differences in market beta; other variables should add nothing to the explanation of expected returns

This prediction plays a prominent role in tests of the CAPM. In the early work, the weapon of choice is cross-section regressions. One simply adds pre-determined explanatory variables to the cross-section regressions of returns on beta. If all differences in expected return are explained by beta, the average slopes on the additional variables should not be reliably different from zero. For example, in Fama and MacBeth [1973] the additional variables are squared market betas (to test the prediction that the relation between expected return and beta is linear), and residual variances from regressions of returns on the market return (to test the prediction that market beta is the only measure of risk needed to explain expected returns). These variables do not add to the explanation of average returns provided by beta.

### ***2.4 Recent Tests***

Starting in the late 1970s, empirical work appears to challenge CAPM. Specifically, evidence mounts that much of the variation in expected return is unrelated to market beta.

The first contradiction is Basu's [1977] evidence that when common stocks are sorted on earnings-price ratios, future returns on high E/P stocks are higher than predicted by the CAPM. Banz [1981] documents a size effect; when stocks are sorted on market capitalization (price times shares

outstanding), average returns on small stocks are higher than predicted by the CAPM. Bhandari [1988] finds that high debt-equity ratios (book value of debt over the market value of equity, a measure of leverage) are associated with returns that are too high relative to their market betas. Finally, Statman [1980] and Rosenberg, Reid, and Lanstein [1985] document that stocks with high book-to-market equity ratios (BE/ME, the ratio of the book value of a common stock to its market value) have high average returns that are not captured by their betas.

There is a theme in the contradictions of the CAPM summarized above. Ratios involving stock prices have information about expected returns missed by market betas. Fama and French [1992] update and synthesize the evidence on the empirical failures of the CAPM. Using the cross-section regression approach, they confirm that size, earnings-price, debt-equity, and book-to-market ratios add to the explanation of expected stock returns provided by market beta. Fama and French [1996] reach the same conclusion using the time-series regression approach applied to portfolios of stocks sorted on price ratios. They also find that different price ratios have much the same information about expected returns.

Kothari, Shanken, and Sloan [1995] try to save the CAPM by arguing that the weak relation between average return and beta is just a chance result. But the strong evidence that other variables capture variation in expected return missed by beta possibly makes this argument irrelevant.

### ***2.5 Explanations on the model's failures***

The evidence on the empirical problems of the CAPM provided by Fama and French [1992] serves as a catalyst, implying that the CAPM may have fatal problems. Research then turns to explanations.

One possibility is that the CAPM's problems are not authentic, meaning that researchers use data and discover contradictions that occur in specific samples as a result of chance. A standard response to this concern is to test for similar findings in other samples. Chan, Hamao, and Lakonishok [1991] find a strong relation between book-to-market equity (BE/ME) and average return for Japanese stocks. Capaul, Rowley, and Sharpe [1993] observe a similar BE/ME effect in four European stock markets and in Japan. Fama and French [1998] find that the price ratios that produce problems for the CAPM in U.S. data show up in the same way in the stock returns of twelve non-U.S. major markets, and they are present in emerging market returns. This evidence suggests that the contradictions of the CAPM associated with price ratios are not sample specific.

Among those who conclude that the empirical failures of the CAPM are fatal, two views emerge. The first view is based on evidence that stocks with high ratios of book value to price are typically firms that have fallen on bad times, while low BE/ME is associated with growth firms (Lakonishok, Shleifer and Vishny, [1994]; Fama and French, [1995]). They argue that sorting firms on book-to-market ratios exposes investor overreaction to good and bad times. Investors over-extrapolate past performance, resulting in stock prices that are too high for growth (low BE/ME) firms and too low for distressed (high BE/ME, so-called value) firms. When the overreaction is eventually corrected, the result is high returns for value stocks and low returns for growth stocks. Proponents of this view include DeBondt and Thaler [1987], Lakonishok, Shleifer, and Vishny [1994], and Haugen [1995].

The second view for the empirical contradictions of the CAPM is based on the need for a more complicated asset pricing model. The CAPM is based on many unrealistic assumptions. For example, the assumption that investors care only about the mean and variance of distributions of one-period portfolio returns is extreme. It is reasonable that investors also care about how their portfolio return covaries with labor income and future investment opportunities, so a portfolio's return variance misses important dimensions of risk. If so, market beta is not a complete description of an asset's risk, and we should not be surprised to find that differences in expected return are not completely explained by differences in beta. In this view, the search should turn to asset pricing models that do a better job explaining average return

### **3. Sample Selection and Data**

#### ***3.1 The sample securities***

The study covers the period from January 1997 to December 2003. This time period was chosen because it is characterized by intense return volatility with historically high and low returns for the Greek stock market incorporating changes in fundamental variables of the enterprises, giving us the opportunity to test the model on differing financial conditions thus obtaining conclusions under varying stock return volatility.

The selected sample consists of the majority of the stocks that were trading on the Athens Stock Exchange over the examination period. We excluded financial firms because the high leverage that is normal for these firms probably does not have the same meaning as for non financial firms, where high leverage more likely indicates distress. The sample companies

account for a major portion of market capitalization as well as average trading volume for the Greek stock market. Shares not included in the sample are either thinly traded or do not have accounting and financial information on a continuous basis.

The share data has been obtained from the Metastock and the Athens stock exchange, financial databases widely used in Greece by practitioners and researchers. The price data has been adjusted for capitalization changes such as bonus rights and stock splits. All the selected securities are traded on the ASE on a continuous basis throughout the full Athens stock exchange trading day, and are chosen according to prespecified liquidity criteria set by the ASE Advisory Committee.<sup>1</sup> The selection was made on the basis of the trading volume and excludes stocks that were traded irregularly or had small trading volumes.

All the selected stocks are included in the formation of the FTSE/ASE 20, FTSE/ASE Mid 40 and FTSE/ASE Small Cap index. These indices are designed to provide real-time measures of the Athens Stock Exchange (ASE).

The above indices are formed subject to the following criteria:

- (i) The FTSE/ASE 20 index is the large cap index, containing the 20 largest blue chip companies listed in the ASE.
- (ii) The FTSE/ASE Mid 40 index is the mid cap index and captures the performance of the next 40 companies in size.
- (iii) The FTSE/ASE Small Cap index is the small cap index and captures the performance of the next 80 companies.

### ***3.2 Data***

The study uses weekly stock returns for the selected companies listed on the Athens stock exchange for the period of January 1997 to December 2003. The data are obtained from MetaStock (Greek) Data Base.

Most firms in Greece have their fiscal year ends on December. So tests did not have to deal with matching the accounting data for all fiscal year ends in every calendar year. We use a firm's market equity at the end of December of each year to compute its book to market, leverage and earnings price ratios and we use its market equity of June of each year to compute its size. The accounting information combined with share price data has been used to construct measures of size and value employed in the study, as discussed in the next section.

---

<sup>1</sup> [www.ase.gr](http://www.ase.gr)

Additionally annual profit information measured as Profit before Depreciation and Taxes (PBDT) has been collected for the sample companies from 1997 to 2003. The choice of profit figure has been guided by the fact that PBDT figures are seldom negative, making them appropriate for growth rate calculations.

In order to obtain better estimates of the value of the beta coefficient, the study utilizes weekly stock returns. Returns calculated using a longer time period (e.g. monthly) might result in changes of beta over the examined period introducing biases in beta estimates. On the other hand, high frequency data such as daily observations covering a relatively short and stable time span can result in the use of very noisy data and thus yield inefficient estimates.

All stock returns used in the study are adjusted for dividends as required by the CAPM. The ASE Composite Share index is used as a proxy for the market portfolio. This index is a market value weighted index, is comprised of the 60 most highly capitalized shares of the main market, and reflects general trends of the Greek stock market.

The 3-month Greek Treasury Bill is used as the proxy for the risk-free asset. The yields were obtained from the Treasury Bonds and Bill Department of the National Bank of Greece. The yield on the 3-month Treasury-bill is specifically chosen as the benchmark that better reflects the short-term changes in the Greek financial markets.

#### **4. Methodology**

The asset pricing model of Sharpe (1964), Lintner (1965), and Black (1972) is related to the way that academics and practitioners think about average returns and risk. The main argument of the model implies that the expected returns on securities are a positive linear function of their market betas (the slope in the regression of a security's return on the market's return), and the market's beta suffice to describe the cross-section of expected returns.

There are several empirical contradictions of the Sharpe-Lintner-Black (SLB) model as previously presented such as the size effect of Banz [1981], the positive relation between leverage and average return documented by Bhandari [1988], the positive relation of the ratio of a firm's book value of equity, BE, to its market value, ME and the E/P effect presented by Ball [1978].

The purpose in this part of the paper is to evaluate the joint roles of market's  $\beta$ , size, E/P and book to market equity in the cross section of average stock returns on the Athens stock exchange (ASE). The relations

between  $\beta$  and average return, the expanded relations between average return, size, E/P, and book-to-market equity will also be tested in order to investigate the sources of dimensions of risk in the SLB model. If assets are priced rationally, then stock risks should be multidimensional. One dimension of risk is proxied by size, ME. Another dimension of risk is proxied by BE/ME, the ratio of the book value of common equity to its market value. Ball [1978] argues that E/P is a proxy for the unnamed factors in the expected returns. This argument for E/P might also apply to size (ME), and book to market equity. All these variables can be regarded as different ways to scale stock prices, to extract information in prices about risk and returns.

In order to accomplish the above tests a significant number of stocks were selected from the ASE covering the period from January 1997 to December 2003. The number of stocks varies from year-to-year based on the criterion of their market capitalisation and their average trading volume. Most firms in Greece have their fiscal year ends on December. So tests did not have to deal with matching the accounting data for all fiscal year ends in every calendar year. We use a firm's market equity at the end of December of each year to compute its book to market, earnings price ratios and we use its market equity of June of each year to compute its size. Then, beta was estimated by regressing each stock's weekly return against the market index according to the following equation:

$$R_{it} - R_{ft} = \alpha + \beta_i(R_{mt} - R_{ft}) + e_t \quad (1)$$

where,  $R_{it}$  is the return on stock  $i$ ,  $R_{ft}$  is the rate of return on a risk-free asset,  $R_{mt}$  is the rate of return on the market index,  $\beta_i$  is the estimate of beta for the stock  $i$ , and  $e_{it}$  is the corresponding random disturbance term in the regression equation.

#### ***4.1 Decile Estimates-Two Dimension Sorting***

In June of each year stocks are sorted by size (ME). After estimating the size of stocks, data were allocated to three deciles according to their size, 30% low size, 40% medium and 30% high size deciles. We split the data on deciles based on the evidence of Chan and Chen [1998] that size produces a wide spread of average returns and betas. To allow for variation in beta that is unrelated to size we subdivide each of the three size deciles into portfolios comprised of eight stocks each, on the basis of their individual beta estimates from the highest to lowest. Thus, a two dimension sorting is conducted firstly

by the fundamental variable criterion, ME, and then by the beta estimate. Having created portfolios the average portfolio return is calculated from the individual stock returns.

The same methodology as described above is followed in constructing portfolios based on individual beta estimates where the criterion for forming deciles in this case, is not the size (ME) of stocks but their beta estimates.

The study continues by constructing portfolios using the criterion of book to market equity and earnings price ratio by allowing variation in beta. Three deciles are constructed 30% low, 40% medium and 30% high deciles using the initial sorting of stocks on the above two criterion. Moreover the data on deciles are categorized based on their individual beta estimates and portfolios of eight stocks in each one are created. In this way a two dimensional sort is also achieved and the intersection of these variables can be examined in scaling stock prices and extracting information about risk and returns.

#### ***4.2 Decile Estimates-One Dimension Sorting***

In order to examine the main prediction of the SLB model that average return is positively related to market beta, portfolios are formed on size and beta alone. Moreover, book to market equity and E/P is also used in order to examine if these variables are good proxies for beta.

The same methodology as previously described is followed by creating three deciles 30% low, 40% medium and 30% high according to the above criteria (size, beta, BE/ME and E/P) but in this case no further sorting is being made, as in the above case where a second pass sort based on beta estimates was conducted.

#### ***4.3 Cross-section examination***

The cross-sectional variation in average stocks returns associated with market  $\beta$ , size, book to market equity and earnings-price ratios is examined by using the time series regression. Tests are conducted on two dimension criterion sorting for each year separately from 1997 to 2003.

The importance of size and book to market equity in explaining the cross section in average stock returns is examined by using the following equation:

$$R_{pt} = \alpha + b_{2t} \cdot \ln(ME_{pt}) + b_{3t} \cdot \ln(BE_{pt} / ME_{pt}) + e_t \quad (2)$$

where  $R_{pt}$  , is the return of the portfolios,  $ME_t$  is the market equity of the constructed portfolios and finally  $BE_{pt}$  over  $ME_{pt}$  is the book equity to market equity of portfolios.

The inclusion of beta provides an interesting insight into the relation between size and book to market and average return. It is examined by the following equation.

$$R_{pt} = \alpha + b_{1t} \cdot \beta_{pt} + b_{2t} \cdot \ln(ME_{pt}) + b_{3t} \cdot \ln(BE_{pt} / ME_{pt}) + e_t \quad (3)$$

The final step is to examine all calculated variables by including in the regression analysis the estimated value of E/P of the portfolios. It is examined the earnings price ratio as a proxy for the omitted sources of risk that the previous variables may have not identified.

$$R_{pt} = \alpha + b_{1t} \cdot \beta_{pt} + b_{2t} \cdot \ln(ME_{pt}) + b_{3t} \cdot \ln(BE_{pt} / ME_{pt}) + b_{4t} \cdot (E_{pt} / P_{pt}) + e_t \quad (4)$$

## 5 Estimates

### 5.1 Beta estimation

Table 1a shows that forming portfolios on size alone, rather than on size and beta magnifies the range of beta for the examined period. In 1997 for instance in the first case (form portfolios on size alone) the lowest value of beta is -0.1979 and the highest is 0.4857 with estimated range between the two of them -1.0558. While in the second case (form portfolios on size and then sort them according to their beta estimates) the lowest value of beta is -0.2385 with highest value 0.4857 and range -0.6836. A different pattern of results are observed in years 2000, 2001 and 2002 where the Greek stock market suffered from a sharp decrease in stock prices returns. In these years the market was highly volatile, stock prices returns became rather unstable with severely fluctuating values of beta.

One important fact about  $\beta$ s is important. The beta sort is not a refined size sort. The deciles firstly are created by the size criterion and then within these deciles, stocks are sorted according to their individual beta estimates. Thus the beta sort achieves its goal to produce a variation in

beta that is unrelated to size. This is important in allowing our tests to distinguish between beta and size effects in returns and any other variable that will be used later in the study.

## *5.2 $\beta$ and Size*

Table 2 shows average returns from 1997 to 2003 for portfolios formed from one-dimensional sort of stocks on size or beta. The portfolios are formed at the end of each year and their returns are calculated from the average returns of stocks that are included in the formation of these portfolios. Portfolios created on December because all firms that have been used in the study have their fiscal year ends on December, so we did not have to deal with matching the accounting data.

The Table shows that when portfolios are formed on size alone, we observe no relation between size and average return and no relation between average return and beta. These contradictory results are met in every year of the study where low beta portfolios provide higher returns than high beta portfolios. Thus, a simple size sort seems not to support the SLB prediction of a positive relation between beta and average return. For the estimation of ME, the study uses natural logs because logs are a good functional form of capturing effects in averaging returns. Using logs also leads to a simple interpretation of the relation between the values of these factors in averaging returns.

When portfolios formed on the basis of the ranked market betas of stocks a wider range of beta is produced than from portfolios formed on size. In the year of 2003 for example when portfolios are formed on betas the lowest value in beta is -0.1065 and the highest value is 2.6445 while the same values when forming portfolios on size alone are 0.7254 and 1.8626 respectively. As in the previous case in the size portfolios the beta sorted portfolios do not support the SLB model.

There is big spread in average returns across the beta portfolios, and there is no obvious relation between beta and average returns. For example, in year 2000 the high beta portfolio produces negative returns while the lowest beta portfolios produces positive returns. The widespread in returns, from 0.0249 in the year 2000 for the low beta portfolio to -1.8336 for the highest beta portfolio is an additional point that comes in contrast to the SLB model prediction.

The portfolios formed on size and then on betas in Table 1b clarify the contradictory evidence to the SLB model on the relation between beta and average return produced by portfolios formed on size or beta alone. Specifically, the two-pass sort gives a clearer picture of the separate roles of size and beta in average returns. Contrary to the central prediction of the SLB model, the second-pass beta sort produces less variation in average returns rather than on sorting portfolios on beta alone. Although the ranking in betas in Table 1b-panel B increase strongly in each size decile, average returns are flat or show a tendency to decline. In Table 1b-panel C, within the columns of the average return and betas, average returns and betas in some cases decrease with increasing size although a clear pattern cannot be inferred.

The two-pass sort on size and beta in Table 1b says that there might be a variation in beta that is related to size and related to average return, but variation in beta unrelated to size is not compensated in the average returns. The proper inference seems to be that there is a slight relation between size and average return, but controlling for size, there is no relation between beta and average return.

One possibility for the poor results in beta is that other explanatory variables are correlated with beta, and this creates problems for the relation between average returns and measured betas. However, this point cannot explain why beta has no power even when is used alone to create portfolios to explain average returns. Another hypothesis is that, as the SLB model assumes there is a positive relation between beta and average return, but the relation might become problematic by noise in the beta estimates.

### ***5.3 Book-to-Market Equity and E/P***

Table 3 shows average returns from 1997 to 2003 for portfolios formed on ranked values of book-to-market equity (BE /ME) or earnings-price ratio (E/P). The BE/ME and E/P portfolios in Table 3 are formed in the same general way (one-dimensional yearly sorts) as the size and beta portfolios in Table 2.

When portfolios are formed on E/P alone there seems to be no evidence about any relation between E/P and average returns. There are cases where portfolios E/P's increase in line with average returns but especially in years from 2000 to 2002, a period of high volatility for the

market, no reliable relation between E/P and stock returns can be inferred.

Ball (1978) argues that the earnings-price ratio captures all omitted risk factors in expected returns. If current earnings are a proxy for expected future earnings then high-risk stocks with high expected returns will have low prices relative to their earnings. Thus, E/P should be related to the expected returns capturing the omitted sources of risk. However, this argument only makes sense, for firms with positive earnings. When current earnings are negative, like in our study for the period from 2000 to 2002-a period of recession for the Greek economy, they are not a proxy for the earnings forecasts embedded in the stock price, and E/P is not a proxy for expected returns.

In the next case when portfolios are formed on their estimated book-to market-equity no relation between average return and book-to-market equity can be derived. Average returns sometimes move in line with the increasing values of BE/ME portfolios but in most times returns do not behave in accordance to the BE/ME increase. It should be noted that the absence of any relation between average returns and betas, as previously presented, could be explained by the majority of firms with negative book equity.

We can report, however, that average returns for negative BE firms are high, like the average returns of high BE/ME firms. Different stock returns behavior, with a significant spread in values between negative BE firms and high BE/ME firms, is met in years from 2000 to 2002 , a period of extreme high volatility for the Greek stock market where most stocks lost much of their values. Negative book equity which results from persistently negative earnings is a signal of poor earnings prospects.

#### ***5.4 The interaction of Size, Beta, Book-to Market-Equity and Earnings Price Ratios in explaining average returns***

Table 4 shows time-series regressions of the portfolios created each year based on the criterion of two pass sort. The purpose is to evaluate the joint roles of market beta, size, E/P and book-to market-equity.

##### **5.4.1 Size Regressions**

In order to explain the role of size in explaining average returns a two dimensional variation has been used, by creating deciles based on their size

and then creating portfolios according to their beta estimates within these deciles, as previously described.

Like average returns in Table 1b, the results from the regressions about the intersection of returns between size and book-to-market equity indicate that there is no relation. The  $R^2$  values are low in all years of the model; their slopes are negative with negative values of t-statistics and standard errors close to zero. The inclusion of beta in explaining the intersection of these variables with average returns does not seem to give different results. Although the  $R^2$  values increase, the values of t-statistics persist to be negative with standard errors close to zero.

Adding E/P to the regression equation provides some useful thoughts. The slopes of the variables increase,  $R^2$  values become significant and standard errors move from zero. The results indicate that by the inclusion of E/P the model works better and all variables together explain average returns. There is a positive relation between E/P and average returns which is due to the positive relation between E/P and  $\ln(\text{BE/ME})$ . Firms with high E/P tend to have high book-to-market-equity ratios.

#### **5.4.2 Beta Regressions**

The study examines now the interaction of size, beta, book-to market-equity and earnings price ratios in explaining average returns when forming portfolios based on the beta estimates of individual stocks. The results support the idea that when beta, size and book-to-market equity are combined together the model explains the variation in average returns. There is a positive relation between beta and these variables.  $R^2$  values are high enough to support this idea with standard errors not close to zero and in addition acceptable values of t-statistics. The inclusion of all variables in the model does not provide supportive evidence in explaining average returns.

#### **5.4.3 BE/ME and E/P Regressions**

Creating portfolios according to their book-to-market equity and examining the cross-sectional variation in average stocks returns associated with market  $\beta$ , size, book to market equity and earnings-price ratios seems to give better results in explaining average returns than in the previous two cases. All statistical criteria have acceptable values to support the model and to provide adequate evidence in explaining the behaviour of stock returns. We should not, however, exaggerate with these results due to the fact that small ME stocks are more likely to have high book-to-market ratios, and high BE/ME stocks tend to be small (they tend to have low ME).

In the two dimensional sorting case based on E/P the model does not provide any positive relation in explaining average returns. The statistical criteria support the absence of relation and no conclusions can be extracted.

## **6 An extended variable model for explaining average returns**

### ***6.1 The multidimensional results***

The conclusions from creating portfolios either on one or two pass-sort are summarized:

- (1) When we form portfolios on the basis of beta values of stocks there is no reliable relation between betas and average returns.
- (2) There is no relation between size and average return and no relation between average return and beta when portfolios are formed on size alone.
- (3) Forming portfolios on size alone, rather than on size and beta magnifies the range of beta for the examined period.
- (4) Contrary to the central prediction of the SLB model, the second-pass beta sort produces less variation in average returns rather than on sorting portfolios on beta alone. Although the ranking in betas increase strongly in each size deciles, average returns are flat or show a tendency to decline.
- (5) The two-pass sort on size says that there might be a variation in beta that is related to size and average return, but variation in beta unrelated to size is not compensated in the average returns. There is a slight relation between size and average return, but controlling for size, there is no relation between beta and average return.
- (6) When portfolios are formed on E/P alone there seems to be no evidence about any relation between E/P and average returns.
- (7) When portfolios are formed on their estimated book-to-market-equity no relation between average return and book-to-market equity can be derived. Average returns sometimes move in line with the increasing values of BE/ME portfolios but in most times returns do not behave in accordance to the BE/ME increase.

## ***6.2 The intersection between Size, Beta, Book-to-Market Equity and E/P***

The evaluation of joint roles of market beta, size, E/P and book-to-market-equity in explaining stock returns in general do not give any supportive evidence. The combination of the above variables when portfolios are formed on size, indicate no power of interpreting average returns. The inclusion of E/P to the regression equation indicates that the model works better and that the intersection of all variables explains average returns. The explanation of the positive relation between E/P and average returns might be due to the positive relation between E/P and  $\ln(\text{BE/ME})$ . Firms with high E/P tend to have high book-to-market-equity ratios

The intersection of the variables with the beta sorting criterion for creating portfolios supports the idea that when beta, size and book-to-market equity are combined together the model explains the variation in average returns. The more reliable results are provided when portfolios are created on the basis of stocks book-to-market equity. But we should not exaggerate with these results due to the fact that small ME stocks are more likely to have high book-to-market ratios, and high BE/ME stocks tend to be small (they tend to have low ME). Finally, in the two dimensional sorting case based on E/P the model does not provide any positive relation in explaining average returns and conclusions can be extracted.

The purpose of the study is to examine the joint roles of market's  $\beta$ , size, E/P and book to market equity in the cross section of average stock returns on the Athens stock exchange covering the period from 1997 to 2003. We emphasize on different methods to approach the Sharpe-Lintner-Black model. In short, our tests do not support the central prediction of the SLB model, that average stock returns are positively related to market beta. One reason for these contradicting results is that some years of the examined period refer to an unstable and highly volatile period for the Greek stock market where stock prices increased significantly and suddenly lost most of their gains. So, is possible that the SLB model cannot incorporate these value fluctuations. Moreover, the tests here are restricted to stocks. It is possible that including other assets will change the inferences about the average premiums for beta, size, and book-to-market equity.

Variables like size, E/P and book-to-market equity are all scaled versions of a firm's stock price. They can be regarded as different ways of extracting information from stock prices about the cross-section of expected stock returns. Since all these variables are scaled versions of

price, it is reasonable to expect that some of them are redundant for explaining average returns.

The relations between returns and economic variables that measure variation in business conditions are affected from the general economic situation and might help expose the nature of the economic risks captured by firm's fundamental variables like size, book-to-market equity and E/P.

## **Abstract**

*Linear and nonlinear dependencies found in the Romanian stock market clearly reject the random walk hypothesis. Still, it is possible that these dependencies to be present just in certain periods of time, while in others the random walk null hypothesis could be accepted. In this situation, the rejection of the random walk hypothesis can be determined by some powerful dependencies in a few sub periods, thing that could provide a better starting point when it comes to debate about the forecasting power in the Romanian stock market. Using the Hinich & Patterson (1995) “windowed” methodology we discovered that, like on other markets, long periods of random walk alternates with short periods of linear/nonlinear correlation while the last ones are more frequent when compared with the Asian markets. Moreover, we developed a methodology for isolating maximum length period with significant linear/nonlinear dependencies and we reached the conclusion that returns are higher in random walk periods rather than in periods exhibiting linear/nonlinear dependencies.*

**Keywords:** *linear/nonlinear dependencies; random walk; windowed methodology.*

## 1. Introduction

Financial economics literature has been dominated in the last decades by the linear concept diffused especially through the linear modeling of financial data time series. The fact that linear dependencies are not found within a time series does not mean that the series observations are random as this series might exhibit other more complex forms of dependencies. As possible factors that might induce significant non-linearity in stock market, Antoniou et al. (1997) enumerates: difficulties in executing arbitrage transactions, market imperfections, irrational investors' behavior, diversity in agents' beliefs and heterogeneity in investors' objectives. Thus, the linear concept, insufficiently sophisticated to capture these complex patterns, is challenged in recent years as a significant number of studies suggest that non-linearity is a universal phenomenon, at least for time series data of stock prices.

The linear and nonlinear dependencies found in the Romanian financial market rejected clearly the random walk hypothesis. However, it is possible that these dependencies to be present just in some sub periods of time while in others we could accept the null hypothesis. In this case, rejecting the random walk hypothesis on the whole sample could be the effect of some strong dependencies existing in certain sub periods. In this context, the main goal of this study is the analysis of the episodic transient behavior of non-linear dependencies in the case of Bucharest Stock Exchange. Bearing this in mind, this study conclusion could lead to a more delicate debate about the degree of predictability in the Romanian stock market.

The first ones to emphasis on the existence of such behavior were Schahter et al. (1985) and Hood et al. (1985). Hinich and Patterson (1995) developed testing methodology of the linear and non-linear dependencies by dividing the whole sample in "windows" and using the portmanteau correlation and bicorrelation test. Using this methodology a great number of studies, such are the one of Brooks and Hinich (1998), Brooks et al. (2000), Ammermann and Patterson (2003) and Lim and Hinich (2005), emphasis the existence of a different stock price behavior on sub periods of time, respectively the existence of long random-walk sub periods alternated with short sub periods characterized by strong linear or nonlinear correlation. Using a different methodology, Ramsey and Zang (1997) discover similar results.

A study that we have in progress proved that the rejection of the random walk hypothesis in the Romanian stock market is due both to a linear correlation determined by the low trading frequency and especially to some additive and multiplicative non-linear dependencies. Developing profitable

forecasting linear and nonlinear models is possible only if these dependencies can be found during the whole sample period. Thus, it's becoming interesting to see how the return behavior of Romanian stocks has the same characteristics with the one from other markets, respectively the alternation of long periods of random-walk with short periods characterized by strong linear and nonlinear dependencies.

In this study we will use the “windowed” methodology developed by Hinich and Patterson (1995) which implies the division of the observations sample in sub samples or “windows” and running linear and nonlinear dependencies identification tests. More than that, the study will propose an improved version of the methodology for delimiting, as accurate as possible, the random walk periods from those exhibiting linear and nonlinear correlation.

## 2. Methodology

The methodology followed in this study is the “windowed” methodology developed by Hinich and Patterson in 1995. The following lines will expose a short description of this procedure. More details regarding the fundamentals and properties of tests in small samples can be found in Hinich and Patterson (1995) or Hinich (1996).

### 2.1 *Hinich & Patterson methodology*

Let the sequence  $\{R(t)\}$  be the realization of a stochastic process, respectively the return sample, where  $t$  is the time unit which is a whole number. The procedure implies the division of the sample in no overlapped sub samples of volume  $n$ , named “windows”. Thus, the  $k$  window is the following sequence  $\{R(t_k), R(t_k+1), \dots, R(t_k+n-1)\}$  while the  $k+1$  window is  $\{R(t_{k+1}), R(t_{k+1}+1), \dots, R(t_{k+1}+n-1)\}$  where  $t_{k+1} = t_k + n$ .

In each window, the null hypothesis is that  $R(t)$  are the realizations of a “white noise” process with null correlations and bi-correlations phenomenon described by the following formulas:  $C_{EE}(r) = E[R(t)R(t+r)]$  and  $C_{EEE}(r, s) = E[R(t)R(t+r)R(t+s)]$ , where  $r$  and  $s$  are whole numbers satisfying the relation  $0 < r < s < L$ ,  $L$  being the number of lags. The identification of linear correlation will be made using the portmanteau  $C$  test (similar to the Box-Pierce test) while in the case of the nonlinear correlations we will use the  $H$  portmanteau test.

We define  $Z(t)$  as the standardized observations series, that is a centered and reduced series:

$$Z(t) = \frac{R(t) - m_R}{\sigma_R} \quad (1)$$

where  $t$  takes values from 1 to  $n$  and  $m_k$ ,  $\sigma_k$  being the mean and the standard deviation within each window. The correlation between these standardized returns within each window will be:

$$C_{RR}(r) = (n-r)^{-1/2} \sum_{t=1}^{n-r} Z(t)Z(t+r) \quad (2)$$

While the bi-correlation is computed as follows:

$$(r, s) = (n-s)^{-1} \sum_{t=1}^{n-s} Z(t)Z(t+r)Z(t+s) \quad 0 \leq r \leq s \quad (3)$$

The C and H statistics, used to detect linear (C) and nonlinear (H) dependencies in each window are distributed according to a  $\chi^2$  law of probability with L respectively  $(L-1)(L/2)$  degrees of freedom and they have the following expressions:

$$C = \sum_{r=1}^L [C_{RR}(r)]^2 \quad (4)$$

$$H = \sum_{s=2}^L \sum_{r=1}^{s-1} G^2(r, s) \quad (5)$$

$$\text{Where } G(r, s) = (n-s)^{1/2} C_{RRR}(r, s) \quad (6)$$

The number of lags, L, is specified as  $L = n^b$ , with  $0 < b < 0.5$ . Using Monte-Carlo simulations, Hinich and Patterson (1995) recommends the usage of  $b=0.4$  in order to maximize the power of the test assuring in the

same time a good asymptotical approximation. Another parameter to be chosen, the window length, must be long enough to offer a robust statistical power and yet short enough for the test to be able to identify the arrival and disappearance of transient dependencies, as changes in the variables behavior. Brooks and Hinich recommended a window length of 35 observations corresponding to an approximate 7 weeks trading period, volume that we will also use in our study.

The rejection of the null hypothesis by the C and H tests is done with a determined risk level, for which we will consider two values 0.05 and 0.01 corresponding to probabilities of 95% and 99%. This means that at a 0.05 risk level, the possibility of a false rejection of the null hypothesis exists in 5 of 100 windows.

## ***2.2 Modified “windowed” methodology***

The procedure of dividing the studied sample in no overlapped windows, proposed by Hinich and Patterson (1995), does not allow a correct identification of the sub periods exhibiting linear and nonlinear dependencies because the test results depends on how the first day of the sample is determined. For example, in a window, the random walk hypothesis can be accepted just because the linear/nonlinear dependencies exist just in a small time fraction of the windowed sub period. Thus, choosing the first day from the whole sample will significantly influence the results of the test.

This disadvantage can be eliminated by running the Hinich and Patterson methodology (1995) in a successive way, considering the first day of the sample each of the first 34 day of the first window. We developed this particular methodology in order to identify all sub periods, of different length, exhibiting linear and nonlinear correlations, from the ones in which the random walk hypothesis is accepted.

The problem to be solved can be schematizing as following: We have a sequence of returns and we want to isolate maximum length sub periods exhibiting linear and/or nonlinear dependencies. To carry out this task we have built a two step algorithm, which firstly isolates the fix length windows exhibiting linear/nonlinear dependencies and secondly join consecutive, both no overlapped (but strictly consecutive) and overlapped windows which rejects the random walk hypothesis. With this methodology we can determine local maximum length sub periods rejecting the random walk null hypothesis.

### 2.3 Todea-Zoicaş algorithm for isolating maximum length sub periods exhibiting linear and/or nonlinear dependencies

Variables:

L=length of a window (integer);

N=total number of observations within the sample period (integer);

NW= number of delimited windows within the sample period (integer);

i,j,r,s= integer variables;

C, H, Lin\_dep, Non\_lin\_dep = matrix of integers.

C\*, H\*= table values for the  $\chi^2$  distribution (degrees of freedom, risk level)

We define a window as a function  $f: \{1, 2, \dots, NW\} \rightarrow N^* \times N^*$ , characterized by two interval extremities, the beginning and the end of the windowed period:  $W(j) := (t_1, t_2)$ .

- *Isolating fix length windows exhibiting linear/nonlinear dependencies*

For i: =1 to L-1 do

NW: = trunc ((N+1-i)/L);

For j: = 1 to NW do

$W(i, j) := ((j-1)*L+i, j*L+i-1)$

$C(i, j) := \sum_{r=1}^L [C_{RR}(r)]^2$  (for  $C_{EE}(r)$  see formula no. 2)

$H(i, j) := \sum_{s=2}^L \sum_{r=1}^{s-1} G^2(r, s)$  (for  $G(r, s)$  and  $C_{EE}(r, s)$ )

see formula 6 and 3)

For i: =1 to L-1 do

For j: = 1 to NW do

If  $C(i, j) > C^*$  then

Lin\_dep (i, j): = 1

Else

Lin\_dep (i, j): = 0

If  $H(i, j) > H^*$  then

Non\_lin\_dep (i, j): = 1

Else

Non\_lin\_dep (i, j): = 0

- *Joining consecutive both no overlapped (but strictly consecutive) and overlapped windows exhibiting linear/nonlinear dependencies*

The windows exhibiting linear and nonlinear dependencies are delimited from all windows within the *Lin\_dep* and *Non\_lin\_dep* matrixes. These matrixes contain all the possible windows that can be delimited from the sample period running the modified H&P methodology; a value of 1 is associated with the windows exhibiting dependencies and 0 for the random walk windows.

For example, suppose that the *Lin\_dep* matrix looks like the following one:

$$Lin\_dep = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 1 & 0 & 1 \end{pmatrix} \quad (7)$$

First we isolate horizontally in case of all the matrix lines, maximum length arrays containing “1” and then we join vertically the overlapping and strictly consecutive arrays found above. Thus, we obtain maximum length windows exhibiting linear dependencies. In a similar way we proceed with the *Non\_lin\_dep* matrix. Finally, we join in the above described manner the maximum length windows exhibiting both linear and nonlinear dependencies obtaining maximum length windows rejecting the random walk hypothesis.

### 3. The data

The data consists of daily closing prices for the top traded stocks in Bucharest Stock exchange (BSE) and BSE main index, BET. All stocks prices and the index values are denominated in the local currency (RON), the period throughout we conducted the study is from 05.01.2000 to 19.12.2003, with a number of 980 observations. From these closing prices we obtained a series of logarithmic returns using the following formula:  $r_t = \ln(p_t/p_{t-1})$  where  $p_t$  and  $p_{t-1}$  are successive closing prices.

### 4. Empirical results

The main objective of the Hinich-Patterson methodology (1995) is to see in what way the stocks prices follow a random walk during the whole sample interval. Choosing a 35 day window, we delimited a number of 28 windows in which we run the C and H tests with 0.05 and 0.01 risk levels.

From table 1 we can observe the higher frequency of windows exhibiting nonlinear dependencies compared to the linear ones. A particular case is the one of ATB (Antibiotics Iasi) where the linear correlation found in previous autocorrelation studies can be met in the great number of C significant windows also.

**Table 1 Number of windows exhibiting linear/nonlinear dependencies**

Index/ Stock	Risk level: 0,05		Risk level: 0,01	
	No. of windows with C significant	No. of windows with H significant	No. of windows with C significant	No. of windows with H significant
<b>BET</b>	1 (3,57%)	2 (7,14%)	0 (0%)	1 (3,57%)
<b>ATB</b>	7 (25%)	3 (10,71%)	4 (14,29%)	3 (10,71%)
<b>AZO</b>	2 (7,14%)	5 (17,86%)	2 (7,14%)	3 (10,71%)
<b>CMP</b>	3 (10,71%)	0 (0%)	1 (3,57%)	0 (0%)
<b>IMP</b>	2 (7,14%)	7 (25%)	0 (0%)	2 (7,14%)
<b>SIF1</b>	3 (10,71%)	2 (7,14%)	1 (3,57%)	1 (3,57%)
<b>SIF2</b>	0 (0%)	6 (21,43%)	0 (0%)	4 (14,29%)
<b>SIF3</b>	3 (10,71%)	7 (25%)	0 (0%)	5 (17,86%)
<b>SIF4</b>	1 (3,57%)	2 (7,14%)	1 (3,57%)	2 (7,14%)
<b>SIF5</b>	2 (7,14%)	5 (17,86%)	0 (0%)	2 (7,14%)
<b>TLV</b>	3 (10,71%)	5 (17,86%)	3 (10,71%)	3 (10,71%)

The results obtained are similar to those found by Lim and Hinich (2005) on 13 stock markets from Asia, namely that long periods of random walk alternates with short periods of linear and nonlinear correlation. However, the percentage of C and H significant windows is higher in the Romanian stock market compared with the Asian markets where the percentage is below the 7% level. As a conclusion, we can say that the Romanian market has a higher forecasting potential, respectively a lower degree of market efficiency in the weak form.

Modeling returns becomes difficult when the variables of the return's stochastic process change their behavior in time. Lim and Hinich (2005) consider this alternate random walk – linear/nonlinear dependencies the main cause of the relative low performance of nonlinear forecast models. A first

step in improving these models should be the exact delimitation of the sub periods rejecting the random walk hypothesis. Once these sup periods are being identified, the next step is a comparative analysis of the returns probabilities distributions.

In the case of the Bucharest Stock Exchange index (BET), running the Hinich & Patterson (1995) methodology led to the delimitation of just three windows in which the random walk hypothesis is rejected with a guarantying probability of 95%. Running our proposed methodology (i.e. applying in a successive way the H&P methodology) changes substantially the results. As we can see in table no.2, in this case there are a number of 6 windows exhibiting linear correlation and 7 windows exhibiting nonlinear correlation, the risk level being 0.05. More than that, these windows have different length, obtaining by summing them a total period of 291 trading days (30%) in the case of linear correlation and 404 days (40%) for the nonlinear correlation.

**Table 2 Windows exhibiting linear and nonlinear correlation - the modified methodology (BET index)**

	Significant C	Insignificant C	Significant H	Insignificant H
<i>No. of windows</i>	6	7	7	8
<i>Windows</i>	06/06/00 07/08/00  14/08/00 11/10/00  20/03/02 14/05/02  13/09/02 13/12/02  08/04/03 08/07/03  11/09/03 10/11/03    11/11/03 19/12/03	06/01/00 05//06/00  08/08/00 13/08/00  12/10/00 19/03/02  15/05/02 12/09/02  14/12//02 07/04/03  09/07/03 10/09/03    11/11/03 19/12/03	06/06/00 11/10/00  26/10/00 19/12//00  15/02/01 02/07/01  01/03/02 29/04/02  15/10/02 04/12/02  06/02/03 07/04/03    15/04/03 11/09/03	06/01/00 05/06/00  12/10/00 25/10/00  20/12/00 14/12/01  03/07/01 28/02/02  30/04/02 14/10/02  05/12//02 05/02/03    08/04/03 14/04/03  12/09/03 19/12/03
<b>No. of days from the sample (percentage)</b>	291 from 985 (29.54%)	694 from 985 (75.46%)	404 from 985 (41.01%)	581 from 985 (58.99%)

In order to completely identify the sub periods exhibiting linear and nonlinear correlations from the random walks ones, we will join the consecutives windows belonging to the same of these two categories in order to obtain the complete sub period in which the null hypothesis is rejected with a probability of 95%. More than that, in order to check if our methodology allows a better delimitation of the two categories sub periods we will determinate both C and H statistic on the longer now, homogenous sub periods.

**Table 3 Acceptance/rejection of the random walk hypothesis - the modified methodology**

<b>Significant C and H windows – rejection of the random walk hypothesis</b>		
Windows	C - statistic (Prob.)	H -statistic (Prob.)
06/06/00 11/10/00	9,59 (0,14)	62,61 (0,000)
15/02/01 02/07/01	4 (0,67)	53,37 (0,000)
01/03/02 14/05/02	14,2 (0,039)	6,75 (0,34)
13/09/02 13/12/02	17,55 (0,002)	19,98 (0,029)
06/02/03 10/11/03	11,89 (0,156)	98,89 (0,000)
<b>Insignificant C and H windows – acceptance of random walk hypothesis</b>		
06/01/00 05/06/00	9,94 (0,127)	12,55 (0,727)
20/12/00 14/02/01	0,36 (0,986)	1,79 (0,938)
03/0701 01/03/02	6,08 (0,64)	4,006 (0,005)
15/05/02 12/09/02	3,89 (0,67)	17,91 (0,06)
16/12/02 05/02/03	1,09 (0,835)	2,48 (0,857)
11/11/03 19/12/03	4,45 (0,41)	2,48 (0,608)

The C and H statistics with the probabilities associated to the acceptance of the random walk null hypothesis, presented in table no.3 prove that the new methodology allows a correct identification of the random walk periods. Another important result is that the long random walk periods are followed by long periods exhibiting linear and nonlinear dependencies. More exactly, from the whole sample the number of trading days in which the random walk hypothesis is rejected is 493 representing approximately 50% from the whole sample.

**Table 4 Statistics of BET index return distribution**

<b>Statistics</b>	<b>Whole sample</b>	<b>Sub periods rejecting the random walk hypothesis</b>	<b>Sub periods accepting the random walk hypothesis</b>
<b>Average</b>	0,00157	0,00135	0,00198
<b>Standard deviation</b>	0,0162	0,0183	0,0153
<b>Skewness</b>	0,223	-0,045	0,634
<b>Kurtosis</b>	10,14	10,76	6,29
<b>Jarque-Bera</b>	2102,07	1120,08	232,22

The statistics from the above table shows that the daily average return in periods accepting the random walk hypothesis is superior to those in which is rejected. On the other hand, the volatility is more powerful in the sub periods rejecting the random walk hypothesis, signaling the existence of a greater number of extreme variations. The presence of these extreme variations in sub periods rejecting the random walk hypothesis can be noticed also from skewness and kurtosis coefficients values. The returns distribution in these sub periods is more distanced from the Gaussian probability law compared to the distribution of random walk returns.

## **5. Conclusions**

The results obtained in this study are similar to those found by Lim and Hinich (2005) on 13 stock markets from Asia, namely that long periods of random walk alternates with short periods of linear and nonlinear correlation. However, the percentage of C and H significant windows is higher in the Romanian stock market compared with the Asian markets where the percentage is below the 7% level. As a conclusion, we can say that

the Romanian market has a higher forecasting potential, respectively a lower degree of market efficiency in the weak form.

The findings throw some interesting light on the ongoing debate of stock market predictability. Though the BET index returns series follow a random walk pattern for long periods of time, there were time when it does not, suggesting the potential for profitability for technical trading rules. In particular, during those periods when the market moves in a significantly non-random and dependent pattern, it is possible for investors to use a certain trading rule to exploit those detected linear and nonlinear dependencies in order to earn abnormal rates of returns.

## **Abstract**

*The Australian dollar's exchange rate (mainly in relation to the American dollar) has received a considerable attention in research and several models have been proposed to explain its trend and fluctuations. Thus, as a conclusion of this research we can say that this commodity currency very much depends on the terms of trade which in turn depend on commodity prices. The present paper is based on this conclusion and hence proposes the possibility that the Australian dollar's behavior is overwhelmingly explained by a handful of cycles of mainly harmonic frequencies. Using the principles of Fourier analysis, a simple regression provides considerable evidence about the existence of these cycles. In addition, and as important, a search into the commodity realm demonstrates that these cycles are for example related to various cycles of mining and producing minerals. If the proposition of the present paper is true, we have a very simple yet substantial explanation of the long term trend and fluctuations of the Australian dollar exchange rate and probably of exchange rates of many other commodity currencies.*

**Key words:** *Australian dollar, Fourier, cycles, minerals.*

## 1. Background

There are many factors as mentioned by many researchers that affect or could affect exchange rates in general. De Grauwe and Grimaldi [10] have pertinently summarized some of the main issues and explained why the fundamentals of exchange rates do not seem to work properly. Overall, there is some sort of puzzle in the determination of these rates. For example there is the puzzle of excess volatility according to which the volatility of the exchange rate by far exceeds the volatility of the underlying economic variables. Also, although the purchasing power parity (PPP) hypothesis was strongly suggested as explaining the behavior of exchange rates, recent research dismisses this hypothesis as being true at least for the Australian dollar [14]; or at least it qualifies it: “our estimate of the longrun elasticity of the exchange rate with respect to commodity prices is 0.939 and statistically not different from unity, which strongly supports the commodity-currency hypothesis” [13 p. 83].

However, these latter authors also remark: “although we fail to reject PPP and UIP1, so long as commodity prices are included in the cointegrating relations, note that the PPP relation is inherently difficult to capture in a study of this type, for domestic price developments will not be uninfluenced by substantial shifts in domestic monetary and fiscal policies, and these are not explicitly accounted for in our model” [13, p. 96]. Masih and Masih [20] have produced some interesting results that probably support our own results indirectly. They showed that the PPP hypothesis is still valid for the Australian dollar because they used fractional cointegration<sup>2</sup>, and hence low frequency dynamics.

Thus, the Australian dollar is one of these commodity currencies (see for example [8]) that are heavily influenced by commodity prices. Usually these currencies are those of small economically defined countries (hence not being able to influence the world economy and to a considerable extent commodity prices). Consequently “the A\$ appreciates (depreciates) in both nominal and real terms when the prices of certain commodities exported by Australia, e.g. coal, metals, and other primary industrial materials, rise (fall) in international markets’ [13, p. 82].

---

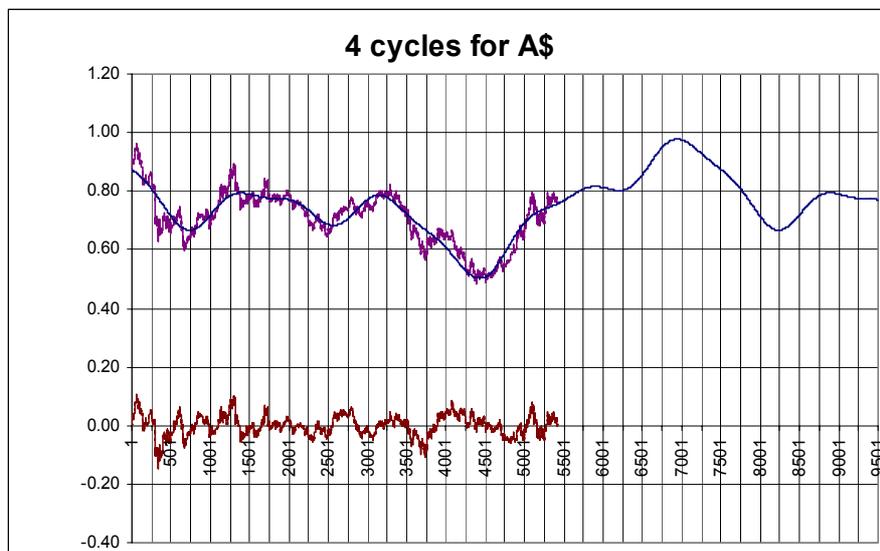

1 UIP stands for uncovered interest parity.

2 However, as these authors admit, cointegration is only a necessary condition for long-run PPP but not a sufficient one.

## 2. Commodity prices cycle and economic cycles

Following this brief background, it is logical to further investigate the relationship between the exchange rate fluctuations and the commodity prices fluctuations<sup>3</sup>. In this paper we will take an indirect approach: we must first see what sort of fluctuations and trends exist in determining commodity prices. Then we must investigate some of the reasons for these fluctuations and trends. Perhaps there are some hidden cycles inside the fluctuations term of commodity prices. If our suspicions are correct then we can examine the Australian dollar series to see whether these cycles constitute a very important component of its long term fluctuations. The quantitative method to be used for this examination is the Fourier analysis of time series.

**Figure 1** Upper diagram: raw data and fitted line; lower diagram: residuals of the fitted model.

Source: graph constructed by the author, based on data of RBA official internet site [25]. The A\$ is expressed in terms of US\$. Note: for the fitted line and residuals see text further below.

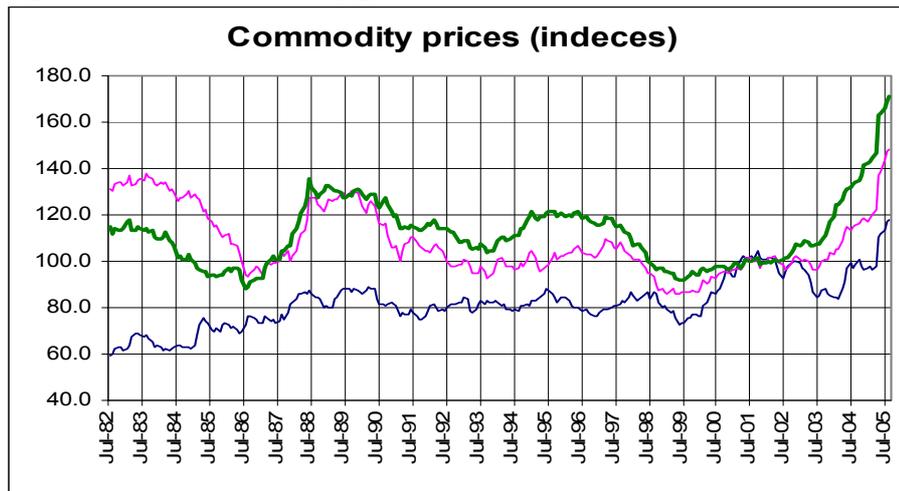

A visual examination of the commodity price and exchange rate series<sup>4</sup> (see Figures 1 and 2) show that there seem to be some noticeable

<sup>3</sup> When we refer to commodity prices we mean rural and mineral commodities primarily. However, industrial commodity prices should not and cannot be absent in a more comprehensive analysis. This is even more pertinent if we remark that recently in the last 40 years or so the peaks (in 1955, 1965, 1973, 1979, 1988, and 1995) and troughs of industrial commodity prices seem to coincide with the prices of all other commodity prices [5].

<sup>4</sup> The Australian dollar started floating in December 12, 1983. Before that from November 1976 to December 1983 it was set in terms of the trade weighted index (TWI) under a

peaks and troughs approximately during the same years for both series. Cashin *et al* [4] have shown that the Australian currency (as well as 18 other currencies) is clearly cointegrated with commodity prices and that the PPP model is subsequently a weak model for countries like Australia<sup>5</sup>. Karfakis and Phipps [16, p. 272] have similarly concluded that “movements in the terms of trade account for much of the long-run variation in the exchange rate” of the Australian dollar (thus having already considered changes in relative price levels and interest rate differentials).

**Figure 2 Commodity prices**

Source of data: RBA internet site [25]. Note: the upper graph is in terms of US dollars, the middle graph in terms of SDRs and the lower graph in terms of Australian dollars.

If our hypothesis of some predetermined cycles is correct then we must search for the reasons of this predetermination. Here in this paper we suggest that these reasons are related to the mining and production cycles of minerals and perhaps other commodities that Australia exports (such as sugar and wool). An indication of how important is the Australian component of minerals in the world production we can cite Humphreys [15, p. 5]: “Australia has managed to increase its share of world iron ore production to 20% from 13%, its share of nickel mine production to 17% from 8%, its share of copper mine production to 7% from 4%, and its share of zinc mine production to 17% from 13%”. Overall, exports of rural and non-rural commodities as a percentage of total exports has been about 60% (RBA site). The main commodities having the largest percentage in the construction of

---

crawling peg system. Up to November 1971 it was fixed to sterling, then to the US dollar up to September 1974, and then to the TWI (see [23]).

<sup>5</sup> These authors examine the two series in real terms.

the commodity price index in Australia are: gold (16.3%), coking coal (13.8%), beef and veal (9.4%), steaming coal (9.3%), iron ore (9.3%), wool (8.6%), aluminium (8.6%), and so on [24].

A report by Western Mining Corporation (WMC) [26, p.31] finds that the average delay between discovery and time startup for Australian (also for Canadian and American) gold firms is 5.4 years, whereas it is 8.3 years for other countries. For copper, Graedel *et al* [12, p. 17] report all the principal uses of copper as percentage of total and the corresponding residence time in each use. Hence the weighted average of this time is about 35 years (author's calculations). Cortazar and Casassus [9] have shown that the optimal timing of a mine expansion is intrinsically related to changes in copper prices via the investment process. Achireko and Ansong [1] have demonstrated that gold prices are required in mine valuations. The relationship between supply and demand as well as inventories in mineral production has been well evidenced (e.g. [17]).

Following the above discussion we can hypothesize that the cycles we need to consider are those of commodity prices *per se* (average period length about 7-8 years) and those of economic business cycles: an average period length of about 3-4, 15-16 and 30-32 years. Cashin *et al* [6, pp. 282-3] have found that most commodities have cycles of an average duration of between 6 and 8 years. In addition, it is important to stress that most commodities are cointegrated thus generating a common cycle for themselves [21, 22]. The so-called business cycle of duration 3-4 years is primarily related to production, inventories, and employment. The "Kuznets" cycles of about 15-16 years and 29-30 years are more linked with the investment process (cf. for example a good paper on all these cycles by Forrester, [11]). In our context these three economic cycles are intrinsically related with the commodity prices cycle of about 7-8 years, since also these prices are a consequence of or a reason for the existence of these economic cycles<sup>6</sup>. All four cycles are generating each other through the "mysterious" properties of harmonics<sup>7</sup>.

As we can see in figure 3 the 4 harmonics (see below for these results) produce consecutive waves with varying height (amplitude) and phase. The sequence from 1988 to 2013 of these waves is as follows (in

---

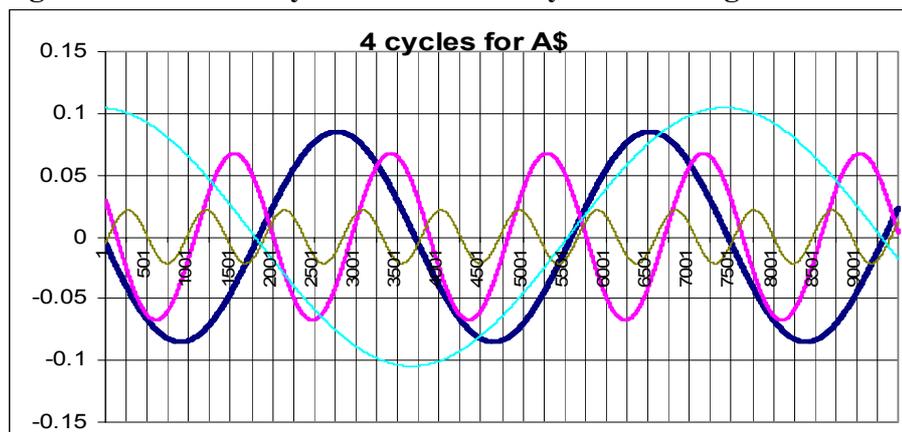

<sup>6</sup> However, as Cashin *et al* [6, p. 292] have remarked, "cycles in economic activity alone do not drive the evolution of commodity prices, and that other factors, particularly supply conditions in individual commodity markets, are likely to be a key determinant of cycles in commodity prices".

<sup>7</sup> A detailed analysis of all these issues is of course out of the scope of this paper which primarily sets the basis via some propositions for more research.

parenthesis is the corresponding period of the cycle): 9/88 (3.75); 1/90 (7.5); 6/92 (3.75); 11/94 (15); 2/96 (3.75); 6/97 (7.5); 10/99 (3.75); 7/03 (3.75); 11/04 (7.5); 5/07 (3.75); 11/09 (15); 2/11 (3.75); 5/12 (7.5); 6/13 (30). This succession of waves of various strength and length is the reason for 85% of fluctuations in the floating exchange rate of Australian dollar (as quantitatively determined below). It is also interesting to note that in 2001 all cycles were found to be at their respective troughs and hence we had a substantial depreciation of the currency.

In addition it is important to stress that our model predicts quite accurately the peaks of economic cycles as analyzed by other scholars. For example, Bajada [2] suggested that significant peaks took place in 1989/90 and 1994/95; these dates coincide with our peaks of the 7.5 year and 15 year waves (see above). Finally, it might be possible to construct a new theory as the mechanics of the links between all four harmonic cycles: thus, 2 consecutive peaks of the 3.75 year business cycle in 11/84 and 9/88 generated the commodity prices cycle (of 7.5 years period) peak of 1/90; the latter in conjunction with another business cycle peak in 6/92 generated the longer investment-caused cycle (of 15 years period) peak in 11/94, and so on.

**Figure 3 The 4 cycles determined by the OLS regression**

Notes: the higher the amplitude the higher the period of the cycle. Thus, the first peak of the 15 year cycle occurs on the 1510<sup>th</sup> day approximately or 1/1990. Every 250 days constitute on year on the x-axis. Thus the 5000<sup>th</sup> datum is in July 2003.

---

8 Layton [18] supports this date of 1989/90 with his analysis.

### 3. Econometric evidence

Fourier analysis is useful in many ways. In this paper this analysis will be used for 2 purposes. First, it will indicate econometrically how good is the assumption that the A\$ can be overwhelmingly approximated by 4 cycles harmonic to each other. And second, it will indicate whether the cycles suggested in the discussion above can be confirmed through the calculation of spectra.

A few important points can summarize the Fourier analysis (see [7]; [3]) as used here. A time series  $f(t)$  can be fully represented by the sum of sinusoidal functions for all harmonic frequencies. Thus it becomes significant for our paper that if we can isolate only a few such sinusoidal functions that mostly explain the initial series  $f(t)$  (for example a high  $R^2$  will indicate how important these cycles are) then we can provide evidence that our preliminary theoretical discussion contains some grains of truth. More precisely mathematically we can summarize the salient points of Fourier functions as follows:

$$f(t) = A + C \cos(\omega_0 t + \theta) = A + B_1 \cos(\omega_0 t) + B_2 \sin(\omega_0 t) \quad (1)$$

where  $C$  is the amplitude,  $\omega_0$  is the angular frequency (related to frequency  $f$  as in cycles per time by  $\omega_0 = 2\pi f$ ; and  $f = 1/T$ , where  $T$  is the period of the cycle); and  $\theta$  is the phase shift. When equation (1) is expressed as a function of both cosine and sine, and estimated in an ordinary least squares (OLS) regression the amplitude and phase shift, if needed, can be indirectly calculated as a function of  $B_1$  and  $B_2$ . If we want to include more than one angular frequency, as in harmonics we can have multiples of  $\omega_0$  as in  $2\omega_0$  or  $3\omega_0$ , etc. and run a multiple regression with as many independent variables as the number of harmonics plus the fundamental frequency  $\omega_0$ .

The suggested best fit (see below the criteria of choosing the “best” fit) Fourier approximation of the Australian dollar by 4 harmonics is the one that uses as fundamental frequency 3.75 years (or 250 active days per year), hence the harmonics being 7.5 years, 15 years and 30 years. Figure 1 shows the raw data, the fitted 4-cycle sinusoidal fitted curve and predictions for the next 16 years<sup>9</sup>.

---

<sup>9</sup> It is well known that what we can do on the frequency domain we can also do on the time domain. Using the 140 quarters of real exchange rate from 1970 to 2005, similar results are obtained; the best fit is the regression that has as independent lagged variables those with 16, 31, 32, 64, and 128 quarters as significant lags (thus corresponding to 4, 8, 16, and 32 years of periods). To correct such a model for serial correlation, it was re-run by using the

The criteria for choosing the above fitted curve are the following:

A] The *a priori* justification on economic and econometric grounds (the commodity prices cycle; the commodity production cycles; the general economic cycles; the “mysterious” connections of harmonics).

B] The  $R^2$  of Fourier regressions as shown in equation (1). See Table 1 below.

**Table 1 Comparative data for 4 similar periods to 16 years**

Period of cycle	14	15	16	17	18
$R^2$	0.78	0.86	0.88	0.83	0.80
Constant	0.725	0.751	0.790	0.862	0.966
When the 4 cycles cancel each other	0.83	0.74	0.67	0.51	0.34
Predictions (June, July, August, September 2005)	Under-estimating	Minimal error (almost 0% to 1% on average each month)	Over-estimating	Over-estimating even more	Over-estimating even more
Maximum peak at about 2010-2013	0.9 (in 2010)	0.98	1.1	1.3	1.6 (in 2013)

Note: the average of the whole sample from December 12, 1983 to May 26, 2005 is 0.707.

C] The out of sample performance of the model, both short run and long run. The short run is also a comparison of actual data with predicted data during the period June to September 2005. The results of this comparison are shown in Table 1. In the long run, it is expected that the Australian dollar will only approach the absolute equality of 1A\$ to 1US\$ but will not surpass it<sup>10</sup>.

D] The value of the constant in the regression, again shown in Table 1. It is expected that this constant should not be too far away from the average over the whole set of data which is 0.707.

E] The significance of the phase between the 4 harmonic cycles (a hint on the differences of phase and some interpretation was given above).

F] The behavior of the residuals of regressions. The standard diagnostic tests of serial correlation, functional form, normality, and heteroscedasticity for the ordinary least squares (OLS) regression are as expected not good because the used model of the four sinusoidal independent variables of long cycles has ignored the very short influence of daily and weekly cycles. This

---

Cochrane-Orcutt method (as autoregressive of order 1); the coefficients remained approximately the same with no serial correlation and the  $R^2$  remained high at about 0.90.

<sup>10</sup> This is of course a “gut feeling”.

can easily be fixed with the re-estimation of the model according to the Cochrane-Orcutt procedure. Effectively lags up to 3-6 days<sup>11</sup> completely eliminated the serial correlation and other related problems. In addition, some of the errors (when the daily and weekly cycles are not included in the original OLS model this becomes even more apparent) seem to well coincide with some ad hoc situations and events, and policy measures. For example, according to Makin [19, p. 336], “intervention was highest in July 1986 to prevent further depreciation by buying Australian dollars, but was also high in February 1989 to stem appreciation”. These two interventions agree with the magnitude and sign of the residuals of our model (negative during 1986 and positive during 1989). A detailed analysis of the residuals is nonetheless out of the scope of this paper.

G] The suggestion of cycles according to spectra. As already mentioned spectral analysis (based on Fourier analysis) can also be used to detect cycles of a time series. In order to have a longer span of time than the 22 years of daily floating Australian dollar, its real exchange rate<sup>12</sup> is used instead for which data are available on a quarterly basis from June 1970 to June 2005 (N=140). The results are quite clear: significant peaks of the spectrum of this series are found for periods of about 30 and 15 quarters allowing for a reasonable window and according to all three approximations (“Bartlett”, “Tukey”, and “Parzen”). Peaks of periods of 60 and 120 quarters are also detected but these periods are only found if a larger window of the spectrum is used and hence their significance is less strong given the limited number of observations.

#### 4. Conclusions

The review of the relevant literature has shown that most standard theories of the determination of exchange rates have failed to explain most issues concerning these rates. It seems that there is now a relative consensus that some sort of non-linear inherent tendency could be the main force of driving trends and fluctuation of exchange rates. In particular the currencies

---

<sup>11</sup> The original daily data were recalculated as 2-day averages thus reducing the original number of data from 5422 to 2711. The ensuing regressions with 2711 data produced as expected similar results and the lags in the autoregressive Cochrane-Orcutt scheme needed lags up to three 2-day data to eliminate serial correlation and related problems.

<sup>12</sup> Thus the use of real exchange rates provides similar results to those found for nominal exchange rates. This is not a surprising outcome for a commodity currency like the Australian dollar which depends on world trade for its determination (the real exchange rate is based on a real trade weighted index). It is also worth noting that since the real exchange rate goes further back from December 1983 (the date of floating the A\$)-thus we have the period June 1970 to June 2005- and since the same cycles exist for this more extended period of time, it is possible to assert that the PPP hypothesis might be to some extent valid.

that are now called commodity currencies, such as the Australian and Canadian dollars are heavily influenced by commodity prices. All this has led the author to investigate the possibility that the Australian dollar is primarily determined by a handful of harmonic cycles which in turn are based on the commodity prices cycles, commodity production cycles and in general on economic cycles that are suspected to be influenced by the commodity world.

Hence the proper econometric approach to this investigation was judged to be the well-known Fourier analysis according to which any time series can be represented by the sum of sinusoidal functions. The application of such analysis to the trend and fluctuations of this currency has produced some very interesting results. The four harmonic cycles used in this respect (3.75, 7.5, 15, and 30 years) explain 85% of the everyday changes of this commodity currency, the remaining being attributed to *ad hoc* situations, policy measures, and so on. These conclusions if true (many people would be very skeptical of such amazing results) have far reaching implications at least for commodity currencies.

First, more investigations should concentrate on the underlying cycles of commodity prices, commodity production cycles (e.g. mining ones) in order to shed more light on the alleged relationship between all aspects of commodities and national currencies. In addition, economic cycles in general which have been neglected in the last 30 years or so should be further reconsidered. Second, we have to reassess what we mean by trend and stationarity in time series; for in our case the remaining 15% of unexplained variance seems to fluctuate around the 4-cycle “trend” as determined in this paper. Third, and as a consequence of the second implication, economic policy is rather powerless in strongly influencing the exchange rate in its floating state.

Fourth, theories such as the PPP version does not hold true at least in its traditional way of integer cointegration. Both this paper and [20] seem to support the idea that once we include low frequency dynamics and hence long period cycles the Australian dollar reverts back to its “mean”. Fifth and probably most important for many speculators, it is possible to predict quite accurately the long run behavior of the Australian dollar. Thus, it is recommended that for the time being let us hold our Australian dollars until about 2012 (the highest peak of the A\$ appreciation); in that year we must start buying American dollars again.

## **Abstract**

*This paper reports the results of various tests of the day of the week effects using daily observations on the National 30 Index for Turkish stock exchange and interbank rates for the period January 3, 1997 and July 23, 2001. It is also searched whether day of the week effect be explained by interbank rates or not. While significant evidence of day of the week effect is reported and tried to explain its reasons in literature, there is no significant explanation about it. The paper reports a significant day of the week effects for both market and investors can beat the markets and earn excess returns by using an active trading strategy than a simple buy and hold strategy. It's also could be said day of the week effect can be explained by interbank rates for an emerging market, namely Turkey.*

**Keywords:** *Day of the Week Effects, Market Anomalies, Turkish Stock Market, Interbank Market, Kruskal Wallis.*

# 1. Introduction

Efficient Market Hypothesis (EMH) says that in an efficient market no one can beat the market systematically because security prices fully reflect all available information<sup>1</sup>. This means, in inefficient market investors can use a strategy to beat the market. Hence, Day of the Week Effect anomaly has an important implication in finance. According to day of the week researchers, holding period returns are lower on Monday than on other days of the week<sup>2,3</sup>.

Vast number of studies provides evidence for day of the week effect and seasonal anomalies in the literature. Defusco<sup>4</sup> have examined returns for U.S. firms in the five-day interval surrounding a board meeting date and found that a firm's Monday return in that interval is more likely to be negative than other Monday returns. Cornell<sup>5</sup> has investigated whether cash and futures markets have some seasonal pattern or not for S&P500 Index. He has reported that weekly pattern of returns was observed in the cash market but no similar pattern for the S&P500 futures. Ayadi<sup>6</sup> has reported that there is no seasonality in the distribution of monthly stock returns in Nigeria, Zimbabwe and Ghanaian market. Kato<sup>7</sup> has reported low Tuesday and high Wednesday returns for the Japanese stock returns. Gibbons and Hess<sup>8</sup> have reported strong and persistent negative mean returns on Mondays for the S&P500 and the value-and-equal weighted portfolios. Athanassakos and

Robinson<sup>9</sup> have tested day of the week effect for Toronto Stock Exchange and they have reported that they found evidence for a strong and statistically significant negative Tuesday effect. Balaban<sup>10</sup> has investigated daily anomalies for Turkish Stock Market and reported that significant day of the week effect for the Turkish market. Metin and et al.<sup>11</sup> have examined the weak form efficiency of Istanbul Stock Exchange (ISE) by using random walk test and the day of the week effect. They have used data January 4, 1988 to December 27, 1996. They have reported Friday and Monday effect but Monday effect was not statistically significant. Bildik<sup>12</sup> has investigated the day of the week effect in overnight interest rates in interbank market, overnight interest rates in interest rates of the Istanbul Stock Exchange (ISE) and daily closing values of the Istanbul Stock Exchange's Composite Index. The researcher has reported that there is no significant difference between the repo rates occurred in the ISE repo Market and interest rates in Interbank Market. He also reported overnight interest rates decrease on Wednesdays and increase on Mondays relative to previous days. In stock market, he has found pattern of low or negative returns over the first part of the week (Monday through Tuesday) and high and positive returns over the second part of the week (Wednesday through Friday).

This study's main aim is to provide further international evidence for the presence of the day of the week effect in Turkish stock exchange and interbank rates market. Second, we try to find whether the day of the week effect be explained by interbank rates or not.

The remainder of the paper is structured as follows: Section I introduces some evidence for day of the effect anomaly. Section II explains data structure and methodology which is followed. In section III we gave the empirical results where Section IV concludes.

## 2. Data and methodology

This study is conducted using data from the Central Bank of Turkey database. The first one of these data sets includes daily average values of the overnight interest rates, which are determined in the Interbank Money Market of the Central Bank of Turkey. The second data set consists of daily closing values of the Istanbul Stock Exchange's National 30 Index.

Daily observations of the ISE National 30 Index are employed to investigate the day of the week effect. ISE National 30 Index includes Turkish blue-chip shares. ISE National 30 Index is composed of National Market companies except investment trusts and will also be used for trading in the Derivatives Market that will start trading soon. The constituent 30 companies are selected on the basis of pre-determined criteria directed for the companies to be included in the indices. The data includes daily closing prices and ranges between January 3, 1997 and July 23, 2001. Daily returns on the ISE National 30 Index that amount to 1113 observations are used. We have excluded extreme four daily interest rate returns (similar to Bildik's paper) and observations for 20-23 February 2001, which have been effected by a severe economic crisis where daily interest rates return jumped to 4018.58.

We have used overnight interest rates instead of ISE repo market variables which have no significant differences between them<sup>13</sup>. Data set consists of the daily return of the overnight interest rates which are determined in the Interbank Market of the Central Bank of Turkey (IMM) for the period January 3, 1997 to July 23, 2001. Data has provided from the Central Bank of Turkey database. Daily returns of the overnight interest rates that amount to 1.138 observations are calculated as follows:

$$R_{t1} = V_t / 365 \quad (1)$$

Where  $V_t$ , and  $R_{t1}$  denote the overnight interest rate on  $t$  and overnight interest rate return, respectively.

ISE National 30 Index return observations are calculated as follows:

$$R_{t1} = (V_t - V_{t-1}) / V_{t-1} \quad (2)$$

Where  $V_t$ ,  $V_{t-1}$  and  $R_{t1}$  denote the daily closed ISE National 30 Index variables on  $t$  and  $t-1$ , and daily return on  $t1$ , respectively.

---

<sup>13</sup> Bildik, 1999.

If we have reason to believe that the returns are not normally distributed, we can use a non-parametric test to evaluate the result. To avoid the strong assumption of a normal distribution, we have used Kruskal-Wallis Test (KW)<sup>14</sup> which is a non-parametric test. The Kruskal-Wallis Test is a rank-sum test that serves to test the assumption that  $k$  independent random samples come from identical populations and in particular that the null hypothesis  $\mu_1 = \mu_2 = \dots = \mu_k$ , against the alternative that these means are not all equal, Kruskal Wallis Test has the following assumptions: (1) The variable of interest is continuous (not discrete). The measurement scale is at least ordinal, (2) The probability distributions of the populations are identical, except for location. Hence, we still require that the population variances are equal, (3) The groups are independent, (4) All groups are simple random samples from their respective populations. Each individual in the population has an equal probability of being selected in the sample.

### 3. Empirical Results

If we consider Table 1 we can clearly see the existence of day of the week effect anomaly in ISE National 30 Index. In full period, Monday has the lowest mean (-0.0019) and the highest mean is observed on Friday (0.0072). The daily average return for the whole period is 0.003118. In a normal distribution the average mean and the average median are not very far apart each other and the average skewness of the distribution is close to zero<sup>15</sup>.

**Table 1. Descriptive Statistics for ISE National 30 Index**

	Average Return	MONDAY Return	TUESDAY Return	WEDNESDAY Return	THURSDAY Return	FRIDAY Return
Number of observations	1113	223	225	222	223	220
Mean (Return)	.003118	-.0019	.0018	.0029	.0056	.0072
Median	.0011	-.0044	-.0005	.0018	.0048	.0037
Std. Deviation	.039	.0435	.0373	.0393	.0392	.0364
Skewness	.262*	.417	.919	-.0194	-.318	.0756
Kurtosis	2.687	1.564	3.911	4.447	1.239	3.585
Jargua-Bera	341.87* 0.00					

Notes: \* Sinificiant at  $\alpha= 1\%, 5\%, 10\%$

Sources: *Central Bank of Turkey database.*

The normal distribution is symetric around the mean; hence the median and the mode are both equal to the mean. The median (because of observing more than one mode, it is not being given mode value) value is 0.0011 and not equal to the mean (0.003118) in full period and all days of the week. Therefore we observe significant skewness. Standard deviation as a measure of risk is 0.039 for whole period. The lowest standard deviation value is on Friday (0.0364) while the highest value on Monday (0.0435). Kurtosis value is less than 3 in most periods and distribution is kurtic. Series is also skewed for all periods which the values are different from 0. If we consider Jargua-Bera test statistics (341.87 and p: 0.00) we can say that return series have a non-normal distribution for full period and days of the week.

**Table 2. T Test Results for ISE 30 Index**

INTEREST	N	Mean	Std. Deviation
MONDAY	$\geq .00$	96	.0352
	$< .00$	127	-.0299

Sources: *Central Bank of Turkey database.*

If we compare positive and negative returns (mean) of the days, we observed Mondays and Tuesdays number of negative returns are larger than theirs positive returns where other days number of positive returns larger than theirs number of negative returns. However, absolute values of negative and positive returns of Mondays are larger than absolute values of negative and positive returns of other days. This result also supports Table 1 results that returns and standard deviations of Mondays are larger than other days.

**Table 3. Kruskal-Wallis Test for ISE 30 Index**

Group	N	Ave. Rank	Chi-Square	Asymp. Sig.
1	223	501.31	12.380	.015
2	225	538.89		
3	222	564.09		
4	223	591.33		
5	220	590.01		
Overall	1113	501.31		

Sources: Central Bank of Turkey database.

As illustrated in Table 3. KW test statistic value is (12.380) and has p value (0.015). We have failed to accept the null hypothesis so, those five days returns are all equal. Kruskal Wallis Test conforms to the descriptive statistics that there is a significant day of the week effect.

After we determined that there are differences between days of the week returns, we applied Mann-Whitney U test to determine which day returns have differences.

**Table 4. Mann Whitney U Test for ISE 30 Index**

Groups	N	Mean Rank	Mann-Whitney U	Z	P*
Monday-Wednesday	223	210.63	21995.00	-2.033	.042
	222	235.42			
Monday-Thursday	223	206.37	21044.00	-2.807	.005
	223	240.63			
Monday-Friday	223	204.04	20526.00	-2.972	.003
	220	240.20			

Source: Central Bank of Turkey database.

\*:  $p \leq 0.05$ , There is significant difference.

$p \leq 0.01$ , There is important significant difference

As could be seen in Table 4, we found significant differences between Monday and Wednesday and Thursday returns. There are no significant differences between other days of the week.

The descriptive statistics results are given in Table 5 and Table 6 and results indicate that series is not a normal distribution and leptokurtic.

**Table 5. Descriptives Statistics for Interbank Rates**

	Average Return	MONDAY Return	TUESDAY Return	WEDNESDAY Return	THURSDAY Return	FRIDAY Return
<b>Number of observations</b>	1138	229	228	227	227	227
<b>Mean (Return)</b>	.1855492	.1890	.1842	.1827	.1824	.1893
<b>Mode</b>	.172	.1726	.172	.172	.172	.172

Notes: \* Significant at  $\alpha=1\%$ ,  $5\%$ ,  $10\%$

Source: Central Bank of Turkey database.

In full period, as could be seen in Table 5 all days of the returns (mean) are almost equal. So, there could be no significant difference between them. The daily average return (mean) of the whole period is 0.1855. The median and the mode values are 0.196 and 0.172, respectively and not equal to the mean (0.1855) in full period and all days of the week. Standard deviation as a measure of risk is 0.1378 for whole period. The lowest standard deviation value is in Wednesday (0.054) while the highest value in Tuesday (0.3678).

The average skewness of the distribution is not equal to zero (12.573) and kurtosis value is larger than 3 (179.275) and distribution is leptokurtic for most days of the week. We can say that series has not a normal distribution as indicated by the J-B test statistics (3644014,  $p=0$ ).

**Table 7. T Test Results for Interbank Rates**

INTEREST		N	Mean	Std. Deviation
RETURN	>=,18554929	710	.2187	.1184
	<,18554929	428	.1305	.0376
MONDAY	>=,18554929	146	.2229	.1609
	<,18554929	83	.1294	.037
TUESDAY	>=,18554929	142	.2164	.072
	<,18554929	86	.1311	.037
WEDNESDAY	>=,18554929	144	.2134	.035
	<,18554929	83	.1293	.038
THURSDAY	>=,18554929	139	.2151	.059
	<,18554929	88	.1308	.039

	<,18554929	88	.1318	.037

Sources: Central Bank of Turkey database.

As it could be seen in Table 7, when for the research period as whole returns which are larger than average are more frequent than returns which are lower than average.

**Table 8. Kruskal-Wallis Test for Interbank Rates**

Group	N	Mean. Rank	Chi-Square	p
1	229	576.39	.532	.970
2	228	561.11		
3	227	573.34		
4	227	559.89		
5	227	571.80		
Overall	1138	576.39		

Sources: Central Bank of Turkey database.

KW test statistic is (0.532) and has p value (0.970) so; we accepted the null hypothesis, which says returns are equal for all days.

**Table 9. Returns for ISE 30 and Interbank Returns**

	Monday	Tuesday	Wednesday	Thursday	Friday
ISE 30 Index Returns	-.0019	.0018	.0029	.0056	.0072
Interbank Returns	.1890	.1842	.1827	.1824	.1893

As could be seen in Table 9, Friday has the highest return for both ISE National 30 Index and Interbank rates. So, investors should be indifference between interest and stock exchange. Because of this we could not explain the day of the week effect of the ISE National 30 Index with using interest rates but we can implement an investment strategy with using this anomaly.

We would sell ISE National 30 Index on Fridays. Because of T+2 pay system we get money on Mondays. Then we invest our money to repo (Interbank) for two days and also give a buy order ISE National 30 Index. Wednesday mornings we get our money from repo and pay to ISE National 30 Index. Then wait till Friday and sell ISE National 30 Index again.

**Table 10. Some Trading Strategies**

Strategy 1 (%)	Strategy 2 (%)	Strategy 3 (%)
0.042	2.04	6.12

Strategy 1: Buy and hold for ISE National 30 Index

Strategy 2: Buy on Monday and sell on Friday satrategy for ISE National 30 Index

Strategy 3: Sell ISE National 30 Index on Fridays. On Mondays get money from ISE National 30 Index and invest in repo during Monday and Tuesdays where give a buy order at the same time (Monday) to ISE National 30 Index. On Wednesdays get money from repo and pay to ISE National 30 Index. Then wait till Friday and sell ISE National 30 Index again.

#### **4. Conclusion**

This paper presents evidence for the existince of the day of the week effect for Turkish stock returns namely ISE National 30 Index. A daily pattern in stock market returns is observed for ISE National 30 Index.

Our results support to the previous literature<sup>16;17</sup> Mondays have the lowest return for ISE National 30 Index and Fridays has the highest return. Low and negative returns are observed on Mondays and getting increase through Friday. Our study also supports to Bildik's (1999) results who stresses low or negative returns over the first part of the week (Monday

---

<sup>16</sup> Muradoglu and Humayun, 2002.

<sup>17</sup> Bildik, 1999.

through Tuesday) and high and positive returns over the second part of the week (Wednesday through Friday). In our results the lowest standard deviation value is on Friday (0.0364) while the highest value on Monday (0.0435) which is also support Bildik's results.

In our paper, in interbank market there is no significant differences between days return where Bildik reports Wednesdays and Mondays, respectively. So we can not claim that there is a pattern in interbank market. The lowest standard deviation value is in Wednesday (0.054) while the highest value in Tuesday (0.3678) where in Bildik's (1999) results are Wednesday and, Friday respectively.

So, the weak form of the efficient market hypothesis does not hold for ISE National 30 Index. Because of the existence of the day of the week effect for ISE National 30 Index, investors could implement an active trading strategy which is based on this anomaly, and they could earn 6.12% return. This strategy is more good than satrategy 1 and 2.

## Abstract

*This paper studies the service quality and relating service quality to satisfaction and subsequent behavior after purchase. There are three stages of model testing in this paper. The first stage was to test the service quality models for its relationship with satisfaction. The second stage was to examine the relationship between satisfaction and word-of-mouth referrals and also re-purchase intentions. The third stage was to look at the moderating effect of warrantee on satisfaction and word-of-mouth referrals and also re-purchase intentions. This research lingers on the perceptions of Malaysians toward the banking institutions in Malaysia using a data sample collected from all the 15 states of Malaysia. Building on a synthesis of the extant literature on service quality measurement, this article identifies the underlying reason why dissatisfied customers would still patronage an organization.*

**Keywords:** *Service quality, satisfaction, word-of-mouth referrals, re-purchases intentions, and warrantee*

## **1. Introduction**

Service quality measurement has been discussed over the past few decades but there is no conclusion among researchers and academicians as to which measurement is the best to measure service quality. Every measurement scales seem to have their own strengths and weaknesses. In this paper, I will re-visit the SERVQUAL model that has been developed by Parasuraman et al. (1988) and the SERVPERF model that was developed by Cronin et al. (1992) to see its applicability in a developing country, such as Malaysia. All the models (SERVQUAL, weighted SERVQUAL, SERVPERF and weighted SERVPERF) will be compared by looking at the perceptions of Malaysians toward the service quality rendered by the banking institutions. It will also look at the moderating effect such as warrantee that might be the main contributor towards the unresolved issue why dissatisfied customers still remain with their current banks.

## **2. Quality Standard**

Many academicians give different definition to quality. Kotler et al. (1969) note that customer satisfaction can be related to value and prices whereas service quality generally does not depend on prices (Anderson et al., 1994). Quality should be accordance to the needs and expectations of the customers. Customers' expectations are the true standard for judging service quality and not the policy of the bank or the management of the bank (Berry et al., 1991). Parasuraman et al. (1994) point out that customers expect service companies to do what they are supposed to do (fundamentals), not fanciness; performance and not empty promises. Defining customer needs in the service industries is more complex compared to the manufacturing because the customers are involved in the production process. The same concept applies to some other researchers.

Quality is how the offer of the bank gains uniqueness and value in the eyes of the customers and it is both the act of making the offer different and its evaluation by customers (Christopher et al., 1994). According to Berry et al. (1988), only the customers know that competing organizations that provide the same types of services do not provide the same quality of service. Quality can be used to operationalise utility, that is satisfaction (Brady & Cronin, 2001; Perreault et al., 1976). According to Dabholkar, Shepherd & Thorpe (2000), quality leads to satisfaction which in turn influences purchasing behavior (Johnson & Gustafsson, 2000). Satisfaction also has a direct influence on customer loyalty (Mittal & Lassar, 1998) and repurchases intentions/behaviors (Kumar, 2002, Mittal & Kamakura, 2001).

One of the most dominant model is service quality is the SERVQUAL model which has been developed by Parasuraman et al. (1988). This model served as the best measurement for service quality till 1992 where Cronin et al. (1992) developed the performance measurement scale (SERVPERF) which becomes great threat to SERVQUAL. There are many followers to both the models and till today, there are no consensus as to which model serves as the best model to measure service quality.

This research will consider what Joseph et al. (1992) has argued. Hence SERVQUAL will be examined as well as SERVPERF since SERVPERF uses the importance measurement to look at the attributes to see how it differs in Malaysia. It will also consider whether the SERVQUAL and the SERVPERF model is only a theory of the west or can be applied throughout the whole world since most of the researches on SERVQUAL and SERVPERF are done in the European countries or America.

### **3. Word-of-mouth Referrals**

Word-of-mouth marketing tends to work very slowly and it is limited by geographical area but it is a very effective marketing mean. The value in word-of-mouth marketing is immense because of its impartiality and its credibility.

Word-of-mouth referrals are important in determining the success of a bank. Word-of-mouth marketing is the cheapest method for a bank to market itself. It needs no additional costs for advertising in local newspapers or in any media. This would lead to higher profit to the bank concerned because they can save a lot of money in attracting customers in this way.

In many situations, customers seek the opinions of others before selecting a service firm. When customers depends on someone else for information (company advertisement or literature), as opposed to customer's experiences, the beliefs they hold about what the product will do (expectations) may be important in forming satisfaction (Goode et al., 1996). Customers' referrals are better prospects since there is the screening process that has taken place in the recommender's mind compared to the advertisement.

Happy and satisfied customers are said to be willing to tell their friends or acquaintances (Zeithaml, 2000, Anderson & Mittal 2000, Johnson, Barksdale & Boles, 2003, Kennedy, Ferrell, & LeChair, 2001) about the particular bank and word-of-mouth marketing is more effective compared to advertisement because of its first hand experiences. Terry (1996) acknowledges that American research indicates that a contented customer will talk about his or her banker to five more individuals while a discontented customer will talk to fifteen other individuals expressing his or her

dissatisfaction. Therefore, how a banker deals with its customers is important because it will have great impact on the perceptions on how potential customers perceive the bank. The effect will be seen in geometrical order whether it is a positive impact or negative impact. Should it be seen as negative impact, it will have great bearings on the amount of potential customers' loss to the bank.

In the study by Tan et al. (1986) in Singapore, they found that friends' advice, neighbors and family members have great impact on the decision to patronage a certain financial institution. These findings are consistent with the Eastern culture that emphasis on the social and family ties (Sudin Haron et al., 1994).

#### **4. Warrantee**

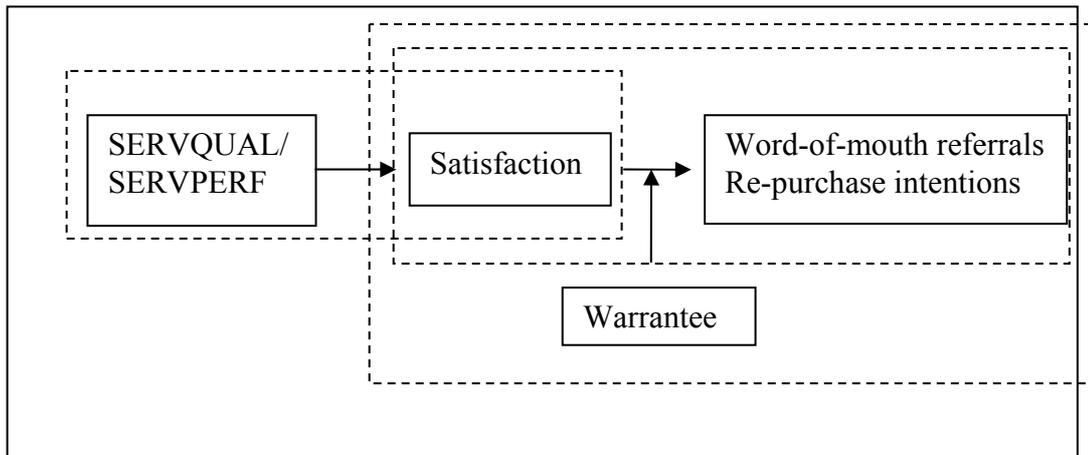

In a long-term relationship, Ravald et al. (1996) states that safety, credibility, security, continuity and etc. together will increase the trust for the supplier and these will thereby support and encourage customer loyalty. This measurement is also supported by Zeithaml et al. (1990) where they suggested a few dimensions for service quality and one of the dimensions is security, that is free from risks and doubts. While according to Avkiran (1994), the credibility factors include the ability of staff to solve problems, security and informing customers. Whereas according to Christopher et al. (1994), the most important element in the banking sectors is the security issues.

In this study, I will use the warrantee by the Malaysian government as the moderator. This is because the government warrants not all banks in Malaysia but only few selected banks. In case of anything happened, those customers at the warranted banks are guaranteed their fund from the government.

#### **5. Testing the Framework**

Figure 1 below shows the relationship used in this study. There are three parts to this study. The first is the relationship between service quality (SERVQUAL/SERVPERF) model and satisfaction, the second part is the relationship between satisfaction and word-of-mouth referrals/re-purchase intentions, and the third part is how word-of-mouth referrals or re-purchase intentions are being moderated by warrantee.

**Figure 1: Relationship of the Variables under Study**

### **5.1 Research Models and Hypothesis**

There are still no concluding statements on whether SERVQUAL or SERVPERF model is a better measurement for satisfaction. Hence, in this paper, I will look into the applicability of SERVQUAL and SERVPERF in Malaysia, a developing country since most of the studies are done in developed countries.

These first two hypotheses provide the basis for this investigation:

Hypothesis 1: SERVQUAL, weighted SERVQUAL, SERVPERF and weighted

SERVPERF do not have generic dimensions

Hypothesis 2: Service quality dimensions are positively related to satisfaction

As for the main objectives of this study, another three hypotheses would identify the questions addressed in this part of the study.

Hypothesis 3: Satisfaction is positively related to word-of-mouth referrals

Hypothesis 4: Satisfaction is positively related to re-purchase intentions

Hypothesis 5: Warrantee would moderate the relationship between the perceptions of

satisfaction and the re-purchase intentions

Hypothesis 6: Warrantee would moderates the relationship between the perceptions of

satisfaction and the word-of-mouth referrals.

With these six hypotheses, the analyses are done so that these research questions could be answered.

## **6. Sample**

The data for this study were gathered from questionnaires sent to all the 15 states in Malaysia. A total of 1025 usable questionnaires were received. Respondents were from all walks of lives ranging from age 18 years old to 60 years old. This age range has been chosen because this category falls into the most frequent users of the banking facilities. From the normality tests using the Kolmogorov-Smirnov Test for normality, all the respondents were distributed normally at  $p < .05$  level.

### **6.1 Measurements**

The measurements needed for the study are expectations and perceptions of service quality to measure customer satisfaction and the consequence behaviors after services are being rendered. The 22 expectations and performance items were taken directly from the SERVQUAL scale (Parasuraman, Zeithaml and Berry, 1988). The direct measure of service quality was based on a 7-point likert scale. As for the satisfaction item, the question is being adapted directly from Cronin et al. (1992), “overall, my satisfaction level towards XYZ is...” The measurements for warrantee re-purchase intentions and word-of-mouth referrals were constructed by the researcher after taking into consideration previous researches (refer to appendix).

Brown et al. (1993) and Carman (1990) argue that the use of disconfirmation approach as in SERVQUAL (Parasuraman et al., 1988) is not an appropriate measurement and stress that it should be changed from “strongly disagree” and “strongly agree” to “Worse than I expected” and “Better than I expected” to measure performance. Brown et al. (1993) acknowledge that this approach is a better measurement since it gives a better psychometric value and is more efficient compared to the disconfirmation paradigm.

## 7. General Model of Study

The following equation gives the general model of the study<sup>1</sup>.

Model 1

$$Y_1 = \beta_1 + \beta_i X_i + \varepsilon$$

where:

$Y_1$  = satisfaction

$\beta_i$  = parameters

$X_i$  = service quality dimensions

$\varepsilon$  = error term

## 8. Results

Using the Varimax Rotation Method, two dimensions were extracted (with eigenvalue greater than 1) as can be seen from table 1. Cross-loadings were also checked to see whether there are any items that have high correlation with other factors. As according to Hair, Anderson, Tatham and Black (1998) and Kline (1991), if an item has loadings of greater than 0.5 in one dimension and more than 0.35 in another dimension, then that particular item must be dropped from further analysis (since there exist the cross-loadings problem). Those values in italic show the existence of cross-loadings, hence, they were dropped from further analysis.

---

<sup>1</sup> Note: Service quality can be either SERVQUAL, weighted SERVQUAL, SERVPERF or weighted SERVPERF

V22	<b>0.576</b>	0.156	<b>0.562</b>	0.142	<b>0.758</b>	0.261	<b>0.677</b>	0.193
Cronbach Alpha	0.935	0.826	0.93	0.823	0.925	0.866	0.925	0.823
R <sup>2</sup>		0.267		0.258		0.246		0.243

\* those in italics have been omitted due to cross loadings

The factor analysis results as extracted only showed two dimensions for service quality. This result is not surprising since as mentioned by Carman

(1990), though SERVQUAL establishes stability, but its five dimensions are not always generic. Hence, the second hypothesis is being supported. The Cronbach Alpha ( $> 0.8$ ) demonstrates that all the measures are reliable. From the analysis between the Perceptions minus Expectations ( $P - E$ ), the result also shows that most of the respondents asked were not satisfied with the services rendered by the banking institution.

From the factor analysis, there are two dimensions extracted. Hence model 1 will be utilized to test the relationship between service quality and satisfaction. The following model was done for the SERVQUAL model. The  $R^2$  for other alternative models are reported in table 1. Since the  $R^2$  is highest for SERVQUAL model, only SERVQUAL model would be used as a base to answer hypothesis 2.

**Table 2: Regression results between service quality and satisfaction**

	B	$R^2$	Adjusted $R^2$
Service Quality	0.678**		
Tangibles	0.568**	0.267	0.266

\*\* is significant at  $p < 0.01$

From table 2, the findings show that there is a positive relationship between dimensions of service quality and satisfaction. Hence, hypothesis 2 is being supported.

### **8.1 Moderating Models**

The second model is to test the second, that is there is a positive relationship between satisfaction and word-of-mouth referrals or re-purchase intentions. On top of that, the moderating variable was also included in the model.

Model 2

$$Y_1 = \beta_1 + \beta_2 X_1 + \beta_3 Z_1 + \varepsilon$$

where:

- $Y_1$  = Word-of-mouth referrals/Re-purchase Intentions
- $\beta_i$  = Parameters
- $X_1$  = Satisfaction
- $Z_1$  = Warrantee Program
- $\varepsilon$  = Error term

In order to capture the moderating effects, model 3 is built. The model incorporates the warranty as the moderator.

Model 3

$$Y_1 = \beta_1 + \beta_2 X_1 + \beta_3 Z_1 + \beta_4 X_1 Z_1 + \varepsilon$$

where:

- $Y_1$  = Word-of-mouth referrals/Re-purchase Intentions
- $\beta_i$  = Parameters
- $X_1$  = Satisfaction
- $Z_1$  = Warranty
- $\varepsilon$  = Error term

In order to proceed with the analysis, factor analysis is run again on the moderators and subsequent behavior after purchase. Table 3 shows the results of the extraction.

**Table 3: Factor Analysis for Moderator and Subsequent Behavior after Purchase**

Items	Warrantee	Word-of-Mouth Referrals	Re-purchase Intentions
I1	<b>0.766</b>	0.325	0.234
I2	<b>0.717</b>	0.216	0.234
W1	0.250	<b>0.750</b>	0.345
W2	0.341	<b>0.777</b>	0.317
W3	0.223	<b>0.767</b>	0.298
L1	0.312	0.253	<b>0.758</b>
L2	0.130	0.294	<b>0.790</b>
L3	0.234	0.189	<b>0.870</b>
Cronbach Alpha	0.927	0.876	0.825

For table 3, out of eight items on moderators and subsequent behavior

after purchase, there are three dimensions extracted. All the dimensions show internal consistency (from the cronbach alpha reading). Thus, further analyses were run using model 2 and model 3 and the subsequent tables provide the output of the analyses.

**Table 4: Warrantee as Moderator for Satisfaction and Word-of-mouth referrals**

	Standard B Step 1	Standard B Step 2	Standard B Step 3
<b>Dependent Variable</b>			
Word-of-mouth referrals			
<b>Independent variable</b>			
Satisfaction	0.761**	0.289**	0.310**
<b>Moderating Variable</b>			
Warrantee		0.617**	0.342**
<b>Interaction Effect</b>			
Satisfaction* Warrantee			0.094**
R <sup>2</sup>	0.278	0.384	0.459
Adjusted R <sup>2</sup>	0.277	0.382	0.458
R <sup>2</sup> Change	0.277	0.106	0.075
Significant F change	0.000	0.000	0.001

Note: The value in the bracket is the t-statistics

\* is significant at  $\rho < 0.05$

\*\* is significant at  $\rho < 0.01$

**Table 5: Warrantee as Moderator for Satisfaction and Re-Purchase Intentions**

	Standard B Step 1	Standard B Step 2	Standard B Step 3
<b>Dependent Variable</b>			
Re-purchase Intentions			
<b>Independent variable</b>			
Satisfaction	0.333*	0.255**	0.468*
<b>Moderating Variable</b>			
Warrantee		0.405**	0.533**
<b>Interaction Effect</b>			
Satisfaction* Warrantee			0.045*
R <sup>2</sup>	0.281	0.324	0.446
Adjusted R <sup>2</sup>	0.280	0.323	0.445
R <sup>2</sup> Change	0.281	0.043	0.122
Significant F change	0.000	0.000	0.000

Note: The value in the bracket is the t-statistics

\* is significant at  $\rho < 0.05$

\*\* is significant at  $\rho < 0.01$

From table 4 and 5, the results show there are positive relationships between satisfaction and word-of-mouth referrals and re-purchase intentions. Therefore, hypotheses 4 and 5 are being supported. The analyses also show that there is moderating effect (warrantee) between satisfaction and word-of-mouth referrals and re-purchase intentions, hence, hypotheses 5 and 6 also being supported.

## **9. Limitations**

In this study, the limitations lie on the sampling methods. From the random samples gathered, the respondents were not screened for whether they have been using the banking services lately or not. This is because there are some customers who have not been using the banking facilities for sometime, yet they might be one of the respondents.

## **10. Discussions and Managerial Implications**

From the findings, there are few points that can be pondered upon. The first is the impact of service quality on satisfaction level. In general, service quality would definitely lead to satisfaction. But how service quality level is being justified is very vague. It depends on individuals and past experiences. In other words, individuals from different background would perceive service quality differently. Therefore, though the service quality level is good, but still there are customers who are dissatisfied and vice versa. Hence, there must be another form or ties that are able to bind the customers to the banking institutions. One of them is through warrantee.

Managers and researchers should put more emphasis on the moderating effect that will moderate the relationship between the service quality, the re-purchase intentions and word-of-mouth referrals. While there are still many customers who are dissatisfied with the current level of services, but due to these moderating effects, they will still remain with the bank and be their ambassador through the word-of-mouth referrals to others.

This is because while there are warrantees, it binds the customers strongly to that particular bank. The customers would feel safe in their transaction with the bank and would not worry in case of any mishaps that might befall. Hence, customers who put great weighs on the security will certainly patronize the same bank.

Therefore, it is suggested that bank institutions should try to seek ways to implement warrantee into their banking environment. What can be done is creating a sense of security in the eyes of customers in terms of strong financial assets if the banks are not warranted by the government. Hence, those banks that have yet to merge should seek alternatives to create strong financial assets in order to create an attractive environment for customers.

## 11. Direction for Future Research

Future research should look at other possible moderators that might moderate the relationship and bind the customers to a particular bank. Emphasis should also be made on the customers' demography to see how these different demographic categories differ in their perception towards warrantee.

## 12. Conclusion

As can be seen from the analysis, though there are customers who are not satisfied with their current bank, there still exist ties that bind them to their current bank. These ties are in the form of warrantee. From this research, it can be concluded that service quality alone does not play a very important role in determining the patronization of customers. In other words, there are other aspects that should be taken into consideration other than service quality in the process of attracting customers to certain banks.

## **Abstract**

*This paper confirms the importance of bank performance to the credit-lending channel of monetary policy in the countries of the EMU and particularly in Portugal during recent years. It uses macro and microeconomic statistical data and introduces three calculated bank-performance indicators – financing of financial assets and financial margins - into an adaptation of the Bernanke and Binder model (1988) using panel data estimations not only to demonstrate the importance of the bank lending channel, but also to analyse the effects of the calculated indicators in bank-lending growth.*

**Keywords:** *bank lending; monetary policy transmission; panel estimates; Portuguese economy.*

## 1. Introduction

This paper makes a contribution to the analysis of the role of the financial systems and the bank lending channel transmission of monetary policy in Portugal during the past decade.

This was a period of rapid growth in bank lending, with Portuguese banks undergoing radical transformations as they moved from a completely protected political environment to a situation of integration in the Single European Market's financial services and then to European Monetary Union.

The structural change arising from the adoption of the single currency and a common monetary policy has had a profound impact, not only in Portugal, but also throughout the Euro area, where the finance sector has been intensifying competition for banking services. It is exerting a profound impact on the Euro area finance sector and intensifying competition for banking services.

More efficient banking sectors are a necessary condition for the transmission of monetary policy, and the way that banks adapt lending in response to monetary policy decisions varies according to their specific characteristics.

Most of the empirical papers testing the existence of a bank lending channel for the transmission of monetary policies make use of three characteristics – size, capitalisation and liquidity – to capture bank-specific sources of heterogeneity. The results obtained for Portugal (Farinha and Marques, 2001) clearly show that only capitalisation provides the expected results, while size and liquidity do not have any special effect on bank lending.

Here we consider two macroeconomic indicators: real GDP and nominal short time interest rate and we also introduce two calculated bank performance indicators - financing of financial assets and financial margins - into an adaptation of the Bernanke and Binder's model (1988).

We use panel static fixed and random effects and Arellano-Bond dynamic panel estimations to analyse the importance of these indicators to bank lending growth. We conclude that there is evidence of the importance not only of the macroeconomic conditions but also of the considered bank performance indicators.

In the next pages of this paper, we start by presenting, in section 2, some recent contributions to the analysis of the transmission channels of monetary policy.

In section 3 we remind the radical transformations that the banking sector has undergone in Portugal during the last decade and we describe the evolution of the two calculated bank performance indicators.

Section 4 describe the simplified model that is use to explain bank lending evolution and then present and discuss obtained with some fixed effects, random effects and Arellano-Bond dynamic panel estimations.

Concluding remarks are presented in section 5.

## **2. The Bank Lending Channel Transmission of Monetary Policy**

The theory and empirical researches that study the monetary transmission process try to explain how monetary impulses affect the whole economy. They also share the view that monetary authorities (central banks) can control money market interest rates because they have the ability to control money supply.

Currently, using open market operations, central banks affect the liquidity of the whole banking system and the interest rates and prices that affect households and firms behaviour. This is described not only by the classical interest rate but also by the other transmission channels of the monetary policy.

The "credit view" of the monetary policy transmission includes five channels: the bank lending channel, the balance sheet channel, the cash flow channel, the unanticipated price level channel and the household liquidity effects (Mishkin, 2001).

The bank lending channel affects investment and residential housing through bank deposits and loans. The balance sheet, cash flow and unanticipated price level channels affect moral hazard and adverse selection and though the lending activity and the investment. Finally, the households liquidity effects concerns the financial wealth of the households and the probability of their financial distress that affects residential housing and expenditures in consumer durable goods.

So, well-developed financial systems are an important and necessary basis for ensuring that credit sectors are able to play their own particular role in economic development processes.

More efficient credit sectors are not only a necessary and important condition for the transmission of monetary policy in the Euro zone, but they are also indispensable for guaranteeing the economic benefits of the other sectors and agents that make use of financial services.

Financial institutions are also a very important channel for the transmission of monetary policy. Seen from the viewpoint of credit and lending, the level of effectiveness of monetary policy is basically determined by the imperfections of capital markets - asymmetric information and the difficulties faced by some economic agents in obtaining finance for their consumption and investment plans. Central banks control the quantity of money, but banking institutions also play an important role in the money-creation process, as well as in the mobilisation and allocation of financial resources.

The introduction of the European Monetary Union may have reduced some of the competitive advantages of local and national banks (advantages that were based on factors such as currency risk, a lack of price transparency and a better knowledge of national monetary policy), but it has also increased competition in all segments of the financial product market.

The structural changes arising from the adoption of a single currency and a common monetary policy have had a profound impact on the Euro area finance sector and are intensifying competition for banking services.

Some common trends may be identified in the context of the pressures exerted by globalisation, which affect the Euro area with particular intensity, namely a process of disintermediation, new technologies and increased competition (Belaisch et al. 2001). The adoption of a common monetary policy and a single currency has provoked a structural change: money markets have been integrated, the deregulation of financial services has considerably increased competition in the banking sector, whilst there has been an increasing integration of Euro area inter-bank markets.

Nowadays, in spite of the structural changes and the necessary concomitant adaptations to the new market and policy conditions, it is still clear that the Euro area's financial and credit systems continue to be bank-dominated and that the ECB (more precisely the European System of Central Banks and its Banking Supervision Committee) has devoted special attention to supervising banking activity and structural developments in the EU banking sector.

Despite all the changes and disintermediation, the asset structure of EU banks reflects the rapid increase in lending that has occurred since the advent of the EMU. It is a process that started before the implementation of the single currency and reflects the growing demand for credit provoked by the downward path of interest rates (especially in countries such as Portugal, where interest rates were rather high at the beginning of the 1990s and were forced to converge to the levels of other EU countries).

Recent studies for several European countries (Angeloni et al. 1995 and 2002, Baumel and Sevestre, 2000, Erhmann and Worms, 2001, Erhmann et al.

2001, Clements, et al. 2001, Farinha and Marques, 2001, Topi and Vilmunen, 2001, Gambacorta, 2001, Van Els et al., 2001, Gardener et al., 2002.) have studied the importance of European bank characteristics during these years of profound transformations.

And although the EU banking sector has been considered as one of the sectors least affected by the Single Market Programme, nowadays financial institutions and particularly the banking institutions play a very important role, namely in the process of monetary policy transmission in the Euro area.

### **3. Bank Performances in Portugal**

Portugal joined the European Economic Community (EEC) in 1986, twelve years after the Revolution that implemented the democracy in the country. During those twelve years there was first, a massive wave of nationalisations, only three small foreign-owned banks were not nationalised, new entries into the market were banned, while banking activities were entirely subordinated to the objectives of economic policy.

By the late 70-ties only three special credit institutions had the monopoly of mortgage lending and only one bank had the monopoly of all institutional and government accounts. All interest rates were administratively fixed by the political authorities and even the opening of new branches depended upon the permission of the central bank. In the early 80-ties the consequences of the political and economical instability became problematic and there was an agreement between the Portuguese government and the International Monetary Fund.

After that agreement, and just before the joining to the EEC the main instrument of the Portuguese monetary policy became the legal establishment of credit ceilings, which were imposed to the whole economy in accordance with the expected growth rate of GDP, but were in fact mainly used to finance government spending. Capital movements were also controlled by the central bank and consumer lending was completely restricted.

These restrictions began to change when Portugal became a member of the EEC and had to adapt to the new institutional and market conditions.

In 1987, the banking sector was opened up to private enterprise and new foreign banks were progressively authorised although they remained small in size. Interest rate regulation continued until 1990 with the administrative imposition of a minimum rate for deposits and a maximum rate for loans.

Under these conditions, not surprisingly, the approval by the EEC of the Single Market Programme (1986-1992) had a special impact in Portugal, and it accelerated the process of deregulation, privatisation and new (national and foreign) entries to the market, as well as adaptation to the competitive environment.

In 1990 a new accounting system was approved for the banking sector and a Cooke solvency ratio was adopted, forcing the Portuguese government to inject large amounts of capital into the banks even during the process of privatisation. Prudential rules were also introduced for loan losses and general credit risks. By the beginning of 1993, with the implementation of the EU Second Banking Directive and the all banks in Portugal had to prove their ability to adapt to the new market and legal conditions.

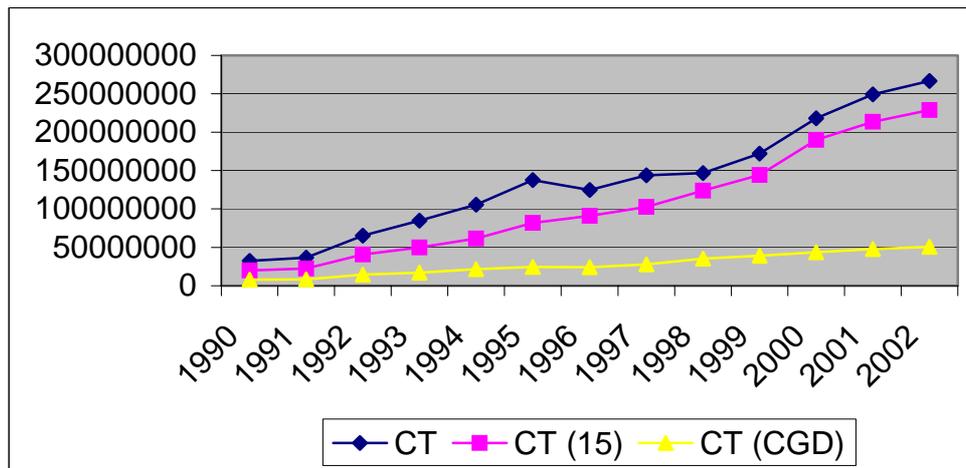

At the same time, the banking sector had to face the enormous challenges introduced by the Maastricht criteria and the preparation to the transformations introduced by European Monetary Union as Portugal was one of the countries which respected the defined criteria and adopted the single currency.

So, the Portuguese banking system has undergone radical changes and has moved from having a completely protected political environment to integration into the Single European Market's financial services and then into the EMU. In order to respect the Maastricht criteria and prepare for the single currency, there was a continuous fall in interest rate levels (as described in the previous section of this paper).

Under these conditions, the monetary policy transmission mechanisms in Portugal during this last decade (before and after the implementation of the single currency) would be expected to show a strong traditional interest-rate channel applied not only to productive investments, but also to housing investments and even to expenditure on consumer durables.

After so many legal and economic restrictions, the data made available in the Bulletins of the Portuguese Association of Banks (Associação Portuguesa de Bancos - APB) show that, since the early 1990s, there has been a very sharp increase in the credit granted by banks (**Graph 1**).

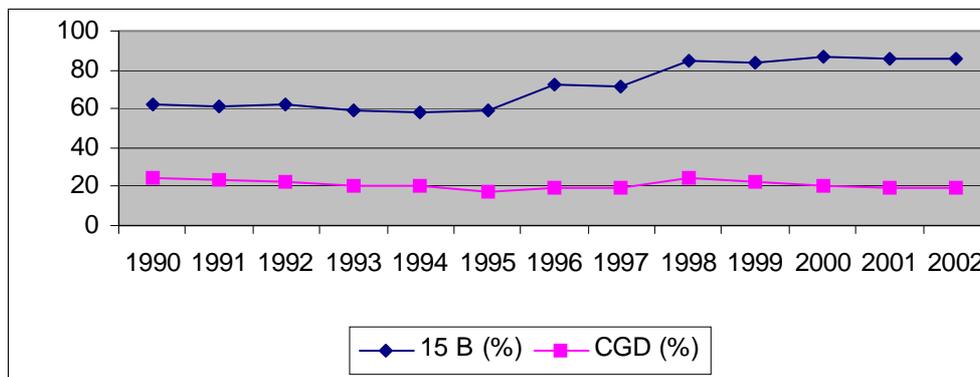

**Graph 1 – Total Credit Granted**

This enormous growth in credit was essentially due to the continued fall in the interest rate, resulting from the new conditions that were established for joining the single currency, but it also derived from the alterations occurring in the operating conditions of the banking sector.

In December 1990, there were 33 banking institutions in Portugal, but by December 2002 there were already 52. Fifteen<sup>2</sup> of these, however, have always remained in operation and have even managed to increase their share of the credit granted to clients. The biggest one, Caixa Geral de Depósitos (CGD) also managed to maintain its dominant position and until recently has been responsible for around 20% of the total credit granted by the sector (**Graph 2**).

**Graph 2 – Share of total credit granted by the 15 main banks and by CGD**

<sup>2</sup> More precisely: Banif, Barclays, BB, BBVA, BCA, BCP, BES, BIC, BNP Paribas, BPI, BTA, CGD, CPP, Deutsche Bank and MG.

In order to better express the performance of the banking institutions operating in Portugal during this period, we continued to make use of the Bulletins of the Portuguese Association of Banks and used two indicators that we calculated from them: the financing of financial assets and the financial margins.

The **financing of financial assets** corresponds to the ratio (in %) between financial liabilities and financial assets. Naturally, it would be better for the security of the banking institutions if this ratio was always not to close to 100. When this ratio is above 100, it is a sign that banks are have increased their responsibilities without correspondence in the growth of their financial assets and this may contribute to more risky situations in the future.

Generally speaking and according to data presented in Table 1, we see that this ratio was always very close to 100 and in the last years it exceeded always the 100. And although the differences in the ratios of the total banking sector, the main 15 banks and the biggest one (CGD) are not very big, it is quite clear that CGD has recorded values above 100, indicating that this institution was not so careful with the financing of its financial assets. This is consistent with the decrease in the last years of the CGD's lending share, although its share is still quite high: around 20% of the total bank lending. It must also be a consequence of the government management decisions, as CGD continues to be the public bank, implementing most of the government's policies, particularly at the level of public finance and changing quite often its administration staff.

**Table 1– Financing of financial assets = financial liabilities /financial assets**

	<b>TOTAL</b>	<b>15 Banks</b>	<b>CGD</b>
<b>1990</b>	98.06	95.86	93.77
<b>1991</b>	102.25	95.86	95.52
<b>1992</b>	97.10	97.05	94.77
<b>1993</b>	96.48	96.29	95.11
<b>1994</b>	97.41	97.87	96.36
<b>1995</b>	98.74	98.85	97.54
<b>1996</b>	99.65	99.41	97.76
<b>1997</b>	99.71	100.09	96.97
<b>1998</b>	99.50	99.76	100.01
<b>1999</b>	99.22	99.60	100.54
<b>2000</b>	101.10	101.71	104.11
<b>2001</b>	101.68	102.30	103.47
<b>2002</b>	100.09	100.80	101.68
average	<b>99.31</b>	<b>98.88</b>	<b>98.28</b>

The **financial margins** are clearly the indicator that show the results obtained by the banking institutions in regard to their main activity – financial intermediation. Basically they correspond to the difference between the received (from applications) and paid (from deposits) interest rates. More precisely, here the financial margins are calculated as the ratio of the difference between interest and equivalent income (basically from credit applications) and interest and equivalent costs (from funds raised, especially from clients' deposits) to the financial assets.

In Portugal, whilst interest rates were established either administratively or under a situation of limited competition, it was possible to maintain relatively high financial margins, especially when compared with those recorded by most of our European partners.

However, in few years, the conditions completely changed with membership of the EEC, the liberalisation of the financial markets and, in particular, the decisions inherent in the enforcement of the single currency policy.

So, not surprisingly, in Table 2, the financial margins show a decrease throughout the decade, due not only to the choices made by the financial institutions and their lending activity, but mainly to the monetary policy imposed during the period of transition to the Euro zone and the subsequent fall in interest rates. But the largest banking institutions (and amongst these CGD in particular) were able to keep their margins somewhat higher than the less powerful banking institutions.

**Table 2 – Financial margins = (interest and equivalent income-interest and equivalent costs)/ financial assets.**

## 4. Panel Data Estimations

The enormous growth noted in credit lending in Portugal during the last decade were surely influenced by macroeconomic conditions, and the reflects of the challenges that the country had to face, and particularly the levels of the interest rates.

However, the banking institutions must not be considered as completely "neutral" intermediaries between borrowers and creditors, and their performances may also be crucial for the explanation of bank lending growth.

In the following panel estimates we used data published by the Portuguese Central Bank (Banco de Portugal) and the International Monetary Fund: the Gross Domestic Income series (at 1995 prices) and the short term interest rates.

Total bank lending and the performance indicators - the financing of financial assets and the financial margins - of Portuguese banks were calculated using data from the Portuguese Association of Banks (Associação Portuguesa de Bancos), which provides only annual data for the last decade.

We therefore used the following series<sup>3</sup>:

**Lend** = Log of bank lending

**GDP** = Log of real GDP

**int. rate** = nominal short term interest rate

**FF** = **financing of financial** assets = financial liabilities /financial assets

**FM** = **financial margins** = (interest and equivalent income-interest and equivalent costs)/ financial assets.

#### 4.1 The estimated model

Our panel estimates follow a simplified version of the Bernanke and Binder model (1988).

First, in the **money market**, we will assume that money equals deposits held at banks by the non-monetary sectors.

So for the demand function, we assume that the nominal deposits held at banks by the private sector will depend on GDP and the interest rate on bonds:

$$\text{Dep}^d = a_0 + a_1 \text{GDP} + a_2 i_{\text{bonds}} \quad [1]$$

(+)            (-)

Money supply will not only depend on the interest rate on bonds, but also on the influence of monetary policy (represented here by the relevant monetary policy interest rate, which is controlled by the Central Bank):

$$\text{Dep}^s = b_0 + b_1 i_{\text{bonds}} + b_2 i_{\text{mon.pol.}} \quad [2]$$

(+)                            (-)

Second, in the **credit market**, the demand for lending depends on GDP, the interest rate on bonds and the interest rate on lending:

Assuming the relevance of  $x$  bank performance characteristics ( $\text{Char}_x$ ) on

$$\text{Lend}^d = c_0 + c_1 \text{GDP} + c_2 i_{\text{lend}} + c_3 i_{\text{bonds}} \quad [3]$$

(+)            (-)            (+)

lending, which a priori may have a positive (or negative) effect on lending, we may define the supply in the money market as depending on the deposits of the private sectors at banks and the product of these deposits, as well as on bank characteristics, the interest rate on lending and the interest rate on bonds:

$$\text{Lend}^s = d_0 + d_1 \text{Dep} + d_2 \text{Dep} \text{Char}_x + d_3 i_{\text{lend}} + d_4 i_{\text{bonds}} \quad [4]$$

(+)            (?)            (+)            (-)

Clearing the money and credit markets (see Appendix I for more details) leads to the reduced form of the model which will be the basic equation for our panel estimations:

$$L = \alpha_0 + \alpha_1 \text{Car}_x + \alpha_2 \text{GDP} + \alpha_3 i_{\text{mon.pol}} + \alpha_4 \text{Car}_x \text{GDP} + \alpha_5 \text{Car}_x i_{\text{mon.pol}} \quad [5]$$

(?) (+)?      (?)      (?)      (-)?      (+)?

Thus, there is no certitude about the magnitude or even the sign of the influence of the macroeconomic conditions (more precisely, here only the GDP growth and the monetary policy interest rate) and the considered bank performance indicators (in our case the two presented ratios: the financing of the financial assets and the financial margins).

## 4.2 Panel estimate results

With the presented data we construct a panel of 221 observations (data for 13 years and a sample of 17 representative banks) and using the STATA program we compare the results of some fixed effects, random effects and Arellano-Bond dynamic panel estimates .

### 4.2.1 Fixed and random effects panel estimates:

Panel data estimates allow to control for unobserved individual heterogeneity that is constant over time. The fixed effects estimator is obtained by OLS on the deviations from the means of each unit (in our case, each bank) or time period. This estimation may be relevant if we expect that the averages of the dependent variable will be different for each bank, but the variance of the errors will not.

The obtained results with fixed effects estimates are presented in Table 5 and confirm the importance of the bank lending channel as there is a clear negative influence of nominal short term interest rates on bank lending. As expected, the financing of financial assets (more precisely, the ratio financial liabilities/financial assets) has also a rather strong influence on bank lending.

With random effects estimates (Table 6) there is an increase of the importance of GDP while the financing of financial assets remains a relevant indicator for the evolution of the bank lending.

The Hausman test is used to compare the results obtained with fixed effects with those obtained with random effects estimates. Given a model in which fixed effects are appropriate, the Hausman test will  $H_0$ : that random effects would also be consistent and efficient, versus  $H_1$ : that random effects would

be inconsistent. The result of the test is a vector of dimension  $b$  ( $b =$  number of instruments) which will be distributed  $\chi^2(b)$ . So if the Hausman test statistic is large, we should use fixed effects estimates. If the statistic is small, we may consider that random effects are also consistent.

**Table 7 – Hausman specification test**

Test: Ho: difference in coefficients not systematic

$$\begin{aligned} \chi^2(18) &= (b-B)'[S^{-1}](b-B), S = (S_{fe} - S_{re}) \\ &= 2.70 \\ \text{Prob} > \chi^2 &= 1.0000 \end{aligned}$$

Here the Hausman test (Table7) does not clearly reject the null hypothesis that the observed heterogeneity is uncorrelated with the regressors. So we may suspect that random effects are more appropriate in this case, assuming that the relative small panel that we are using is drawn from a larger population of values (in our case, we should consider that the included banks during this time period are representing a larger set of banks during a longer period of time).

Nevertheless, as we are using a relative small panel ( $N=221$ ) and the main 15 banks were chosen by their dominance in the shares of the bank lending, fixed effects can be considered more adequate. This is consistent

also with the results of the Rsq and the comparison of the within, between and overall values which indicate a better explanation of changes by year than by the group differences.

#### 4.2.2 Arellano-Bond dynamic panel estimates:

Dynamic panel estimates with relative short panels require the introduction of instrumental variables as the time-invariant group specific (here bank specific) effects are correlated with the lagged dependent variable (the total bank lending growth). But if we try to avoid the bank specific effects through first-differencing the equation we will introduce serial correlation in the error term and regressor error correlation. To solve these problems and the potential endogeneity of the explanatory variables, we introduce GMM estimations.

Following Bundel and Bond (1998) we use the GMM system estimator in levels, which introduces the lagged differences of the explanatory variables as instruments. But these instruments have to satisfy two conditions: they should not be correlated with the error term in the estimated equation and they should be correlated with the endogenous explanatory variables.

To test whether the instruments are correlated with the error term we use a Sargan test which is a test of the overidentifying restrictions. The hypothesis being tested is that the instrumental variables are uncorrelated to some set of residuals, and therefore they may be considered as acceptable, healthy, instruments. If the null hypothesis is not rejected it is concluded the instruments pass the test and are valid for the estimation.

The validity of the instruments is also tested by the Arrelano-Bond test of serial correlations of the error term. The  $H_0$  hypothesis of this test is that the error terms in the first-difference regression exhibit no serial correlations.

Sargan test of overid. restrictions:  $\chi^2(35) = 20.63$  Prob >  $\chi^2 = 0.974$

Arellano-Bond test for AR(1) in first differences:  $z = -0.82$  Pr >  $z = 0.409$

Arellano-Bond test for AR(2) in first differences:  $z = -1.00$  Pr >  $z = 0.320$

The one step GMM results are presented in Table 8. The Sargan test does not reject the null that the instruments are valid in that they are not correlated with the errors. The autocorrelation Arrelano-Bond tests also confirm the validity of the instruments.

Comparing the results of the dynamic estimation with those obtained with fixed effects estimates (Table 5) we see that the main differences are detected in the results for the short term interest rate and the financial margins. Now financial margins are more relevant to the explanation of bank lending growth, both directly and indirectly through GDP and the interest rates.

## 5. Concluding Remarks

In keeping with studies that had already confirmed the need to complement the whole Euro zone evidence with research undertaken at a national level, this paper centred the attention on the conditions and transmission mechanisms of monetary policy.

It presents two bank performance indicators: the financing of financial assets (more precisely the ration between the financial liabilities and the financial assets) and the financial margins and through panel data estimates, and analyses their joint importance with two macroeconomic indicators (real GDP and nominal short time interest rate) for bank lending in Portugal during the past decade.

The obtained results with fixed and random effect estimates were compared through a Hausmann test which does not clearly reject the null that the observed heterogeneity is uncorrelated with the regressors. So we could accept that random estimates are appropriate but, as we are dealing with a relatively small panel, fixed effects will always be more appropriate.

And as fixed effects (or within) estimates assume common slopes but that each cross section unit, more precisely here , each bank, has its own intercept we may also conclude that the initial conditions may be different for each bank but afterwards their reactions to the considered instruments are similar because they are all competing in the same market and have to face the same macroeconomic conditions.

Further, the fixed effects estimates confirm the importance of real GDP and interest rates on bank lending. At the same time, the chosen bank performance indicators also contribute to the explanation of the bank credit during this period, specially the financing of financial assets which showed its relevance for the credit not only directly but also indirectly, through GDP and interest rates.

These conclusions are consistent with the results obtained with the other dynamic panel estimates. We use a GMM system estimator in levels and confirm the validity of the instruments through Sargan and Arellano-Bond tests of serial correlations.

So, clearly the total bank credit depends on macroeconomic conditions, including monetary policy decisions. At the same time, bank lending is an essential transmission channel of monetary policy decisions, but it still depends on the performance and strategy of the different banking institutions.

## APPENDIX I

Remembering the model presented in section 4.1. of this paper, demand in the money market depends on real GDP and the interest rate on bonds, while supply depends on the interest rate on bonds and also on the interest rate established by monetary policy:

$$\text{Dep}^d = a_0 + a_1 \text{GDP} + a_2 i_{\text{bonds}} \quad [1]$$

(+)            (-)

$$\text{Dep}^s = b_0 + b_1 i_{\text{bonds}} + b_2 i_{\text{mon.pol.}} \quad [2]$$

(+)            (-)

Demand in the credit market depends on real GDP, the interest rate on lending and also on the interest rate on bonds.

Including another variable, which will capture the bank-specific performance indicator, the credit supply will depend on the deposits of the private sectors at banks, the combined influence of these deposits and the bank performance indicator on the interest rate on lending and the interest rate on bonds.

$$\text{Lend}^d = c_0 + c_1 \text{GDP} + c_2 i_{\text{lend}} + c_3 i_{\text{bonds}} \quad [3]$$

(+)            (-)            (+)

$$\text{Lend}^s = d_0 + d_1 \text{Dep} + d_2 \text{Dep Car}_x + d_3 i_{\text{lend}} + d_4 i_{\text{bonds}} \quad [4]$$

(+)            (?)                    (+)            (-)

Clearing the money market - equations [1] and [2] - we obtain:

$$i_{\text{bonds}} = \frac{b_0 - a_0}{a_2 - b_1} - \frac{a_1}{a_2 - b_1} \text{GDP} + \frac{b_2}{a_2 - b_1} i_{\text{mon.pol}}$$

or

$$i_{\text{bonds}} = e_0 + e_1 \text{GDP} + e_2 i_{\text{mon.pol}} \quad [5]$$

(?)            (+)            (+)

and also

$$\text{Dep}^d = \text{Dep}^s = \frac{a_2 b_0 - a_0 b_1}{a_2 - b_1} - \frac{a_1 b_1}{a_2 - b_1} \text{GDP} + \frac{a_2 b_2}{a_2 - b_1} i_{\text{mon.pol}}$$

or

$$\text{Dep} = f_0 + f_1 \text{GDP} + f_2 i_{\text{mon.pol}} \quad [6]$$

(?)            (+)            (+)

Clearing the credit market - equations [3] and [4] - we first obtain the expression of the interest rate of lending:

$$i_{\text{lend}} = \frac{d_0 - c_0}{c_3 - d_3} + \frac{d_1}{c_3 - d_3} \text{Dep} + \frac{d_2}{c_3 - d_3} \text{Dep Car}_x - \frac{c_1}{c_3 - d_3} \text{GDP} + \frac{d_4 - c_4}{c_3 - d_3} i_{\text{bond}}$$

or

$$i_{\text{lend}} = g_0 + g_1 \text{Dep} + g_2 \text{Dep Car}_x + g_3 \text{GDP} + g_4 i_{\text{bond}} \quad [7]$$

(?)
(-)
(+)?
(+)
(+)

Using this expression, we then obtain for the credit market equilibrium:

$$\text{Lend}^d = \text{Lend}^s = \frac{c_3 d_0 - c_0 d_3}{c_3 - d_1} + \frac{c_3 d_1}{c_3 - d_1} \text{Dep} + \frac{c_3 d_2}{c_3 - d_1} \text{Dep Car}_x + \frac{c_1 d_3}{c_3 - d_1} \text{GDP} + \frac{c_3 d_4 - c_4 d_3}{c_3 - d_1} i_{\text{bond}}$$

or

$$\text{Lend} = h_0 + h_1 \text{Dep} + h_2 \text{Dep Car}_x + h_3 \text{GDP} + h_4 i_{\text{bond}} \quad [8]$$

(?)
(+)
(-)?
(+)
(?)

Remembering the definitions obtained for the interest rate on bonds and deposits - equations [5] and [6]

$$i_{\text{bonds}} = e_0 + e_1 \text{GDP} + e_2 i_{\text{mon.pol}} \quad [5]$$

$$\text{Dep} = f_0 + f_1 \text{GDP} + f_2 i_{\text{mon.pol}} \quad [6]$$

and introducing these expressions into equation [8], we may obtain the reduced form of the expression for lending, which is the basis of our estimations

$$L = \alpha_0 + \alpha_1 \text{Car}_x + \alpha_2 \text{GDP} + \alpha_3 i_{\text{mon.pol}} + \alpha_4 \text{Car}_x \text{GDP} + \alpha_5 \text{Car}_x i_{\text{mon.pol}}$$

(?)   (?)        (?)        (?)        (-)?        (+)?

where

$$\alpha_0 = h_0 + h_1 f_0 + h_4 e_0$$

(?)       (-)(?)       (?) (?)

$$\alpha_1 = h_2 f_0$$

(-)(?)

$$\alpha_2 = h_0 f_0 + h_3 + h_4 e_1$$

(+)(+)       (+)       (?) (+)

$$\alpha_3 = h_1 f_0 + h_4 e_2$$

(+)(+)       (?) (+)

$$\alpha_4 = h_2 f_1$$

(-)? (+)

$$\alpha_5 = h_2 f_2$$

## **Abstract**

*The problem of inflation is at the present time in the centre of attention in the Slovak Republic and also in other new member states of the European Union in connection with the necessity of fulfilment of the Maastricht criteria which is required for the country's qualifying for the Eurozone. The theoretical approach of monetarism, which gained ground in the 70's of the last century, represents a significant contribution to the study of reasons and mechanism of inflation expansion as well as to the necessity of an antiinflationary monetary policy implementation. The aim of this paper is to present Friedman's monetaristic theory of inflation inclusive of implications for the monetary policy of the central bank, moreover to critically generalize the experience of implemented monetaristic reference of economic policy in practice. Finally, against this background, the paper also outlines the perspectives of the abovementioned theoretical doctrine.*

**Keywords:** *monetarism, inflation, M. Friedman, transmission mechanism, monetaristic experiment*

## 1. Introduction

The problem of inflation is at the present time in the centre of attention in the Slovak Republic and also in other new member states of the European Union in connection with the necessity of fulfilment of the Maastricht criteria which is required for the country's qualifying for the Eurozone. The theoretical approach of monetarism represents a significant contribution to the study of reasons and mechanism of inflation expansion, monetary dynamics, relations of money demand formation, velocity of money, effect of monetary factors on economic behavior of subjects, the necessity of an antiinflationary monetary policy implementation etc. The aim of this paper is to present Friedman's monetaristic theory of inflation inclusive of implications for the monetary policy of the central bank, moreover to critically generalize the experience of implemented monetaristic reference of economic policy in practice. Finally, against this background, the paper also outlines the perspectives of the abovementioned theoretical doctrine.

## 2. Monetaristic theory of inflation

Monetarism originated as a reaction to a long period of disregarding money and money factors by macroeconomics<sup>1</sup> on the one hand, and overestimating of state intervention by Keynesian economists on the other hand. Keynes' concept of state regulation of the economy was directed to achieve full employment, while inflation was in the background. It has a logical justification: J. M. Keynes elaborated his theory under the Great Depression, when the uppermost problem was the huge unemployment and not the rise in price (prices rather fall in this term)<sup>2</sup>. In a postwar period there was not paid any high attention to inflation, because the inflation was low. Money and credit (lending) policy played a secondary role – their task was to sustain interest rates on a level, which could promote (assist) to achieve economic growth and to solve budgetary problems.

The world-wide rise in prices at the beginning of the 70's of the last century stimulated economist's interest in inflation. Exactly the issue of inflation represented a key point of a critical reinterpretation of the

---

<sup>1</sup> In literature we can find an argument, that J. M. Keynes had ignored the role of Money and money stock. We have to agree with the author of *Live thoughts of dead economists*, that such an accusation is not correct ([1], p.203). A great value that Keynes accredited to money is indirectly supported by proofs (verified) in his most important works such as – *Tractate about Money Reform* (1923), *Discourse about Money* (1930), *General Theory of Employment, Interest Rates and Money* (1936).

<sup>2</sup> Theory of J. M. Keynes is based on presumption of rigid prices.

Keynesian doctrine by the monetarists, which finally led to the revival of the reflections of the quantitative money theory of classic economics.

Theory of inflation and analysis of money demand represent important building stones of Friedman's money theory. It has also significantly effected the monetary policy of central banks as well as the stabilization policy in transitive economies.

In Friedman's study of inflation we can distinguish 2 phases: in the first phase (until the end of 60's of the last century) he analyzed the mechanism of inflation formation, in the second phase (beginning of the 70's) he examined the relation between inflation and unemployment.

Friedman's interpretation of inflation can be integrated into monetary conception of inflation.

M. Friedman linked to the learning of quantitative money theory. In the work *The Counter-Revolution in Monetary Theory* he entitled the inflation „purely monetary phenomenon in terms of faster money stock growth in comparison with product growth“ ([3], p. 16). According to him inflation is a result of excess money in circulation.

M. Friedman analyzed the mechanism by means of which money affect prices. He postulated, that if the money market equilibrium was violated, general price level would be changed in consequence of an adjustment process.

Till the end of the 60's of the last century Friedman's monetaristic version of inflation developed as a theory of partial equilibrium in the money sector. Fluctuation of money level was interpreted exclusively as a result of „jumps“ of money stock (money shocks) against the static money demand. Later on, in the 70's M. Friedman expanded his theory of inflation with correlation of inflation and unemployment on the basis of critical analysis of the (keynesian) Phillips curve. The natural unemployment rate and the (adaptive) inflation expectation represent in his concept the pivot elements by examination of relative linkage between inflation process and situation on labour market.

M. Friedman does differentiate between short-term and long-term Phillips curve. According to him the original (initial) Phillips curve is valid only in a short-term period when inflationary expectations decline from the existing higher inflation rate and the adoption occurs additionally. It represents temporal, transition state – divergence of actual unemployment from natural rate of unemployment evocated by economic policy and its

effect on inflation. In a long-term period the Phillips curve has a vertical line shape and is identical with the line on the level of the natural rate of unemployment, that has substantial consequence of the long-term economic policy.

The motive force of the examined features in Friedman's monetaristic conception is the rise in money stock. M. Friedman is susceptible of the fact, that in a short-term period monetary impulses could have some impact on real variables (employment, production, investments), but this impact is only temporary. In a long-term period these parameters return to their initial level, so that means, that only a rise in price occurs. According to him, money are neutral in a long-term perspective.

Friedman's conception of a vertical Phillips curve and the hypothesis of natural rate of unemployment offer new arguments against the Keynesian forms of economic policy. M. Friedman denied compromise – dilemmatic choice between inflation and unemployment – as illusion and refused the Neokeynesian recipes (formulary) that are supposed to ensure high economic growth by proportioning of inflation. In compliance with his analysis, the tendency to increase employment above the „iron“ limit of natural rate of unemployment leads to intensive inflationary pressure, to inflation acceleration without any noticeable long-term effect on the labour market. Therefore he requests to put an end to the meaningless policy of aggregate demand stimulation and to the supporting of full employment.

Forasmuch as Friedman does consider inflation as a pure monetary phenomenon, he comes to the conclusion that we can fight inflation only by means of arrangements in the monetary sphere. The only way to heal inflation is to constrain the growth of money supply. At the same time he emphasises the fact, that it is not possible to avoid the uncomfortable incidental effects of inflation in form of slowdown of economic growth and higher unemployment<sup>3</sup>.

### **3. Implication for monetary policy of central banks**

Specialties of monetaristic approach to economic regulation in comparison with Keynesian approach could be summarized as follows. Whereas the goal of the Keynesian economic policy is full employment and high rate of economic growth, the monetarists prefer price stability. The

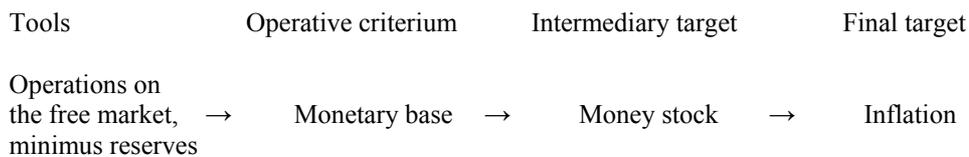

---

<sup>3</sup> In this connection is Friedman's analogy between inflation and alcoholism very interesting and eloquent, which refers to inflation formation as well as to its treatment ([2], s. 266 - 267).

Keynesians emphasize the role of interest rate in macroregulation (it is assumed, that interest rate affects volume and dynamics of investments), on the other hand, Monetarists emphasise the role of money stock. Friedman considers its regulation as main instrument (tool) to compete against inflation<sup>4</sup>.

The monetaristic transmission mechanism is based on monetary base regulation by the money aggregate (M1 or M2) as an intermediary target. The following diagram shows the monetaristic transmission mechanism:

**Diagram 1: Monetaristic transmission mechanism**

The monetaristic transmission mechanism is able to operate ideal under fulfilling some conditions:

1. the central bank is able to fully control the monetary base (that means measure, monitor and change if necessary),
2. money multiplier represents a fixed (stationary) parameter or its changes can be anticipated (foreseen),
3. income velocity of money is a fixed (stationary) parameter.

Provided that the abovementioned conditions are fulfilled the central bank can effectively influence the money mass in circulation and control the aggregate demand. One question has to be answered yet, how big the annual growth of monetary base should be in order to ensure an optimal economic growth and at the same time to eliminate inflationary (or deflationary) pressure.

M. Friedman in this connection does not consider the flexible money and credit policy to be suitable for market economy stabilization. On the contrary, he considers it as a destabilizing factor. According to him the most suitable antiinflationary strategy is a non-activist monetary policy, because this could ensure stable growth rate of money mass, which would be

---

<sup>4</sup> The main paradox of monetarism as a monetary theory consists in the fact, that it is professed to principle of laissez-faire, but at the same time it considers money stock as an exogenous parameter, that should be determined by state power (central bank).

a stable rule (so called Money rule). In the case of the USA he recommended 3-5 % annual growth rate of the money mass.

According to R. Holman ([9], s. 670 – 672) the advantages of such a monetary policy consist in following facts:

- monetary policy of the central bank is neutral (no expansionary, no restrictive),
- it is isolated from political pressure and pressure of interest groups,
- inflationary expectations are stabilized and on a low level.

Expectation of stable prices in combination with elastic wages have to, according to M. Friedman, facilitate to take economically justified and effective decisions.

#### **4. Experience of implemented monetaristic reference of economic policy in practice**

Money mass targeting as an intermediary target was applied by almost every central bank<sup>5</sup>, even though monetary targeting (rule of stable growth rate of money stock) was not carried out consistently. The central bank personnel did realize in the 80's of the last century, that the central bank does not hold full control over the money mass growth (because of the fact, that commercial banks can decide to change reserve holding, and it occurs changes in money multiplier and money mass as well) and did not restrict management of monetary policy to only monetaristic recipes.

As reference standard of monetary targeting is considered the policy applied by the German Bundesbank, that succeed in combination of uninflated development and economic growth. The Bundesbank began to implement it 1975 after the decay of the Bretton Woods Monetary System. Until 1988 it targeted the regulation of the monetary base and later of M3<sup>6</sup>. Bundesbank stopped publicly proclaiming target values of M3 growth from 1999, because from that time the ECB was liable for monetary policy implementation.

The American FED began to apply the policy of monetary targeting in 1979. This policy is in literature called as „monetaristic experiment“. During

---

<sup>5</sup> Among economically developed countries e.g. USA, Canada, Japan, Great Britain, Germany, France, Italy etc.

<sup>6</sup> Bundesbank did not monitor only the development of money aggregates, but also other parameters such as expected inflation rate ([5],s.525).

its exercitation it came to an increase in interest rate variability and to loss of stable money velocity. This policy was rejected in 1982. As reason of failure are considered financial innovation and market deregulation, which occurred at the beginning of the 80's of the last century and which led to an increase in money velocity. Thereby the stable linkage between money mass and GDP was violated and it began to change in an unpredictable way.

Practice showed (USA), that outwards logical and because of their simplicity attractive references of money mass regulation by means of monetary base are actually very difficult to carry out. Experts from the FED in St. Louis postulated, that the monetary base consists of 2 parts: the first part – monetary – is controllable, the second part – autonomous – is difficult to influence, practically it is beside of control.

We can present some reasons, why the central bank is not able to fully control all the items in its balance:

- credit volume extended to commercial banks depends on their demand and readiness to drawdown,
- turnover of net foreign assets depend on the applied exchange rate system. In a system of fixed exchange rate, when the central bank has to intervene according to the development of balance of payments, the turnover of net foreign assets is determined by the current and capital balance of the country,
- net credit development fully depend on the development in the management of the state budget, which the central bank can not influence ([15], s. 453).

1. The monetaristic assumption of stable money multiplier has not approved. The money multiplier tends to behave pro-cyclic during the economic cycle – during recession does the demand for cash (money) rise. A subsequent increase in the amount of money in circulation and reserves evokes a fall in value of the money multiplier.
2. Money velocity has become very unstable. Therefore the FED switched from M1 to M2. When in 1992 also money velocity of M2 began to deviate from its historical trend, the FED stopped using M2 as key-indicator of the monetary policy ([16], s. 655).

As we can see the practice of monetary policy did not confirm the stability of links between monetary aggregates and inflation. Some not fulfilled premises of monetaristic transmission mechanism in the 80's of the

last century with regard of the income velocity of money and money multipliers led central banks to create new schemes of management of monetary policy. Especially small economies prefer the implication of fixed exchange rate regime – they have fixed the exchange rate against a stable single currency (or against a currency basket). Because of the increasing globalization of financial markets and capital mobility it become more and more difficult to sustain fixed exchange rates. Central banks were with time forced to switch to the regime of managed float. Standard type of monetary policy did gradually loose its nominal bonding.

This was the case also in the SR, that from its formation in 1993 has applied some of the monetary policy regimes. At first the Slovak National Bank operated a „monetaristic“ transmission mechanism, which it inherited from the State Bank of the Czechoslovakian Federation: growth of M2 was monitored as a monetary intermediary target by the means of its effect on the monetary base. At the same time the National Bank tried to fix the exchange rate through foreign exchange intervention (from autumn 1996 with a fluctuation band of +/- 5%, from the beginning 1997 with an expanded fluctuation band of +/- 7%). From 1<sup>st</sup> October 1998 it came to an expressive (striking) turnover (change) in currency area, because the National Bank was constrained to replace the regime it used until that time with the regime of managed float.

In the 90's of last century central banks of many countries announced a switch to a new strategy of monetary policy – inflation targeting. It is necessary to remark, that the monetary policy target was not concerned – price stability have got left -, but the strategy of its achieving has changed. Under inflation targeting it came to an orientation on those macroeconomic parameters, which, as assumed, could significantly determine the price stability (first of all money aggregates and exchange rate).

**Diagram 2: Scheme of transmission mechanism with inflation targeting**

System of inflation targeting was implemented from 2000 also by the Slovak National Bank, even though it was not officially scheduled in the monetary program. But it was indicated by the transition from quantitative management of liquidity to the qualitative management on the basis of own key interest rates and shifting money aggregates from the position of an

intermediary target into the position of (only) indicators of monetary development<sup>7</sup>.

## **5. Assessment and perspectives of monetarism**

Monetarism enjoyed the most popularity in the 70's and 80's of the last century. Monetarists uncovered some new relations in economics – dependability of GDP from money mass, inflationary expectations, dependability of inflation from the level of money supply. Waiver of fiscalism had relatively good results (thatcherism, reaganomics). The suggested methods by Friedman to fight inflation were accepted practically in the whole world.

Monetarism was relatively successful in many countries of the world, although we can hardly talk about its absolute dominance in any country. It has merit in overcharging of depression, structural changes in developing countries (especially in Latin America), monetary sanitation of Israel, modernization of countries in Southeast Asia. The monetaristic doctrine adopted also some international organizations such as the International Monetary Fund, the World Bank, OECD, the European Bank for Reconstruction and Development etc. Monetaristic postulates became a keystone of the recommendation that financial institutions gave to countries, which apply for help by forming their economy policy (inclusive of countries in Middle-East Europe).

Within the frame of monetaristic streams we can differentiate some schools – Friedman's monetarism, theory of rational expectations (monetarism II), global monetarism, reagonomics, thatcherism, school of polish „ shock therapy“ etc. Among the economists, who really supported practical implementation of monetaristic theory by economy policy formation, we can mention M. Freidman, K. Brunner, A. H. Meltzer, A. J. Schwartz, J. Jordan, H. G. Johnson (USA), L. Balcerowicz (Poland), J. Gajdara (Russia), V. Klaus (Czech Republic) and others.

Mainly under pressure and force of top financial institutions (IMF, World Bank), the monetaristic restriction and stabilization policy has become a basis and resource point of the transformation policy in transitive

---

<sup>7</sup> The National Bank of Slovakia has defined the inflation targeting for the first time in the Monetary program until 2008, which was approved 21. december 2004 by the Bank Board. The framework of the monetary policy was clearly defined in a medium-term look-out in the form of binding target. Hereby the NBS has also defined the administration of the monetary policy as inflation targeting under the conditions of ERM II ([14], s.2).

economies first of all in the last decade of last century in the countries of Middle and East Europe<sup>8</sup>. However, the attained results fall behind the expectations, which is reflected also by the fact, that the scissors (lag) between the anticipated and real economic overfall are (is) surprisingly big.

In this connection series of questions arise, for example: Were the conditions in these countries sufficient for the implementation of monetarism? Was it really an implementation of an academic monetaristic doctrine? etc.

Even if we leave the controversial questions of monetaristic theory (e.g. stability of money demand function, definition of money stock, basically refusal of the impact of interest rates on money demand, reduction of reasons of inflation only on an excess amount of money in circulation, supposed stability of an income velocity of money and money multiplier, overestimating of the central banks ability to control monetary base etc), we have to state, that the practical results of this policy are much behind the anticipated results. Where to look for reasons?

We believe, that in the Slovak republic (and other countries of Middle and East Europe), where it came to the implementation of the monetaritic shocking therapy, because it was recommended by the IMF, the conditions were not entirely adequate. In transitive economies existed non-standard environment: no established infrastructure, no real market subjects, the reactions of existing subjects on economic and political steps was difficult to anticipate, persisting of monopoly position, no free pricing (as a result of the impact of monopoly and price regulation by the state).

A huge decrease in production and increase in unemployment led to an expressive decrease in real incomes of population, which considerable lowerd (weakened) Friedman's basic theoretical presumption about stable money demand<sup>9</sup>, which has a key importance by determining other macroeconomic parameters.

Substance of monetarism consists in interpretation of factors, which determine the money demand. In spirit of the monetaristic conception the main roads of macroeconomic stabilization do not consist only in limitation

---

<sup>8</sup> As Z. Komínková states, these institutions remain „industrial manufacturers“ of orthodox transformation policy, in which there is no much operating room for „national economic and political solutions“ ([12], s. 672).

<sup>9</sup> Let me remind you, that M. Friedman understands income as an important determinant of money demand.

of money supply, but mainly in way finding of market stabilization of money supply. This calls for ensuring e.g. free option between the various forms of wealth – this is contingent on a functioning and developed capital market -, competitive environment (for bigger price and wage elasticity) etc.

It is also necessary to remark, that the implemented economic policy in the SR in the 90's of the last century was not pure monetaristic – this suggests strict maintenance of money rule and no intervention into the economy by the government (it allows only monetary regulation)<sup>10</sup>, the expansionary fiscal policy of government was Keynesian and at the same time it was combined with price regulation (e.g. energy, water, partly wages). The in the economic policy applied pragmatism represented rather an eclectic mixture of monetarism, keynesianism and residual elements of socialistic management.

## 6. Conclusion

Even though there are various opinions concerning monetarism, we can state, that the monetaristic theory presented without dispute a gain for economic theory by emphasizing the importance of money and necessity of anticyclic monetary policy implementation. Hereby it is also necessary to mention, that at present time monetarism is not any more the most popular theory in the world<sup>11</sup>. In economic literature were identified 2 basic reasons of failure of monetaristic experiment: (1) loss of stability of the money demand function (because of the changed conditions of global financial markets, large capital flows and structural changes in economy), and (2) decreasing reliability of money aggregates.

In developed market economies as well as in transitive economies it was to observe in the 90's of the last century the gradual regression from monetarism<sup>12</sup>. This was first of all caused by general retraction of the western economic thoughts from the monetaristic-supply paradigm of the 80's and in transitive economies also by disappointment of the results of transformation.

---

<sup>10</sup> According to O. Sobek, the NBS implemented from 1993 a moderate monetaristic policy. That means, that it focused exclusively on inflation fighting and maintaining of stable exchange rate and did not want to actively influence the economic development, as is it in case of Keynesian economic policy ([17], s. 174).

<sup>11</sup> It was the most popular theory at the end of 70's and beginning of 80's of 20th century.

<sup>12</sup> In monetary policy it was for example expressed by the fact, that central banks acceded to inflation targeting as to a new monetary policy strategy instead of managing money supply through money aggregates (e.g. in the Czech Republic in 1998).

Even though we have to admit, that M. Friedman as an architect of monetarism fixed the professional and laic public's attention to the importance of inflation and he also contributed to the further development of economic (particularly money) theory – also due to the fact, that many of his theses were subject of critical polemics among economists.

# ADOPTION OF THE EURO AND INFLATION IN THE CZECH REPUBLIC

**Monika Bialonczyková**

Řadová 1121

735 14 Orlová – Poruba

Czech Republic

e-mail: moni.bial@seznam.cz

## **Abstract**

*The admission of the Czech Republic into the European Union means that the Czech Republic has been obliged to make an effort for the admission into the European Monetary Union and so for the adoption of single currency. Adoption of euro is for the Czech Republic the next irreversible step in the process of European integration. Inflation is very often adverted as a cost of single currency's adoption. This paper discusses the problem of inflation in the EMU's countries after the adoption of euro and makes an attempt to clarify the next trends in prices in the Czech Republic.*

**Keywords:** *euro; inflation; European Monetary Union; Czech Republic*

## **1. Introduction**

The admission of the Czech Republic (CR) into the European Union (EU) means that CR has been obliged to make an effort for the admission into the Eurosystem and so for the adoption of the single currency.

The Czech National Bank (CNB), as a central bank of CR, has been the part of the European System of Central Banks (ESCB) since the admission of CR into EU, but it still conducts its independent monetary policy. The admission into the Eurosystem will be mean that CR will relinquish its monetary sovereignty and CNB will be only participate on the single monetary policy.

The European Central Bank (ECB), as the core of ESCB is responsible for the monetary policy in the euro area.

The ECB's primary objective is the same like the objective of CNB (in 2005) – the maintaining of price stability. Price stability is defined by ECB as a year-on-year increase in the Harmonised Index of Consumer Prices (HICP) for the euro area of below but close to 2 % over the medium term. This objective is defined for the euro area as a whole, not for every country. So, this definition allows the differences between countries in the euro area. In this sense, price stability in the euro area need not to mean price stability in single countries.

This paper does not discuss price stability in all countries in the euro area, but it focuses on inflation as a problem which has been discussed as a cost of the single currency's adoption. The next goal of this paper is to make an attempt to clarify the next trends in prices in CR after the adoption of the euro.

First chapter is a short summary of CR's integration. The second one discusses the potential reasons of inflation differentials among euro area countries and inflation development in some countries. The last chapter makes an attempt to clarify the next trends in price development in CR after the admission into the Eurosystem.

## **2. The Czech Republic's Integration into the Euro Area**

Integration of CR into EU officialy started in 1995, when the Europe Agreement came into force. One year later CR asked for EU membership and in May 2004 it has become the member of EU.

The membership of CR in EU can be divided into three stages: 1) the EU membership and starting of convergence criteria fulfilment, 2) participation in the ERM II exchange rate mechanism and 3) the Eurosystem membership and adoption of the single currency euro.

Theoretically, the year 2007 could be the first year of the euro adoption in CR. Practically, it will be later, because the joint document of the Czech Government and CNB<sup>1</sup> recommends the Eurosystem membership as soon as economic conditions allow for doing so. It depends on the speed of real and nominal convergence process.

Especially, on the basis of document called “Assessment of the Fulfilment of the Maastricht Convergence Criteria and the Degree of Alignment of the Czech Economy with the Euro Area<sup>2</sup>”, where the government budget deficit was identified as the main problem, the The Government and CNB in September 2005 agreed accession of CR into EMU in 2010<sup>3</sup>.

### **3. Inflation and Potential Causes of its Differentials**

This ECB’s primary objective is defined for the euro area as a whole, not for single countries. So, this definition allows the differencies between countries in the euro area.

Next figure shows the different average annual inflation rates in the euro area.

**Figure 1 Average annual inflation rates in the euro area since the start of EMU**

Source: HOFMANN. B..REMSPERGER. H.(2005)

As we can see, inflation in single countries differs. The lowest one has been in Germany (1.3 %) and the highest one in Ireland (3.8 %). Both values are quite far from the ECB's goal (2 %).

The potential causes of inflation differentials in the euro area can be divided into two groups<sup>4</sup>: 1) price level convergence and 2) persistent effects of temporary shocks.

In the first case, inflation differentials may be a structural phenomenon arising from convergence of price levels. It may occur due to convergence of tradable goods prices as a result of increased trade integration, as well as because of convergence of non-tradable goods prices in the wake of real income convergence.

Countries differ in consumption pattern and economic structure. That is the reason why temporary shocks may impact differently on all countries. Persistent inflation differentials may also be caused by temporary supply and demand shocks. Asymmetric shocks (e.g. a change in indirect taxes or in fiscal stance) may give rise to persistent inflation differentials if there is a significant degree of persistence in inflation. But also temporary shocks which hit all member countries alike (e.g. changes in the euro change rate) may occur inflation differentials across countries.

We can see (Table 1) that Ireland, as a faster-growing country, was a country with high inflation rate during the period 2000 – 2003. The highest

<sup>4</sup> HOFMANN B..REMSPERGER H.(2005)

inflation rate in Ireland was in 2000 (5.3 %), one year after the single currency euro came into existence. It was about 3.2% points more than in previous year and more than 3% points than was inflation rate in period 1996 – 1999 (exclude inflation rate in 1997, inflation rate in that period was close to 2 %) . The same situation was evident in other countries (in Germany too).

But we would like to focus on inflation after the cash euro was launched. At the end of 2001 there were only 3 countries, where inflation rate was higher than in previous year (Germany from 1.4 up to 1.9 %, Portugal 2.8 up to 4.4 % and the highest change of inflation rate was in Netherland - from 2,3 up to 5.1 %). But these changes were only temporary, because in

2002 the inflation rates in these countries were lower again (in Germany lower than in 2000).

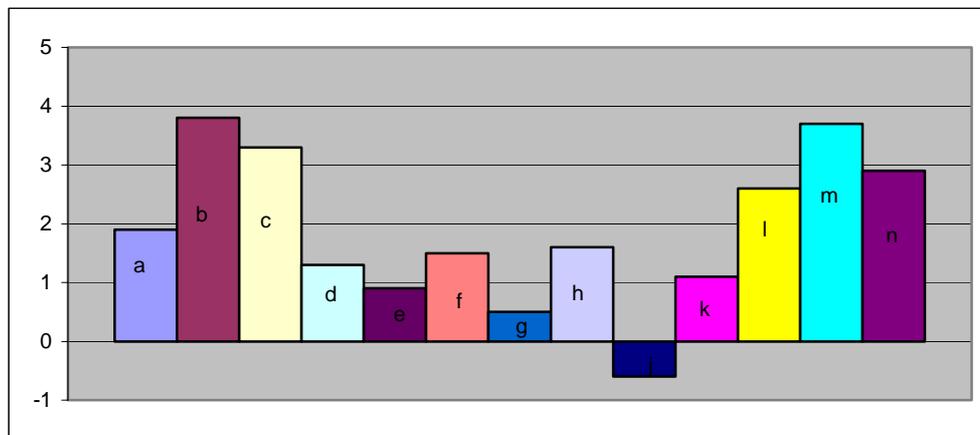

In all other countries, the inflation rates in 2001 were lower than in previous year. On the base of this table, it seems the introduction of the euro had not any significant impact on inflation rates.

But this is the same situation as the average inflation rate in the euro area (2.1 % in 2004) and inflation rates in the single countries, where the highest inflation rate is in Luxemburg (3.2 %) in contrast to the lowest one in Finland (0.1 %). We can not say about inflation rates in these countries, that they are below (not in Finland) and close 2 % like the ECB's objective is.

Now, we can explain the term „teuro“ used in Germany. As we can see, the inflation rate in Germany was below 2 %. In some period, the inflation rate in Germany was really close to 0 % (this level of inflation rate is quite dangerous for economy, which is in recession<sup>5</sup>).

„Teuro“ and low inflation in Germany seem they are not compactible. Next table discusses an annual rates of change of main categories of HICP in Germany. There we can see, that after the euro was launched, especially the prices of food and hotels and restaurant were gong up. There is the main reason, why German people apprehend the euro currency as „teuro“. Generally, we can confirm, that situation in all other countries was similar.

**Figure 2 Main Categories of HICP in Germany – Annual Rates of Change 3/2002 (%)**

#### **4. Inflation and the Euro Currency in the Czech Republic**

As we said above, CR will not accept the euro currency in 2007, when is the first possible term of the euro adoption for new EU member countries. The first term of the euro adoption for CR (according to the Government and CNB's Agreement in September 2005) will be in 2010. Of course, the real term will be able to come later. It depends on many factors for example on the results of next Parliament election. Because the present-day Government is left-wing and opposite right-wing is quite eurosceptic. There is no chance to not accept the euro, but if the right-wing wins the election, the CR's membership in the Eurosystem will may be later than in 2010.

During last years, the inflation rate in CR has been quite low in compare with other new EU member countries and with the former EU member countries too (Table 1).

In 2004, when CR became the EU member, the inflation rate was higher than in previous years (2.6 % - it was about 2.7% points more than in 2003). Next figure shows the main significant changes.

**Figure 3 Main Categories of HICP in CR – Annual Rates of Change 8/2005 (%)**

Source: Eurostat

As we can see, the structure of changes in compare with Germany is quite different. In case of CR we can confirm diverse development of the single categories. For example, the biggest differential of changes is between “communications” and “clothing and footwear” (13.6 % points). The result of this view is that there are some categories in CR those have been going up (this fact is understandable – e.g. price deregulation). An of course, it can be expected the growth of the others, because at least price level in CR is at (approximately) one half price level in EMU. So, there is necessary (as we said above) nominal convergence process, as well as the real one.

We can expect inflation pressures. Nowadays, the monetary policy in CR is conducted by CNB and CNB has got other tools to eliminate inflation

pressures. As well the conservative government expenditures (because of fiscal Maastricht criteria) should be expected too.

The timing of CR's joining to the Eurosystem is quite important. It is necessary to be prepared to adopt the euro at the moment when CR's economy will be restored to health and real and nominal convergence will be adequate. These assumptions should eliminate the growth of prices.

On the other side – after the adoption of the euro, the monetary policy in CR will be conducted by the ECB. Because the ECB's objective (inflation 2 %) is quite criticised – it is low for countries, those are characterized by deflation and recession, it can be expected the change of the present HICP's level. On the base of this, the inflation rate in CR could be higher.

## 5. Conclusion

The combination of monetary and fiscal policy is quite important for next CR's development. Nowadays, CR can use the possibility to form its own monetary policy and so it can eliminate inflation pressures.

It is necessary to fulfill all Maastricht criteria, but especially to restore to health the public finance. The timing of the adoption of the euro should be time really quite responsibly and so CR should adopt the euro really at the moment when CR will be prepared.

The price growth can be expected before the adoption of the euro as well as after that. The price and real level of convergence will be quite important for next price development after adoption of the euro.

# THE INDEPENDENCE OF CENTRAL BANK

**Daniela Beju**

Finance Department, Faculty of Economics  
“Babes – Bolyai” University  
Cluj – Napoca, Romania  
e-mail: bdaniela@econ.ubbcluj.ro, danibeju@yahoo.com  
telephone: +40264418652

## **Abstract**

*The independence of a central bank from the government contributes to its credibility and allows it to focus on price stability. Recent research studies demonstrate that there is a correlation between the degree of independence of a central bank and the inflation rate: countries whose central bank have enjoyed a high degree of independence from the political factor have managed to keep the inflation rate under control. Our paper raises the questions of how to ensure the independence of a central bank and how to measure the independence of a central bank. The study also makes reference to the current situation of the Central Bank of Romania in the context of our preoccupation with the EU integration.*

**Keywords:** *the credibility of central bank, the correlation between the independence of central bank and economic variables, the measurement of the independence of central bank*

## **1. Introduction**

Central banks involved in the combating inflation are in need of credibility, which can be earned through their independence. The farther a central bank is free from political influence, the more independent and credible it becomes, being thus able to focus on the maintenance of price stability.

The central bank's authority and scope of action depends on government. But governments often pass laws and follow customs that grant their central bank authority and autonomy to pursue price stability, even when it conflicts with other government objectives. Making the central bank an agency with the mandate and reputation for maintaining price stability benefits the economy and the government itself in various ways. Central bank independence is one of the means by which a government can choose the strength of its commitment to price stability.

A single, clearly defined price stability objective is very important and desirable for central bank's monetary policy to be independent. Multiple objectives are likely to be conflicting objectives. Multiple or unclear objectives are not likely to be consistent with the desire to promote the credibility of monetary policy because this credibility arises from the fact that the policymakers have a propensity to shift between different objectives. When central banks are granted more independence to achieve their objective, they must be subject to strong accountability and monitoring mechanism. In order for the central banks to be monitored and judged, their objectives and policies must be clearly stated and their actions must be transparent to the public.

The central bank's independence from the government has been a controversial issue in the last years. One of the preconditions for joining EMU is, according to the Maastricht Treaty, a sufficiently high level of independence of central bank. This formal precondition have induced the Central and Eastern European countries on the track to join the monetary union to grant more independence to their central banks.

## **2. The independence of central bank: A current issue**

### ***2.1. Definitions of the central bank independence***

The independence of a central bank has several senses. Some of them are presented below<sup>6</sup>:

A basic distinction has been made between “political” and “economic” independence by Grilli (1991). On the one hand, political independence is defined as the ability of the central bank to determine its policy objectives free from the government’s influence. Economic independence, on the other hand, represents the ability of the central bank to determine and implement its policies towards the achievement of its objectives.

According to Issing (1993), there are also personal elements of independence. Criteria in measuring the personal independence are likely to incorporate the appointment of the members of the central bank’s governing body, the duration of their respective contracts, the possibility of dismissing the central bank’s governor and other members of the governing body. It seems difficult to determine personal independence.

Baka (1994-1995) states that the central bank independence is analysed taking into account three aspects: 1) institutional independence, which is primarily defined in terms of the bank’s position within the system of governmental institutions and procedures applied in appointing and recalling the bank’s authorities; 2) functional independence expressed in the powers and capacity of the bank as regards determining and applying monetary policy and in its autonomy in taking decisions on the performance of the other functions specified in its statute; 3) financial independence, i.e. a permanent definition of the procedures for accumulating and distributing the bank’s resources that exclude any possibility of financial pressure being exerted.

Fraser<sup>7</sup> considers that the independence of central bank means to give to central bank a charter that includes a strong commitment to price stability and the freedom to pursue it.

Thus, many theoreticians and practitioners are concerned with the independence of central banks and, as a result, there are more definitions of

---

<sup>6</sup> Gokbudak N., *Central bank independence, the Bundesbank experience and the central bank of the Republic of Turkey*”, Discussion Paper No.9610, March 1996, pp.5-8

<sup>7</sup> Fraser B. W., “Central bank independence: what does it mean?”, Reserve Bank of Australia Bulletin, December 1994, p.3

this concept, each of them focusing on certain aspects of this important matter.

## ***2.2. Arguments for and against the independence of central bank***

Central bank independence obstructs the influence of politician on the authority in charge of the elaboration and implementation of monetary policy. Practical experience has demonstrated that in many cases the political power has given up the long-term objective of price stability in favour of their electoral interests. In order to impress the public and therefore win the elections political power attempts to obtain short-term economic growth through an expansionist monetary policy that generated inflation<sup>8</sup>. It follows that a government has more reasons to ‘trick’ with the aim of stimulating the economy before the elections or reduce real public deficit (financing through monetary issuance of the budgetary deficit). A central bank that is independent from the government does not take such political considerations into account, being rather interested in securing price stability.

So, there are two particular threats which bear upon the issue of central bank independence<sup>9</sup>:

- the tendency for policy makers and politicians to push the economy to run faster and further than its capacity limits allow;
- the temptation that governments have to incur budget deficit and fund this by borrowings from the central bank.

To avoid such situations central banks need to be independent. Central banks are more concerned about price stability than the political authorities. Because the actual policy is normally the outcome of a compromise between the central bank and the executive branch, a more independent central bank will have a stronger impact on actual policy and, therefore, average inflation will be lower.

Besides the arguments in favour of central bank independence there are severe criticisms against this solution:

- independence can be only “apparent”, with a strong political dependence hidden behind it, i.e. the political power exerts real but discreet influence on the central bank;

---

<sup>8</sup> Brociner A., *Monetary Europe*, Ed. Institutul European, Iași, 1999, p. 57

<sup>9</sup> Fraser B. W., “Central bank independence: what does it mean?”, *Reserve Bank of Australia Bulletin*, December 1994, p.2

- central bank independence involves a bureaucratic administration of monetary supply, carried out by the banks management and personnel; this is not necessarily better than political administration;
- central bank independence can affect the coherence of economic policy which includes monetary policy in the sense that the objectives of monetary policy can clash with those of the other components of economic policy.

### **2. 3. *The credibility of central bank***

Credibility is helpful to central bank in implementing monetary policy and a pre-condition for this is that the central bank be perceived to be independent and free from political interference. It is well known that at present the main objective of most central banks is the assurance of price stability. Since the 1980s the efforts to fight inflation have been oriented in these two complementary directions:

- adoption of monetary rules (e.g. Friedman's famous "golden rule");
- assurance of central bank independence.

What connects these orientations is the necessity for the central bank to be credible in its fight against inflation. A central bank enjoys credibility when the rate of inflation corresponding to its monetary policy is used by individuals as a starting point in their expectations. The credibility of a central bank reflects its capacity to announce a certain monetary policy and consequently a certain inflation rate, which is taken for granted by individuals and which, for this reason, serves as a point of reference in their estimations. To outplay the expectations of the public the central bank applies two methods<sup>10</sup>:

- influences the process of understanding by the public of the decisions regarding monetary policy

If the central bank opts for ambiguous information, the public will have difficulty in understanding the coordinates of the recommended policy. This possibility is appropriate for a central bank whose main concern is economic stimulation rather than price stability through the creation of monetary surprises. Instead, if the primary objective is price stability, then it is not recommended to withhold information, as the central bank is interested in the rapid gain of its credibility. During the time the central bank is preoccupied with the reduction of inflation, there should be a rigorous control over the monetary mass and a rapid process of social understanding.

---

<sup>10</sup> Cerna S., Central bank: credibility and independence, Ed. Sedona, Timișoara, 2002, pag.27-38,

- provides partial disclosures

Provision of partial information is usual practice among central banks in many developed countries, such as the United States, England, France, Germany, Canada, Switzerland, Australia, etc. This practice consists in the elaboration by the central bank of certain procedures that are intended to allow it to disclose only incomplete information regarding its monetary policy.

Although, as a rule, the information on the monetary policy of central banks is rather vague, the degree of imprecision differs from one country to another. A central bank that aims at stimulating the economy will provide imprecise information on its monetary policy, while a central bank that is interested in achieving price stability will provide accurate information.

Central bank credibility increases as the ambiguity of the announcements decreases. As a result, complete transparency of a monetary policy can increase the ability of the monetary authority to meet its objectives. But the risk of opaque practices depends on the influence that the political power has on the central bank. Hence the solution is to ensure central bank independence.

Central bank independence will confer credibility to it. This credibility is dependent on whether the central bank was committed to its promises in the past. If its reputation is poor, monetary policy will incur considerable costs, which will be covered by the entire society and not by the central bank. No matter what monetary policy the central bank implements, reduced credibility will translate into an inflationist factor and the society will bear the consequences. It follows that central bank credibility is of utmost importance, as one of the factors that sustain fight against inflation.

## ***2.4. Correlations between central bank independence and economic variables***

### **2.4.1. Relationship between central bank independence and inflation**

Many recent studies (e.g. Alesina, 1988; Bade and Parker, 1987) have shown that there is a significant correlation between the degree of central bank independence and the inflation rate. For example, Germany and Switzerland, whose central banks enjoy extensive independence, had an inflation rate of approximately 3.5% between 1974 and 1990, while Italy, whose central bank is under governmental control, posted an annual inflation rate of about 12.4% during the same period. These studies lead to the conclusion that economic performance is better (at least in terms of price

stability) in countries where the central bank is granted independence from political and governmental pressure.

Nevertheless, there exist some exceptions, such as Japan, which has one of the lowest rates of inflation and which cooperates closely with the Ministry of Finance. In addition, the Ministry of Finance controls the minimum compulsory reserves of the banks and is entitled to alter the regulations and order the resolution of political problems by the central bank. All the seven members of the Council for monetary policy of the Bank of Japan are appointed by the government. The Bank of Japan is not allowed to buy long-term government bonds on the market, but it can grant short-term advance money to the government<sup>11</sup>.

The conclusion is that the legal independence of the central bank is neither a necessary nor a sufficient condition for low inflation, although, other things being equal, less legal independence contributes to higher inflation. This is because monetary policies, on their own, can not guarantee to deliver lower inflation without other politicians' support.

Empirical research has indicated that the hypothesis of a strong connection between the degree of central bank independence and inflation rate is not fully confirmed. The relation exists, no doubt, but other elements have to be taken into account, such as<sup>12</sup>:

- attitude of the public towards inflation (in situations with the same degree of independence, inflation is lower in those countries where the public is adverse to inflation);
- ideological orientation of government (in situations with the same degree of independence, inflation is higher where governments are oriented towards centralisation and lower where governments have a liberal orientation. )

Since in situations with a similar degree of central bank independence the decisive factor seems to be the ideology of the governing party, it follows that between the political power and the central bank there exist certain means of communication beyond the official relations.

#### **2.4.2. Relationship between central bank independence and economic growth**

Empirical studies have demonstrated the existence of a close relationship between the degree of central bank independence and inflation, but the conclusions were not very convincing regarding the relationship

---

<sup>11</sup> Rose P., Money and capital markets, McGraw – Hill, Boston, 2000, pp. 509-510

<sup>12</sup> Cerna S., Central bank: credibility and independence, Ed. Sedona, Timișoara, 2002, p. 54

between central bank independence and economic growth. This can be inferred if we consider the countries whose central banks have a high level of independence but which have not necessarily had good economic results.

For example, in the 1980s, Italy and Spain, whose central banks have a reduced level of independence, registered the same average annual growth as Germany and the United States, where central banks enjoy a high degree of independence. In this case, an explanation could be that the level of development reached by Germany and the US is high enough for a slow pace to represent an acceptable level of economic growth in absolute terms<sup>13</sup>.

Independent central banks are more likely to achieve lower growth because politicians have less opportunity to manipulate interest rates for short-term political gain. However, low inflation is good for long-term growth.

#### **2.4.3. Relationship between central bank independence and budgetary deficit**

The third type of relationship that has been demonstrated empirically refers to the connection between central bank independence and budgetary deficit. It goes without saying that an independent central bank is able to resist the government's attempts to monetise budgetary deficits by imposing real austerity in most of the cases.

Data indicate that countries like Switzerland and Germany, where central banks are truly independent, have the lowest budgetary deficits. Other countries like Norway, Denmark, England, and France, where central banks have a lower degree of independence than the Federal Reserve System of the US, have incurred lower budgetary deficits than the US.

The various conditions in each country lead to different results even if the central banks are granted the same level of independence. This is the case of Norway, Sweden and Belgium, countries with comparable central bank independence, which incurred budgetary deficits of 2%, 3% and, respectively, 8% of GDP in the 1980s.

---

<sup>13</sup> Brociner A., *Monetary Europe*, Ed. Institutul European, Iași, 1999., p.59

### **3. Achievement of central bank independence**

Central bank independence raises another question: How can it be achieved? Among the measures that can increase it we mention the following:

- central bank can enjoy independence from the government in outlining its monetary policy;
- central bank's governor is not to be appointed by the government and his term in office will be long and irrevocable;
- price stability will be stipulated in the statute of the central bank as a primary objective and possibly as the single objective;
- central bank will not accept automatic financing of budgetary deficit through monetary issuance.

All these measures lead to the conclusion that the more a central bank avoids political interference, the more independent it becomes. For example, if the mandate of the central bank's governor is longer than the government's mandate, the central bank can concentrate on long-term objectives. Conversely, if the governor is constrained by the governing political party, the monetary policy will be influenced by governmental directives and thus it will lose sight of the long-term objectives connected with price stability. If the central bank has set a single objective, namely price stability, then there will be no dilemma as to which of the contradictory objectives to opt for.

### **4. Measurement of central bank independence**

Central bank independence from governments varies from country to country and from one period to another. Measurement of central bank independence is difficult to carry out, as it depends on a series of qualitative factors. Most of the researchers in the field (K Banaian, L. Laney and T. Willet, V. Grilli, D. Masciandaro and G. Tabellini, A. Cukierman, etc.) resort to procedures based on diverse criteria that define legal independence<sup>14</sup>. These procedures have two shortcomings:

- organisational and functioning laws of central banks in various countries are rather vague and thus the legal aspects quantified through these procedures are relative;

---

<sup>14</sup> Cerna S., The independence of central bank, Ed. Mirton, Timișoara, 1999, p.17

- the law regarding central bank's organisation and functioning is as significant as the manner in which it is applied and respected.

In 1992, Cukierman, Webb and Neyapty<sup>15</sup> conceived one of the most famous classifications of central banks using an index that measures their legal independence and taking into account various stipulations in the law regarding the organisation and functioning of central banks. This index was based on a coding of sixteen different legal characteristics of central bank as stated in charter which are grouped in four clusters of issues:

- formulation of procedures for the appointment and dismissal of the governor of the central bank (term of office, who appoints, who dismisses);
- formulation of the policy concerning the resolution of conflicts between the government and the central bank over monetary policy and the participation of the central bank in budget process;
- objectives of monetary policy (the relative importance of price stability among the central bank's objectives as stated in the law);
- establishment of limits on lending by the central bank to the public sector (such restrictions refer to the volume, maturity, interest rate, conditions for direct advances and from the central bank to the public sector, potential borrowers from central bank and the prohibition for central bank to buy or sell government securities on the primary market)

Each variable was coded on a scale between 0 (lowest level of independence) to 1 (highest level of independence). Without going into technical details about how the aggregate that measures the legal independence of the central bank is constructed, we list below the situations in which the highest ratings are obtained:

- legal term of governor is longer than 8 years and the government has little autonomy in appointing or dismissing the governor;
- central bank has a wider authority to formulate monetary policy and to resist government in cases of conflicts;
- price stability is stipulated in law as the only or the main objective of monetary policy;
- central bank sets tighter limits on its lending to the public sector.

---

<sup>15</sup> Cuckierman A., Webb S., Neyapty B., *Measuring the independence of central bank and its effect on policy outcomes*, World Bank Economic Review No.6, September 1992. pp. 356-359

These authors presented a weighted index of those sixteen characteristics that measured the legal independence of the central bank for four decades (1950-1989) in 72 countries (21 industrial countries and 51 developing countries). Their investigation shows that legal independence is inversely related to inflation in industrial countries, but not in developing countries. By contrast, in developing countries the governors' turnover is strongly and positively associated with inflation. The divergence between the letter of the law and actual practice seems to be substantially higher in developing than in industrial countries.

Meanwhile, the situation has changed, as reforms of central banks have taken place in many countries that go through the transition process. A recent paper, coordinated by Cukierman<sup>16</sup>, develops extensive new data on the legal independence of the new central bank in 26 former socialist economies. This data are constructed using the same codification system for measuring legal independence developed in 1992 by Cuckierman, Webb and Neyapti. This makes it possible to analyse comparatively the legal independence of the central banks in various countries. This classification is shown in the table below.

These data show that the legal independence of the central bank in former socialist countries is higher than that of the central bank in developed countries during the eighties. In particular, at least eight of the central banks in transition countries have levels of aggregate legal independence that exceed that of the highly independent Bundesbank during the 1980s.

This indicates that the central bank reform in the former socialist economies during the nineties was quite ambitious. The reformers in these countries chose to create central banks with levels of legal independence that are substantially higher, on average, than those in developed countries. But since it is likely that the average level of compliance with the law in the transition countries is lower than the compliance with it in Western countries, the discrepancy in actual independence may not be as large as it appears to be from this comparison.

*Source: Cukierman A., Geoffrey P. M., Bilin N., Central bank reform, liberalization and inflation in transition economies. An international perspective, Center for Economic Research, No. 106, October, 2000, p.11*

The fact that the average level of legal independence of the central bank of economies in transition is substantially higher than that of developed economies during the eighties at least partially reflects the shift in professional consensus among economists and policymakers in favour of the independence of central bank between those two decades. We believe that if the central bank reforms in the transition economies had taken place during the eighties rather than during the nineties, the level of independence of the central bank embodied in the new laws would have been significantly lower.

The main finding of Cuckierman is that in the case of developed economies the familiar negative relation between inflation and legal independence appears also in the transition economies but only at sufficiently high levels of sustained liberalization. In transition countries the legal independence of central bank is unrelated to inflation during the early phases of liberalization because the process of decontrol of domestic prices had a powerful impact on inflation.

The legal statute of a central bank is only one of the several elements that determinate its actual independence. Many central bank laws are highly incomplete and leave a lot of room for interpretation. As a result, factors such as tradition or the personality of the governor and other high officials of the central bank at least partially shape the actual level of central bank independence. Even when the law is very explicit, reality may be very different.

In 1992, Cukierman, Webb and Neyapti<sup>17</sup> developed an indicator of actual central bank independence from the actual frequency of the change of the governor. This indicator is based on the presumption that, at least above some threshold, a more rapid turnover of the governor reflects a lower level of central bank independence. If the political authorities frequently have the possibility to choose a new governor, they will at least have the opportunity to pick those who will do their will.

A high turnover rate indicates that the tenure of the central bank governor is shorter than that of an executive branch. This makes the central bank governor susceptible of being influenced by the executive branch and discourages the governor from trying to implement longer-term policies, especially those that would extend beyond the election cycle. If the governor stays on for several years and perhaps outlasts several heads of government, thus presiding over price stability, the governor's reputation can become strong enough to resist considerable pressure.

A low turnover does not necessarily imply a high level of central bank independence, because a relatively subservient governor may stay in office a long time. A governor's legal term of office does not seem to have much effect on the actual turnover. In most countries actual average terms in office of governor are shorter than the legal term.

Cukierman, Webb and Neyapti calculated the average annual turnover rates in the industrial and developing countries between 1950 and 1989 and

---

<sup>17</sup> Cuckierman A., Webb S., Neyapti B., *Measuring the independence of central bank and its effect on policy outcomes*, World Bank Economic Review No.6, September 1992, pp. 363-367

for each decade within that period. They found that the turnover rates in developing countries are considerably higher than those in industrial country. The turnover rate is not significant in explaining the variation of inflation within industrial countries. But, in developing countries, there is a positive relation between the governors' turnover and inflation. In other words, the lower the actual term in office of the governor is, the lower the actual independence of central bank and the higher the inflation rate are.

Another solution for the measurement of central bank independence is the use of some complementary evaluation criteria<sup>18</sup>:

- quality of the research department of the central bank: in the decision-making process the Board of Directors of the central bank relies on the reports, studies and publications elaborated by this department;
- level of development of capital market: the higher it is, the stronger the authority of the central bank, as this is the only representative of the state in some of these markets;
- method of remuneration of Board members: if the legislative or the executive cannot interfere in establishing the salary of the governor and Board members, and if the length of the mandate is considerable, a central bank is considered to enjoy a high level of independence;
- government's strategy concerning public debt: Some authors (T. Person and L. Svenson, A. Alesina and G. Tabellini, etc.) argue that the bigger the public debt is, the more tempted the government is to limit the independence of the central bank so that it will use monetary issuance as a means of reimbursing its debt to the state.

## **5. Central bank independence in Romania**

After 1989, three laws were passed on the statute of the National Bank of Romania (1991, 1998 and 2004), and each of them amended considerably the previous one with regard to the independence of the central bank. Law 312/2004 confers a high degree of independence to the central bank.

The law stipulates clearly that the National Bank of Romania (NBR) lays down and applies the monetary policy and the exchange rate policy and that "the primary objective of NBR is to secure and maintain price stability.

---

<sup>18</sup> Cerna S., Central bank: credibility and independence, Ed. Sedona, Timișoara, 2002, p.52

NBR can support the overall economic policy of Romania without impeding the achievement of its main goal, namely price stability” (Article 2).

It further specifies that “ in the accomplishment of its responsibilities, NBR and the leadership members will not demand or receive instructions from public authorities or from any other institution or authority” (Article 3).

Following the proposals forwarded by the permanent specialised commissions of the two chambers, Members of the Board are appointed by the Parliament for a five-year term (government is appointed for a four-year term), which can be renewed. The Parliament is entitled to dismiss a Board member on the basis of a common proposal by the aforementioned commissions of the two chambers of the Parliament if the official in question does not meet the requirements for exercising certain prerogatives or if he/she is guilty of misconduct (Article 33).

The Board of directors is made up of nine members (who cannot sit in Parliament, be politically affiliated or be part of a judicial authority or public administration), five of are personalities from outside the bank (Article 34).

A step forward towards the independence of NBR is the express provision according to which the central bank cannot acquire government securities from the primary market (Article 29), which is in fact one of the basic provisions of the Maastricht Treaty. The law also “bans the NBR from granting overdraft or any other type of credit to the state, central and local authorities, public limited companies, national companies and other enterprises in which the state has a stake (Article 7).

As we can notice, the Romanian legislation comprises many elements that confer independence to the central bank. Nevertheless, for the accomplishment of its fundamental objective, the real independence of the central bank is much more important than its legal independence. We contend that at present NBR enjoys not only legal independence but also real independence in the implementation of its monetary policy, a fact that can be proved by the positive results in reducing inflation in the last years.

## **6. Conclusion**

The importance of central bank independence as a signal of financial respectability and gaining access to international credit markets, rose through the nineties with the further abolition of restrictions on capital flows and further widening of international capital markets. Yet in the midst of theoretical and political disputes, this issue tends to turn into a problem in itself. That is why we should take into account the following:

- there are just different degrees of independence of the central bank for a certain economy, in a certain period, or for different economies in the same period;
- appreciation of the independence of central bank often has a formal character, with focus on its the relationship with the government, as it is formulated in the charter.

But behind the legal independence of central bank there may hide some political complicity or a trade off of politico-bureaucratic privileges. For this reason, we can argue that the decoding of the communication channels between the central bank and the political world is far from being completed. Moreover, legal independence of a state's central bank can be a mere formality for the achievement of certain requirements for EU accession or for the general impression on a country's economy. The real issue is the manner in which legal independence contributes or not to the creation of a favourable environment for the effective implementation of the policy of price stability.

In spite of the fact that legal independence does not always fully translate into actual independence, it is nonetheless associated with significantly lower inflation. Examination of the relation between the inflation and legal independence in the transition and developed countries strengthens the conclusion that legal independence and inflation are negatively related. A higher level of legal independence of central bank is generally associated with a lower inflation. But, for a given level of independence from the political authorities a more focused legal mandate to pursue price stability is expected to result in a lower rate of inflation

## **Abstract**

*On 1 May 2004 ten new Member States joined the European Union. The new members will adopt the euro only when they fulfil convergence criteria. The governors of the central banks of the new EU countries are now members of the General Council of the ECB but they will not join the main decision-making body – the Governing Council – until they adopt the euro. Out of a great number of open questions in this article the specific attention is paid to the ERM II. Participation in the Exchange Rate Mechanism II is one of the core requirements when entering the European Monetary Union. In 2005, there are 7 countries only, which are the members of this system. Six of them are using the broad bands for the exchange rate movements and one (Danish krone) is using +/-2,25 % fluctuation bands. For the moment, each country out of these 7, has met the criterion of a stable exchange rate. V4 countries are also preparing for the accession to the ERM II. The Slovak Republic would like to participate in the ERM II as soon as possible..*

## **1. Introduction**

In the system of a society's government a key role is played by central banking. Since the 17<sup>th</sup> century, which can be considered the period when central banking emerged, we have been witness to the creation of a variety of institutional arrangements. In this article we want to take attention to the changes in the central banking in Europe, especially in European Union after the enlargement in 2004.

## **2. Institutional arrangements in central banking in general**

By a variety of institutional arrangements we mean the differential coverage of monetary policy by entities – in history we can find examples formed for central banks created at the national and regional level; we can likewise find various central banking systems – from simple homogenous systems (one institution forming the central bank, e.g. the NBS) through to structured systems (for example the Federal Reserve System in the USA).

Besides the different institutional arrangement, we can see also a differentiated approach among central banks in carrying out their individual functions. Monetary authorities began to be considered as central banks only following the incorporation of an issuing function into their activities. This was not always however the primary function these institutions oversaw. From the historical aspect, the first “future” central banks at first performed the function of a bank to the state, only later becoming issuing banks, to which were progressively added a series of further functions.

Besides institutional and functional characteristics, central banks also differed in terms of their operating framework, meaning that there were differences in the use of direct and indirect monetary policy instruments. The latter, of course, resulted from the characteristics of the monetary circulation and from the need to solve, at a given moment, a problem in monetary development. In this regard therefore neither were the constructions of monetary objectives always identical, even if in the broader sense it is possible to find certain common elements.

As regards the legal standing and subsequently financial aspects of central banks, we can in this case speak of public institutions, companies formed from share capital (shareholder structure is differentiated), as well as of specific subjects, where in certain activities the central bank has the status of a body of general government, and in other activities (for example in the acquisition and administration of own assets) has the status of a business.

Despite these differences, it may be claimed that monetary authorities always featured as sophisticated institutions, recognised by the public. From both the aspect of aims fulfilled, as well as functions entrusted to them, central banks were, alongside governments, the most important entities in any country.

Enlarging European Union with 10 new member countries has led to important changes in central banking too:

- changes in the structure of the ESCB,
- changes in the volume, the number of stake holders and even in the structure of the participation of the EU member countries in the ECB capital,
- changes in the system of voting in the decisive body of the ECB,
- changes in the monetary tools of the single monetary policy,
- the newly accepted member countries are preparing the transition of some competences of the national central bank to the ECB,
- some changes take place in the ERM II, too.

### **3. Current state of central banking in EMU**

Since May <sup>1st</sup>, 2004 the ESCB contains 25 national central banks of the EU led by the European Central Bank. The monetary policy is managed by the Eurosystem represented by the ECB and the central banks of the countries which accepted the euro currency.

The ESCB has three organs – the Governing Council, the Executive Board and the General Council. In the Governing Council and the Executive Board the member countries of the Eurozone are represented, whereas the General Council contains the president and vicepresident of the ECB as well as the governors of the EU national central banks. As the countries which have not accepted the euro don't participate in the single monetary policy, this institution mainly supports the ECB, however it has the possibility to participate in some objections as to statistics, rules for rational banking business etc.

The capital of ECB, too, was modified after the EU enlargement. Since 1. 5. 2004 it means 5 564 669 247,19 EUR. Up to this date the central banks of the Eurozone had to pay the full amount of their part and the central banks not in the Eurozone 7 % (before the enlargement 5 %). So the total paid amount of the ECB capital is 4 089 277 550,12 EUR. The main stake holders are the central banks of Germany, France, Italy and Great Britain. The participation of the new member countries is no more than 10,1474 % (there of belongs to the central bank of Poland 5,1380 %). The participation

in the capital is connected with the limitation for foreign currency reserves managed by the ECB (ten times as much).

The new voting system in the ECB Governing Council presupposes already the future membership of 27 countries in EMU. The members of the ECB Executive Board will have 6 stable votes and 15 votes will be flexible according to the group to which the given central bank will belong according to the proportion of the GDP of the member countries without derogation in market prices and the proportion in the aggregate balance sheet of the monetary financial institutions of the member countries without derogation. Since 1. 6. 2004 the number of voting persons must not exceed 15.

The single monetary policy of the Eurosystem continues to be based on two principal pillars. The main aim of monetary policy in the eurozone in this context is to ensure price stability, which in quantitative terms is set as the upper limit for growth of the harmonised index of consumer prices – HICP<sup>2</sup> on an annual basis, and this of up to 2%, where the ECB takes this parameter to be a medium-term target. The monetary policy strategy of the ECB is a certain mix of the theoretically defined monetaristic transmission mechanism and inflation targeting. The first, basic pillar of the Eurosystem's monetary policy strategy is the analysis of the development of a broad set of economic and financial indicators, the second pillar is the analysis of the development of the M3 money aggregate. The combination of the two pillars of the Eurosystem ensures that monetary, financial and economic development is carefully and thoroughly monitored. This thorough analysis enables the ECB to set interest rates at a level best serving to maintain price stability.

Beginning from March 10<sup>th</sup> 2004 however the maturity of main refinancing operations is reduced from two weeks to one week and the maintenance period for the Eurosystem's required reserve system is redefined to start on the settlement day of the main refinancing operation following the Governing Council meeting at which the monthly assessment of the monetary policy stance is pre-scheduled, rather than on the 24<sup>th</sup> day of month. From 14. 1. 2005 the Governing Council of ECB decided to increase the allotment amount for each of the longer-term refinancing operations from 25 mld. EUR do 30 mld. EUR and the operation day is defined as the last Wednesday in

---

<sup>2</sup> Note: HICP – the basic components of this index are prices of goods – in the division into processed and non-processed, further industrial goods and energy, and the second component of this index are prices of services. For example in 2001 the prices of goods represented 61.9% of the index, whereas prices of services only 38.1%.

the month and not the first Wednesday in the maintenance period for minimum reserve.

After the foundation of the EMU the central banks of the member countries fulfill eurosystem and non-eurosystem functions. The eurosystem functions mean the fulfillment of the obligations given by the participation in the Eurozone and the single monetary policy of the Eurosystem, whereas the non-eurosystem functions mean all other functions which can be fulfilled by the national central banks on their own choice but not contrary to the Eurosystem aims. Non-eurosystem functions are first of all banking supervision and in some countries financial market supervision, the management of foreign currency reserves exceeding the ECB, state agency on the emission of state bonds or in the operating of state operations accounts, the emission of eurocoins (if agreed by the ECB), the direction of interbank payment system connected with TARGET, economic research, collection of statistical data, representation of the country versus international monetary institutions.

As regards changes in the system of exchange rates applicable in EMU – with the fact that the EU has expanded to 25 states, the first step on the road to EMU is to enter the ERM II exchange rate system, which in essence means the fixing of the national currency's exchange rate to EUR and maintaining its fluctuation band within  $\pm 15\%$  without currency devaluation for a period of two years. Of the old non-EMU member states only Denmark is presently participating, using the narrower band of  $\pm 2.25\%$ ; of the new EU member states Estonia, Slovenia and Lithuania joined the ERM II system in June 2004, in the broader band and since May 2005 Cyprus, Malta and Latvia also with a broader defined band.

**Table 1 Fixed exchange rates of participants in ERM II**

<b>Country</b>	<b>Min limit</b>	<b>Central parity</b>	<b>Max limit</b>
Danish krone (DKK)	7,62824	7,46038	7,29252
Estonian kroon (EEK)	17,9936	15,6466	13,2996
Lithuanian litas (LTL)	3,97072	3,45280	2,93488
Slovenian tolar (SIT)	275,586	239,640	203,694
Maltese lira (MTL)	0,493695	0,429300	0,364905
Cyprus pound (CYP)	0,673065	0,585274	0,497483
Latvian lats (LVL)	0,808225	0,702804	0,597383

#### 4. The future development in the ERM II

The Resolution of the Committee on the Exchange Rate Mechanism II (ERM II) establishment (97/C 236/03 dated June 16, 1997) and the Agreement between the European Central Bank (ECB) and national central banks of the member states excluded from the euro zone dated September 1, 1998, supplemented by the Agreement dated April 29, 2004 regulate the ERM II entrance as well as domestic currency exchange rate (ER) in relation to EUR procedurally. The Procedural steps to allow participation in ERM II document comprises the individual steps, which allow the countries to participate in the ERM II. This document was prepared by the European Commission (EC) on the summit meeting, that took place in Athens on 28 May, 2003.

V4 countries are also preparing for the accession to the ERM II. The first step that allows the participation in the ERM II is the request of the Minister of Finance as well as the head/president of the central bank submitted to the ECOFIN board Minister, who comes from the country, which chairs the European Union (EU). Submitted request is thereafter discussed in the Economic and Financial Committee (EFC), whose members are the member states representatives, as well as the representatives from the EC and ECB. ERM II Committee reviews the macroeconomic consistency of the candidate country with the Principal direction of the economic policies and the Stability and Growth Pact. Hereby, it discusses the future central parity and the fluctuation band.

**Table 2 Entry to the ERM II a adoption of single currency**

Country	Entry to the ERM II	Adoption of single currency - plan
Estonia	June 2004 (R)	June 2006
Lithuania	June 2004 (R)	1 January 2007
Slovenia	June 2004 (R)	2007
Latvia	April 2005 (R)	2008
Malta	April 2005 (R)	2008
Cyprus	April 2005 (R)	Non specified
Czech Republic	2007 (P)	2009 – 2010
Slovak Republic	2006 (P)	1. 1. 2009
Hungary	6/2004 – 6/2005 (P)	1. 1. 2008
Poland	As soon as possible (P)	2007

*Note.:* (R) reality (P) plan

*Source:* internet pages of national central banks

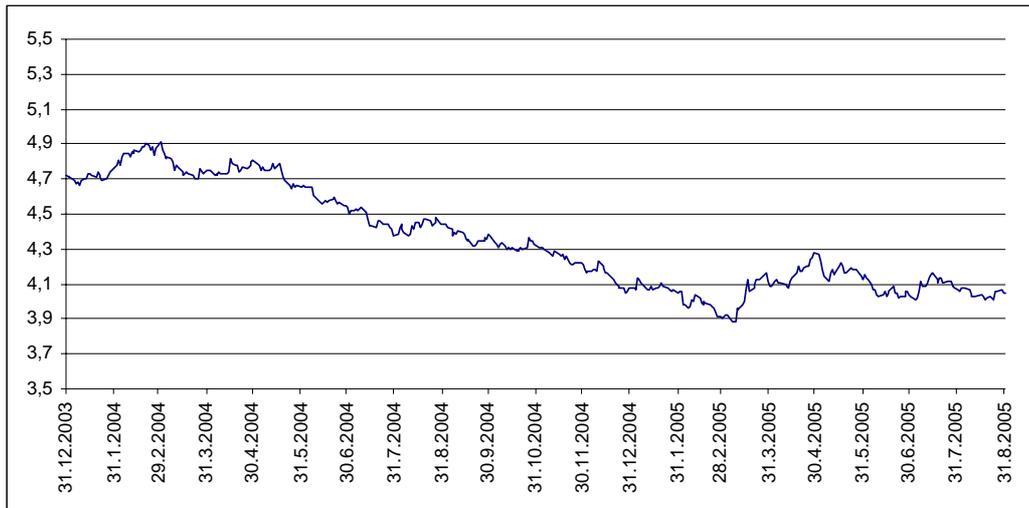

Underestimation of the central parity can lead to economy overheating and consequently to higher inflation. This could endanger and slow the process of reaching the inflation convergence criterion. On the contrary, overestimated central parity could weaken/lower economy competitiveness. Besides this it could support the speculative attacks against the currency indirectly.

The decisions related to the central parity changes as well as the fluctuation band are made based on the Agreement reached by the following parties: Ministers of individual euro zone countries, the president of ECB, ministers and the governors of the EU member states central banks excluded from the euro zone, engaged in the Mechanism, European Commission representative and the president and the secretary of EFC. The General Board is responsible for monitoring of the ERM II operations. It serves as an international cooperation forum and the cooperation in the field of exchange rates.

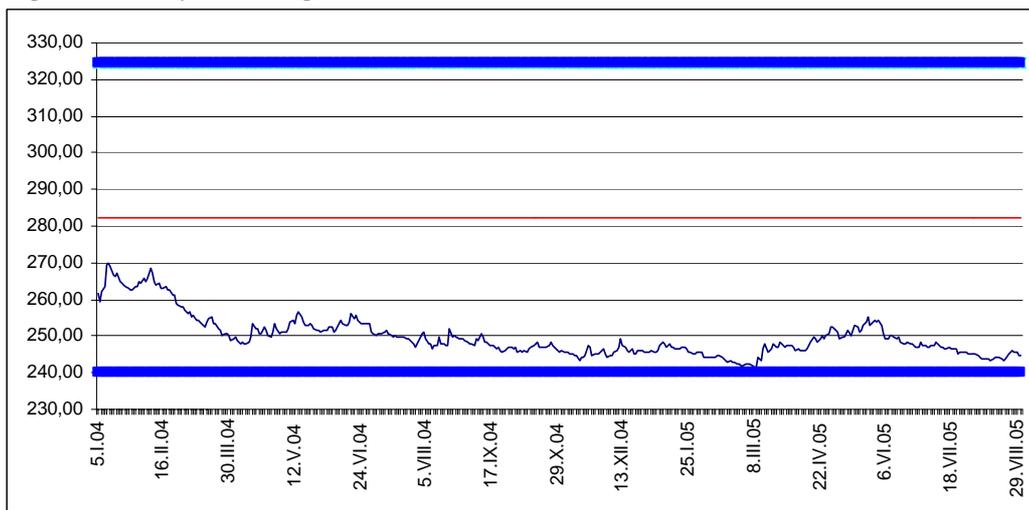

## **5. Conclusion**

In 2005, the Danish crone and the Slovenian toliar have found their selves near their central parity to EUR. Estonian koruna ER and the Lithuanian litas have stayed unaffected. When speaking about other countries of EU, in April 2005, euro has depreciated in relation to British Pound. During the period starting March till May, EUR has appreciated in relation to Polish Zloty (in amount of 3, 6%) and less significantly to Hungarian Forint, Slovak and Czech koruna, too (in the following amounts: 1, 8%, 1, 5% and 1, 2%). The main reason of mentioned depreciation in the currencies lies in the reduced willingness to undergo the risk on the financial market. Simultaneously, EUR has appreciated in relation to Swedish koruna by approximately 1%.

**Figure 1 Daily exchange rate of PLZ/EUR**

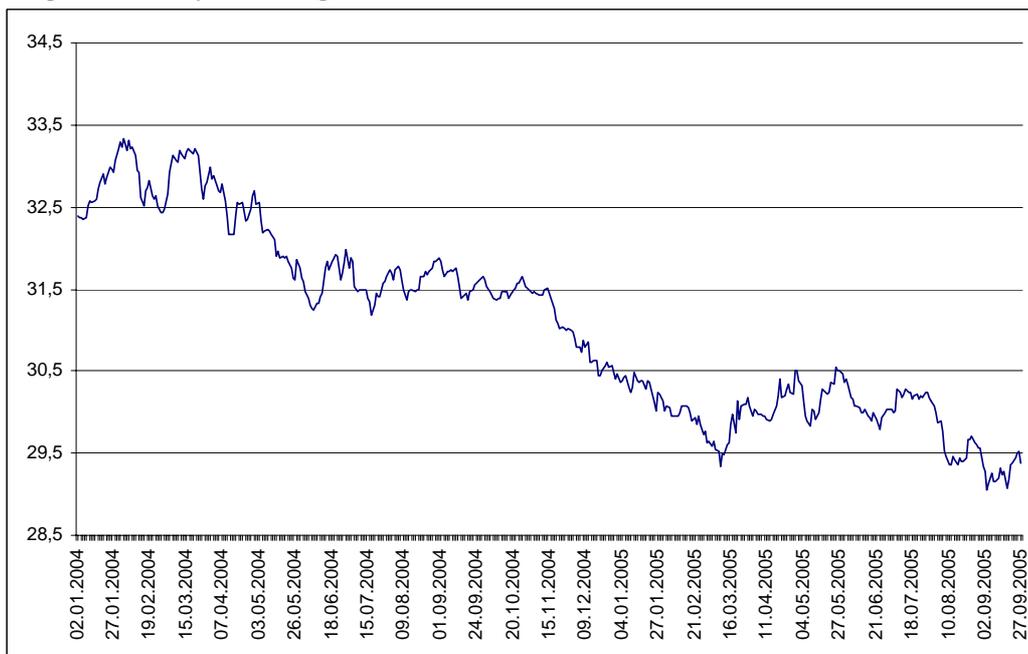

**Figure 2 Daily exchange rate of HUF/EUR**

**Figure 3 Daily exchange rate of SKK/EUR**

**Figure 4 Daily exchange rate of CZK/EUR**

The macroeconomic views of the ECB specialists/experts on the euro zone deal with the fact, that in the near future the ER of EUR in relation to USD and JPY would not be changed significantly. Their view on economic

growth for the euro zone is promising, i.e. 1- 1, 6% in the year 2005 and 1, 3-2, 3% in the year 2006. However some changes can occur with respect to the increasing oil price at the world market.

The Slovak Republic too is preparing to join the Eurozone. It is supposed to join the ERM II in 2006 and after having fulfilled the Maastricht criteria to join the Eurozone in 2009.

## **Abstract**

*The monetary policy in Romania is implemented by The National Bank of Romania, whose main objective is to ensure price stability. At the first stage of the transition to the market economy, the monetary policy, had a secondary role, due to its slow evolution from a direct control of monetary expansion towards indirect instruments and from multiple and contradictory objectives (imposed by the state policy) towards what should represent the sole objective of monetary policy namely price stability. Consequently the results obtained in controlling inflation are much more modest as compared to those of other candidate countries to European integration. For many years, the strategy of monetary policy had consisted in the control of monetary aggregates. Using monetary aggregates as an intermediate objective of the monetary policy proved to be effective during the time when inflation was diminished to the current level. Recently, the central bank has reshaped its monetary policy by the adoption of a new strategy - inflation targeting. The reduction of the inflation rate to the European level constitutes a major concern for The National Bank of Romania in following years. The article also refers to the stage of fulfillment of the other convergence criteria required for Romania's accession to the EU.*

**Keywords:** *inflation targeting, stage of fulfillment of convergence criteria.*

## **1. Introduction**

At present, the main responsibility of the central bank, almost everywhere in the world, is to establish and implement the monetary policy, which is the most important task for the National Bank of Romania, our central bank, as well.

Monetary policy has the same final objectives as economic policy, such as: sustained economic growth, full employment of resources, a stable balance of payments for the nation vis-à-vis the rest of the world and price stability. But, frequently these objectives are contradictory, because the achievement of one of them may cause the failure of the others. This is the reason why the monetary policy has its own fundamental objective, which is to ensure the price stability. The price stability may create a favourable economic framework that can allow sustained economic development

## **2. A critical analysis of Romania`s monetary policy between 1990 and 2004**

As in the case of the Romania's economic reform, the monetary policy has made slow progress from the direct control of monetary expansion to the indirect instruments and from multiple and contradictory objectives to what should represent the only concern of monetary policy, namely price stability.

In the first years of the transition period the monetary policy was oriented towards the achievement of some objectives that were not compatible with maintenance of price stability (e.g. the stimulation of production or full employment of labor resources). This tendency was favoured by the ambiguous formulation of Law no.34/1991, whose article 1 stipulated that “ The National Bank of Romania (abbreviated as NBR) establishes and implements the monetary policy within the economic and financial policy of the state”. As a results, the monetary policy was constrained to pursue multiple objectives, such as:

- preferential crediting of unprofitable sectors;
- sustaining the exchange rate artificially, as an anti-inflationist anchor;
- administration of public debt and financing budgetary deficit;
- maintenance of current account deficit within the established limits;
- the central bank's acting as a lender of last resort due to problems derived from the unsatisfactory state of the banking system.

Consequently, inflation was maintained at high levels, during the first years, being measured by three figures annually (see table 1), with most disastrous effects, both socially and economically. Only towards the end of 1993, by promoting a restrictive policy based on strict control of liquidity and rapid escalation of interest rates, NBR managed to limit the size of inflationist process. Nevertheless, against the slow rhythm of restructuring of the real sector and the stop-and-go character of authorities' policies, inflation returned in 1997 to the level of three-digit figure.

**Table 1 Inflation rate (%)**

<i>Year</i>	<b>1990</b>	<b>1991</b>	<b>1992</b>	<b>1993</b>	<b>1994</b>	<b>1995</b>	<b>1996</b>	<b>1997</b>
<i>Annual average</i>	5.1	170.2	210.4	256.1	136.7	32.3	38.8	154.8
<i>End of year</i>	37.7	222.8	199.2	295.5	61.7	27.8	56.9	151.4

*Source: National Bank of Romania*

The new laws regarding the Statute of NBR (Law no. 101/1998 and Law no. 312/2004, respectively) have made a significant amendment by specifying that "the main objective of NBR is to ensure of price stability". This allowed the central bank to gradually disburden its monetary policy of multiple objectives and thus consolidate its independence. These changes created a favourable framework that made it possible for the central bank to focus on price stability.

Indeed, in the last years, there has been a clear tendency to orient the monetary policy towards the mechanism of market economy. Nevertheless, the results obtained in controlling inflation are much more modest compared to those of other Central and Eastern European countries (see table 2).

**Table 2 Inflation rate (%)**

<i>Year</i>	<b>1998</b>	<b>1999</b>	<b>2000</b>	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2004</b>
<i>Annual average</i>	59.1	45.8	45.7	34.5	22.5	15.3	11.9
<i>End of year</i>	40.6	54.8	40.7	30.3	17.8	14.1	9.3

*Source: National Bank of Romania*

The strategy of monetary policy had consisted in the control of monetary aggregates. The main instruments used in recent years by the central bank for controlling monetary supply were: minimum reserve requirements, open market operations and collection deposits from commercial banks. Among these, the main role was conferred to minimum reserve requirements, whose current rate is 18% for deposits in the national currency and 30% for deposits in foreign currency.

Using monetary aggregates as an intermediate objective provide to be effective during the time when inflation was diminished to the current level.

But, starting with August 2005, NBR has reshaped its monetary policy by adoption of a new strategy – inflation targeting – which represent a superior stage in maintaining inflation under control and a component of the process of economic convergence with the EU countries..

### **3. Inflation targeting – the new monetary policy strategy**

#### ***3.1. The concept of inflation targeting***

In the last decades, as the factors that effect price stability in an economy have become more and more familiar, and with the development of a relatively sophisticated system of analysis, the central banks have adopted a new objective that is directly connected with the assurance of price stability.

The first country to adopt this strategy was New Zealand (in 1989). Until now almost 20 countries have opted for the inflation targeting, among which we mention Canada, Great Britain, Finland, Spain, Brazil, Chile, Israel, the Czech Republic, Poland, Hungary. In all these countries, inflation rate decrease after the adoption of this new strategy.

Inflation targeting represent a framework of monetary policy characterized by the public announcement of the quantitative targets of the inflation rate for one or more time horizons and by explicit recognition of the fact that a low level of inflation constitutes the primary long-term objective of the monetary policy.

The main characteristic of this strategy consists in the primacy of the inflation target over any other objective of the monetary policy . All the other monetary variables, i.e. monetary supply, interest rate, exchange rate etc., become of secondary importance, being taken into account only if they can be subordinated to the inflation objective.

#### ***3.2. Condition for inflation targeting***

The adoption of any mix of economic policies has to consider the existing conditions in the respective country, the effects of the policy implemented in the preceding period and, obviously, the established targets. The transition to the inflation targeting requires the fulfillment of certain conditions<sup>3</sup>. These are presented bellow:

---

<sup>3</sup> Isărescu M., Towards a new strategy of monetary policy: inflation targeting, Craiova, October 2003, pp. 19-29

➤ **The cultural component**

This is the most important qualitative element because the monetary policy cannot achieve very ambitious objectives without the support of the civil society. It follows that the success of inflation targeting depends, to a large extent, on the acceptance by the whole society of the importance of the price stability.

➤ **Credibility of the central bank**

This condition is closely related to the cultural component and has an essential role in the success of the inflation targeting. If people trust the forecasts of the central bank, they will integrate them in their business plans and ultimately contribute to the realization of the predictions formulated by the central bank.

➤ **The central bank's capacity of intervention**

Firstly, the central bank has to be autonomous in order to set its objectives and decide on the adequate measures for their attainment. The primacy of the central bank's anti-inflationist objective has to be explicitly stipulated by the law. Secondly, the central bank needs at least one effective instrument in order to control the inflationist process and anchor the inflationist expectations of the public.

➤ **Full harmonization between the monetary policy and the general policy of the government**

This requirement has a significant part in the successful implementation of the inflation targeting, given that the government's decisions for realization of the economic objectives can affect price stability. Consequently, close cooperation is required between the government and the central bank, not only in the form of public declarations, but also in practice. The government is supposed to support the attainment of the inflation target through its fiscal policy.

➤ **Technical requirements**

First of all, it is required that the price index for the quantification of inflation should be adequately selected. Next, the public should become familiar with the transmission mechanism of the monetary policy. Last, but not least, the quantitative targets and the calendar for their attainment should be established.

### ***3.3. Analysis of the conditions of inflation targeting in Romania***

The adoption of the inflation targeting is not only a matter of the choice, but also a matter of meeting some significant requirements. Most of the conditions for successful implementation of inflation targeting have been fulfilled in our country. In what follows, we refer to principal aspects that have created the favourable conditions for the introduction of this new strategy<sup>4</sup>.

1. At the end of 2004, the inflation rate reached a one-digit value (9.3%) for the first time after 1990, as a result of a productive cooperation between the government and the central bank.

2. Since the summer of 2004, NBR has been benefiting from a complete operational independence, a condition stipulated in Law no.312/2004 regarding the State of NBR.

3. The successful des-inflationist process recorded through the last years has increased the credibility of the central bank.

4. After 5 years of continuous development and appropriate supervision, we can speak about a solid and stable financial system.

5. Fiscal dominance has ceased to be a problem given the above-mentioned legal independence of the central bank, the relatively low public deficit and the more and more consistent mix of financial policies.

6. The decision to implement inflation targeting for the following years was taken by the NBR in cooperation with the government.

7. A more flexible exchange rate in the context of maintaining the regime of controlled flotation is compatible with inflation targeting.

8. For many years, the central bank has informed the public about the economic development and the monetary and exchange rate policy through the publication of periodical reports and the press release; in addition, since 2003 the BNR has published a report on inflation every semester.

9. The quantitative targets, including those regarding the inflation rate, and the calendar for their attainment, have already been established as there exists the decision to join the EU and the euro zone, and to meet the convergence criteria agreed upon in the Maastricht Treaty by the end of 2009.

10. Since the latter half of 2004, the central bank has been testing an econometrical model for forecasting purposes, which has been adjusted by BNR` specialists to the specific conditions existing in our country.

---

## **4. Towards Romania`s European monetary integration**

### ***4.1. Convergence criteria for the adopting of the euro***

#### **4.1.1. Nominal convergence**

The Maastricht Treaty specified that for EMU participations, a EU member state will have to meet just the following criteria for nominal convergence<sup>5</sup>:

- inflation rate criterion: the increase of inflation rate measured through consumer prices should be no more than 1.5% higher than the average inflation rate of the three best-performing EU member states in terms of price stability;
- long-term interest rate criterion: long term interest rate should not exceed the average rate of the three best-performing EU countries in terms of price stability;
- budgetary deficit criterion: budgetary deficit should not exceed 3% of GDP;
- government debt criterion: government debt should not exceed 60% of GDP;
- exchange rate criterion: exchange rate should remain within the normal fluctuation margins of the ERM II<sup>6</sup> without severe tensions for at least two years.

After the new EU candidate states become EU members, they will participate in ERM II, and then, on the basis of the fulfillment of the nominal convergence criteria, they will adopt the common European currency.

#### **4.1.2 Real convergence**

The Maastricht Treaty does not make reference to the real convergence criteria to ensure a high degree of similarity among the economic structures of the EU member states, given the fact that before the early 90s the European Union comprised only countries with similar economic systems. Real convergence became an important issue only when

---

<sup>5</sup> Brociner A., Monetary Europe, Ed. Institutul European, Iași, 1999, pp. 22-24

<sup>6</sup> ERM is the abbreviation for Exchange Rate Mechanism. ERM II is a bilateral mechanism in which the currency of each participant has a central parity against euro with a fluctuation margins of the market exchange rate of +/-15%

the accession of the Central and Eastern European countries was considered. The main convergence criteria are<sup>7</sup>:

- degree of economic openness (expressed by the proportion of a country's exports and imports in the GDP);
- proportion of bilateral trade with the EU member states in the whole volume of international trade;
- economic structure (expressed in the contribution of the principal sectors (agriculture, industry and services to the creation of GDP);
- level of GDP/inhabitant (evaluated either at the nominal value or through the parity of the purchasing power).

Real convergence is as important as nominal convergence, as according to the Optimal Currency Area Theory the states in a group cannot mutually gain from a common currency unless their economic structures are similar and when there is no risk of asymmetric shocks only in some of these countries<sup>8</sup>. As a result, the unitary monetary policy concerns a group of supposedly homogeneous economies and not the peculiarities of each economy. In these circumstances, the Central and Eastern European countries cannot give up their own monetary policy as long as the risk of some asymmetric shocks (caused by differences in economic structure) is considerable. This is explained by the fact that the final objective is not just the adoption of the common European currency but also the generation of profits.

#### ***4.2 An analysis of the fulfillment of the convergence criteria in Romania***

There is a strong consensus in Romania concerning the necessity of our integration in the European structures, both by the public at large and at the political level/by the politicians. But integration requires the realization of those convergence criteria stipulated for the superior stage of integration, i.e. the monetary union. These criteria are related not just to the aspects under the control of the authorities (e.g. budgetary deficit) but also to the indicators through which the market carries out its own evaluations (e.g. long-term interest). Ultimately, the Maastricht criteria represent absolutely normal

---

<sup>7</sup> Isărescu M., Romania's transition to the Euro, "Babeş-Bolyai" University, Cluj-Napoca, 2004, pp. 5-6

<sup>8</sup> Isărescu M., Romania's Transition to the Euro, presentation at the Conference organized by the Academic College of Babeş-Bolyai University, Cluj-Napoca, March 2004, p. 3

objectives for any country that aspires to long-term sustainable development within or outside the European Union.

Of all the nominal convergence criteria Romania meets those concerning the budgetary deficit and public debt (see table 3). Thus, Romania differs from the majority of the countries in Central and Eastern Europe which encounter difficulties exactly in these domains, being obliged to make substantial adjustments.

**Table 3 The state of public finance** (%)

<i>Years</i>	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2004</b>
<i>Budgetary deficit/GDP</i>	3.2	2.5	2.3	1.1
<i>Public debt/GDP</i>	23.1	22.7	23.7	21.5

*Source: National Bank of Romania (author's calculation)*

As far as the budgetary deficit is concerned the performance is good as in the last years it has been beneath 3%, the level established by the Maastricht Treaty. Romania's results are better than the performance of others countries that jointed the EU on May 1<sup>st</sup> 2004. The situation of the public debt is also favourable and superior to all the Central and East Europe countries<sup>9</sup>.

By contrast, Romania's position in terms of the inflation rate is much weaker than that of other Central and East Europe countries. Although, the results obtain in recent years (14.1% in 2003, and 9.3% in 2004) are remarkable, Romania is ranked outside the optimal level stated in the Maastricht Treaty, being exceed even by the weaker countries in this sense, namely Slovakia, Slovenia and Hungry, whose inflation rate is two or three times lower than Romania.

This situation can be explain by the slow process of price liberalization, on the one hand, and by the conscious adoption of strategy for gradual reduction of inflation, on the other hand. In Romania, the last substantial price liberalization took place only in 1997, while in other more advanced countries this process occurred between 1992 and 1994. Moreover, we preferred the gradual reduction of inflation by approximately a quarter of its value in the preceding year to a radical solution of the Currency Board type.

The criterion of log-term interest rate on government securities in the national currency is closely linked with the failure to meet the inflation criterion. As for the long-term interest rate, Maastricht Treaty criterion is difficult to apply to Romania, as the instruments for long-term borrowing are

---

<sup>9</sup> the comparative analysis is based on the information made available by NBR

not yet developed and the banks do not offer interest rate for longer than one year. In spite of the fact that in 2002 government bonds in euro with 10-year maturity were issued on the foreign exchange markets, Romania issued government bonds with the maximum maturity of 5 years on the domestic capital market. This can be accounted for by the still high and volatile inflation. The issuance of government bonds with a longer maturity will only be possible as disinflation advances.

The criterion of exchange rate stability is closely related to the inflation rate criterion. The real depreciation of our currency against euro in 2002 and 2003 followed the trend of inflation, in order not to effect the competitiveness of Romania's exports. Since November 2004, NBR applied a new operational strategy of exchange rate policy by reducing the frequency of its interventions on the foreign exchange market. As a result, the national currency entered a process of gradual real appreciation against euro.

In spite of this, we will be able to speak about the stability of the exchange rate only when the inflation is sufficiently low. As a rule, the exchange rate and inflation mutually influence each other positively. A more stable exchange rate is not only the outcome of lower inflation rate. It can also lead to a reduction in the rate of inflation through a smaller nominal depreciation (on through a higher real appreciation, which in essence means the same).

The situation is also unfavourable in what the criteria of real convergence are concerned. The openness of Romania's economy (see table 4), although on the increase, is much lower than that of the Czech Republic, Slovakia and Hungary. Nevertheless, our economy is more open than economy of Poland, which is justified by the reverse correlation between economic openness and the size of the domestic market.

Romania's favourable evolution in terms of the weight of its trade with EU in entire foreign trade has placed it close to the Czech Republic, Poland and Hungary. Yet, the structure of our foreign trade is unsatisfactory, as it is based on low-processed products (clothes, furniture, iron-and-steel products) as compared with Hungary, for example, which exports automobile, household appliances and computers. This deficiency can be remedied through the attraction of foreign investments in areas for business with high added value.

**Table 4 Foreign trade** (%)

<i>Years</i>	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2004</b>
<i>Degree of economic openness</i>	74.5	76.4	79.8	83.5
<i>Weight of trade with EU</i>	67.8 for exp. 57.4 for imp.	67.2 for exp. 58.4 for imp.	67.7 for exp. 57.7 for imp.	67.8 for exp. 57.9 for imp.

*Source: Popa C., NBR policy & regulations and investment in Romania, Bucharest, April 2005*

The level of fulfillment of the other criteria for real convergence is not as advanced as our economic openness. In terms of the sectorial structure of GDP, the agriculture still has too much weight (approximately 12-13%), similar to Bulgaria, but three or four times as big as the Central - European Countries (see table 5). The same is valid for population working in the agriculture sector (25%).

**Table 5 The structure of GDP by sectors** (%)

Services are relatively underdeveloped accounting for less than 50% of GDP (see table 6), a result which is inferior to the other countries in Central and Eastern Europe.

**Table 6 The weight of services in GDP** (%)

<i>Years</i>	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2004</b>
<i>Weight of services</i>	44.0	44.7	43.7	44.1

*Source: National Bank of Romania*

The level of the GDP per capita is the most synthetic criterion of real convergence. Expressed at the nominal exchange rate (see table 7), its value of 2,300 Euro in 2003 and of 2,700 Euro in 2004 ranks Romania on the same place as Bulgaria and 10% lower than the average of the European Union. The indicator GDP per capita is more relevant if expressed through the parity of the purchasing power. Its value of 7,000 Euro situates Romania 30% behind the European average level in the last years and rather lower than

<sup>10</sup> "Others" refers to: transport and storage; postal services and telecommunications; commerce, tourism, hotels and restaurants; real estate transactions and other services; financial, banking and insurance services; public administration

other countries that became EU members in 2004. Consequently, the task of surpassing this handicap represents a real challenge for the following period.

**Table 7 GDP per capita**

<i>Years</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>
<i>Thousand ROL<sup>11</sup>/inhabitat</i>	52,109.4	69,500.6	87,576.7	110,179.2
<i>Annual average exchange rate ROL/Euro</i>	26,027	31,225	37,556	40,532
<i>Euro/inhabitat</i>	2,002	2,224	2,332	2,718

*Source: National Bank of Romania (author`s calculation)*

In a scenario with a 4% difference in the long-term GDP growth (i.e. 1.5% average annual growth of European GDP and 5.5% growth of Romania's GDP) it would take 60 years to recover the gap without taking into account the appreciation of our currency against the Euro. Imposing economic growth by 7-8% per year is not recommended because this measure cannot be sustained for a long time, as it can cause economic superheating and periods of recession, stimulating thus the stop-and-go model of the macroeconomic policies. In addition, it would generate either inflation or current account deficit, or a combination of these two effects.

The annual growth of GDP in the last years is presented below:

<b>Table 8 GDP`s evolution</b>	<b>(%)</b>			
<i>Years</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>
<i>Annual growth</i>	5.7	5.1	5.2	8.3

*Source: National Bank of Romania*

The solution would be a reduction in the time horizon by adding a level of about 3-4% annual real appreciation to the difference in GDP growth until stage ERM II is reached. This solution should be applied provided the golden rule of the correlation with productivity is observed. More concretely, growth in productivity should be bigger than or at least equal to the sum of the real appreciation of the national currency and the real growth in the average salary. Even after the adoption of the Euro, Romania will be able to post an appreciation in real terms of GDP per capita through a marginally bigger inflation than that of the other EMU member countries in order to diminish the difference between the GDP expressed in current prices and the GDP expressed in the parity of purchasing power. In this scenario, Romania

---

<sup>11</sup> ROL is the abbreviation for Romanian leu

would reach the average level estimated for that moment of GDP per capita in the European Union around 2044<sup>7</sup>.

### ***4.3. The prospects of our national currency***

#### **4.3.1. The denomination of ROL**

After 1989, our Romanian currency went through a process of continuous depreciation and as a result prices were expressed in too long figures. The denomination of ROL was much talking about, but it came into effect only in July 2005.

The main argument in favour of denomination was the necessity to express prices in Romania at the European levels. A parity of 3.5:1 of RON<sup>12</sup> against euro is more logical than one of 35,000:1, the exchange rate in the period that preceded denomination.

“Why denomination and not direct transition to euro?” Because the adoption of European currency is estimated to take place around 2013 – 2014 and operating with long figures had become more and more difficult for everyone, especially in IT applications and in financial documents, where some constraints exist. In addition, we will be able to take advantage of the experience of denomination in the more complex process involved in adopting the euro.

Our new currency is the “new leu” (1 RON = 10,000 ROL), divided into 100 “bani”. NBR has decided on RON as the new international code of the Romanian currency.

The denomination of our national currency involved more stages<sup>13</sup>:

- 1 March 2005 – 30 June 2006: parallel expression of prices in both currency;
- 1 July 2005: introduction of new currency;
- 1 July 2005 – 31 December 2007: parallel circulation of both ROL and RON;
- 1 July 2007: expiry of ROL;

---

<sup>7</sup> Isarescu M., Romania’s Transition to euro, presentation delivered at the Conference organized by the Academic College of Babeş-Bolyai University, Cluj-Napoca, March 2004, pp. 6-7

<sup>12</sup> RON is the abbreviation for Romanian new leu

<sup>13</sup> Isarescu M. The new leu: everything will become simpler, Press conference by the Governor of NBR, February, 2005, pp.4-5

- 1 July 2005 onwards: exchange of ROL against RON at NBR branches and other credit institutions.

In order to help the public get used to the new monetary insignia, the central bank decided to keep the dominant colours and the design of the new banknotes as well as the portraits of the personalities. The new banknotes have smaller dimensions, which make it easier to keep and handle them. As new banknotes have the same size as the euro it will not be necessary for the banks to adapt their ATMs when the European currency is adopted. Below is the presentation of the new banknotes in comparison the old ones:

1 RON = 10.000 ROL

5 RON = 50.000 ROL

10 RON = 100.000 ROL

50 RON = 500.000 ROL

100 RON = 1.000.000 ROL

500 RON

As for the new coins, their dimensions are close to the euro coins, and their values are as follows:

1 new ban = 100 ROL

5 new bani = 500 ROL

10 new bani = 1.000 ROL

50 new bani = 5.000 ROL

The denomination of our currency is a matter of objective necessity from the economic and monetary perspective. Through it the Romanian authorities aimed to create the framework required for the transition to euro in the following years.

#### **4.3.2. The transition to the common European currency**

The transition to the common European currency constitutes a great challenge for the Romanian economy and society. Most likely the adoption of euro will become a fact between 2012 and 2014. This will involve these three important moments:

- prior joining the EU, the monetary policy remains Romania's responsibility;

- once Romania becomes a EU member, our monetary policy will be a common concern of EU and our country; the new EU member benefit from at least 2-year period preceding the adoption of ERM II;
- after the fulfillment of the convergence criteria according to the Maastricht Treaty, Romania is to actually adopt euro.

The transition to euro is not an option or an alternative, but an obligation to participate in EMU. ERM II represents a stage towards the adoption of euro as a national currency. The transition to ERM II is conditioned by the achievement of the nominal convergence criteria and by the progress made in connection with the reduction in differences between our economy and that of the EU members.

Romania should not hasten the process of joining the Eurozone since it has to make much more considerable efforts than the countries that joined the EU in May 2004. A realistic deadline for Romania to reach stage ERM II is 2010 – 2012. This will create the conditions for the adoption of the common currency between 2012 and 2014 (6-8 years after the accession to EU), provided that our real economy improves. In the three/four-year period between our joining the EU and reaching ERM II, Romania will have to restructure its economy radically and implement investment programmes that will bring Romania closer to the EU standards in this respect.

The nominal convergence criteria as well as those of real convergence can be met only on the basis of long-term consistent efforts. Our joining the EU in 2007 will facilitate the acceleration of real convergence, a process stimulated by both private investors and European special funds.

Even if the nominal convergence criteria are reached in a shorter time, its sustainability is guaranteed by the existence of real convergence. In addition, the adoption of monetary restrictions to accelerate the realization of the nominal convergence criteria in a very short time may have a negative impact on the pace of economic growth, which will in turn cause a delay in the fulfillment of the real convergence criteria.

To conclude, the transition to Euro should be carried out cautiously, given that the forceful of the convergence criteria could generate substantial costs in our real economy. A sustainable convergence with the European common currency depends on constant and permanent progress in the structural reforms, fiscal consolidation, the promotion of a responsible salary policy, and the establishment of clear and realistic objectives in order to support the accelerated development of our economy even after the transition to Euro is accomplished.

## 5. Orientations on monetary policy

Of all the convergence criteria stipulated by the Maastricht Treaty, Romania meets just those regarding fiscal policy. The fulfillment of the other criteria demands sustained efforts, through a set of consistent policies connected with:

- continuation of a controlled flotation of the exchange rate in order to maintain its real stability and external competitiveness;
- increase in domestic savings and attraction of external capital in order to ensure a high rate of investment that will stimulate a stable and long-term growth of the economy;
- orientation to exports of foreign trade, so that the pace of its growth should exceed growth in GDP;
- implementation of radical structural reforms for viable and solid economic development, as it is in real economy rather than in monetary economy that the fundamental causes of inflation in Romania are found;
- reduction in inflation rate toward average European level.

The reduction in inflation remains a top priority in the future: as long as the inflation is high we cannot have low interest rate or a completely stable exchange rate. The one-digit inflation rate in 2004 allowed NBR to adopt the inflation targeting strategy in August 2005. The experience of other countries that have also implemented this strategy shows that it is especially effective when the objective is to diminish inflation from 10 – 15% to 4 – 5%. The transition to inflation targeting was facilitated by the adoption of the new Statute on NBR in 2004.

The defining characteristics of NBR's current monetary policy are<sup>14</sup>:

- the main objective of monetary policy : achievement and maintenance of price stability;
- use of all monetary policy instruments for the attainment of inflation target;
- future-oriented proactive attitude of monetary policy, i.e. present responses to anticipated future phenomena;

---

<sup>14</sup> Isarescu M., Inflation targeting, NBR's governor press release, Bucharest, July 2005, pp. 3-4

- independence of central bank and its responsibility for the realization of inflation target;
- transparency of monetary policy through informing the public on objectives, decisions and arguments behind them, as well as the risks involved

NBR's monetary policy strategy for the present and future has the following coordinates:

- inflation rate is expressed by consumer price index;
- inflation rate is established as a point of reference situated in a variation interval of +/-1%;
- annual inflation targets for the near future are: 7% for 2005, 5% for 2006 and 2 – 3% for 2007 – 2008;
- inflation targeting strategy is applied in a flexible manner along with the controlled floating exchange rate;
- main instrument of communication with the public in order to anchor inflationist expectations is the report on inflation, published by NBR every other three months.

The inflation targets set for the following years are quite challenging, but they can be attained through a consistent anti-inflationist monetary policy, supported by the other component of the mix of macroeconomic policies. Nevertheless, the des-inflationist process will have to continue after 2007, with the aim of meeting the convergence criteria of price stability prior to adoption euro.

## **6. Priorities of real convergence**

Both disinflation and the acceleration of economic growth for the attainment of real convergence depend to a large extent on the overall coherence of the economic programmes of Romania's authorities. The macroeconomic policies and decisions with a significant impact on the nominal and real convergence objectives should consider at least three important problems<sup>15</sup>.

---

<sup>15</sup>Isarescu M., Romania's Transition to euro, presentation delivered at the Conference organized by the Academic College of Babeş-Bolyai University, Cluj-Napoca, March 2004, pp. 13

Firstly, they should deal with outstanding debts and quasifiscal deficit. Outstanding debts are first-rank inflationist factors and are a means of survival for inefficient industries, which leads causes a waste of resources.

Some of the outstanding debts represent quasifiscal deficit, i.e. amounts of money owed by public authorities and losses accumulated by public enterprises, and the official recognition of those debts would increase the budgetary deficit and, consequently, worsen the state of nominal convergence criterion for fiscal situation.

Another issue is the pension system, which needs to be radically changed through the transition to a system based on the accumulation of funds so that each person's pension should depend directly on their own contribution. Accurate and competent administration of such a pension system can generate significant resources for investments, which will lead to a more solid internal accumulation and a faster pace of development. Those countries that have adopted rigorously administered private pension systems (e.g. Chile) have experienced substantial economic growth partly on the basis of the resources provided by these funds.

The third major priority is the allocation of significant financial resources to projects for the infrastructure that will take Romania closer to the European standards. Since these funds cannot be allocated entirely from budgetary funds, the need arises for partnerships between the public and the private sectors and for coherent strategies that will stimulate private investments in domains of public interest. Such projects are meant to accelerate economic growth and consequently contribute to real convergence. Nevertheless, we should take into account the fact that these programmes can exert pressure on public expenditure and therefore make it difficult for us to maintain the budgetary deficit and public debt within the recommended parameters for the current stage.

## **7. Conclusion**

European integration requires the simultaneous achievement of both nominal convergence (the attainment of the Maastricht criteria) and real convergence (improvement of living standards, sustainable economic growth, decrease in the discrepancy between Romania and the EU countries). These objectives call for sustained efforts in radical economic restructuring and the realization of investment programmes for the reduction of the gap between our country and the EU standards.

The transition to the Euro should be carried out cautiously given the fact that a forceful accomplishment of the convergence criteria could

generate considerable costs in the real economy. The sustainability of the transition to the common European currency is dependent on constant progress in the structural reforms, fiscal consolidation, promotion of a responsible salary policy, and adoption of clear and realistic objectives that will ensure the accelerated development of our economy even after the transition to the Euro.

Monetary policy cannot solve by itself all the problems involved by European integration. That is why it has to be correlated with solid and coherent macroeconomic policies. Yet monetary policy can accelerate the integration process and attenuate the difficulties involved. The success of the monetary policy as well as that of the whole mix of macroeconomic policies will depend to a great extent on their credibility. It follows that the objectives will have to be both ambitious and realistic and that the authorities should not resort to administrative measures in order to adjust some developments imposed by the market.

## **Abstract**

*As part of the new budgetary reform, the Constitutional bylaw of August 1st, 2001 on budget acts introduced new rules and methods for preparing and implementing the state budget. The main purpose is to move from a resource-based to a results-based logic. Indeed, debate will focus on the objectives and the effectiveness of public expenditures. The paper aims to highlight the main aspects of the new managerial approach adopted by French administration within the framework of budgetary reform and the expected difficulties that would be encountered in its implementation. In the new budgetary system, appropriations may be freely apportioned among the so-called Programmes. Programme managers have to be fully dedicated to their goals and be accountable for their management acts via results indicators and target values so as to make public spending more efficient. Therefore, under such framework, the budgetary reform poses a number of questions about the manner of implementing the performance-related aspects of the Constitutional bylaw on public policies. This reform, effectively operational in 2006, calls for a different administrative organisation based on clearer relations between both players engaged in forwarding policies and those managing activities. Another issue raised by the reform is the need to alleviate regulations.*

**Keywords :** *Budget reform ; mission ; programme budget ; globalisation ; performance goals.*

## 1. Introduction

At a time when the government's call for reforms has differently been understood by the French people, and when the financial and budgetary situation requires a strict control of expenditure, it seems more urgent to provide a meaning to the reform and explain the constraints, and the management model which is the best suitable.

Like any other complex entity, the state always needs to evolve. Indeed, it doesn't risk, for lack of adaptation, to disappear, but a failure to achieve its objectives will give rise to a society crisis. Therefore, the political crisis and the question of optimizing public finance management call for a better transparency.

This requires a real revolution in behaviour ; it supposes a change from a resource-based logic, also called a logic of control, to a results-based approach, called now a logic of evaluation.

As part of the new budgetary reform, the Constitutional bylaw of August 1st, 2001 on budget acts (*Loi organique relative aux lois de finances, LOLF*) introduced new rules and methods for preparing and implementing the state budget. Under the new rules, the parliament provides ministers with overall budgets for setting objectives and defining indicators for measuring results.

The purpose of defining performance goals and measuring results is to make public spending more efficient at two levels :

- in the budget decision making process at governmental and parliamentary level ;
- in the management of internal units themselves.

The speed of this reform, and the consensus around which it was agreed constitute a political event; it will allow the emergence of a cultural change, which consists of many other advances in the state's management method.

We need to know how the constitutional bylaw complies with different transformations of the organisational and regulatory model. In other words, will the new constitutional bylaw enable the government to move from a resource-based budget to a budget designed to reflect the results of government action? The answer to this question depends on the implementation procedures, most of which still need to be worked out.

## **2. A new budgetary architecture for greater transparency**

The aim of budget reform is to move public management from resource-based to a results-based approach. At present, state budget appropriations to ministers are divided into about 850 chapters organised by category of expenditure.

In 2006, the state budget will be drawn on the basis of a results-based approach. It will be decided by end purpose in the form of overall budgets, the amount of which will generally be larger than that of current budget chapters. The information joined to the budget act will provide an account of the results expected and obtained.

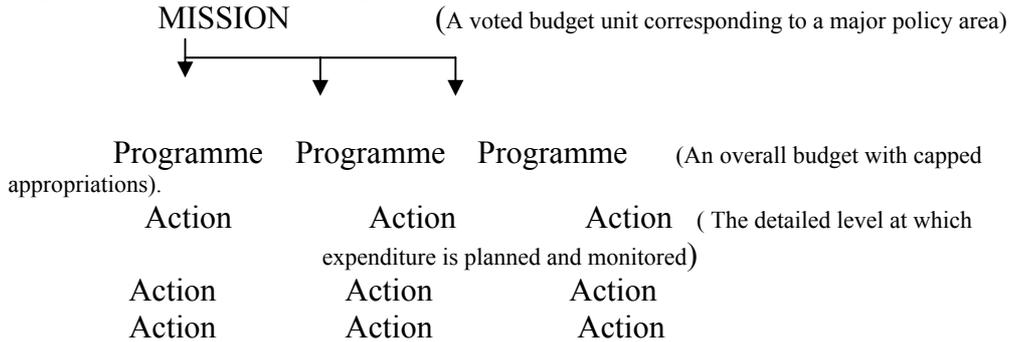

### ***2.1 A Programme Budget based on political objectives***

Under such reform, the Programme budget is organised around the purpose of expenditure. It has three levels (*Fig. 1*) :

- Forty missions correspond to the state's major public policy : the parliament approves the budget act at mission level. The emphasis can be placed on the aim of public policy. Each mission contains a set of programmes which need to be appropriated. Different ministries can be in charge of the programmes. The parliament may modify the allocation of expenditures between programmes within a mission proposed by the government.
- 150 programmes describing the responsibility for policy implementation. Each programme is subdivided into sub-programmes (actions), and is confided to a programme coordinator appointed by the minister concerned. Programme coordinators receive a fungible overall budget which enables them to choose the best-suited resources to achieve the objectives defined. A programme is a single-purpose appropriation unit .
- About 500 actions describe the programmes more detailed. The actions give the managers the information about the use of the budget resources. At this level, an expenditure is planned as it is incurred, specially for guidance purposes. By describing the budget at the objective's level, the state's missions and public service goals become fully transparent.

For each programme a strategy, objectives, performance indicators, and targets are defined. The programme coordinator uses the managerial flexibility, within the framework of the allocated resources, to steer public management according to objectives defined.

**Fig. 1. A Programme budget based on a three-tier structure.**

*Source : Un nouveau cadre budgétaire pour réformer l'Etat, Ministry of the Economy, Finance and Industry, Department of Budgetary Reform, 2004.*

**2.2. Globalisation and greater autonomy for a more reactive administration**

In the new budgetary system, appropriations may be freely apportioned among the programmes. Their breakdown according to the type of expenditure is purely indicative. This globalisation will make management more flexible because programme managers will be able to reallocate appropriations between types of expenditure. Personnel expenditure is the only exception to such globalisation. Because of its long term effect on public finance, it cannot be topped by other appropriations. The system will operate on a commitment accounting basis, which will make much more clearer the multiyear programme management.

In exchange of the high degree of autonomy they have, managers have to be committed to their goals and be accountable for their acts via results indicators. In order to measure the management performance, three criteria are used : social and economic effectiveness, the quality of service, and efficiency (*Fig. 2*)

Through an Annual Performance Plan (APP) appended to the budget act, ministers and programmes managers have to make a commitment to reach specific results. The APP will state programme appropriations, the performance indicators, the expected results and related tax expenditure. Financial data and performance measurements are included. They give more information and better assessment on the efficiency of the public policy.

Once the budget has been executed, performance results of management and expenditure acts are included in an Annual Performance Report (APR) appended to the Budget Review Act. The APR is built on the same model as the APP to make it easier to compare authorisations with execution.

**Fig. 2. The three lines of performance analysis**

	<b>Goal</b>	<b>Sample goal</b>	<b>Sample indicator</b>
Citizen	<b>Social and economic effectiveness</b>	Health : cut breast cancer screening time	Average time elapsing before breast cancers are detected
User	<b>Quality of services provided</b>	Police : cut police intervention time	Average time between police being alerted and their arrival on the scene
Taxpayer	<b>Efficiency</b>	Roads : reduce maintenance costs	Average maintenance cost per kilometre

### **3. Budget Reform and the challenges of the reform of the public management model**

As any other reform which aims at changing the reality of behaviours, and not only the rules of law, the public finance reform of 1<sup>st</sup> August is particularly based on the challenges of the transformation of budgetary, organisational and regulatory models.

At the budgetary level, in order to judge the results and derive the consequences from the choice of actions, it is necessary for us to clarify the relationship between the objectives defined and the resources used to achieve them. The budgetary architecture based on the programme is a compromise between two requirements : identifying the policies and defining the activities that they include.

Hence, the Constitutional- by law shows clearly an intention to keep performance plans within a rigorous framework. However, the confirmation of this intention depends on two factors : the quality and as well

as the accuracy of the norms that will be defined in order to frame the content of the information associated with the programmes; in addition, the quality of controls that will be carried out.

The Constitutional- by law doesn't say anything about the processes of information control in relation to the performance of the programmes. This field is entrusted to finance commissions as well as to regulation authorities.

The budget reform success depends tightly on an evolution of management style within the administration. With regard to this question, it is normal that the Constitutional- by law doesn't say anything, but, it is placed in the procedures of its implementation. This evolution is based on a reform of the organisational model as well as the regulatory framework.

### ***3.1. Budget reform and the organisational model change***

The French model of administration is fundamentally based on one particular organisation, which ensures that all the authorities and initiatives result from a unique center: within a unique actor which is the state, the prerogatives take a hierarchical direction from the summit of state to those in charge of their implementation. This administrative model is no more suited to the new management system introduced which calls for a participative approach between the different actors involved in the decision – making process. Also, the actual administrative model prevents the autonomy of management, especially for those who are charged with the implementation of public policies.

The budget reform reveals that this organisation is outdated. It distinguishes two major roles of the state. The first one consists of supervising policies, defining programmes and setting up objectives, while the second role is related to programmes implementation and resources management. As for the managers, they have a large spectrum of freedom of action and initiatives.

The overall budget puts in concrete form this sphere of autonomous responsibility, which is necessary to provide to public managers.

However, many features of state organisation impede this evolution. On the one hand, within the central administrations, the functions of supervising policies and those of managing activities are mixed. Under such conditions, the confusion between roles make it hard to define the concept of command. On the other hand, and at the decentralized level, every service

will find it difficult to gather the necessary competences for an autonomous management. The management unit is rather a service network.

### ***3.2. Budget reform and the transformation of the regulatory model***

The functioning of administrations is based on the application and control of detailed and universal legal rules. All fields of state's action take place within a regulatory provision (laws, decrees, etc). So, is this compatible with the intention to implement a management model based on results ?

Confronted with many regulations, and a great number of controls, the public manager, will merely respect and implement the provisions of these regulations and forget the indications of programme.

The main challenge is to emphasize a concrete and measurable definition of performance goals, beside a reduced regulation adapted to the actual context. The major effort consists, thus, in realizing the transition from a resource- based to result-based approach.

## **4. Conclusion**

The new Constitutional bylaw constitutes the basis of a concrete public finance reform. Therefore, it is considered only as a foundation: many rules should still be specified without which the new framework will remain formal.

Indeed, the budget reform, effectively operational in 2006, calls for a different administrative organisation based on much more clearer relations between those engaged in designing policies and those in charge of their implementation and follow up actions. Another issue, raised by the reform, is the need to alleviate the current regulations, which are still reflecting a resource-based logic.

## **Abstract**

*Turkish financial management system has undergone a long lasting reform process for years. Finally a new organic law (Public Financial Management and Control Law) was passed in late 2003 and its full implementation will start in 2006. The new law requires introduction of MTEF for next three years in all general government agencies. Although the new law captures necessary provisions for MTEF, implementation of the new system rises some questions and causes some concerns for the agencies in terms of well working implementation of the new system since it is a system newly introduced. So, 2006 budget will be the first one to start for MTEF. This paper first covers the disadvantages and advantages of the former and new Turkish financial management system. It also analyses MTEF, more importantly policy formulation process within the context of international best practices. It then lays out new Turkish MTEF system and also deals with some potential problems that Turkish authorities will be challenged with. The paper ends with recommendations on how best to implement the new MTEF system in Turkey.*

**Keywords:** *Medium Term Expenditure Framework, Turkish Budgetary System, policy formulation.*

<sup>1</sup> I like to express my appreciation to Mr. Mehmet Şahin, Ph. D., from Çanakkale Onsekiz Mart University of Turkey to complete this work.

## 1. Introduction

The economic and financial problems experienced in the today's economies have created pressure towards an increase in budget expenditures; increasing pressures undoubtedly caused the governments to increase taxes and resort to borrowing. These developments brought along with the questioning of the public financial management systems of countries and therefore the reform efforts. In order to bring a solution to their problems, the countries tended to change their public financial management systems that constitute the focal point of the problem; within this scope, they have undertaken significant structural changes towards ensuring effective, efficient and economic use of public resources.

Also in Turkey, the economic structure has rapidly deteriorated starting from the beginning of 1970s, several interventions made to capture stability has proved fruitless when combined with fluctuations in the political structure. Turkey constantly struggled with high inflation, public deficit, instable growth, high interest and deterioration of income distribution, could not bring radical solutions to its problems other than short term recoveries and could not capture the stability it seeks. Meanwhile, the lifespan of the economic stability packages that were not supported with structural reforms were short termed. Although improvements in economic and financial situation have been recorded, the system has not lost its feature of being easily distorted.

Therefore, the problems arising from the public financial management system and following thought that the public resources have not used in an effective, efficient and economic way have accelerated the reform efforts. As a matter of fact, the reform efforts in Turkey have usually arisen in the aftermath of economic and financial crises. Right after the economic crisis experienced in April 1994, it was concluded that it was necessary to undertake some changes in the public financial management system and to this end, working commissions were set up composing of representatives from key economic agencies. The commissions made their studies, prepared their reports and submitted to then the government. However, with lack of sufficient political will supporting the reform efforts, these efforts were inconclusive. The second step in the public financial management reform, consequent to the significant economic problems experienced in the economy, started with the new economic program introduced in the year 2000 and has accelerated following the economic and financial crisis undergone in 2001. Within this scope, the quasi-fiscal transactions of the state have been set in order, the budgetary and extra-budgetary funds as well

as special accounts outside the budget, which were great problems for long years, were eliminated leaving out some exceptions, the provisions allowing agencies to add appropriation within the year without the authorization of the parliament have been abolished, state borrowing and the procurement system have been brought under discipline through framework laws. The most radical and comprehensive change in the public financial management system has been realized with the adoption of the Public Financial Management and Control Law numbered 5018 at the end of the year 2003. By abolishing the Public Accounting Law numbered 1050 which was in implementation for approximately eighty years but unable to meet the requirements of the best international practices in today's world, the new public financial management approach has been introduced with Law numbered 5018. This new law brings important changes to the fundamental principles of public finance and utilization of public resources.

The significant changes brought by the new public financial management concept can be listed as; strengthening of the generality and unity principles of budget in execution, highlighting financial transparency, accountability in the utilization of public resources as well as performance based budgeting and MTEF, introduction of the mechanisms necessary for the effective, economic and efficient utilization of public resources and one of the principles of modern public financial management, giving freedom to the managers in the line agencies beforehand and strengthening the ex post audit by increasing its efficiency.

In this paper, firstly the content of the changes undergone in the public financial management systems in the world and the problems experienced in Turkey during the period of implementation of the Law numbered 1050 and in the following period and new practices that are brought will be explained. Afterwards, the introduction of MTEF in Turkey which is one of the important practices brought by the Law numbered 5018 in terms of efficient, effective and economic use of public resources will be discussed. The paper will end with a short conclusion part.

## 2. Recent Developments in Public Financial Management System

### 2.1 The World

Significant arrangements are being undertaken in several countries in the area of public financial management in recent years. The established economic, social and cultural structure of every country may set different forms to the public management and public financial management systems. However, in the world, the public financial management reforms have some common characteristics; public financial management reforms are realized to affect three fundamental elements. These are; overall financial discipline, distribution and utilization of resources according to strategic priorities and ensuring effectiveness and efficiency in the provision of public services. The budget reforms continuing for centuries to realize these focused on reformulating three basic functions of the public. These are; control of public resources, medium term resource allocation and management of resources<sup>2</sup>.

Realization of the institutional arrangements necessary for fiscal discipline is important in terms of the outcome of budget implementation. In this context, allocation of public resources should be in line with the expenditure ceilings and the agencies have no any authorization to exceed the appropriations set by the budget except for the supplementary budget approved by the Parliament. The most fundamental element of the fiscal discipline concept is that the budgets are formed by taking into account the available resources. Actually, together with the budgetary restrictions introduced in the public financial management system and the flexibilities given to the public agencies in the realization of public services will play an important role in the realization of the goals mentioned above, and at the same time they will pave the way for change in public financial management. The second aim of the reforms made in the public financial management system are the arrangements made towards taking into account the program efficiency and strategic priorities of the government and hence the agency in the allocation of public resources. In allocation of resources, taking into account the national priorities determined by the government is a requirement

---

<sup>2</sup> THE WORLD BANK. *Public Expenditure Management Handbook*, Washington D.C.: The World Bank, 1999, pp. 17; ZEVENBERGEN, J. *Budgetary Reforms in Transition Countries: The Role of Capacity Building-Summary and Main Conclusions. (Special Report Prepared for OECD Budget Officials Meeting)*. Rooterdam, 2004. pp. 1.

of accountability. Because, resource allocation is basically a political issue. In this regard, in the policy formulation process which is the first stage of the budgeting process, the areas which will be allocated public resources among the priorities of the government are identified by also using the efficiency analyses. The third element is increasing the performance of public sector, in other words, the efficiency. Provision of public services with the most possible cost is an issue that occupies the agenda of many countries in the world including developed countries. On this issue, particularly developed countries have made significant progress and they have changed their public financial management systems towards this direction.

On the other hand, OECD has reached the conclusion that the performance about the fiscal discipline is closely related and the countries which generally have budgetary surplus are those that reform their budgeting process and implement modern budgetary systems<sup>3</sup>. In this framework, five basic institutional arrangements are recommended in the budgetary system in order to control the public expenditure efficiently. These are; MTEF, prudent economic assumptions, top-down allocation of public resources, departure from input oriented resource allocation towards output oriented resource allocation, highlighting financial transparency and accountability.

MTEF is basically the most important tool of establishing policy, plan and budget link. Determination of policies independent from available resources and budgets is the result of a decision-making mechanism away from efficiency. This also shows that policies are not identified according to available resources or strategic priorities<sup>4</sup>. An efficient budgeting requires efficient balancing between needs and resources. MTEF contributes to increasing predictability and reliability of budgets by establishing the link between policy and budget.

On the other hand, over-optimistic economic assumptions and unnecessary increase of public expenditures bring together resource allocation to inefficient budget practices. The old practice that used to be applied in resource allocation to public agencies was to receive appropriation requests from the agencies, examine these requests one by one, make negotiations with the relevant agency and to identify the appropriation to be allocated in term expenditure areas. Among many drawbacks of this system, the most important drawbacks that it does not reflect the priorities of the government. However, this practice is now abandoned in many countries.

---

<sup>3</sup> BLÖNDAL, J. R. Budget Reform in OECD Member Countries: Common Trends. *OECD Journal on Budgeting*. 2003, vol. 2, no. 4, pp. 7 – 14.

<sup>4</sup> THE WORLD BANK. *Ibid.* pp. 32.

Instead, the top down appropriation allocation is implemented, where the government predetermines the total appropriation to be allocated in the relevant year and also puts a ceiling for the appropriations to be allocated to public agencies, the resource distribution for the activities and projects to be carried out within the predetermined ceilings is made by the public agencies without the intervention of the Ministry of Finance.

However, it is possible to encounter views opposing to this approach; it is underlined that the ministries of finance should somehow be involved in the distribution or redistribution process of public resources in the budgets of relevant public administrations in terms of the financial objectives and political priorities of the government<sup>5</sup>.

On the other hand, there is a common understanding that departure from input oriented resource allocation to output oriented resource allocation, in other words caring about what is done in the public sector rather than how the public activities are performed, will increase efficiency in the utilization of resources. Besides, transparency and accountability are regarded as significant tools for the governments to give assurance to the parliaments and the people that they have efficiently used the public funds entrusted them.

As can be observed, generally the same methods and tools are being used in the reformation of public financial management systems in the world. The arrangements focus on financial discipline and highlighting efficiency and effectiveness in the allocation and utilization of public resources. To this end, innovations are made in the national budget systems, international best practices emerge. Now, through the budget reforms, the governments take the necessary steps not to have the public budgets, which have a significant position in the economy in terms of magnitude and quality, to be the sole cause of economic and financial crises.

## ***2.2 In Turkey***

### **2.2.1 Period before the Law numbered 5018**

In Turkey, the Parliament's right to approve the national budget has been recognized with the 1924 Constitution and the first arrangement related

---

<sup>5</sup> SCHICK, A. Does Budgeting Have a Future?. *OECD Journal on Budgeting*. 2002, vol. 2, no. 2, pp. 28.

to public financial management system in the Republic period has been realized with the Law numbered 1050 adopted in the year 1927. The Law numbered 1050 which is the constitution of the public financial management system has been implemented in Turkey for almost eighty years since 1927 with a few amendments. During this term, significant changes have been undergone in the public financial management and control systems in the world and international best practices have emerged. In Turkey, in the same period of time, the number of public administrations has gradually increased and significant changes have occurred in terms of their quality and organizational forms as well as in terms of quality and quantity in the production of public goods. Besides these, the changes in the world have brought by the appearance of great changes in the approaches in the area of public financial management system in Turkey.

The criticisms concerning the period when the Law numbered 1050 was implemented can be summarized as follows; rather than a single budget, emergence of different budgets (extra budgetary funds, revolving funds, etc.); failure of the budget system to establish the policy-plan-budget relationship; not making strategic plans for agencies; failure to perform functional analysis of the state and therefore lack of clear duty definition of the public agencies; performance of audit in the Turkish budget system basically in terms of compliance audit; neglecting the efficient economic and effective use of resources; taking into account only the expenditures incurred in the previous year for the allocation of appropriations; lack of defining managerial responsibilities in a clear way; magnitude of the appropriations recorded throughout the year, although not included in the budgeted appropriations, without parliament's approval, on the grounds of powers vested by some laws, the Law No 1050 being the dominant; failure of the registry and control system of state's assets to reach a sufficient efficiency level and that fact that the state does not have the full set of information on its commitments; not budgeting the tax exceptions, discounts and exemption created by the state through incentive policies<sup>6</sup>

These drawbacks that are mentioned have accelerated the restructuring of public financial management system especially in recent years. Consequent to these studies, the Law No 5018 has been adopted to

---

<sup>6</sup> DPT. *Sekizinci Beş Yıllık Kalkınma Planı Kamu Mali Yönetiminin Yeniden Yapılandırılması ve Mali Saydamlık Özel İhtisas Komisyonu Raporu*, Ankara: DPT, 2000, pp. 28-82. ARCAGÖK, M. S., YÖRÜK, B., ORAL, E., KORKMAZ, U. Kamu Mali Yönetimi ve Kontrol Kanununda Öngörülen Düzenlemeler. *Bütçe Dünyası Dergisi*. 2004, İlkbahar, no. 18, pp. 3-4.

replace the Law No 1050 and it has been foreseen that the 2006 budget will be prepared in accordance with this approach.

### **2.2.2 Changes to the Public Financial Management System with Law No 5018**

The Law No 5018 that constitutes the financial pillar of the public management reform has been adopted by the Parliament on 10 December 2003. Law No 5018 takes a new approach on the structure and functioning of our financial management and control system and regulates the fundamental principles of these issues, and determines how the transactions for the preparation, implementation and control transactions of public budgets will be carried out as well as accounting and reporting of financial transactions.

The changes brought and the issues aimed with this Law that has the objective of the establishment of a new public financial management system can be stated as follows:

- ◆ It is ensured that all revenues and expenditures of public agencies are included in the budgets and it is aimed to prevent obtaining revenues and incurring expenditures from outside the budget.
- ◆ A close connection has been established for policy-plan-budget<sup>7</sup>. Strategic planning and performance based budgeting have been fundamental pillars of the new system. Besides, special provisions for the purpose of ensuring efficiency in budget preparation and implementation process and MTEF is introduced.
- ◆ The duties, powers and responsibilities of public administrations in the budget process are rearranged. Within this scope, the power-responsibility balance in public financial management is re-established and the problem of responsibility without powers and irresponsibility with powers is overcome. The duties of performing ex ante control and ex post internal audit have been transferred to the relevant public administrations and it has been stipulated that they will undertake a new structuring in this regard.
- ◆ The duty of giving visa to commitments and contract drafts still performed ex ante by the Ministry of Finance is abolished. Within his

---

<sup>7</sup> ARCAGÖK, M. S., YÖRÜK, B., ORAL, E., KORKMAZ, U. Ibid. pp. 6.

scope, transaction of giving visa on utilization of appropriation and transaction of registering contracts performed by the Court of Accounts has been ended as of 2005. Therefore, through reducing ex ante controls, the necessary environment for swift provision of public services is prepared.

- ◆ Through paving the way for specialising in audit, establishment of an internal audit system that has certain rules and standards, constantly functioning and that will take place within the relevant public administration is targeted. Appointment of internal auditors is provided for in order to ensure the performance of auditing activity operating within a determined system and to perform ex post internal audit. As a requirement of the newly adopted system, strengthening of ex post auditing activity is required.
- ◆ In the public sector, the obligation to use the same accounting system has been introduced. In all public agencies within the scope of general government, common accounting and reporting standards as well as chart of accounts shall be implemented. Furthermore, the Ministry of Finance has been delegated to prepare and announce publicly the financial statistics<sup>8</sup>. Implementation of a new budget classification in accordance with the International Monetary Fund Government Finance Statistics (GFS) is introduced.
- ◆ Tax expenditures chart renounced due to tax exemption, exception and reductions as well as similar implementations shall be added to budget laws.

To summarize all that have been explained above, this Law; ensures budget unity, highlights effective, economic and efficient utilization of public resources as well as financial transparency and accountability and allows for wide initiative power to the public agencies for decision making and implementation.

### **3. New Approach in the Utilization of Public Resources: Medium Term Expenditure Framework (MTEF)**

The main objective of fiscal policy is to increase economic welfare. Fiscal policy employs three elements in order to realize this. These are; the allocation of public resources, redistribution of welfare and income and regulation of economic activities. Budget, which is an important instrument for the implementation of fiscal policy, has its own effect on the other elements, mainly on the allocation of public resources, directly and/or indirectly. It is possible to see how budgeting process affects the aforementioned instruments. The first in this process is policy formulation (making). Afterwards, a budget that is suitable for the outcoming policy is prepared and implemented, and the process ends with the evaluation and auditing of the implementation. The rationale of the budgeting process is exercising the authority granted by citizens to the government, and the government should be able to give account of what it does and what it produces as it exercises this authority.

As regards the historical development process, whereas budgets used to be prepared based on input sources such as money, human and accounting; a new budgeting approach became prominent in budgeting in OECD countries especially in the last twenty years and public budgeting and administration started to develop in an output-outcome oriented rather than input oriented manner.

In the traditional public management approach, accountability takes place in the form of conforming to legislation; consequently managers do not encounter any problems as long as they comply with the rules. In the new public management approach, what the managers do is more important than how they do it<sup>9</sup>. Thus, being outcome-oriented in rendering public services and evaluating the success of the managers based on the output and outcome generated by public activity, find wide implementation today.

On the other hand, the main problem encountered in the budgeting process in many countries is downplaying the importance of strategic decisions, namely absence of certain strategic rules while the budget implementation is strict and centralist. In other words, the loose policy making process is endeavoured to be balanced by means of over-strict budget implementation rules. The reason why the strategic decision-making process

---

<sup>9</sup> BLÖNDAL, J. R. Ibid. pp. 18.

is weak is because the policy making process is distributed among different public agencies. Therefore, an efficient coordination mechanism is needed within the government for an efficient strategic management. In fact a centralist and strict policy making process and decentralist and flexible implementation processes are desirable for an efficient MTEF process<sup>10</sup>.

MTEF is implemented in order to provide information on the medium terms strategies to be implemented by the governments in terms of public financing. Therefore, MTEF is an instrument that provides information on the areas where the public expenditure will be directed to in the medium term. MTEF sets expenditure ceilings for central government and agency level to accomplish fiscal discipline and to allocate public resources in line with the strategic priorities of the governments within these ceilings. However, agency level ceilings might be shifted from one agency to the another if necessary, provided that overall ceiling for the budget will not be exceeded. Strategic priorities are determined for two steps, first on national level and next on agency level. The agencies' priorities should be more detailed compared to the national one. Strategic priorities should also cover macroeconomic framework (inflation, growth, export, import, budget deficit, public debt stock), otherwise setting priorities itself will not make sense for well working MTEF. The agencies should be careful that their priorities are to comply with the national priorities. Consequently, MTEF finds wide implementation around the world in recent years, for overcoming challenges encountered in the budget systems.

### ***3.1 Definition of MTEF***

MTEF is defined as a budget approach where the annual budget process is evaluated with a multi year approach, especially such as multi year forecasting of expenditures or a multi year fiscal strategy, and where the policy-plan-budget link is realized<sup>11</sup>. Disconnection between policy-plan-budget causes budgets to give negative economic outcomes especially in developing countries. In many countries, these three elements operate independently from each other. Therefore, budgeting is seen as an instrument for the central agencies to meet the appropriation requests of agencies in the pertaining year. However, budgeting should be seen as an activity that is based on policy. An efficient decision making process should ensure that the

---

<sup>10</sup> THE WORLD BANK. Ibid. pp. 24.

<sup>11</sup> KIZILTAŞ, E. Çok Yıllı Bütçeleme Sistemi, *Bütçe Dünyası Dergisi*, 2003, Sonbahar, no. 16, pp. 13. ARSLAN, M. Orta Vadeli Harcama Sistemi (Çok Yıllı Bütçeleme) ve Türkiye'ye Uygulanabilirliği. *Sayıştay Dergisi*. 2004, no. 54, pp. 11.

link of policy making and planning with budgeting is established and it should also require them to be limited by the available resource level and priorities. Otherwise, budgeting process turns into an activity which is no more than a challenge to save the day. Consequently, predictability in budgeting process will enable public agencies to plan and manage their resources in the medium term. In consequence, MTEF also brings about the control of public expenditures and efficient utilization of resources and thus the resource allocation process is eliminated from uncertainty.

MTEF process generally covers the budget year to be prepared for the coming year and sent to the parliament for approval and the following two years. In terms of time, the same approach has been followed in the Law No 5018. This process basically has been founded over three structures. The first one of these is the top-down estimation of total resources that can be allocated for public expenditures in coherence with the macroeconomic structure; the second one is bottom-up estimation of the costs of the activities and projects that are underway and that are to be put into practice shortly; and the third one is a process that compares total resources with these costs<sup>12</sup>. The most important innovation brought by such a practice is drawing up of the framework of the size of the service to be rendered as per the available resources, in other words existence of a very close link between decision making mechanism and the available resource package and as a natural outcome of this, distribution of resources according to determined strategic priorities.

Thanks to MTEF, budget resources are mobilized in a way to cover a period longer than one year for realizing the strategic priorities which cover more than a year, which are determined by politicians and which reflect the choice of the electorates so to speak; therefore, medium term policies are formulated and these policies are integrated into the budget process. Thereby, a transition has been foreseen from the budgeting system based on traditional cash management to a budgeting system based on expenditure management<sup>13</sup>. As a natural outcome of the given information, planning and handling the expenditure areas in the budget with a medium term approach is required. For instance, welfare payment to those older than 65 or agricultural subsidies to farmers are not policies that differ from year to year. Lately, the agriculture strategy to be implemented in the coming five years has been declared by the Ministry of Agriculture and Rural Affairs in Turkey. Therefore, the best way

---

<sup>12</sup> YILMAZ, H. H. Kamu Mali Yönetiminin Yeniden Yapılandırılması: Dünya Bankası Orta Vadeli Harcama Sistemi. Ankara: DPT, 1999, pp. 16.

<sup>13</sup> YILMAZ, H. H. Ibid. pp. 19.

to formulate this declared agricultural strategy within the budget is to take up the issue with a medium term approach.

### 3.2 *The Objectives of MTEF*

There are many reasons MTEF has been given place in budgeting process in recent years. It is possible to enumerate these as follows:

- ◆ It makes it obligatory for the governments to determine their medium term goals and objectives clearly. Thus, it is ensured that the public resources to be raised in the medium term are allocated between and across the sectors. So it improves predictability of funding for line agencies and is sort of budget planning given policy choices<sup>14</sup>,
- ◆ It sets out major policy directions, fiscal aggregates and the sectoral resource allocation<sup>15</sup>,
- ◆ It enables the redistribution of resources among the budgets of public agencies and/or within the budgets of public agencies so that the changes which took place in the government's priorities are included into the next year budgets<sup>16</sup>. So efficiency in the allocation and utilization of public resources is encouraged<sup>17</sup>. However, minimizing the redistribution of resources in the budget execution is also important because the frequent repetition of such a practice might cause budgets not to reflect the real priorities or might cause a deviation from fiscal/political discipline<sup>18</sup>,
- ◆ By way of establishing a consistent resource-expenditure balance, it ensures fiscal discipline and contributes to the enhancement of the macroeconomic balance<sup>19</sup>,

<sup>16</sup> SCHICK, A. Opportunity, Strategy and Tactics in Reforming Public Management. *OECD Journal on Budgeting*. 2002, vol. 2, no. 3, pp. 27.

<sup>17</sup> KIZILTAŞ, E. *Ibid.* pp. 18.

<sup>18</sup> THE WORLD BANK. *Ibid.* pp. 22.

<sup>19</sup> WILDAVSKY, A. Controlling Public Expenditure: The Theory of Expenditure Limitation. *OECD Journal on Budgeting*, 2003, vol. 2, no. 4, pp. 40.

- ◆ It provides necessary information to the political decision makers on the possible costs of the political priorities of the government and of new programs and projects that are put into implementation<sup>20</sup>.
- ◆ It ensures the continuity of programs that are being implemented as a result of the increased predictability in the allocation of public resources for certain policies. Furthermore it assists the establishment of the necessary incentive mechanisms for the effective and efficient utilization of the public resources as a result of the budget constraints introduced and the flexibilities provided to public agencies<sup>21</sup>.

MTEF approach has certain disadvantages although it ensures, by way of realistic analyses, the allocation of the limited public resources to the areas where they can be effective and efficient. It is possible to enumerate these disadvantages as follows:

- ◆ Future oriented estimations in MTEF practice might appear as earned rights by the agencies, and this might prevent the top down revision of the expenditures in case a need arises for the correction of the estimates made beforehand,
- ◆ Over optimistic multi year estimations might lead to continuation of unnecessary public services and might form an upward pressure over the budget expenditures,
- ◆ If multi year estimations are made in a way to include real increases, expenditures might automatically increase in the inflationist periods, these increases taking place independently from the developments in the budget revenues might make it difficult to ensure fiscal discipline<sup>22</sup>. There are also claims that this situation might inhibit rendering public services at a required level, furthermore, that the position of the public and private sectors in the economy might change against the favor of public sector<sup>23</sup>.

However, it is within the bounds of possibility to eliminate the enumerated disadvantages of MTEF using multi year budget estimations

---

<sup>20</sup> BLÖNDAL, J. R. Ibid. pp. 11.

<sup>21</sup> YILMAZ, H. H. Ibid. pp. 22.

<sup>22</sup> BLÖNDAL, J. R. Ibid. pp. 12.

<sup>23</sup> WILDAVSKY, A. Ibid. pp. 40.

which are prepared on the basis of economic presumptions determined realistically as well as nominally and which are not responsive to inflationist increases.

We should bear in mind that MTEF may fail due to the some circumstances encountered such as macroeconomic instability, weak financial management system, lack of enough administrative capacity and fiscal discipline and introducing new programs with no resources available<sup>24</sup>. If successfully applied, it would improve macroeconomic balance by developing a multi year resource framework.

Therefore, budgets are the most important instruments used by governments to realize the services committed by them to citizens. This also indicates that budgets are important texts which reflect political choices. However, it is not possible to limit the commitments of the governments to a year, besides they have a nature of covering many years. Therefore the budget systems should take account of the economic activities and commitments that exceed a year and that are related to budget. For this reason, budgeting should be thought together with the planning process and establishment of the plan-budget link becomes inevitable for an efficient budget process. Consequently it will be possible for this kind of a budget, which is not disconnected from other periods, to generate policies.

### ***3.3 Policy Making, Planning and Budget Relationship***

Medium term approach facilitates the allocation and realization of public resources in compliance with the resource-expenditure balance and considering the determined priorities. Therefore we can state that from the two most important objectives of the medium term approach, the first one is setting the fiscal objectives and the second one is distributing the resources as per strategic priorities within the framework of the said objectives.

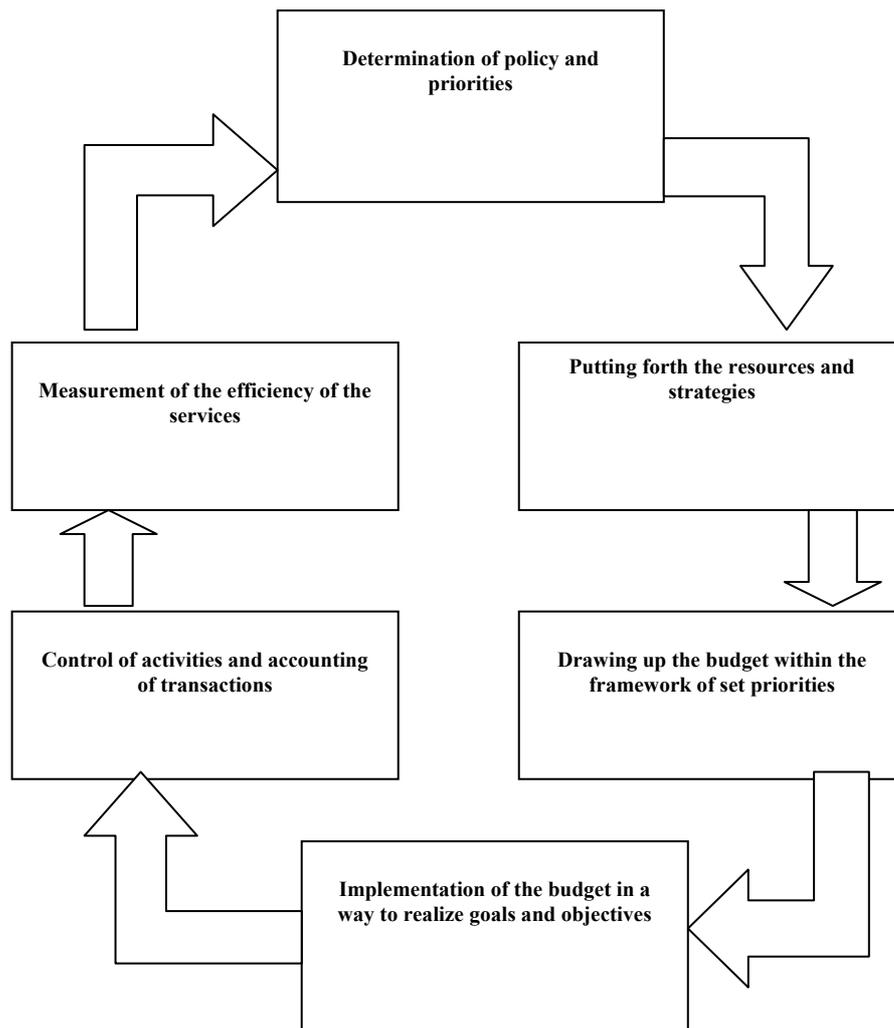

Figure 1 indicates the process that is necessary for the establishment of the link between efficient policy making, planning and budgeting. First and foremost, the process starts with the government determining on its policies and priorities as per sectors. In the following stage, goals and strategies as well as available resources oriented towards realizing these policies and priorities will be put forth. As the third stage, preparing a budget as per certain sectors in conformity with the determined policies, goals and available resources will be required. In this stage, what amount of resources

---

<sup>24</sup> PEARSON, M. *Medium Term Expenditure Frameworks. (Briefing Paper)*. UK: DFID Health Systems Resource Centre, 2002, pp. 4.

will be distributed to which expenditure areas will be determined. Budget implementation, which includes the collection of revenues for the realization of determined public activities and the mobilization of the necessary personnel and resources, comes up as the next stage. Monitoring of the activities and keeping of the necessary accounting records are required in the fifth stage. The process will have been completed with the evaluation of the efficiency of the activities and auditing of the implementation and at the same time with the acquisition of the necessary experience for the policies to be implemented in the future.

**Figure 1-Policy Making, Planning and Budget Relationship**

*Source: THE WORLD BANK. Public Expenditure Management Handbook, Washington D.C.: The World Bank, 1999, pp. 32.*

Resource allocation process in the developing countries faces important problems due to uncertainties experienced and it prevents proper planning oriented towards future. For example, over-optimistic estimation of budget revenues might lead to an uncertainty in terms of resource levels and might inhibit efficient planning oriented towards future.

The budget process does not take into account the possible problems to be encountered in the coming years and the multi year budgets are not binding or the set objectives are not taken seriously, the government operates in order to carry out the given duties only, as in the case of classical budget approach, rather than to use public resources for the realization of certain goals and objectives. For this reason, especially in the developing countries the policy-plan-budget link is required to be strengthened<sup>25</sup>.

### ***3.4 Introduction of MTEF in Turkey***

MTEF is a newly introduced approach in Turkish financial management system. One of the deficiencies Turkish budgetary system had in the past is the lack of prudent macroeconomic framework and assumptions in estimating revenues and expenditures for coming years. More importantly, revenue and expenditure estimations were not compatible with the existing macroeconomic framework. So MTEF for Turkey shall be prepared in a rolling structure, capture some more flexibilities in case of changing priorities and circumstances within the year. MTEF should also be in detail and comprehensive enough to link with national priorities set forth in medium term program and fiscal plan as required by the new Law, No 5018.

MTEF should be handled as a process and roles and responsibilities of key central agencies (Ministry of Finance and Undersecretary of State Planning Organization) as well as public agencies should be defined within this process. In reference to the Law No 5018, we see that no clear and simple process relating to MTEF has been set forth. As for the MTEF practices across the world, the most important element of MTEF is that the priorities of the government are determined by the council of ministers and the priorities at the level of administrations are determined by the ministries together with the agencies strategic plans. First stage in MTEF is the determination of the macroeconomic framework. Macroeconomic framework will at the same time facilitate the estimation of expenditures pertaining to

---

<sup>25</sup> IŞIK, H. Kamu Harcamalarında Performansa Dayalı Bütçe Yönetimi ve Denetimi ile Türkiye’de Uygulanabilirliği, Ankara: Devlet Bütçe Uzmanlığı Araştırma Raporu, 2003, pp. 73-74.

the next three years. Therefore it is required to ensure mutual harmony by means of combining economic estimates and financial objectives; and consequently to estimate the macroeconomic framework for the next three years employing different methods of analysis. Furthermore, it is required that the costs of current and new policies are identified and effects of these policies on economic balances are estimated. For example, economic forecast office operating independently in the Netherlands is obliged to assist the ruling government and the opposition especially in the calculation of the costs of new policies as well as in the estimation of the effects of these policies on economic balances.

Medium Term Program to be prepared pursuant to Article 16 of the law No 5018 could be functional in this respect. Thus this program could be taken as the starting point of MTEF. The Council of ministers that will convene by the end of May will adopt the medium term program prepared by State Planning Organization in a way to cover macro economic policies, principles, targets and main economic magnitudes as indicators (sectoral priorities, growth, inflation, exchange rate, payment balance, interest, etc.) in line with requirements of the development plans, strategic plans and general economic conditions and the Program will be published on the Official Gazette within the same time period.

The second stage in MTEF is the revision of sectors. In this stage goals and activities of a sector/ministry should be revised and the costs of these goals and activities should be calculated and information on their outputs and outcomes should be obtained. As a result, the programs and subprograms that will ensure the realization of these goals and activities should be prioritized taking account of the available resources. As regards Article 16 of the Law No 5018, this stage has not been given any place. However in Article 9 of the Law, strategic plans are mentioned and this stage will be realized by the strategic plans of the administrations. Nevertheless, as mentioned just a while ago, the fact that multi year budgeting process is not given in a certain order in the Law has the potential to cause complications in practice. What is more, the fact that MTEF will be introduced with 2006 budget while only certain administrations are piloted in terms strategic planning, indicates that this stage will not be given place in the budgeting process at least for a while.

The third stage should entail negotiations of the Ministry of Finance and State Planning Organization with the sectoral ministries. In this stage negotiations take place on the outputs of the sectoral study conducted in the

previous stage. Similarly, law No 5018 provides no certain calendar for these negotiations.

The fourth stage is the determination of expenditure ceilings of the sectors/ministries for the coming three years. Expenditure ceilings are set bearing in mind the priorities determined in the previous stages and the macroeconomic structure. In other words, a detailed framework on the sectoral and institutional distribution of the expenditures is formed. Furthermore, targets relating to the total revenues of the coming three years are determined. However, the final decision about the expenditure ceilings of sectors/ministries and total revenues will be taken the Council of Ministers.

In stage five, expenditure ceilings of sectors/ministries will be approved by the Council of Ministers. The most important stage in MTEF is this stage where the expenditure areas for which the public resources will be allocated in the medium term are transformed into a government declaration by the council of ministers by staying within the boundaries of available resources. This stage is not a simple stage where budget ceilings are determined only. It is a stage where the medium term priorities of the government and thus its policies as well as the economic role of the state are reflected to the budgeting process.

According to the Law No 5018, medium term fiscal strategy, which includes total revenue and expenditure estimates relating to the coming three years, the target balance, the borrowing status if any and appropriation ceilings of the public administration, shall be prepared by the Ministry of Finance in compliance with the medium term program and shall be approved by the High Planning Council in the first half of June. However, the Law No 5018 has brought a structure that does not comply with this general rule mentioned above. This is because the medium term fiscal strategy will be adopted by the High Planning Council instead of the Council of Ministers. Therefore a policy declaration which many ministers are not involved in, in other words, a resource allocation process which might not be agreed upon by the members of the cabinet will be brought about.

In the final stage, public agencies are required to prepare their budgets for the coming three years taking account of the sectoral/institutional priorities and ceilings. However, in the budget preparation stage the Ministry of Finance and State Planning Organization is required to check how much the budget proposals sent by the institutions comply with the sectoral/institutional ceilings and priorities set forth by the medium term program and fiscal strategy. It would provide an important contribution for

the realization of policy and budget link if they talked with the representatives of the sectors/institutions on ruling out the inconsistencies if any, thereby ensuring consistency.

There is no doubt that a successful and sustainable public financial management reform reveals the need for strengthening of the institutions involved in the budget process and the realization of the institutional arrangements other than the budget. Because realizing the transformation does not depend on setting the necessary rules only. It also depends on a public financial management system whose authorities and responsibilities are well defined, an internal control mechanism that operates efficiently together with the necessary mentality change in the public institutions and the public sector personnel with sufficient capacity. On the other hand, presentation of information on time and in a reliable manner and monitoring and evaluation capacity of the administrations thereof will play an important role. Furthermore, external audit is an important element. For this reason, administrative capacity building in public agencies and creating necessary infrastructure to this end is essential. Transfer of the public financial management system, which has been the duty of the ministry for many years in our country, to the public agencies from now on, as a requirement of the Law No 5018, should be seen as a very important and fundamental mentality change.

#### **4. Conclusion**

A transformation need in public financial management system has become prominent in a rapidly changing world, based on the methodology approach brought by globalization and information society. Reconstruction need appeared not only in the public financial management systems but also in the public administration approach and the transition from an industrial society to an information society revealed the difficulty of adaptation of public administrations to the changing conditions within the existing patterns. As a consequence of this, the new public administration approach came out and public administrations in many countries initiated a change in their approach and implementation.

Public administration systems have undergone change in parallel with the new public administration approach and activities carried out towards reconstruction hastened in recent years. A need for transformation especially appeared in developing countries rather than in developed countries;

however, transformation activities carried out in public financial management systems became prominent more in developed countries. As a consequence of this, with the efforts of international organizations too, international examples of the best practices were opened up and the developing countries have been affected by the wind of transformation too.

The need for transformation appeared especially after the economic crises in our country and the problems encountered by the Public financial management system have been among the issues which have always been a matter of discussion. And the idea became prominent that a budgeting system, which is founded over an audit system that is fragmented, that operates on strict principles and procedures and that is not intense or efficient; and which adopts an input oriented budgeting approach that does not include fiscal transparency and accountability in itself, that does not provide initiatives to administrations, can no longer be continued<sup>26</sup>.

One of the important approaches brought by the new financial management approach has become MTEF. Reflecting the governmental policies to the planning and budget process is the most important tool for providing resource-expenditure balance in the public sector. A decision making process prepared without taking account of the available resources might cause deviation from fiscal discipline and accumulation of economic problems. For this reason, MTEF is seen as an important element for ensuring discipline in the utilization of resources. Therefore, efficiency and effectiveness in the allocation and utilization of public resources have been highlighted and policy, plan and budget link has been endeavoured to be strengthened, through the Law No 5018, and necessary legal infrastructure for performance based budgeting and MTEF has been created within this context.

So MTEF may pave the way to evaluate the outcome of the policies adopted and to finance the provision of public and semi-public goods. MTEF should not be as detail as the budget but should capture certain sectors and sub-sectors in terms of resource allocation and output-outcome of the programs. However, we should not expect beyond the capability of MTEF such as solving all service delivery problems because there are other crucial factors that the public service delivery is affected. In conclusion, MTEF is important approach to provide the expenditure areas that the government is diverting to and ensure predictability and reliability of government policies.

## **Abstract**

*This paper analyzes some aspects concerning tax havens and their existence in the context of globalization. The tax havens are a consequence of the existence of the tax hells. Also, the paper presents development of tax havens by comparing with a few developed countries and reveals the impact of expansion of tax havens and how they influence the economic activity in the other countries – non-haven countries. The ability to avoid taxes by using tax havens seems to be favorable for economic activity, especially for the countries in the same region. A few types of firms which are establish tax haven operations are presented, and what purposes do these operations serve. In conclusion, many of developed countries fight against the tax havens, but other are in competition with tax haven adopting the flat tax rate on corporate income.*

**Keywords:** *tax havens, tax competition, offshore companies*

<sup>1</sup> I would like to thank Lawyer Titi Mureşan (Alba-Iulia) for his important contribution on realization of this paper.

## 1. Introduction

Tax havens are one of the most important subjects for an international entrepreneur or investor, yet few understand and use them properly. One group discounts them as hiding holes for dirty money, which is not a legitimate use for tax havens. Others think they are only for banking money after you have made it. Not true either. Money grows much faster if a tax haven is part of your business planning, and almost any international business has an opportunity to use tax havens.

Called a “*paradis fiscal*” by the French, a “*rifugio fiscal*” by the Italians, and a “*Steuereroase*” by the Germans, it obviously means a place where the “fiscal grass is greener than in your own particular backyard”. But an effective tax haven is not determined simply by geography; it all depends on what particular asset or transaction you are trying to defend from the tax collector. Simply stated, a tax haven is any country whose laws, regulations, traditions, and, in some cases, treaty arrangements make it possible for one to reduce his overall tax burden.

This paper presents some aspect regarding the tax haven concept and his proliferation directly linked by tax hells. Tax hells can be defined as the country with a very high level of taxation and an increasing tax burden. There is no tax haven without tax hell, thus the tax haven is a consequence of the increasing tax burden for companies and individuals. In this context the tax haven is a proper way to escape from the tax burden of tax hells, it is a way of international tax avoidance.

Also, the paper presents development of tax havens by comparing with a few developed countries and reveals the impact of expansion of tax havens and how they influence the economic activity in the other countries – non-haven countries. The ability to avoid taxes by using tax havens seems to be favorable for economic activity, especially for the countries in the same region. A few types of firms which are establish tax haven operations are presented, and what purposes do these operations serve. In conclusion, many of developed countries fight against the tax havens, but other are in competition with tax haven adopting the flat tax rate on corporate income.

## 2. Tax hells – the effect of social-economical development

The growth of social-economic role of the state supposes, in the first place, financial resources at his disposal, resources that are coming from taxes paid by citizens. In this context the level of taxation is increasing,

especially after the Big Crisis from 1929-1933, moment that represents a big turn of point for the idea of state interventionism promoted by Keynes.

The state interventionism in economy has positive effects through social-economical development, but also negative effects when it affects the individual liberty –the situation of centralized economies in the communist countries. If in the 1702, Vauban appreciates the level of taxation at 10% in the now days there are countries where the rate of taxation it is about 50% from GDP.<sup>2</sup> In these countries the level of burden of taxation it is justified through the welfare and social protection programs for population, reason for that are known as tax hells.

Hansen and Kessler (1999) analysis a few states concerning the geographical area and the tax rate on income and concluded that is double connection between the level of development, geographical area and tax rate. The countries with a high level of development and with a large area are characterized by high tax rates comparative with the countries more and less developed but very small like we can see from the Table 1 (the analysis take in consideration only the tax rate on income).

Hansen and Kessler (1999) reveal another regularity, in the tax policies. Despite many cultural and historical differences between the nations in the sample, one observes not only those taxes are high in large and modest sized countries, but also that rates are surprisingly similar within the two groups. Given the displayed figures, one immediately wonders whether the geography of a country is related to its pattern of taxation.<sup>3</sup>

Central point of argumentation is oriented to an international integration. Diminishing transportation costs and the removal of political barriers to mobility have increased trade and exchange of productive factors in the last decades. For example, in the European Union the process has advanced to the point where all formal constraints to mobility have been abandoned. This development has also greatly improved the mobility of households across states or national borders.

Decision of migration is based on local fiscal policy, but the migration of households determines fiscal policies through the interplay of two basic effects:

---

<sup>2</sup> Tulai, C., 2003, *Finanțele publice și fiscalitatea*, Printing House Casa Cărții de Știință, Cluj-Napoca, 2003, p. 292

<sup>3</sup> Hansen, N. A., Kessler, A. S., 1999, *Financial Management Analysis of Tax H(e)avens and Tax Hells: Focus on Residence Pprinciple of Taxation*, Journal of Financial Management & Analysis; Jul-Dec 1999; 12, 2; ABI\INFORM Global, p. 54

1. residential choices determine tax rates through a process in which a jurisdiction's inhabitants select their local policies, and

2. tax and welfare policies in each country influence residential decisions.<sup>4</sup>

More precisely households with different incomes differ in their policy preferences: as a natural implication of their earning characteristics, high income households prefer to live in countries with low taxation and low income households are rather interested in generous public spending than in low income tax rates because they prefer to live in countries with large welfare programs financed by substantial taxation – tax hells. Thus individual preferences imply a self-selection process which leads to the segregation of households across countries according to income classes.<sup>5</sup>

In 1956 Tiebout reveals a segregation of populations by political preferences, point that the main and determinant factor for migration is the preference for the public goods.

There is a mechanism which stops the extensive migration to the tax haven – the limited land which determines a very high price for property, thus only the wealthiest households can buy it.

In the specialized literature there are similar results – low taxes in small countries and high taxes in large countries based on tax competition for attracting more capital, especially for increasing base of taxation, what is known as “tax base effect”. The differentiation of tax policy based on segregation of populations by level of income is called “politico-geographical effect”.<sup>6</sup>

But in the present, many countries with tax hells reputation, because tax competition had permitted to establish a real “fiscal oasis” on their territories, for example in SUA: Delaware, Wyoming, New York, Nevada, Utah.

### **3. The concept of tax haven**

Despite the fact that tax haven phenomenon is by no means a recent occurrence and multilateral struggle against it spans more than 70 years, there is, as yet, no clear understanding of the nature of the phenomenon.

The term “tax haven” has been loosely defined to include *any country having a low or zero rate of tax on all or certain categories of income, and*

---

<sup>4</sup> Hansen, N. A., Kessler, A.S., 1999, Ibid.

<sup>5</sup> Hansen, N. A., Kessler, A.S., 1999, Ibid.

<sup>6</sup> Hansen, N. A., Kessler, A.S., 1999, Ibid.

*offering a certain level of banking or commercial secrecy.*<sup>7</sup> Applied literally, however, this definition would sweep in many industrialized countries not generally considered tax havens including the United States (the U.S. does not tax interest on bank deposits of foreigners).

The Modern Dictionary for the Legal Professions states the following: *tax haven is a tax shelter in a foreign country that is preferable to other countries because of that country's educated labor force, modern commerce system, advanced equipment and technology, good transportation, and good climate.*<sup>8</sup>

Black's Law Dictionary makes a different emphasis when defining the tax havens as: "*A country that imposes little or no tax on the profits from transactions carried on in that country*"<sup>9</sup>. Sometimes, within the same definition several criteria interfere with each other and even the common division of tax haven on the basis of, for example, their policies towards income taxation turns out to be by no means universal. Thus, some of the researches identify the following groupings:<sup>10</sup>

- The so-called "classical" tax havens or "no-income tax havens";
- Tax havens with no tax on income from foreign sources;
- Tax havens with special (privileged) tax regime;
- Treaty tax havens

The term "tax haven" suggests that a jurisdiction allows foreigners tax saving. This saving can take place in three ways. Activity can take place in the haven; activity can be assigned to the haven for fiscal purposes, regardless of reality; or the haven can mask reality through secrecy. Tax havens may therefore *produce* goods and services, they may *shift* claims among jurisdictions, or they may *hide* claims; frequently they do a bit of two or all three.

Therefore, the term tax havens is used to indicate any tax practice of a state or a jurisdiction related to the establishment, for any purpose, of a more privileged tax regime in comparison with other states or jurisdictions. The first uses of this term date back at least to 1950s. Back then it had a positive

<sup>10</sup> Mykola Orlov, 2004, *The Concept of Tax Haven: A Legal Analysis*, *International Tax Review*, INTERTAX, Volume 32, Issue 2 Kluwer Law International

meaning of escape from the otherwise drastic tax regimes of the developed countries. However, gradually, the term acquired a marked negative connotation of the erosion of tax bases of countries and unfair tax competition. Of late this has been aggravated by the added implications of money laundering and assistance to international terrorism.<sup>11</sup>

There are three main ways for the escape of the burdensome taxation imposed by welfare state through the movement of the income and property:

**Temporally:** that is, from one *time period* to another; for example, from one year into another, in anticipation of either an increase (or decrease) in tax rates and burdens.

**Geographically:** that is, from one *location* (or tax jurisdiction) within a country to another, or between countries, or from one corporate form to another.

**Subterraneously:** that is, from the above-ground (taxable) economy to the underground (untaxed) economy usually when it is become difficult or impossible to move temporally or geographically.

Tax havens represent a *geographic* form of escape from tax burdens.<sup>12</sup>

When viewing tax havens in a political context it becomes natural to differentiate between tax privileges within otherwise “normal” tax systems and tax havens as tax systems. Tax haven is not synonymous with an absence of neither taxes nor a tax system. Tax havens describe a *type or family of states*<sup>13</sup>. Without a political criterion it is not possible to differentiate between tax incentives and tax systems.

Examples of Tax Havens:

- The United Kingdom is a tax haven for people of foreign domicile, even if they are UK resident (*residence* and *domicile* being separate legal concepts in the UK), in that they pay no tax on foreign income not remitted to the UK. Similar arrangements are to be found in a few other countries including Ireland.

## 4. History of Tax Haven

To understand the logic behind the development of tax havens and their proliferation, it is necessary to trace the history of the respective policies and the rationale for the respective practices. Tax havens are not a modern invention. The use of tax haven policies were often used by states to further their goals, even, as it happens in world politics, to the detriment of their neighbors.

To put tax havens in proper perspective we have to go back 3500 years to the Book of Joshua, even to the Books of Moses, where the Lord ordered the Children of Israel to set aside cities of refuge where a person could gain asylum from the punitive laws of Moses. Recently, Hawaiian kings on the big island of Hawaii, set aside a city of refuge.<sup>14</sup>

A tax haven is somewhat similar. It is a kind of economic sanctuary, a modern city of refuge for those oppressed with the fiscal laws of their homeland. People can bring their wealth to a tax haven and avoid government confiscations by tax or exchange controls, or just plain confiscations like Castro and other totalitarian rulers have done. These oppressive acts by their governments are as much an evil to them, as those oppressed politically.<sup>15</sup>

Tax havens, or something like them, have been used for centuries. While some tax havens have evolved through a history of laissez-faire economic policies, others, particularly those specializing in attracting corporations, have been created as a matter of deliberate government policy. People have been looking for ways to avoid taxes for many years. Likewise, governments have been using tax incentives to attract or maintain business for many years.

For example, the ancient city of Athens imposed a tax on merchants of two percent of the value of exports and imports. Merchants would detour twenty miles to avoid these duties. The small neighboring islands became safe havens in which to hide merchandise to be smuggled into the country at a later date. In the middle ages, the City of London (as well as other jurisdictions) exempted Hanseatic traders resident in London from all taxes.<sup>16</sup>

In the fifteenth century, Flanders (now Belgium) was a thriving international commercial center. Its government imposed few restrictions on

<sup>15</sup> Adams, C., 2003, *Ibid*.

<sup>16</sup> Gordon, Richard, 1981, *The Gordon Report – Tax Havens and Their Use by United States Tax Payers – An Overview*, A Report to the Commissioner of Internal Revenue

domestic or foreign exchange and freed much trade from duties. English merchants supplied the needed raw materials, preferring to sell wool to Belgium rather than to England where they would incur numerous duties.<sup>17</sup>

Today, most major havens are also offshore financial centers (centers for international borrowing and lending in non-local currency). But tax haven is not the same thing with offshore financial center, even if some of the tax havens in fact, are offshore centers. The offshore financial centers suppose the high financial techniques which are developing progressively on some types of structures and products giving a comparative advantage on world market level.

Historically, the type of tax haven practices adopted by the states and jurisdictions at different periods of time depended on the features of the tax systems in the respective period of time. Thus, until the beginning of the twentieth century with the mass introduction of income taxation, the majority of tax havens focused mainly on granting relief from import and excise duties.

Admittedly, tax haven practices were used not only in the competition between states. Since the Middle Ages, tax privileges have been actively used for achieving certain developmental objectives.

## **5. Determinants factors for tax havens proliferation**

The political and economic catalysts that influenced the growth of the tax havens industry in the last decades are:

- *political and economic instability;*
- *market globalization and deregulation;*
- *the internationalization of business;*
- *the lifting of trade barriers;*
- *a trend towards steady global economic growth;*
- *a global relaxation of foreign exchange controls.*

In addition to political and economic catalysts there are also global tax related catalysts that continue to influence the growth of the offshore industry. These include:

- ❖ high tax regime with an increasing tax burden for companies and individuals;

---

<sup>17</sup> Gordon, R. 1981, Ibid.

- ❖ tax competition and migration;
- ❖ fiscal harmonization;
- ❖ opportunities of utilizing double taxation treaties.

By simply stating that tax haven proliferation was as a consequence of rising taxation in the industrialized world. The same factors that explain an increasing private sector demand for less regulated and taxed jurisdictions are used to explain tax haven developments. They do not separate between the growing the use of tax havens, and the growing number of tax havens. As a consequence the theories cannot differentiate and explain why certain states become tax havens. Haslerud (2004) through a statistical test of the neoclassical perspective laid the ground for further analyses. Tax haven developments were explored in light of size, colonial heritage and rule of law. Logistic regression was used and all factors were significant at the 1973 model. The analysis showed that tax haven developments can be understood by historical, structural and institutional factors.<sup>18</sup>

In contrast to other states, tax havens have distinguished themselves by enacting legislation that provides corporations and individuals with anonymity and shelter from their home governments. Lacking adequate mechanisms of "internal profit generation," these so-called paper financial centers have learned to take advantage of what *The Economist* scornfully describes as their main asset: the right to write the laws. But in so doing, tax havens are like the sovereign equivalent of parking lot proprietors: they could not care less about the business of their customers only that they pay for parking their vehicles there. Likewise, tax havens are unconcerned with the true nature of the companies residing within their borders. Those using tax havens rarely relocate to them; instead they pay for the privilege of "renting" a residence there. That is, they take advantage of the juridical facilities offered to them for what is euphemistically called "effective international tax strategy," which is another way of saying avoiding or evading taxes.<sup>19</sup> But with increasing numbers of tax havens and those who use them, the principles of supply and demand appear to regulate the cost of license fees and the character of the legal protection that tax havens offer. In other words, tax havens are introducing choice and marginal utility into issues of residency and sovereignty.

## **6. The main features of the tax havens**

Tax havens are generally characterized by the low or zero tax on income, high standards of financial, including banking, and commercial secrecy; no or liberal currency controls; developed infrastructure; available professional help of, first of all, lawyers, auditors, accountants and financial analysts; and lower standards for the regulation of financial institutions, in particular banks and insurance companies, stable government, equitable treatment of foreigners, existence of free trade zones, local consumer and labour markets, investment incentives or self-promotion

### ***Low Tax***

Many of the jurisdictions that are considered tax havens do impose taxes. All, however, either impose no income tax on all or certain categories of income, or impose a tax which is low when compared to the tax imposed by the countries whose resident taxpayers use them.

Some jurisdictions do not impose income taxes, or impose very low rates of tax. In the Caribbean, the Bahamas, Bermuda, the Cayman Islands, and the Turks and Caicos do not impose any income or wealth taxes. In some cases the tax situation may be part of a policy to attract banking, trust or corporation business. In other cases it may exist because they country never found the need to impose tax.

Often low tax rates are considered an evil. However, many tax havens are small less-developed countries whose residents are generally poor. In many cases, the small population of the country makes an income tax system impractical. Instead, the country will establish a license or fee system for generating revenue. Instead of imposing an income tax, fees can be charged for bank licenses, commercial charters, and the like. Administration costs of collecting those revenues are kept to a minimum.

Often jurisdictions, while imposing significant domestic taxes, impose low rates on certain income from foreign sources, a tax system used by a number of developed high tax countries (such as France) as well as by some tax havens. Panama is an example. Accordingly, a local corporation can be formed and managed in the tax haven with no tax being paid to the tax haven on its income from other jurisdictions.

Some tax havens impose low rates of tax on income from specific types of business. Some jurisdictions, for example, offer special tax regimes to holding companies, making them especially useful as financial centers or suits for holding companies.

### ***Secrecy***

By definition, all of the jurisdictions with which we are concerned, afford some level of secrecy or confidentiality, afford some level of secrecy or confidentiality to persons transacting business, particularly with banks. This secrecy has its origin in either the common law or in statutory law.

Common law secrecy is found in those jurisdictions which were or still are British Colonies. It derives from the finding of an implied contract between a banker and his customer that the banker will treat all of his customer's affairs as confidential. If violated, an action for damages for breach of contract lies against the banker.

Some level of secrecy is a characteristic common to both tax havens and non-tax havens. Most countries do impose some level of protection for banking or commercial information.

### ***Relative Importance of Banking***

Banking tends to be more important to the economy of a tax haven than it is to the economy of a non-tax haven. Most tax havens follow a policy of encouraging offshore banking business. This is done by distinguishing between resident and nonresident banking activity. Generally, nonresident activity will not have reserve requirements, will be taxed differently (if at all), and will not be subject to foreign exchange or other controls.

The banking industry has a significant effect on the economy of the tax haven. Financial business yields revenues in the form of fees and modest taxes on financial institutions. The tax haven also benefits from employment of personnel and rental of facilities.

***Availability of Modern Communications:*** many of the countries considered tax havens have excellent communications facilities.

### ***Lack of Currency Controls***

Many tax havens have a dual currency control system, which distinguishes between residents and non-residents, and between local currency and foreign currency. As a general rule, residents are subject to the currency controls; non-residents are not. However, non-residents will normally be subject to controls with respect to local currency. A company, formed in the tax haven, which is beneficially owned by non-residents and which conducts most of its business outside the tax haven, is generally treated as non-resident for exchange control purposes. Accordingly, a foreign person can form a tax haven company to do business in other jurisdictions. It will not be subject to the tax havens' exchange controls as long as it is

dealing in currency of other jurisdictions and is not doing business in the tax haven.

These rules are adapted to facilitate the use of the tax haven by a person wishing to establish a tax haven corporation to do business in other jurisdictions.

**Tax Treaties:** it is important for a tax haven to have an extensive network of tax treaties to be attractive for potential users.

## 7. Types of tax havens

Kudrle and Eden (2003) classified tax havens from the substantial activity which these are developed:<sup>20</sup>

- **“Production” haven:** where a jurisdiction’s tax attraction induces a significant change in real haven value added, Ireland, until it recently changed its laws, was cited as the prime example. Although some complain that jurisdictions with generally low taxation should be called “havens” because they attract real foreign activity, most observers look only at discrimination: are foreigners treated differently from otherwise similar domestic persons and businesses? If they are not, then one is simply looking at a low tax state.
- **“Headquarters” havens:** lower corporate taxes by providing tax advantages to firms that incorporate in that jurisdiction, wherever their shareholders are located. Examples usually offered are Belgium and Singapore.
- **“Sham” havens:** host low corporate-tax financial intermediaries that may be little more than an address for investment activity directed from elsewhere. Nearly all of the Caribbean and Pacific tax havens fall into this category. Some sham havens have also emerged as headquarters havens. The low value-added activity may not be a subsidiary of a foreign firm but independent and legally based in the haven despite negligible local ownership. Some Liberian and Panamanian

---

<sup>20</sup> Robert T. Kudrle, Lorraine Eden, 2003, The Campaign Against Tax Havens: Will It Last? Will it Work? Stanford Journal of Law, Business, and Finance

shipping firms and some Bermudan insurance companies serve as examples. In addition, there is the rapidly rising phenomenon of “corporate inversions,” in which corporations based in high-income countries simply shift their declared nationality to a sham haven.

### *Types of tax havens by aims*

In terms of the targeted types of taxation, tax havens can be divided into:

1. income tax havens offering complete or partial shelter from income taxation: individual income tax, corporate income tax or capital gains tax;
2. import duties (excise) tax havens;
3. estate tax havens;

4. tax havens with privileged regimes for the taxation of certain forms of activities, for example ‘flags of convenience’, tax haven for captive insurance companies or IBC regimes.<sup>21</sup> It should be noted that one state or jurisdiction, in its tax haven practices, may target several types of taxation, for example Panama is known as a ‘flag of convenience’ state .

At the same time, tax havens may also be limited to a particular type of tax relief, e.g. the US is generally considered to be a tax haven for income earned on the deposits of non-residents in US banks.

Approached from a different angle, tax havens can be further categorized in terms of the taxpayers that use them:

- *havens for individuals* (Cayman Islands is one of the most favored);
- *corporate havens* for companies like captive insurance companies, banks, holding companies etc.

A **corporate haven** is a jurisdiction with laws friendly to corporations thereby encouraging them to choose that jurisdiction as a legal domicile. Within the United States, Delaware is considered the pre-eminent corporate haven. However it is facing competition from Nevada and Wyoming. While Delaware through its developed legal system and laws protecting shareholder rights is geared toward the large complex public corporation, Nevada and

---

<sup>21</sup> Mykola Orlov, 2004, The Concept of Tax Haven: A Legal Analysis, International Tax Review, INTERTAX, Volume 32, Issue 2 Kluwer Law International

Wyoming are more attractive to the small privately-held corporation. Delaware law tends to protect the rights of shareholders, and Nevada and Wyoming tend to favor management.

Corporate havens include British crown colonies such as Bermuda, Cayman Islands. Increasingly, U.S. corporations are using these havens, either by incorporating subsidiary corporations in these locations or by moving their corporate domicile there.

- havens for trusts (Luxembourg, Liechtenstein;)
- offshore financial centers;
- free economic zones;
- ‘flags of convenience’, etc.

## 8. Offshore companies

An **offshore company** is one which does not conduct substantial business in its country of incorporation. They are sometimes known as non-resident companies.

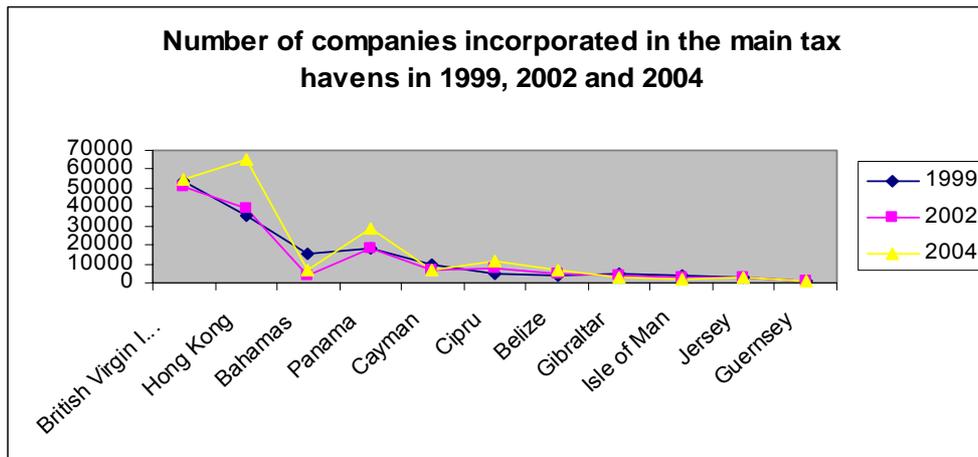

Theoretical, anywhere in the world it can be set up an offshore company, but not everywhere it is possible to obtain fiscal advantages, because a company will not be exempted from taxes because is an offshore company, it must be an offshore set up in a tax haven.

The main reason for establish an offshore company in a tax haven is the minimization of taxation and reducing of burden taxation, also a good management of the risk and an important costs reduction.

Offshore companies can be set up as Limited Liability Company (LLC), International Business Corporation (IBC – specific for the jurisdiction of British Crown), trust, exempted company, non-resident company. These companies can develop any kind of activity without restrictions. Only, for banking and insurances activities it is necessary a special approval.

Basically, an LLC allows for the flexibility of a partnership structure within the framework of limited liability, such as that granted to corporations. Another advantage of an LLC over a limited partnership is that the formalities required for creating and registering LLCs are much simpler than the requirements most states place on forming corporations; often they are no more complex than creating a corporate structure.

**Figure 1 Number of companies incorporated in the main tax havens in 1999, 2002, 2004**

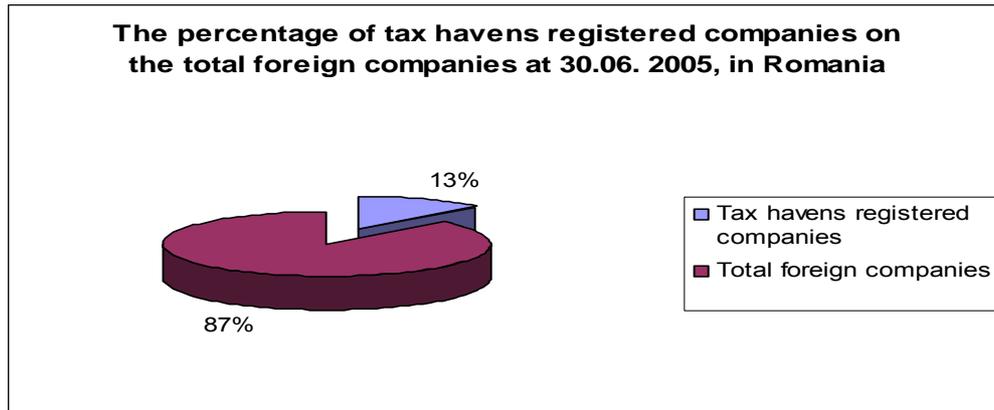

*Source: Author's calculation based on statistical data provides by National Commercial Office*

The figure 1 reveal the evolution of the main tax havens regarding the number of companies inregistered on their territories. British Virgin Islands was on the first position with 54361 incorporeted companies, but in 2004 Hong Kong is on the first position with 65558 incorporeted companies.

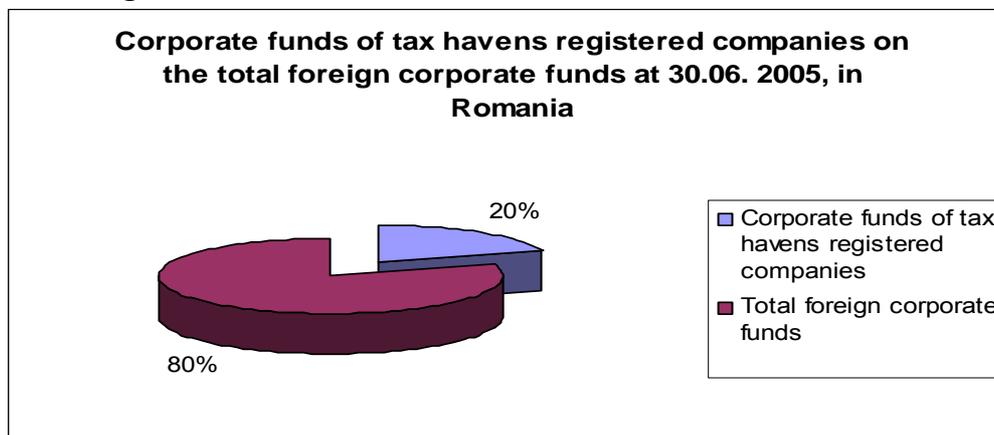

In Romania, the tax burden for companies and individuals was very high until recently. Beginning with this year, was introduced a flat tax rate – 16% for income (of companies and individuals), thus we can consider that Romania it is almost a “tax haven”, but this is far from reality. Many companies which are operating in Romania coming from tax havens. Figure 2 indicates that 13% of the foreign companies are from tax havens, and the percentage of corporate funds of this companies in total foreign corporate funds is much bigger 20% (figure 3).

**Figure 2**

## **9. The growth of tax havens**

According to some estimates, as much as half of the world's stock of money either resides in tax havens or passes through them.<sup>22</sup>

Palan (2002) explain the growth of tax havens in recent decades through increasing regulation and taxation in the post-war OECD economies. Also, he suggests that haven activity is a "state strategy" for economic development in the context of the globalization.

James R. Hines, in a National Bureau of Economic Research (NBER) paper co-authored by Mihir Desai and Fritz Foley of Harvard Business School, found that "haven activity does not appear to divert activity from non-havens." In fact, their calculations indicate that "firms establishing tax haven operations expand, rather than contract, their foreign activities in nearby countries."<sup>23</sup> When firms can reduce their tax burden by means of affiliates in tax haven countries, the authors argue, sales and investment in nearby nonhaven nations increase. A one percent greater likelihood of

<sup>22</sup> Palan Ronen, 2002, *Tax Havens and the Comercialization of State Sovereignty*, International Organization 56.1, p. 151-176,

<sup>23</sup> Desai, M. A., Foley, C. F., Hines, J. R. Jr., 2004, *Economic Effects of Regional Tax Havens*, National Bureau of Economic Research, available at <http://www.nber.org/papers/w10806>

establishing a tax haven affiliate is associated with 0.5 to 0.7 percent greater sales and investment growth by non-haven affiliates, implying a complementary relationship between haven and nonhaven activity. The ability to avoid taxes by using tax haven affiliates therefore appears to facilitate economic activity in non-haven countries within regions.<sup>24</sup>

But don't the haven countries shortchange their own citizens by offering such favorable conditions for multinational corporations? In another NBER working paper, Hines suggests they don't. Per capita real GDP in tax haven countries grew at an average annual rate of 3.3 percent between 1982 and 1999, which compares favorably to the world average of 1.4 percent. Tax haven governments appear to be adequately funded, with an average 25 percent ratio of government to GDP that exceeds the 20 percent ratio for the world as a whole, though the small populations and relative affluence of these countries would normally be associated with even larger governments.<sup>25</sup> Table 2 presents a ranking of the countries based on GNI per capita. As we can see on the two first positions are Bermuda and Luxembourg (both tax havens).

Source: World Development Indicators database, World Bank, September 2004

Notes: .. Not available.

GNI is gross national income (gross national product)

PPP is purchasing power parity.

Figures in italics are for 2002 or 2001.

a. 2003 data not available; ranking is approximate.

c. Estimate is based on regression; other PPP figures are extrapolated from the latest International Comparison Programme benchmark estimates.

From this ranking made by World Bank we can pointed that “tax haven strategy” is very efficient specially for microstates, which have no other sources of revenues except the tourism and the “tax haven strategy”.

## 10. Conclusion

As long as welfare states exist and expand there will be pressure to raise taxes. That's why there's been an intensifying assault lately by high-tax governments (including the U.S.) on the world's low-tax nations. A coordinated campaign organized by the Organization for Economic Development (OECD), European Union (EU), the World Bank, the International Monetary Fund (IMF), the U.N., the World Trade Organization (WTO), the U.S. Treasury Department and the U.S. Congress has targeted what are referred to as the harmful tax practices of low-tax nations, territories and jurisdictions – tax havens.

However tax havens are used for sheltering illegal money and also for legitimate business because of their peculiar characteristics such as secrecy, lack of exchange control, good banking, communication and transport structure, tax advantages end up being their major attraction both to wealthy individuals and large corporations.

As long as economic agents have become more sensitive to differences in effective tax rates and capital gained mobility within the process of growing integration of world's economies, capital tends to flow from high to low tax countries, mainly to those regarded as classical tax havens. Thus, tax havens have imposed an unfair tax competition for international capital, not only by means of reducing tax rates, but also introducing changes or distortions in the tax bases, which is less visible than low tax rates. Even some studies demonstrate that impact of tax haven is positive, developed countries try and fight for stopping the proliferation of tax haven. OECD issues a few reports in this context (1998 *Harmful Tax Competition: An Emerging Global Issue*, 2000 *Towards Global Tax Cooperation: Progress in Identifying and Eliminating Harmful Tax Practices*), but many of developed countries are veritable tax haven (United Kingdom, United States).

Tax havens will continue to exist and even in the globalization context their proliferation it is hard to stop because neither international authority has any right to affect the state sovereignty.

## **Abstract**

*Recently accepted tax reform is one of the most important initiatives of Slovak government towards creating a highly competitive and non-distortive market environment in Slovakia. In its Policy Statement, the government undertook to reduce income tax rates and to analyse the possibility of implementing a flat-rate tax. In fact, the actual reform goes even beyond these original ambitious objectives. Its ultimate goal is to transform the Slovak tax system into the most competitive one in the entire EU and OECD area. Assessment of the tax reform in Slovak Republic represents complicated issue from both professional and political point of view. Indisputably, there are positive effects, such as simplification of tax system, higher degree of transparency and creation of business-friendly environment. However, we can't notice also negative impacts. The resources of the society are being redistributed to higher income groups.*

**Keywords:** *Tax reform, direct taxes, indirect taxes, VAT, GDP*

## 1. Introduction

Recently accepted tax reform is one of the most important initiatives of Slovak government towards creating a highly competitive and non-distortive market environment in Slovakia. In its Policy Statement, the government undertook to reduce income tax rates and to analyse the possibility of implementing a flat-rate tax. In fact, the actual reform goes even beyond these original ambitious objectives. Its ultimate goal is to transform the Slovak tax system into the most competitive one in the entire EU and OECD area.

Assessment of the tax reform in Slovak Republic represents complicated issue from both professional and political point of view. Indisputably, there are positive effects, such as simplification of tax system, higher degree of transparency and creation of business-friendly environment. However, we can't notice also negative impacts. The resources of the society are being redistributed to higher income groups.

## 2. Macro-economic trends in Slovak Republic between January 1, 2001 and December 31, 2004

The trend of basic macro-economic indicators, indicating the development in Slovak Republic, is specified in the table below:

Indicator	2004	2003	2002	2001	Difference
1. GDP in constant prices in bill. SKK	827	783	750	713	+114
2. Unemployment rate in %	13,1	15,6	17,5	18,6	-5,5
3. Increase of consumer prices	5,9	9,3	3,4	6,5	- 0,60
4. Average monthly wage in SKK (1 Euro = 38,5 SKK)	15.825	14.365	13.511	12.365	+ 3.460
5. Nominal Wage Index in %	110,2	106,3	109,3	108,2	+ 2,00
6. Real Wage Index in % *	102,5	98,0	105,8	101,0	+ 1,50

Source: [www.nbs.sk](http://www.nbs.sk)  
[www.statistics.sk](http://www.statistics.sk)

\* Real Wage Index is counted as Nominal Wage Index divided by Index of consumer prices

**Basic socio-economic problems** in the Slovak Republic are concentrated in the following areas:

2. high unemployment rate despite the high rate of GDP growth
3. low GDP per capita (in 2004 it reached 153 580 SKK, i.e. approx. 3 989 Euro)
4. low average monthly wage (average monthly wage in 2004 was approx. 411 Euro)
5. tax reform impact on households (relatively high tax burden on middle and low-income earners)
6. distribution of sources to higher income groups after the implementation of tax reform in Slovak Republic (January 1, 2004)

### **3. Main principals and objectives of tax reform in Slovak Republic**

Recently accepted tax reform is one of the most important initiatives of Slovak government towards creating a highly competitive and non-distortive market environment in Slovakia. In its Policy Statement, the government undertook to reduce income tax rates and to analyse the possibility of implementing a flat-rate tax. In fact, the actual reform goes even beyond these original ambitious objectives. Its ultimate goal is to transform the Slovak tax system into the most competitive one in the entire EU and OECD area.

By a competitive tax system, the government does not merely mean low degree of taxation – far from it. The Slovak tax system should be competitive mainly because of the unusually high degree of its efficiency, transparency and non-distortiveness.

Designed as fiscally neutral, the reform is intended to achieve the following broad objectives:

1. creation of a business and investment friendly environment for both individuals and companies
2. elimination of existing weaknesses and distortionary effects of the tax law
3. achievement of a high degree of tax fairness by taxing all types and amounts of income equally

These goals should be achieved by a careful implementation of several simple **principles on which the tax reform is based:**

1. shifting of the tax burden from direct toward indirect taxes, from taxing of production towards taxing of consumption
2. introduction of low standard tax rates and elimination of all exceptions, exemptions and special regimes
3. introduction of flat tax rate in personal income tax, replacing the regime with different tax brackets
4. elimination of distortive roles of tax policy as instruments for achieving non-fiscal goals
5. elimination, as much as possible, of double taxation of income

### ***3.1 Implementation of flat tax rate***

In the area of direct income taxation, the tax reform concentrates on the implementation of the flat-rate tax. In accordance with the principle of **taxing all incomes of individuals and corporations equally**, only **one linear percentage rate of 19%** has been applied since January 1, 2004. The new legislation eliminated the 21 different types of taxation of direct income that were in force in Slovakia until January 1, 2004, including five different personal income tax rates (10%, 20%, 28%, 35% and 38%.) This radical change has several major advantages. First, the flat-rate tax still maintains the progressive nature of effective tax rates faced by individuals with different amounts of income. All personal income of up to 1.6 times the poverty line will be exempt from taxation. As a result, the effective tax rate for individuals below this threshold will be null. However, the average tax rate will start increasing once the individual surpasses this threshold. Hence, the introduction of flat tax on direct income will have no negative impact on low-income earners, negligible impact in the medium range of income distribution and a positive impact on people with the highest incomes. Second, the existence of single marginal tax rate for all income above the standard exemption sharply decreases the distortive effect of personal income taxation and limits the economic disincentives associated with it. This should increase labour productivity both in the short and long term, as it encourages higher work effort at any given point in time, as well more investments in human capital.

Effective January 1, 2004, the **corporate income tax rate was reduced to 19%** from the previous rate of 25%. At the same time, the new tax system follows the principle of taxing the investment and capital gains income only once as it is transferred from the corporate to the personal level. Thus,

dividend taxation has been cancelled and investment income will be taxed only once, at the level of corporate profits.

### ***3.2. Radical simplification on the tax law***

The Income Tax Act also radically simplifies the taxation of both individual and corporate income. In order to achieve the highest possible degree of tax transparency and to minimise economic distortions, the new tax law eliminates virtually all exceptions, exemptions and special regimes. In the area of personal income taxation, many exceptions, exemptions, deductions, etc. were established in the past with various non-fiscal goals in mind, for instance in the area of social policy. However, these measures usually generate significant negative side-effects, such as economic inefficiencies and distortions. The tax reform was coordinated with the social insurance reform, pension reform and healthcare system reform. Virtually all tax deductions and exemptions that were originally intended to achieve non-fiscal policy goals were replaced by targeted measures in the relevant policy areas. For instance, the child allowance was cancelled and a new form of targeted social compensations and entitlements was introduced, which should ensure a fairer distribution of income particularly benefiting low-income families with children. Exceptions and exemptions, including tax holidays, tax brakes, individual tax bases, and special tax rates were eliminated from the corporate tax law as well. Lump-sum taxes for entrepreneurs were cancelled and a regime of deductible lump-sum expenditures was introduced. The simplification of the tax law dramatically improves its transparency and business-friendliness. It eliminates one of the main business barriers identified in Slovakia by business surveys – the excessive complexity and frequent changes in the tax law. Thus, the implementation of the tax reform should positively affect the business environment in the medium-term and long-term and should serve as a major stimulus for further inflow of foreign direct investment. Moreover, the government expects that the low corporate tax rates and high transparency of corporate and investment tax laws should sharply reduce the scope for tax evasion and tax avoidance. As a result, tax collection should improve in medium and long-term in spite of decreased nominal tax rates.

In Income Tax Act (valid in 2003) **21** different income tax rates and 443 types of income were presented. Each type of income had to be assigned to particular tax rate. This was one of the reasons why was the Income Tax Act

so complicated. In case of flat tax rate there is only one tax rate introduced and any complications are avoided.

In Income Tax Act valid in 2003, for example, these rates could be recognised: 1 % - rent from financial lease, 2 % - lump-sum income tax from income up to 500.000, 2,25 % - lump-sum income tax from income up to 1.000.000, 2,5 % - lump-sum income tax from income up to 1.500.000, 2,75 % - lump-sum income tax from income up to 2.000.000, 10 % - social fund income, 15 % - income from shares, revenues from participations in limited liability company.

### *3.3 Unification of VAT rates*

The immediate result of the introduction of relatively low flat-rate direct tax would be a lower absolute amount of collected direct taxes. The lost revenue is therefore compensated by increased indirect tax revenues generated by higher indirect tax rates introduced as a part of the reform. Prior to the reform, Slovakia had a standard value added tax (VAT) rate of 20% and a reduced rate of 14%. As a part of the reform, the reduced VAT was cancelled entirely and a **unified 19% rate was introduced for all goods and services** as of January 1, 2004. In addition to generating increased tax revenues, the unification of VAT rates will also eliminate important economic distortions and inefficiencies associated with taxing of the consumption of various goods differently. The existence of reduced VAT rates was usually being justified by non-fiscal arguments. Reduced VAT rates were supposed to lead towards the achievement of non-fiscal policy goals. They were expected to generate lower prices, leading to better access of low income groups to basic food and other selected goods, or to increased consumption of goods deemed to be socially desirable. However, there is plentiful evidence casting serious doubt on whether reduced VAT rates truly support the fulfilment of such objectives in spite of the inefficiencies which they introduce. As a result, the Slovak government decided to replace these inefficient fiscal policy instruments with targeted instruments directly in the relevant policy areas, such as social policy and health care.

The tax reform also includes amendments to acts on excise duty on mineral oils, tobacco and tobacco products, and beer, which came into effect on August 1, 2003.

The amendments increased excise duty rates on these types of products. The increased excise taxes on tobacco products harmonised the Slovak tax law with EU regulations earlier than was expected in Slovakia's accession

treaty with the European Union. A new act on excise taxes on spirits also introduced stricter conditions for spirit producers and tax warehouses, which should prevent tax evasion and increase tax collection.

### ***3.4 Elimination of other forms of taxation***

**Real estate transfer tax, donation tax and inheritance tax were also cancelled** as a part of the tax reform. Donation tax and inheritance tax was eliminated as of January 1, 2004. With the elimination of the donation tax, donations are no longer recognised as tax-deductible expenditures. The real estate transfer tax was eliminated as of January 1, 2005.

The tax reform was followed by fiscal decentralisation, which includes significant changes in the structure of local taxes concerning real estate tax, road tax and local fees. In principle, the fiscal decentralisation significantly strengthens the fiscal competences of municipalities in the field of local taxes. The successful realisation of the tax and customs administration reform closely depends on a smooth adjustment of the Slovak tax system to the principals of the tax system in the European Union. Some of the most important activities that are currently being realised include the e-DP project (input of tax declarations via the internet) and e-TAX project (Electronic taxation and electronic communication with tax subjects).

### ***3.5 Fiscal impacts of the reform***

The government paid serious attention to ensuring that the tax reform will not have a negative impact on its fiscal position. In order **to ensure a fiscally neutral outcome** in the first year after the reform, the government produced and commissioned five independent estimates of its fiscal impact. A highly precise estimation of these effects was difficult to make because of complications with estimating precise tax elasticity, due to the lack of detailed data on the structure and development of tax revenues of households. In order to mitigate the negative effects associated with this uncertainty, the government based the reform on the most conservative of these estimates, which was also more conservative than one of the International Monetary Fund. The development of tax revenues in 2004 confirmed that these estimates were correct. The collected tax revenues correspond to the expectations and direct taxes even slightly surpass the expectations.

The responses from companies and economists from Slovakia and abroad confirm that the fundamental tax reform concept created in the Slovak Republic is one of the most competitive tax systems in the entire EU and

OECD area. The contribution of individual types of taxes to GDP in 2002 and the estimated development in 2006 are specified in the table below.

% GDP	2002	2006
Income tax	6,9	5,0
Personal income tax	3,4	2,4
Corporate income tax	2,7	2,2
Withholding income tax	0,9	0,4
Value added tax	7,6	8,4
Excise taxes	3,1	3,2
Donation, inheritance, real estate transfer tax	0,2	0,0
Local taxes	0,6	0,7
Road tax	0,2	0,0
Other tax revenues	0,4	0,1
Total tax revenues	19,0	17,3

*www.finance.gov.sk*

The government plans to decrease tax burden in 2006 in comparison to 2002 by 1,7 % on condition of high rate of GDP growth. Contribution of personal and corporate income taxes to GDP should be smaller and contribution of value added tax should, on the other hand, be higher.

#### **4. Assessment of tax reform effects**

For the purpose of assessment of first tax reform effects we have chosen the basic indicators of taxation system effectiveness, i.e. direct and indirect taxes.

Comparison of individual indicators in the year 2004 and 2003 can be seen in the table below:

Indicator in bill. SKK	2004	2003	Difference
1. VAT in bill. SKK	99,6	83,4	+ 18,8
2. Excise taxes ( on mineral oils, alcohol, tobacco )	43,4	38,0	+ 5,4
3. Personal and corporate income tax	55,8	61,0	- 5,2

Source: www.finance.gov.sk

There is a **basic economical assessment** of tax reform:

1. The expectations of government were met – the tax burden was directed from direct taxes to indirect taxes. Personal and corporate income tax revenues fell by 5,2 bill. SKK and value added tax and excise taxes rose by 24,2 bill. SKK in 2004 in comparison with 2003.
2. Tax reform in the first year of its introduction did not prove to be neutral as government supposed, as the excess taxation represent the amount of 19 bill. SKK.
3. Evidently, the positive effects of the reform on unemployment have not been observed yet. The unemployment fell by 2,5 % in 2004 in comparison to preceding year, the average fall being 1,83% for each of three preceding years.
4. The government presents the tax reform as a stimulus for direct foreign investments which reached the amount of 43 bill. SKK in 2004 (the government expects inflow of investments in the amount of 280,5 bill. SKK in the period of 2005 – 2008), in this context the professionals present the perspective of the investors not being interested in the amount of tax rate in the first place, but the qualification and price of labour in Slovakia.

## **5. Anticipated macro-economic trends in Slovak Republic in connection with entering the Eurocurrency market according to National Bank of Slovakia**

To define the date when Slovakia is going to enter the Eurocurrency market (1.1.2009) was a **big challenge for the central bank as well as for**

**the whole society.** Monetary policy of National Bank of Slovakia (NBS) should ensure meeting the inflation target and Maastricht exchange rate criterion. That's why NBS clearly defined its monetary policy in medium long term, not in the form of expectations but in a form of binding goals. NBS defines its monetary policy as inflation targeting in terms of ERM II. Monetary Programme of NBS was elaborated in cooperation with Ministry of Finance and Slovak government.

Monetary Programme of NBS for the period till 2008 is **based on real macro-economic results of the Slovak Republic in 2004.** At the same time it reflects the most up-to-dated information and predictions regarding the trends of basic external factors, e.g. oil prices, exchange rate changes or expected economical growth in other countries of European Union.

Estimated trend of selected macro-economic indicators in the period of 2004 – 2008 is presented in the table below:

Indicator	2004	2005	2006	2007	2008
1. HICP*	6,2 – 6,5	3,5 +/-0,5	below 2,5	below 2,5	below 2,0
2. GDP in constant prices	5,3 – 5,7	4,5 – 5,3	4,7 – 5,7	6,0 – 7,2	4,0 – 5,2
3. Real wages	1,9	2,3 – 3,4	2,4 – 3,1	2,8 – 3,6	2,8 – 3,6
4. Share of public sector on GDP (including expenses on pension reform)	- 4,0	- 3,8	- 3,9	- 3,0	- 2,1

Source: [www.nbs.sk](http://www.nbs.sk)

Note: HICP - Harmonised index of consumer prices

Macro-economic trend in Slovakia **in 2004** as a whole can be characterised by high GDP growth, higher deficit of current account of balance of payments, while the inflation was affected especially by its cost basis.

**In 2005 and later on strong deflationary development of Slovak Crown** is expected. The decrease of consumer prices in 2005 in comparison with 2004 should be based on less significant impact of increase of regulated prices and on the change of monetary policy of NBS that would concentrate primarily on identification and targeting of demand inflation.

Inflation development in 2005 – 2008 will be influenced by **administrative interventions** to economy to some extent, such as increase of tax on tobacco and tobacco products and introduction of tax on energy. These taxes should be increased in 2007 and 2008 and the estimated impact on inflation is 0,8% in 2007 and 1,1% in 2008.

Monetary Programme of NBS for the period till 2008 is based on **optimistic assumptions** of both public finance consolidation and economical growth.

**Share of public sector on GDP** (including the expenses on pension reform) is determined by individual phases of electoral cycle to the certain extent. In our opinion presented values of this indicator do not sufficiently take this correlation into consideration. We suppose that the indicator will worsen its position in 2006, when the elections will be held. Political influences after the elections in 2006 in Slovakia and their impact on indicator can not be predicted with high probability.

Although the acceptability of implemented reforms by inhabitants of Slovak republic is probably the highest possible, it would be good for Slovakia to ensure their positive fiscal results also after 2006, based on lower government consumption and higher activity of small and medium enterprises.

The development of political situation in European Union might be problematic as well, especially where European constitution, European monetary integration or meeting the Maastricht criteria by Germany or France is concerned.

NBS expects **high rate of GDP growth** in 2005 – 2008. Average rate of GDP growth in constant prices represents 5,32 %, while in 2007 it is expected to be 6,6%.

Presented GDP growth represents **ambitious estimation** that is based on assumption that the fundamental accelerating factor of economic growth in Slovak Republic in medium - long term will be the direct foreign investments to automobile industry. It is probable that due to increase of investment demand, import of production technologies will rise at first. That will lead to higher deficit of net export with negative influence on GDP growth. In the following period (probably in second half of 2006) NBS expects, in connection with the start of production in automobile companies PSA and

Kia – Hyundai, a significant increase of export of goods and services and the change of deficit of net export to surplus of balance of goods and services, with positive impact on economy growth.

This assumption is not free of the **risk**, which is also included in Monetary Programme of NBS and in prediction of macro-economical indicators. The risk arises from the fact that automobile industry build out of foreign investments is at present non-existing part of Slovak economy; and therefore the foreign investments as a accelerating factor of economical growth are very complicated to quantify, especially in connection with always changing economical environment. The assumption also reflects branch asymmetry of economical environment in Slovakia and too strong dependence on one industrial branch.

Convergence Programme defines **risks of GDP development** as follows:

1. Dynamics of final consumption of households will depend on particular **impact of implemented tax, pension and health care system reform** on development of gross available income of households.
2. Private consumption trend will be determined by actual real wages trend. Increase of expenses on consumption depends not only on real wages but also on preferences of consumer. NBS assumes that propensity to consume will be encouraged by wide offer of credit products of commercial banks as well as by positive trend of client interest rates.
3. The development of **final consumption of public administration** will depend on the level of meeting the planned deficit of public finance and on other factors.
4. Real level of investment demand will depend on constantly changing macro and micro-economic conditions in Slovakia, on economic development in neighbour countries and on expectations of domestic and foreign companies. The expectations of the companies will have an influence on willingness or unwillingness to realise investments in Slovak Republic.

The development of **labour productivity** should also be determined by inflow of direct foreign investments to automobile industry in 2006 and 2007. Inflow of direct foreign investments should create a solid base for non-inflationary growth of nominal and real wages. NBS assumes 5 to 6% growth of nominal wages in national economy that would be sustainable and acceptable. Assumed average growth of real wages would then be 3%.

**The risks for inflation trend in the period of 2005 to 2008 are the following:**

1. **Increase of prices of mineral resources.** The price of oil represents the main risk factor for consumer prices development. NBS assumes that price of oil will reach in average 40,8 USD for barrel in 2005; 36,8 USD for barrel in 2006; 34,6 USD for barrel in 2007 and 34,2 USD for barrel in 2008. More rapid growth of supply in comparison with demand is expected because of the fact that member states of OECD do not respect the quotas and restrictions. Considerable increase of oil production in non-member states and decrease of demand in China are also expected. Other risk factors affecting the price of oil are: conflict in Near East and Middle East, political instability in Russia, Venezuela and Nigeria, slow increase of capacities for oil producing in Iraq and continuous economical expansion in China.
2. **Development of exchange rate of SKK against EUR and USD.** The projection of inflation prepared by NBS is based on assumption of appreciation of balanced exchange rate in accordance with economy development. More significant depreciation of nominal exchange rate of SKK could endanger meeting the inflation target as it causes the increase of prices in trading sector.
3. **Increase of food prices.** Potential increase of food prices represents another risk. Food prices trend will be influenced by acceptance of principles of Common agricultural policy, by fertility of soil in following years and by impacts of implemented reform of Common agricultural policy. NBS assumes that acceptance of Common agricultural policy will have an impact on inflation in the amount of 0,3% in 2005.
4. **Regulated prices trend.** Certain amount of risk is connected with increase of regulated prices of energy and other commodities (for example in 2005 deregulation of prices of heat, transport, postage services and rent is expected). It is relatively hard to estimate possible secondarily effects in non-regulated part of the consumption basket. According to the data provided by NBS, deregulation of prices will have 1,6 % impact on inflation in 2005 (while the greatest impact is expected in connection with deregulation of gas prices – 0,5%). The impact of deregulated prices will gradually fall - to 0,4% in 2008.
5. **Changes in the area of excise taxes.** The impact of expected changes of excise tax rates on tobacco and tobacco products on inflation will be significant, approx. 0,8% in 2007 and 1,1% in 2008. NBS admits

that this represents a risk in regards to timing and extent of changes in the area of excise taxes, which are uncertain. Other risks can be seen in unexpected decisions of European Commission in the next period.

6. **Higher fiscal deficit in comparison with projected deficit.** Risk of higher fiscal deficit is defined in previous sections (the year of elections 2006, optimistic assumption of the economy growth, etc.)

## 6. Conclusion

Assessment of the tax reform in Slovak Republic represents complicated issue from both professional and political point of view. Indisputably, there are positive effects, such as simplification of tax system, higher degree of transparency and creation of business-friendly environment. However, we can not notice also negative impacts. The resources of the society are being redistributed to higher income groups.

Due to the insufficient competitiveness for example in the branch of distribution of petrol or banking, not much earning Slovak people are confronted with high level of prices of petrol, banking services or health care products.

Current government is being criticised by its political competitors for generous support of foreign investors (for example a state support in the amount of 5 bill. SKK has been approved for Peugeot Citroen Automobiles Slovakia or 5,4 bill. SKK for Kia), as there is a minimum state support of Slovak small and medium enterprises.

When presenting the ideas about future trends in Slovakia we used the information mentioned in Monetary Programme of NBS (central bank of the state, respected institution in Slovakia). Monetary Programme of NBS till 2008 is a very ambitious document, contents and orientation of which is influenced by the entering to European Union and later obligation to enter to European Economical and Monetary Union (Eurocurrency market).

The greatest challenge for NBS and a chance as well is to **obtain support of public** for meeting the targets of Monetary Programme till 2008. Formation of inflationary expectations in national economy represents a strong monetary instrument that has to be taken into consideration when making decisions on investments, savings and wages. Optimistic inflationary

expectations of public in combination with other monetary and fiscal measures of government and NBS may create favourable macro-economic environment for dynamic growth of Slovak economy and in the end increase standard of living of the inhabitants of the Slovak Republic.

In the period of nominal and real convergence of Slovak Republic with Eurocurrency market also several risks may occur. These have to be eliminated using reasonable and balanced monetary and fiscal policy by responsible institutions in the Slovak Republic.

## **Abstract**

*After 1989, the Romanian taxation system has been subjected to major transformations. It has adapted to the requirements of the market economy by taking over the main taxes levied in the developed countries. In the present, Romanian taxation system meets to a great extent the requirements imposed by a competitive economy. However, there are still certain problems, both general problems, regarding the entire fiscal system and the way it functions, and specific problems regarding each and every tax. The present paper tackles about the general problems of the fiscal system as well as problems regarding the direct taxes, profit taxes, income taxes, problems connected with the main indirect taxes, value added taxes and excise duties. As far as the fiscal reform is concerned, the present paper analyses mainly the fiscal simplification implemented by the present government, as a means to reduce the taxation in the business environment, to encourage the private initiative and to achieve the economic growth by expanding the scope of the taxes as a result of expanding the official economic activities.*

**Keywords:** *fiscal reform, fiscal policy, taxation system*

## **1. Introduction**

After 1989, Romanian taxation system has been subjected to major transformations, adapting to the market economy by taking the main taxes levied in the developed countries. In the present, Romanian fiscal system meets to a great extent the requirements improved by a competitive economy. However, there are still certain problems, both general problems, regarding the entire fiscal system and every important tax. First, we will tackle about the general problems of the fiscal system.

## **2. General Problems of Romanian Taxation System**

One first major problem which arises from the analysis of the evolution of the fiscal system after 1989 is the instability of the legal framework. In time, each of the main taxes has been subjected to repeated, more or less important changes. In fact, in many cases, the former settlements have been replaced by new ones, because of the repeated changes to which they have been subjected and which have made difficult the keeping under observation of the tax evolution and its levying.

One reason why the main taxes have been subjected to changes is the necessity to adapt them to the E.U. requirements. Another one is the necessity to have in view the practical experience of levying different taxes as well as their adaptation to economic circumstances. However, irrespective of the reasons, much instability of the legal framework in the fiscal field can not be justified, because it makes almost impossible long-term business plans, fails to attract the foreign investors and reduces the internal and external investments. Apart from this, the legal framework makes more difficult both for the tax payer and control authorities (because of the number and rapidity of changes) to know the content of the respective law and the way it is put into practice.

Another problem is the way in which the fiscal legislation is put into practice and the embezzlements. In Romania, only half of the taxes and contributions owed by the companies according to the data in the balance sheets are paid. In this case, there is a matter of nonobservance the fiscal legislation. The Romanian authorities have tolerated it and, some cases even supported it. There are various reasons why this happened but they all have in common the bad "habit" of the state-owned enterprises to pay their debits to the state only partially. The enterprises pay less than half of their debits because they are inefficient and because of the influence of the trade unions in the large state-owned companies which has been a real problem for all the

governments after 1989. Lately, this negative “habit” of unpaying the debits has extended to private firms.

Another reason which has made the applying of fiscal legislation difficult was the fact that Romanian authorities have derated or postponed the payment of debits for a large number of enterprises. In many cases, the tolerance for not paying the debits and derating or postponing the payment of debits has been influenced by the business and political circles, the politicians having in view to obtain extra-votes to find financing sources for their party, especially in election campaigns, and even to have some personal advantages. All these generate an uneven distribution taxation which has negative effects for the economic competition and makes private firms to turn their attention to subterranean economy.

A negative effect when putting the fiscal legislation into practice was generated by the fact that, usually, the laws and governmental order in the fiscal field are not very clear and can be subjected to interpretations and, sometimes the Ministry of Finances gives instructions which contradict or distort the settlements which they are supposed to interpret. In some cases, these instructions have a restrict circulation which makes them even more difficult to be understood by the tax payers and control authorities.

Another important problem Romanian taxation system has to face is the existence of a powerful subterranean economy. Taking into account various evaluations, the Romanian subterranean economy is 30-40% of the gross domestic product or even more which is a lot and has major fiscal consequences. Apart from all these controversies we must keep in mind the fact that this phenomenon is wide spread. It has been caused by the high level of taxation (especially that regarding the labour force) and its uneven distribution the legislative instability and the incorrect putting into practice of the fiscal legislation the corruption of the civil servants; the regress of the economic environment, etc.

Although there are voices that try to find the positive part of tax evasion (one of the arguments being that using this method one can risk capitals which, then, can be invested this contributing to economic growth) we must enlighten the negative effects it can have in economy. If the firms working in the field of the subterranean economy do not pay the taxes, the fiscal revenue (of the state) is reduced which makes necessary an increase of fiscality which, in its turn, will increase the numbers of the firms working in the field of the subterranean economy. This will diminish the fiscal revenue and generate a vicious circle. If the public expenses in Romania have significantly been reduced and many of them pay the public debit, a new diminishing of public expenses due to diminishing the fiscal revenue, will

jeopardize the very functioning of public institutions and the entire society. The most affected would be the socio-cultural expenses (education, health, culture) and those regarding the maintenance and the development of the infrastructure, which will affect the long-term economic and social development irremediably.

Therefore, urgent measures must be taken to reduce this. There have been voices which insisted to increase of the similar to those for crime. But we must have in view the fact that only enforcing coercive measures can not make this disappear. Other measures are needed, such as: reducing taxation and a more even distribution of it; drawing up a stable and clear legislative framework and its coherent putting into practice; the efficient use of some fiscal tools capable to discover the incomes obtained in subterranean economy and levy taxes in them.

A measure which could have important effects on fighting fiscal evasion and a better putting into practice of the legislation in the fiscal field would be the use of computerized data bases of the entire process of fiscal administration. At the same time, in order to fight the fiscal evasion a special attention must be paid to enhancing the fiscal control. This can be achieved by proper human and financial resources and new priorities for control. In this sense, we must have in view the professional training of the tax inspectors as well as applying modern criteria to select those tax payers that are to be controlled.

Without a fighting fiscal evasion which limits the range of the state's actions by embezzling funds it is impossible to rapidly achieve the goals for the accession in the E.U., as we have planned.

Other problems regarding the fiscal system as a whole are those connected to the amount of the taxes and the ratio between direct and indirect taxes.

As regards the amount of the taxes, as it was shown above, the Romanian fiscal system meets the requirements imposed by the European standards, especially those of the Eastern Europe, except the taxation of the labour force, case in which the amount is increased, due to the large social contributions. Being aware of this situation, the Romanian authorities took measures reducing the level of social funds from 60% to 57% in 2002. This continued in 2003, when level of social funds diminished with 5 percentages down to 52%. In 2004, it diminished down to 49.5%. The present government considers that since 2006 the contribution to social public funds will go on diminished so that in 2008 they will come to 39.5%. The contribution will significantly reduce in the case of the employer as compared to that of the employee.

As far as the ratio between direct and indirect taxes is concerned, the present government speculates that the indirect taxes will be the main source for the budget of the state. This makes the fiscal balance created by the Romanian fiscal system to be fragile. In order to solve this problem, the value of direct taxes when forms I the fiscal revenue must increase. This can be achieved only simultaneously with reducing the level of social contributions and increasing the tax base both by including of the economic growth in it and reducing the tax evasion.

It is normal that the organization / structure of the public financial resources vary from one country to another. But, if in many developed countries most of the public financial resources are determined / influenced by direct taxes, in the case of developing countries. Romania is one of them, they are determined by indirect ones, especially consumption / expenditure taxes (value-added taxes, excise duties).

Only by solving all the above-mentioned problems, Romania may increase the level of the fiscal returns without increasing the value of the taxes, thus reducing the discrepancy between it and other countries in Eastern Europe which at similar taxation quotas get several extra percentages of fiscal revenues in gross domestic product.

### **3. Problems Regarding Direct Taxes**

The system of levying taxes on legal entities incomes has undergone significant changes since the 1<sup>st</sup> of January 2000, when the taxation quota of the profit tax was reduced from 38% to 25%, as well as since the 1<sup>st</sup> of January 2004, when the present government decided to levy only one income tax. The taxation quota of 16% is wanted to be competitive as compared to the other states in order to attract direct foreign investments. Resorting to this measure, they fight against the fiscal evasion and encourage the economic activity.

In the present, the rate of the profit tax is only 16%, one of the lowest in Europe: in Hungary, it is 18%, in Croatia 20%, in Czech Republic 31%, Poland 27%, and Germany 39.58% and in Italy 38.25%

Starting from the 1<sup>st</sup> of July 2001, in the case of small companies, the profit tax has been replaced by a tax levied on their incomes, calculated with a quota of 1.5% from the incomes, irrespective of their source. The quota has increased with 3% starting with the 1<sup>st</sup> of January 2005. At the beginning all small companies, had to calculate the tax according to this quota. Later on, it was allowed to choose between the tax levied on small companies and the

profit tax which was not a very good idea, because of the possible fiscal evasion.

As far as the process of levying taxes on natural persons, incomes is concerned, an important step forward in the modernization of Romanian fiscal system is the introducing of the global income tax. In general levying this tax has many advantages as compared to levying taxes on incomes, each of them taken separately chancy these, mention can be made of:

- it contributes to fiscal balance; both the exact incomes of each individual and the personal situation of the tax payer are taken into account (which was not possible in the later above-mentioned case);
- it is more efficient by including in the tax base the income of a tax payer;
- it is an excellent way of fighting against fiscal evasion and criminal activation.

Up to the 1<sup>st</sup> of January 2005, for levying taxes on physical persons there were 5 taxation quotas which ranged between 18 and 40%. After the above-mentioned moment, a unique quota of 16% was introduced. This will has as main effect the significant reduction of the fiscal administration costs. The measure of reducing the taxation quota is similar to what has happened lately in the countries of the Central and Eastern Europe. Then, Russia has applied a unique 13% taxation quota of incomes Estonia and Latvia, also apply unique taxation quotas of 26% (the former) and 25% (the later). At the mine time, Croatia has three levels of taxation of 15.25% and 35%, Bulgaria – 4 quotas of 18, 24 28 and 29% and Czech – 5 of 15, 20, 25 and 32% in the present quota diminishing from 40% in 1982 to 32% in the present.

Another problem that arises when cones to levying the income tax in Romania is the fact no deductible expenses were provided from the taxable income. Granting these fiscal deductible expenses is a frequent in the developed countries and has a double function: on the one hand to bring to other to support certain economic branches by encouraging the consumption of the goods produced by them. The measure of granting much facility in Romania, too, would have positive effects on the receipts / returns resulting from this tax, as well as on the development of economy.

The most important problem of levying of the declared incomes is controlled. Normally, by controller the tax payers regularly and correlating the declared income mitt the level of the expenses in the same period, the undeclared incomes can be revealed if the value of the expenses exceeds that the incomes. In Romania, this control can not be made because the tax payers will say that the expenses that can not be justified by the level of the incomes are made due to the fortune acquired before the levying of this tax.

#### **4. The Problems Regarding Indirect Taxes**

The main indirect tax, the value added tax was introduced in Romania by law in July 1992 from the 1<sup>st</sup> of January 1993; it was enforced on the 1<sup>st</sup> of July 1993. Initially, Romania introduced a system with 2 quotas: a normal one of 18% and the zero quotas. A diminished quota, of 9 %, was added to these two ones, and it was applied to food, medication and medical equipment etc. In time the settlements regarding the value added tax have been subjected to many changes, the most important ones stipulating the diminishing of the number of products and services exempted by value added tax (VAT), the number and the value of the quotas, changed on the 1<sup>st</sup> of February 1998, the normal quota becoming 22% and the reduced one 11%. Starting from the 1<sup>st</sup> of January 2000, the normal quota has become 19% and the reduced one has been given up.

Latterly, value added tax has undergone significant changes having in view the harmonization with the provisions of the 6<sup>th</sup> Directive of the E.U. Comity Council. In this sense mention must be made of the fact that Romania not only has completed the harmonization measures which had 31<sup>st</sup> of December 2002 as deadline but also has completed in advance some of the commitments it has understood. This process of bringing Romania to a balance with various European provisions will go on. About 25 tax brackets that are not in accordance with the European standards in the respective field will have been eliminated up to 2006. At the same time, some exemptions stipulated in 6<sup>th</sup> Directive will be introduced in the Romania legislation, together with some special treatments for small entrepreneurs, agricultural producers and tourism companies.

As a result of the negotiations with the E.U. to temporarily close the 10<sup>th</sup> chapter "Taxation", Romania was all wed to keep the exemption VAT for the passengers transport for all kinds of transport: land, water, railway all these are to remain after Romania's accessions in the E.U. At the same time, E.U. also accepted the appliance of a taxation level of 3,500 € for VAT payer, in the condition in which this is of 5,000 € in the E.U. In the present Romania applies a taxation level of 5,000 € and will continue to do so up to its accession in the E.U. when it will go down to 3,500 €.

E.U. has also accepted the appliance of a reduced VAT quota (of minimum 5%) for the basic food, medication and flat building, but we must mention the fact that I.M.F. recommended the Romanian authorities to reject the introducing of a reduced VAT quota. The argument brought was the fact that this measure diminished significantly the efficiency of fiscal

administration, whose goal should be the VAT reimbursable in much many cases.

At the same time, it was enlightened the fact that the transfers for the homesteads with small incomes are superior to the possible social effects of a reduced VAT quota.

In the present in Romania there is a 19% standard quota and a 9% reduce one. Although the 2005-2008 governing programmer stipulates that, for a certain period of time, the present for VAT will be kept the positive effects of the tax relief on income and profit allowing a future level of 10% at the political level it is discussed the opportunity of increasing the 22% VAT normal quota and eliminating the reduced quota.

The main concern of the authorities is to bring the excise duties to the minimum E.U. quotas. As a result, the value of the excise duties has increased especially in the case of alcoholic drinks and cigarettes and this will go on in the future, too. Mention must be made of the fact that the European Commission has come to an agreement regarding a gradual and not a linear increase of the value of the excise duties. The gradual calendar has been adopted to increase the future incomes of the population so that the future price increase may be bearable. The same thing will happen mitt the excise duties for fuels.

## **5. Problems of Fiscal Policy**

Fiscal policy is a part of the state's economic policy which comprises the totality of the settlements / regulation regarding the setting and levying the taxes, having as main goal the encouragement of the economic growth and diminishing the oscillations of economic cycles.

The role of the fiscal policy is to protect or encourage certain economic branches; in this way, the fiscal intervention has various goals such as:

- encouraging the companies to make investments in certain fields;
- increasing the quality and the competitiveness of products;
- encouraging the export and small producers;
- protecting the environment etc.

When making decisions of fiscal policy, public authorities must satisfy some conditions being confronted with a series of restrictions and claims which can have certain consequences on using tools of fiscal policy in connection with the stage of development of the respective economy, the economic relations with other states; the degree of international integration

etc. Then the enforcing of fiscal policy measures must face certain restrictions such as:

- dimensional restrictions (the fiscal policy is in accordance with the financial potential of the country);
- the development of financial market, of credit market as well as the extent the state's intervention in economy;
- structural restrictions, calculated according to the taxation base and the development of various components of public economy;
- institutional restriction, which correlate the fiscal policy with the way in which the central and territorial institutions with fiscal functions are organized as well as with the existence of private companies;
- informative restrictions, which have in view the rapidity (in due time) of necessary information referring to the tax base and to the correlation with the incomes obtained from the taxes at a certain moment;
- instrumental restrictions which are closely connected to the previous restrictions and refer to the existing fiscal structures and mechanisms which generate fiscal instruments / tools.

In this initial stage, the fiscal reform in Romania had in view a system of taxes capable to assure adequate budgetary incomes, equitably and not really influence the prices. But unfortunately, the fiscal policy of Romania authorities hasn't taken into account the socio-economic evolutions. Imposing austerity budgets and increasing the value of the taxes, levying new taxes have all hindered for a long time the development and gradually affected the purchasing / buying power and the consumption.

The main goal of Romania's present government in the field of the fiscal policy is to assure stimulating role of taxes, having in view the economic growth and development, the fiscal stability and the development of the middle classes. The fiscal policy is wanted to function rather in favor of the tax producers / creators rather than of the tax collectors and to rely on a real partnership between the state and the tax payers.

The efficiency of the taxation system is seen both in the way in which the taxes are collected for the state's budget's and return in the form of the quality of the public services, and in the way in which they assure the maintaining and extension of tax base. The reform of fiscal legislation has in view the continuous reduction of immunities and exception regarding the taxes, having in view the improvement of the transparency of the business environment, the improvement of competition and the extending of the tax base.

The keystone of the present government's fiscal policy in the tax relief as a means to induce a relaxation in the business environment, to

stimulate the private initiative and to make legal the subterranean economy. At the same time, the tax relief will contribute to the economic growth by extending the tax base as a result of the extension of the range of official economic activities (both at the entrepreneurial level and at the level of the jobs offered). The tax relief will make the business environment in Romania more flexible and predictable. The government promotes the tax relief mainly because an increased value of taxes would have negative effects on the unreal economy: the evolution and the reorganization of the internal offer are no longer flexible; there are no records of a part of economic activity.

For the 2004 fiscal year the tax quotas levied on incomes were between 18 and 40% and that levied on the taxable profit was 25%. According to the Order for the modifying and completing the Law No. 571/2003 concerning the Fiscal Code, promulgated by Adrian Nastase government which was to come into force on the 1<sup>st</sup> of January 2005, the income tax was levied with distinct annual quotas between 14-38% and the tax quota levied on the taxable profit was 19%.

According to the Emergency Order No. 138/30<sup>th</sup> December 2004 for modifying and completing the Law No. 571/2003 concerning the Fiscal Code promulgated by Tăriceanu government, the tax quota for determining the tax levied on the incomes obtained from independent activities, wages, demising the right of using certain goods, pensions, agricultural activities, prizes and other sources, is of 16% and it is levied on the taxable income corresponding to each source and category, and the profit tax quota levied on the taxable profit is also of 16%. In this way for the unique taxable quota it is necessary that the taxation of incomes should be equal with flat of the profits.

The modification of the fiscal policy was Tăriceanu governments, first measure and one of the priorities of the governing programmer. The fiscal reform was initially presented as tax relief, having in view the support of private entrepreneurs, the encouragement of foreign investments and of free initiative, which should contribute to the consolidation and development of market economy in Romania, which is one of the main requirements that Romania has to fulfill in the its process of accession to the E.U.

Some critics have considered the unique taxable quota a rash / hasty measure, not justified by an impact analysis, one which theaters the budgetary balance. It should be accompanied by the increase of the value of other taxes, by levying menu taxes, the increase of the utilities prices and reducing the budgetary expenses.

To fill the budgetary emptiness's generated by the tax relief, the Finance Ministry, as a result of its negotiations with the I.M.F., had to suggest unpopular fiscal measures:

- doubling the tax levied on the turnover of small companies;
- the social insurance contributions are no longer reduced;
- postponing the increase of the budgetary person's salaries;
- postponing one of the stages of recalculating the pensions;
- doubling the tax levied on the dividends from natural persons;
- the 10 times increase of the taxation of the bank interests and of the earnings obtained the capital market;
- the more drastic taxation of the earning from the real estate transactions and rents, etc.

The unique tax is the most frequent topic of discussion in the states that have recently been made E.U. members and requests for simplifying and reducing the value of taxes have become common all over the Europe. In such a complex system, instead of a complex set of taxation rules the state declares a limit and if it is surpassed them everybody pays a fixed tax their own incomes. Usually limit has a low value in order to encourage the citizens to pay their taxes, instead of trying to avoid paying them. Such a system is instead of the idea that taxes are levied on all incomes only once.

The unique tax used to be a rule in all industrialized states in the former half of the XIX<sup>th</sup> century. But, finally, the capitalist states were the ones which adopted such a progressive or gradual system of taxes. Since then, the idea of a unique tax has been "brought to life" several times, many countries adopting one variant or another of the unique tax. The modern "renaissance" of the unique tax levied on income was initiated by Estonia in 1991, followed by Latvia (1994), Lithuania (1994), Russia (2001), Serbia (2003) and Romania (2005). It seems that Hungary and Poland take into account the introduction of one version of the unique tax in the near future. Here are the advantages and the disadvantages of the unique taxation quota.

#### Arguments in Favor of the Unique Taxation Quota and Its Positive Effects

- the unique quota does not run counter of communitary acquis. Chapter 10 "Taxation" in communitary acquis has in view the indirect taxes (VAT, excise duties) and not the direct ones (the tax levied on income is not a part of the category). It is not necessary a harmonization of the taxes levied in those states that are members of the E.U.
- the unique quota encourages work and exposes illegal work. It encourages a second job.
- the unique quota eliminates the complicated and expensive procedure of the yearly forms of return for certain categories of tax payers.
- it is characterized by simplicity, transparency and efficiency in the raising / collecting process.

- it is a system suitable for those states with reduced administrative and fiscal discipline.

- it reduces the subterranean economy. It exposes a part of the “grey” and “black” economy.

- it simplifies the producers of calculating, collecting and controlling the taxes.

- the exceptions, the deductions and the special regimes are easier exploited by the wealthy and informed persons than by the poor.

- the equality between the rates of the taxes levied on income and profit will no longer artificially stimulate a factor of production in detriment of another.

- the social redistribution will be made only by means of the expense policies, not by means of those for collecting the incomes.

- the distinction between personal deductions is a progress, even in the case of levying the unique quota.

- the unique quota coincides with the regional evolution of the fiscal policy. Countries that have already introduced it or are about to introduce it: Estonia, Latvia, Russia, Ukraine, Slovakia, Poland, The Czech Republic, Hungary, and Slovenia.

- the reduced taxes will encourage the Romanian investments and will attract foreign investments, allowing the capitalization of Romanian companies which will become more competitive on the external market.

- the discouraging of speculative transactions and the encouraging of capital investment in productive business that creates jobs.

Arguments Against the Unique Taxation Quota and Its Negative Effects

- the lack of coherence in the case of governmental declarations and measures.

- the lack of consultancy with the associations of employers and trade unions regarding the modification of fiscal policy.

- the lack of stability and predictability of fiscal policy.

- diminishing the local budgets taken from the income tax.

- the entrepreneurs can no longer evaluate the effect of the new taxes introduced in order to diminish the effect of the unique quota on budget.

- fiscal equity and social justice require a distinctive, progressive taxation, one in accordance with contributive capacity given by the value of the respective fortune, income and consumption.

- the modification of the Fiscal Code was made by an emergency decree and not by law, and this modification had to be put into practice 6 months before its effects become visible.

- this fiscal policy decision was taken without consulting the World Bank, I.M.F. and E.U. The developed countries in the E.U. do not do

something like that. At the same time, this decision is not supported by a large part of the political class (the parliamentary opposition) and by the trade unions. The government and the opposition have conflicting fiscal policies. The introduction of the unique quota requires the modification of the state budget.

- the taxation the social divisions and is a real advantage only for 1% of the population.

- it increases the value of the tax levied on the interests on bank deposits and on the earnings from the capital market (capital investments).

- the increase of the price for utilities (electricity, gases etc.).

- doubling the value of the tax levied on the dividends of natural persons.

- reducing to one half the deduction in case of the incomes obtained from rents, the lack of profitableness in the case of the business consisting in hiring out buildings, the temptation to hire out buildings illegally, without paying the respective taxes.

- doubling the tax levied on the turnover in the case of small enterprises.

- it increases the value of the excise duties imposed by the E.U. in the case of petrol, cigarettes, coffee and alcoholic drinks much sooner than it was established.

- postponing one of the stages of recalculating the pensions.

- increasing the value of the tax levied on the earnings from real estate transactions.

- the introduction of the unique quota might affect the process of reducing the inflation in 2005 by increasing the incomes of the population and the consumption. The increase of the product and service demand will generate inflation.

- the members of social assistance are more carefully selected and the social security benefit is reduced.

- the increase of the salaries of those paid by the state is stopped.

In order to be efficient, the tax relief must be accompanied by a strategy which has in view the improvement of the capacity of fiscal administration by:

- separating the fiscal administration from the fiscal policy;

- giving up on those policies having in view the exemption or rescheduling of the debts for the public budgets;

- considering the fiscal evasion an economic-financial offence and its punishment should be done with this fact;

- eliminating the policies of modification the fiscal norms by means of inferior laws;

- an increasing the administrative of those institutions which collect the taxes;
- assessing the fiscal control procedures and establishing strict ethical rules for fiscal control activity as the result of the good expiration between public authorities and businessmen.

## 6. Conclusion

We must keep in mind the fact that only applying the fiscal legislation correctly and coherently we can speak about an economic framework which will be one for all companies this being an advantage for those which are really efficient then contributing to the progress of economy. At the same time, an even distribution of fiscal tasks duties may reduce the level of fiscality which can diminish the subterranean economy and offer better conditions for the development of firms.

In order to change the way in which the fiscal legislation is applied, in practice, one needs political will and a separation clear cut distinction between the public and private interests, which is very difficult to accomplish. It is necessary that the measures which have been taken so far in this sense to be continued firmly, because, otherwise, their putting into practice must be a failure even if we improve the taxation system and adopt the E.U. standards.

The fiscal policy promoted by the present government is expected to have a favorable impact on economy to contribute to economic stability and reorganization and to economic growth.

## **Abstract**

*This paper refers to relations between policy of public finance and projects of public private partnership in the Czech Republic. In 2004 the government set out on a reform of public finances, which is aimed not only at gradually reducing the budgetary deficits but also at improving the quality of public finances. The Czech government has confirmed these objectives in its Programme Declaration. The government's declared expenditure priorities are as follows: research and development, education, transport infrastructure and programmes co-financed from the EU budget. The Czech Government has also adopted a policy introducing public private partnership ("PPP") as a standard tool serving the provision of public services and public infrastructure. The introduction of PPP represents a measure based on the requirement for fiscal moderation and a systematic control over the formation of long-term public sector liabilities. This measure, too, is of a pro-growth nature, stimulating as it is an increase of private investment in the building of public goods and provision of public services.*

**Keywords:** *public finance; project; public private partnership; public service*

## **1. Introduction**

In August 2004 a new Czech government was created and installed in office. The government confirmed in its Programme Declaration that it will follow up on the economic policy of previous governments, focussed in particular on promoting economic growth, reducing the unemployment rate and improving the competitiveness of the Czech economy, and will persist in the reform efforts that had been initiated. An updated medium-term economic strategy is relying on the following two basic pillars: the reduction of public finances deficit and effective promotion of economic growth.

The economic policy is aimed first and foremost at the acceleration of economic growth and at the reduction of unemployment in the nearest period. The government wants to concentrate on improving the legislative and institutional environment for entrepreneurship in the Czech Republic, both for domestic and foreign entities, and on preparation of the labour force to be able to withstand global competition. To ensure long-lasting and sustainable prosperity, this aim has to be incorporated into the final stages of public finance reform, so as to create the conditions for economic convergence with developed countries. Financing of joint programmes of the EU and the CR and promotion of expenditures on research and development and education have been made the budgetary priorities for 2005.

## **2. Government Objectives and Priorities**

The Czech government determined the following economic priorities in its Programme Declaration:

- Stabilization of public budgets and improvement of the effectiveness of public expenditure, with the aim of joining the euro area by 2010;
- Reduction of unemployment by creating better conditions for businesses, active employment policy (particularly in regions affected by structural imbalance) and enforcement of equal opportunities;
- Improvement of the legal environment for entrepreneurship, particularly in the area of bankruptcy legislation, shortening of waiting times for registration in the Commercial Register, introduction of measures aimed at reducing the administrative burden for entrepreneurs and simplifying the communication between entrepreneurs and state institutions; strengthening of law enforcement and continuation of the fight against the shadow economy;

- Improvement of targeting and implementation of government programmes aimed at the promotion of entrepreneurship, so that these would effectively encourage investment in production and services with high value added, creation of new jobs and economic growth based on innovations, investments in modern technologies and on support of small and medium-sized enterprises;
- Support of science, research and education through the development of a knowledge-based society, wider access of the population to lifelong learning and increased government investment in research and development;
- Development of transport infrastructure, including the construction of a high-capacity transport infrastructure and the promotion of public passenger transport;
- Support of families with children through the creation of a favourable social and economic environment;
- Improvement of conditions for a better quality of life in rural areas and respect for the environment;
- Preparation and submission of draft reform of the pension system.

A prerequisite for meeting the said priorities is maintenance of a stable political and macroeconomic environment by applying an optimal economic policy mix. Economic policy is focused on speeding up the process of economic convergence and increasing the adaptability of the economy, in order to reduce the risk of an economic slowdown caused by asymmetrical shocks. Since the beginning of transformation, the characteristics of the Czech economy have moved much closer to those of EU countries, but a certain degree of economic misalignment and structural differences still persist and will persist even after joining the euro area. Stabilisation of fiscal policy, flexibility of the labour market and effective functioning of the financial markets will be crucial for making the Czech economy sufficiently responsive to changes.

Fiscal reforms are prevented the public finances from becoming a barrier to full participation in the euro area (due to excessive deficits and insufficient structural adjustment, notably on the expenditure side). Completion of public finance reform is a basic prerequisite for achieving compliance with the Maastricht criteria.

Fiscal policy should be based on a process of fiscal consolidation and gradual reduction of the current excessive deficit. This process was launched by the public finance reform approved in year 2003. According to this strategy, the general government deficit should not exceed 3.8 % of GDP in 2006 and 3 % in 2008. The adopted system of fiscal targeting is based on two pillars that anchor the budgetary process - on legally binding medium-term nominal expenditure ceilings for central government and on the policy of earmarking any higher-than-budgeted revenues for swifter deficit reduction. Measures carried out during the first stage of public finance reform were primarily aimed at reversing the inbuilt deficit tendencies of public finance and reducing the growth dynamics of general government deficit.

In the next stage of public finance reform the Czech authorities will focus on neutralizing the fiscal impact of current economic policy priorities, i.e. of measures aiming to support the supply side of the economy and create conditions for faster growth of potential output, and on fiscal policy measures aiming for long-term sustainability of the fiscal targets achieved.

### **3. Reform of Public Finance**

In 2004 a number of legislative measures focused on rationalising public expenditure came into force. The government is striving to restructure public expenditure in a way that is strengthening the areas of research and development, education, transport infrastructure, while ensuring that spending on the government's priorities is not endanger the approved expenditure frameworks. Higher expenditure in priority areas should be financed from savings combined with a reassessment of other expenditure, including mandatory expenditure. Further opportunities for the financing of these priorities arise thanks to the savings measures approved in year and implemented in the 2004 state budget.

Furthermore, certain tax changes were approved towards the end of 2003 and have been effective since the beginning of 2004. These tax changes reduce the role of income taxes and raise the importance of indirect taxes. This means a shift from the taxation of labour and profit (which has a negative effect on the markets of production factors) towards the taxation of consumption. This autumn brought the beginning of a debate focussed on changes in income taxes, with special focus on the promotion of investment activity, research and development, as well as support of families with children

The preparation of public finance reform was based on the principle that in the process of deficit reduction expenditure savings should prevail over tax changes. Over the next three years the ratio of general government

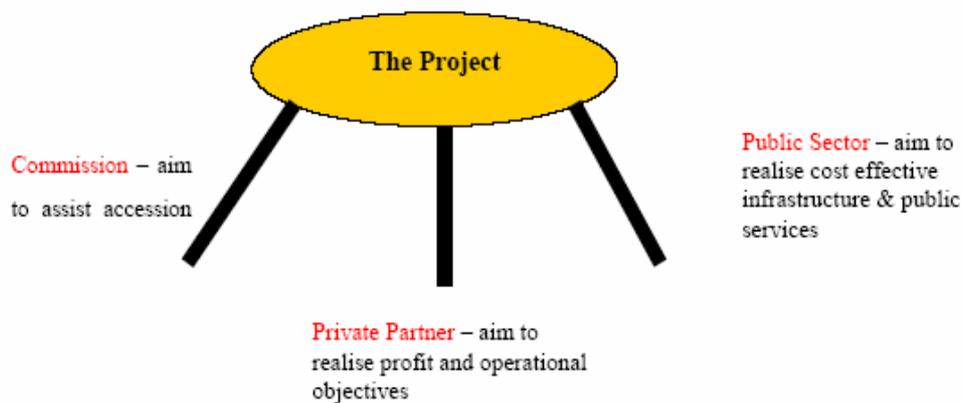

spending to GDP should drop by almost 4 p.p. Fiscal consolidation will affect almost all expenditure items; government consumption, social transfers and subsidies will experience the most significant decline. Starting in 2005, the government expenditures should no longer be burdened by transformation costs. In accordance with government priorities, government investment should increase. It will also be possible to fund additional investments from the Structural Funds and the Cohesion Fund.

#### 4. Public Private Partnership

One of the main commissions of a public sector is to provide public goods and public services in a high quality. As possibilities of public finance are very limited, it demands to look for new resources of financing and investing of these services. One of an alternative or supplemental form of financing of public services and goods could be public private partnership (PPP).

Conception of PPP is based on a partnership between the public and private sector for the purpose of delivering a project or service traditionally provided by the public sector. Public Private Partnership recognises that both the public sector and the private sector have certain advantages relative to the other in the performance of specific tasks. By allowing each sector to do what it does best, public services and infrastructure can be provided in the most economically efficient manner.

**Picture 1 PPP Relationship**

*Source: EUROPEAN COMMISSION. Guidelines for Successful Public - Private Partnerships, European Commission, 2003, page 67.*

Therefore the Czech Government has adopted a policy introducing public private partnership ("PPP") as a standard tool serving the provision of public services and public infrastructure.

The Government believes that a systematic and programmed application of PPP can bring about the following:

- real financial benefit and a better utilisation and allocation of public funds;
- development of efficient public infrastructures in shorter terms than otherwise;
- ensuring good quality public services;
- economic growth and boosted direct international investments by giving incentives to private investment in public infrastructure and public services;
- efficient control over the formation of long-term private sector liabilities;
- limitation of negative impact of non-systematic execution of PPP projects;
- increased possibility of drawing on EU funds by a higher co-financing share taken by the private sector in projects of public interest.

The introduction of PPP represents a measure based on the requirement for fiscal moderation and a systematic control over the formation of long-term public sector liabilities. This measure, too, is of a pro-growth nature, stimulating as it is an increase of private investment in the building of public goods and provision of public services. Thus, it is directly linked to the Czech Government's policy of long-term economic growth and social stability in the country. Its nature will facilitate investments into certain socially sensitive areas that otherwise could not be implemented due to fiscal reasons.

The introduction of PPP is conditioned by its programme and systematic application that makes known the PPP fiscal concept and that guarantees compliance with the following fundamental principles set out by the Czech Government:

- Value for Money – It is the main requirement that the resulting economic value of a PPP project should be lower than if implemented in a traditional manner of public sector funding. Since PPP represents a long-term and comprehensive concept, the total resulting economic value should also be viewed in a comprehensive manner (total costs of the public sector and opportunity costs) rather than solely from the sum of the cash payable from public budgets. The total economic value of a PPP project must be determined prior to launching the relevant PPP tender.
- Risk Transfer – That party best capable of managing risk should be that party to bear it; any material risks should be transferred to the private sector.
- Specification of Public Service Standards – The public sector in the capacity of a client must define standards applicable to public services, both in order to guarantee optimum public services and taking into account the economics of such standards.
- Maintenance of Public Assets Value – Since public assets would not be usually transferred to the PPP operator or they should come back to the public sector upon the expiration of the contract, it is essential to define clearly the relevant rules applicable to the maintenance of the value of such public assets managed by the private sector under PPP contracts (as a rule, 5-60 years)
- Ensuring Innovation and Competition – PPP contracts must not result in a monopoly of a single contractor; rather, PPP should manage competition so that it brings about utmost innovations in the given public service.

Those contracts between the public and private sectors can be considered PPP if they would bind the private sector to supply and/or operate public services or infrastructure projects that have typically been the realm of the public sector. They should mainly be projects or services that meet any of the following features:

- Shared responsibility for the supply of infrastructures or services whereby the private sector accepts higher risk, typically combining the design, construction, funding, management and maintenance elements.

- A long-term commitment (at least 3 years) by the private sector to provide good quality public services defined by the public sector.
- Shared expertise and capabilities by the private and public sectors so that the public sector may optimise the exposure and guarantee a higher value of public expenditure application, mainly while making use of qualities inherent to the private sector in the technical, financial, management, and innovation fields.

The implementation of PPP projects in individual sectors and the funding of the relevant infrastructure may also require amendments made to certain special legislative provisions. PPP projects are affected by a wide variety of legal provision. Although it is recommended to amend certain legislation and to adopt some new, it is not suggested that a specific PPP projects act be made.

There is no unique model suggest the development of one. Each project will define what is suitable and what is required. Additionally there is a growing realisation that cooperation with the private sector, in PPP projects, is able to offer a number of advantages, including:

- Acceleration of infrastructure provision - PPPs often allow the public sector to translate upfront capital expenditure into a flow of ongoing service payments. This enables projects to proceed when the availability of public capital may be constrained (either by public spending caps or annual budgeting cycles), thus bringing forward much needed investment.
- Faster implementation - the allocation of design and construction responsibility to the private sector, combined with payments linked to the availability of a service, provides significant incentives for the private sector to deliver capital projects within shorter construction timeframes.
- Reduced whole life costs - PPP projects which require operational and maintenance service provision provide the private sector with strong incentives to minimise costs over the whole life of a project, something that is inherently difficult to achieve within the constraints of traditional public sector budgeting.
- Better risk allocation - a core principle of any PPP is the allocation of risk to the party best able to manage it at least cost. The aim is to

optimise rather than maximise risk transfer, to ensure that best value is achieved.

- Better incentives to perform – the allocation of project risk should incentivise a private sector contractor to improve its management and performance on any given project. Under most PPP projects, full payment to the private sector contractor will only occur if the required service standards are being met on an ongoing basis.
- Improved quality of service - international experience suggests that the quality of service achieved under a PPP is often better than that achieved by traditional procurement. This may reflect the better integration of services with supporting assets, improved economies of scale, the introduction of innovation in service delivery, or the performance incentives and penalties typically included within a PPP contract.
- Generation of additional revenues – the private sector may be able to generate additional revenues from third parties, thereby reducing the cost of any public sector subvention required. Additional revenue may be generated through the use of spare capacity or the disposal of surplus assets.
- Enhanced public management – by transferring responsibility for providing public services government officials will act as regulators and will focus upon service planning and performance monitoring instead of the management of the day to day delivery of public services. In addition, by exposing public services to competition, PPPs enable the cost of public services to be benchmarked against market standards to ensure that the very best value for money is being achieved. International interest in PPPs is attributable generally to three main drivers:
- Investment in infrastructure -economic growth is highly dependent on the development and enhancement of infrastructure, particularly in utilities (such as power, water and telecommunications) and transport systems. Furthermore, in many countries there is an urgent need for new social infrastructure such as hospitals and healthcare equipment, prisons, education facilities and housing. For many governments this is seen as the most pressing area for private sector involvement.

- Greater efficiency in the use of resources - the experience of privatisation has shown that many activities, even those traditionally undertaken by the public sector, can be undertaken more cost effectively with the application of private sector management disciplines and competencies.
- Generating commercial value from public sector assets – significant amounts of public resources are invested in the development of assets such as defence technology and leading edge information systems that are then often used for a narrow range of applications within the public sector. Engaging private sector expertise to exploit these assets in a wider range of applications can lead to the realisation of substantial incremental value for the public sector.

However while certain advantages do exist and can be harnessed, PPP should not be regarded as representing a miracle cure nor indeed a quick fix to infrastructure and service development. PPP should be regarded as an option amongst a range of possible tools to be applied only where the situation and project characteristics permit it and where clear advantages and benefits can be demonstrated. Indeed consideration of PPP should not preclude other options including the traditional public – public models

## **5. Conclusion**

The Czech Republic is currently reporting an excessive deficit, which poses an obstacle on the way towards compliance with convergence criteria. Public finance consolidation and gradual budgetary deficit reduction are the main government priorities. Spending reforms of public finance are aimed not only at gradually reducing the budgetary deficits but also at improving the quality of public finances. As resources of public finance are strong limited, it demands to look for new ways of financing public goods and public services. One of an alternative or supplemental form of financing can be projects of public private partnership (PPP).

Conception of PPP is based on a partnership between the public and private sector for the purpose of delivering a project or service traditionally provided by the public sector. Public Private Partnership recognises that both the public sector and the private sector have certain advantages relative to the other in the performance of specific tasks. By allowing each sector to do what it does best, public services and infrastructure can be provided in the most economically efficient manner.

## **Abstract**

*Public Private Partnership (PPP) or more specifically Public Participation in Infrastructure (PPI) represents one of the most common tools of project finance nowadays. So we will define the project finance in the first place and differentiate it from the other kinds of crediting instruments. The article shall give you overview of commence, development and present state of the PPP, its forms as various ways of cooperation between state and private corporation in the role of creditors, sponsors, builders or operators. Application for transportation infrastructure, namely projects of motorways in the Central and Eastern European Countries (CEECs) and some of the largest motorway-projects in the world will follow.*

**Keywords:** *project finance, public private partnership, special purpose vehicle*

## 1. Project finance

There are a lot of definitions for project finance in literature. For example, J. D. Finnerty defines project finance as: "...the raising for funds to finance an economically separable capital investment project in which the providers of the funds look primarily to the cash flow from the project as the source of funds to service their loans and provide the return of and a return on their equity invested in the project."<sup>1</sup>, while F. J. Fabozzi define it as: "A financing of a particular economic unit in which a lender is satisfied to look initially to the cash flow and earnings of the economic unit as the source of funds from which a loan will be repaid and to the assets of the economic unit as collateral for the loan."<sup>2</sup> and the International Project Finance Association (IPFA) defines project financing as: "... the financing of long-term infrastructure, industrial projects and public services based upon a non-recourse financial structure where project debt and equity used to finance the project are paid back from the cash flow generated by the project."<sup>3</sup> Relatedly, Standard & Poor's Corporation defines a "project company" as: "... a group of agreements and contracts between lenders, project sponsors, and other interested parties that creates a form of business organization that will issue a finite amount of debt on inception; will operate in a focused line of business; and will ask that lenders look only to a specific asset to generate cash flow as the sole source of principal and interest payments and collateral."<sup>4</sup>

Although none of these definitions uses the term "nonrecourse debt" explicitly (i.e., debt repayment comes from the project company only rather than from any other entity), they all recognize that it is an essential feature of project finance.<sup>5</sup>

The following definition, albeit slightly more cumbersome, allows one to distinguish project company finance from other financing vehicles, something the previous two definitions cannot do: Project finance involves the creation of a legally and economically independent project company

<sup>3</sup> **www.ipfa.org**

<sup>4</sup> **Standard & Poor's corporation:** Project Finance Summary Debt Rating Criteria, 2003

<sup>5</sup> Limited recourse debt – debt that carries a repayment guarantee for a defined period of time, for a fraction of the total principal, or until a certain milestone is achieved (e.g., until construction is complete or the project achieves a minimum level of output) – is a subset of nonrecourse debt. The distinguishing feature is that at least some portion of the debt becomes nonrecourse at some point in time.

financed with nonresource debt (and equity from one or more corporate sponsors) for the purpose of financing a single purpose, capital asset usually with a limited life. (See the following chart)

**Figure 1 Distinguishing between project and corporate financing**

Source: Benjamin C., Esty, Harvard Business School, 2004

### 1.1 History of project finance

Private investment in major infrastructure projects is not unusual. Prior to World War I, railways, roads, bridges, power plants, ports, water works and gas-distribution systems were being built all over the world by private entrepreneurs willing to risk all in return for high rewards. Fortune were made and lost.

During the 19<sup>th</sup> century ambitious projects such as the Suez Canal and the Trans-Siberian Railway were constructed, financed and owned by private companies. However, the private-sector entrepreneur disappeared after World War I and as colonial powers lost control, new governments financed infrastructure projects through public sector borrowing. The state and public-utility organizations became the main clients in commissioning of public works, which were then paid for out of general taxation.

During this post – World War I period in Europe, states invested in the reconstruction of war-damaged infrastructure and new nationalized industries. After World War II most infrastructure projects in industrialized countries were built under supervision of the state and were funded from their respective budgetary resources of sovereign borrowings.

This traditional approach of government in identifying needs, setting policy and procuring infrastructure was by and large followed by developing countries, with the public finance being supported by bond instruments or

direct sovereign loans by such organizations as The World Bank, The Asian Development Bank and The International Monetary Fund.

### **Development in the early 1980s**

The convergence of a number of factors by the early 1980s led to the search for alternative ways to develop and finance infrastructure projects around the world. These factors include following:

- Continued population and economic growth meant that the need for additional infrastructure – roads, power plants, water-treatment plants – continued to grow;
- The debt crisis meant that many countries had less borrowing capacity and fewer budgetary resources to finance badly needed projects; the debt burden required them to adopt an austere approach when planning fiscal spending, compelling them to look to the private sector for investors for projects which in the past would have been constructed and operated in the public sector;
- Major international contracting firms which in the mid-1970s had been kept busy, particularly in the oil-rich Middle East, were, by the early 1980s, facing a significant downturn in business and looking for creative ways to promote additional projects;
- Competition for global markets among major equipment suppliers and operators (particularly in the power and transportation industries) led them to become promoters of projects to enable them to sell their products or services;
- Outright privatization was not acceptable in some countries or appropriate in some sectors for political or strategic reasons and governments were reluctant to relinquish total control of what may be regarded as state assets.

During the 1980s as a number of governments, as well as international lending institutions, became increasingly interested in promoting the development of the private sector, a consensus developed. It supported tapping in the energy and initiative of the private sector, and the discipline imposed by its profit motive, to enhance the efficiency and productivity of what had previously been considered public-sector services.

It is now increasingly recognized that the private sector can play a dynamic role in accelerating growth and development. Many countries are encouraging direct private-sector involvement and making strong efforts to attract new money through new project financing techniques.

Such encouragement is not borne solely out of the need for additional financing, but it has been recognized that private-sector involvement can

bring with it the ability to implement projects in a shorter time, the expectation of more efficient operation, better management and higher technical capability and, in some cases, the introduction of an element of competition into monopolistic structures.

Project Finance is being introduced in both developed and developing countries as an alternative way to finance infrastructure and industrial projects, both small and large. The concept is being used in transportation (toll roads, toll bridges, toll estuarial crossings and railways); energy (private power stations, waste-to-energy plants and gas-distribution pipelines); sewage and water-treatment plants, health care (construction and operation of new hospital buildings and clinical waste disposal plants); education (provision of student accommodation and facilities for universities, colleges and schools); and provision of government offices.

### **1.1.1 Development of BOOT**

#### **Concessions**

The search for a new way to promote and finance infrastructure projects led to the introduction of technique, originally used in the 19<sup>th</sup> and 20<sup>th</sup> centuries, known as concessions. Concessions were widely used in many parts of the world to develop infrastructure. The Suez Canal is one of many examples of a privately financed concession and this method was also used to build canals, railroads, tramways, water works, electric utilities and similar projects in both industrialized and less-developed countries.

The BOOT formula adds to the old system of concessions, providing new possibilities for reducing or eliminating the direct financial burden which governments would otherwise bear. The objective is to transfer as much borrowing risk as possible to the private-sector promoter and the project itself. Therefore the BOOT promoter must finance the project. (The promoter typically does this by obtaining financing from groups of commercial banks, other financial institutions, export credit agencies and multilateral finance agencies.) Financing is made available on the strength of the project's projected revenue stream and its other assets including the promoter's equity. Normally the lenders would have limited or no resources to the promoter or shareholder of the promoting company.

#### **Project finance**

This financing technique, generally known as project finance, was perfected in the 1970s for major private-sector projects, mainly in the area of oil and gas exploration and extraction, but has been extended widely since then. Project techniques are now applied across the world to numerous privately promoted infrastructure projects including power stations, gas pipelines, waste-disposal plants, waste-to energy plants, telecommunication

facilities, bridges, tunnels, toll roads, railway networks, city-centre tram links and now the building of hospitals, education facilities, government accommodation and tourist facilities. Financial markets have become increasingly sophisticated in engineering financing packages to finance almost any type of reasonably predictable revenue stream.

Over the last two decades major international contracting firms, individual entrepreneurs and a number of developing countries have begun to promote infrastructure projects on a BOOT basis. Projects are financed on a limited-resource basis and built operated under a concession from the state or similar public body as a private venture. At the end of the concession the project is transferred back to the state or public body.

### **What is BOOT?**

One method used to involve the private sector in large-scale infrastructure investments is where the private sector is granted a concession from the state to build, finance, own and operate a facility and after the time specified in the concession period is obliged to hand it back to the state. This concept is variously described as BOT, BOOT, BOO, BRL, BLT, BT and BTO, depending on the terms of the agreement.

The acronym BOT stands for “Build, Own and Transfer”, or “Build, Operate and Transfer” (these terms are often used interchangeably). The “owning” is an essential element since the main attraction to host governments is that the promoter’s equity stake underwrites its commitment to a project’s success.

Other variants include BOOT (Build, Own, Operate and Transfer) and BOO (Build, Own, Operate). In BOO projects the promoter finances, designs, constructs and operates a facility over a given period but it does not revert to the government as it would using the BOOT strategy.

Further extensions of the concept are BRT or BLT (Build, Rent/Lease and Transfer) or simply BT (Build and Transfer immediately, but possibly subject to instalment payments of the purchase price).

Another approach, BTO (Build, Transfer and Operate), has become increasingly popular in the Far East and is particularly preferred by power and telecommunications authorities. It is a simpler transaction or concept than BOT and BOOT that can be implemented in a shorter time without the need for the formation of a project company and with the project assets being owned by the public sector.

### **Stages of a BOOT project**

- Build
- Design

- Manage project implementation
- Carry out procurement
- Finance
- Construct

**Own**

- Hold interest under concession

**Operates**

- Manage and operate facility
- Carry out maintenance
- Deliver products/service
- Receive payment for product/service

**Transfer**

- Hand over project in operating condition at end of concession period

**1.1.2 The development of PPP**

The concept of a PPP – Public Private Partnership has been adopted by various governments in recent years. Instead of the public-sector producing a capital asset and providing a public service, the private sector create the asset through a single stand alone business (financed and operated by the private sector) and then deliver a service to the public sector client, in return for payment linked to the service levels provided.

**2. Public Private Partnership**

**2.1 Requirements for successful PPPs**

*Political support* at the policy level is important for the private sector, because unless PPP is seen to offer continuing business opportunities, firms will be reluctant to develop the necessary that is required to bid for contracts.

*Enabling legislation* PPP projects need to be supported by enabling legislation that is firmly embedded in the legal structure of the host country. A key aspect of this enabling legislation is the existence of a concession law that can be readily applied to projects.

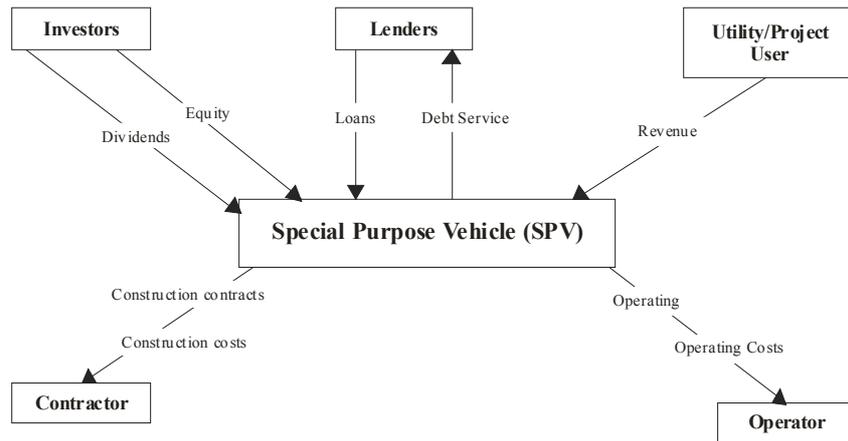

*Expertise*. Both the public and private sectors must have the necessary expertise to deal with the PPP process.

*Project prioritization*. The government needs to identify those sectors and projects that should take priority in the PPP process and undertake a review of the viability of each scheme before the project is procured. This avoids unnecessary failures and high bidding costs.

**Heavy Deal flow and standardization.** A regular and predictable flow of deals based on recognized risk allocation templates, assists the development of a successful PPP programme. Guidance on contract structure also helps to keep costs down.

## 2.2 The BOOT/PPP structure

**Figure 2: Example of a simple BOOT/PPP Structure**

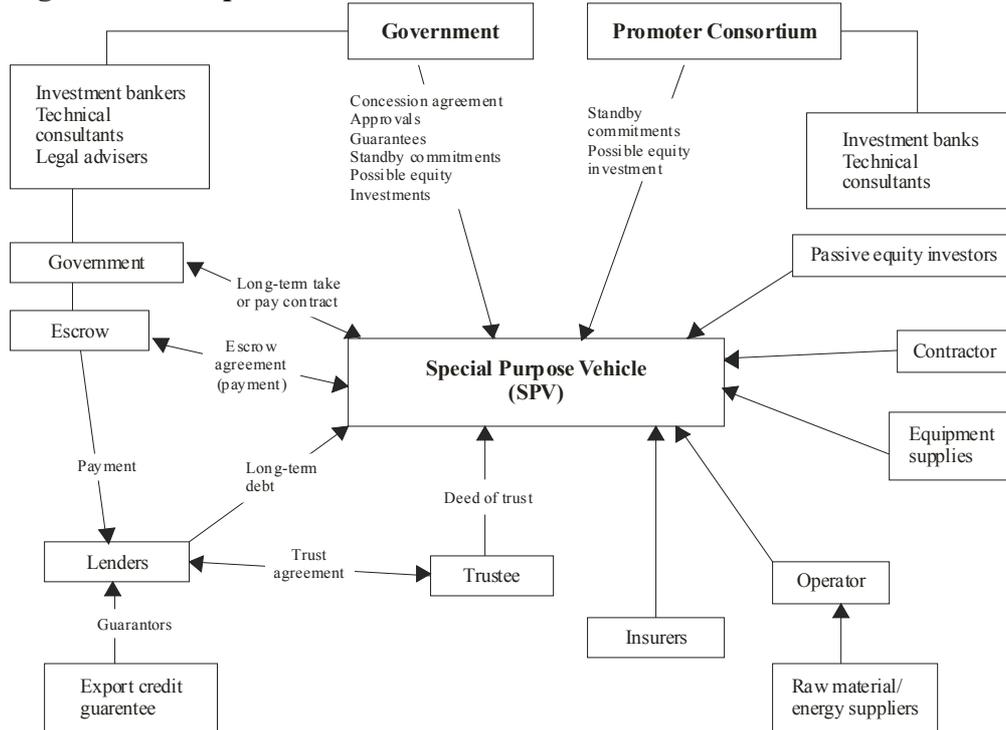

Source: [www.ipfa.org](http://www.ipfa.org)

- The concession company promotes the project and has the ultimate liability to the government under concession agreement.
- The concession agreement (sometimes referred to as the implementation or project agreement) is the primary contract between the government and the concession company and forms the contractual basis from which the order contracts are developed. It entitles the concession company to build, finance and operate the facility and imposes conditions as to design, construction, operation of the project and establishes the concession or operation period.
- The equity investors' and lenders' security for their loans and investment is limited to the revenues to be received by the concession company. They will therefore have considerable interest in the revenue forecasts produced by the concession company. Likewise the two areas that place the concession company and equity investors and lenders are the construction contract and operating contract.
- The construction contract. The parties would prefer a contractor to give a fixed price for completion by a fixed date without exclusions.

This is rarely possible in projects of this nature. Finance providers are therefore only prepared to commit themselves to a fixed amount because if the project costs more their funds will be in jeopardy due to the interest burden. Lenders will not accept the risk of delay to completion, although they will normally provide a standby facility to offer some protection against time-and-cost overruns.

- The operating contract. The lenders have to be assured that an experienced operator will be available on completion of construction.

**Figure 3: Example of an international BOOT/PPP Structure**

Source: [www.ipfa.org](http://www.ipfa.org)

- The offtake contract. This is one of the key contracts. As limited-resource projects are, by definition, funded on the security of the future cash flow, there has to be some form of buyer. Projects fall into two categories: those where the identity of the buyer is obvious, for example toll roads and some power stations and those where there is physical product which has to be sold, often on the world market. Where there is a product involved it is essential to identify the offtaker or buyer and to establish the basic terms. Lenders prefer

guaranteed minimum or “floor” prices, but these are frequently unobtainable. There is then the need to establish whether the future price of the product is something upon which the potential lenders to the project are prepared to take a risk. There may be an opportunity for the offtaker to take some of the downside risk by providing a very low floor price, for example one which is below the level; at which the debt would have to be rescheduled with the lenders risking such rescheduling. In exchange the offtaker would expect a high reward in good times.

### **3. PPP in transportation**

Today 30 – 40 percent of PPP are transport-related and the majority of these for motorways and toll roads. The list of PPPs issued by the UK and other industry associations suggests that – on average – including both existing and newly built, there will be about 5 to 10 toll roads/tunnels in each of EU countries over the next 10 years, says Isabelle Kayaloff of IJK & Associates in Germany.

For example, a person driving from the UK in 2004 to Belgrade will have to cover 1.200 km of road and pay € 15 of tolls. The optimal itinerary suggests that that person will travel through at least six countries. Estimated travel time without stopping is about 19 hours. For such a journey, an average car will require a minimum of three tanks of fuel. Total cost of the trip is thus about € 213. The same calculation applies if a traveller wishes to drive to Athens. Total mileage is 1.670 km with a travel time of 30,5 hours and an estimated toll cost of € 160.

In 2008 that picture will change. The same person departing for Belgrade will travel through six countries, of which half will have now some toll system in place. If the standard of 7,5 cents per km is applied – which is generally used in France and Spain – the total toll cost alone of a journey to Belgrade will be in excess of € 54 and for Athens, close to € 200.

#### **What are the solutions?**

PPPs need to be relevant to the real needs of the communities they are intended to service. Transportation PPP’s need to be rationalised to address:

- Segregation of road/tunnels that are designed to mitigate specific traffic congestion particularly in urban areas.
- Investment in alternative means of mass transit.
- Re-routing proposed motorways away from towns and residential areas.

- Addressing the traveller's capacity to pay, through possible cross-border harmonisation of tolls (likely to be controversial and not achievable in short term).
- Liberalising rail freight markets and creating efficient management railway networks.

### **3.1 Case studies<sup>6</sup>**

#### **3.1.1 Hungary's M Motorway**

Hungary's M5 motorway is a pioneering project in the Central Europe region. It is the first genuine road PPP transaction to close in the region and beat neighbouring countries off the mark to draw in foreign investment to its roads infrastructure, writes Angus Leslie Melville.

The financing was put in place to pay off the existing project debt, provide a payment to equity and fund the construction of a new, 46 km stretch of motorway linking Budapest to the Serbian border.

Indeed, the deal was so impressive that it was nominated as one of the top 10 transactions of 2004 at the Infrastructure Journal Annual Awards 2004, held on 20 January at the Victoria & Albert Museum, London.

The project was popular with the banks from its inception as it forms a vital link in the Trans-European motorway network linking Berlin with Thessaloniki and was seen as a sound investment.

In short, the project was set up to refinance Phase 1 of the M5 motorway and finance Phase 2. The first phase was finished in 1998 and operated as a real toll road up to March 2004 when Hungary incorporated the motorway into the national vignette system.

The existing project financing was refinancing and switched from a toll-based financing structure to a structure based on availability payments by the Hungarian government.

The deal took many industry observers by surprise as it was structured in less than six months and it involved converting a real toll road into an availability road – a first in the project finance world.

Hungary is seen as being pivotal to European efforts to develop an integrated transport system. Success in Hungary is key as it has six essential international roads pass through it – each one representing a major channel of trade economy and communication.

---

<sup>6</sup> Case studies are taken from International Journal on Infrastructure

The Hungarian government has been forward-thinking over its role in Europe and had the wisdom to see how it could benefit from being seen as a vital link in the Trans-European Network.

It set forth its objectives back in 2003 for the road sector within the framework of its general transport policy until 2015 – by which time it aims to have reached the EU network density average.

In order to achieve these objectives, the government legislated to enable the use of PPPs in its road building and maintenance regime. Prior to its acceptance of the PPP structure, Hungary favoured wholly-privatized concessions.

As Hungarian transport minister Istvan Csillag says of the M5 project: ‘This is a truly ground breaking transaction, the first of its kind in Hungary – and the professional advisors have contributed significantly to the success of the project.’

‘I am convinced that the success of the M5 will give a boost to the smooth implementation of the M6 motorway currently taking place as well as underlining the importance of the PPP structure in the rapid development of infrastructure sector in Hungary and the whole CEE region.’

### **Transaction**

The M5 motorway was originally financed, built and operated on a private basis, but the government decided to scrap the real toll system at the start of the year and replace it with an availability-dependent PPP deal.

The change to the model means that the government now has to pay AKA an annual unitary charge of €80 m until the end of the concession in 2030 – which covers national vignette holders using the road and compensates for the loss of real toll revenues.

In addition, the government – through its highway management company AKA – has taken a 40 percent stake in the concession company, with Bouygues and Strabag still holding equal shares of the scheme and control of the project.

The financing was also fairly complicated as the lead arrangers – having refinanced the real toll road at the end of 2003 for €205 m – on 11 March 2004 had to buy back the €205 m refinancing from seven syndicate banks when the real toll system was scrapped. They then held it themselves with the debt being serviced via the availability dependent deal to AKA. This debt was taken out as part of the €750 m refinancing.

The second phase closed on 22 September 2004 and involved raising €750 m (US \$ m). Phase 2 financing and implementation of an availability-based payment and performance mechanism for the project.

**Table 1: M5 Road Project Restructuring at a Glance**

Project name	M5 Road Project Restructuring
Location	Hungary
Description	The M5 motorway comprises an existing 27 km motorway (the already operational Budapest - Szeged section) and a new 40 km new dual lane motorway (from Szeged - Kiskunfélegyháza towards the Serbian border). The first phase of the transaction was closed in March 2004 and saw the motorway brought into the national vignette system of the Hungarian motorways and, following the relevant amendments to the concession agreement, the first Hungarian PPP structure was implemented on the basis of the availability fee model. The second phase, which signed in September 2004, included the refinancing of the facility for the existing section of the motorway and new financing for the extension to the road.
Sponsors	Strabag, Bouygues and Colas
Project Company	Alföld Koncessziós Autópálya (AKA)
Operator	Magyar Intertoll
EPC Contractor	A joint venture between Colas, Bouygues and Strabag
Total project value	€853m (For Phase I and II)
Total debt	€750m
Equity	€83m
Financing	The €750m financing for the project will refinance the original €205m facility for the existing section of the motorway and also finance the extension to the road. EBRD's involvement in the financing is as a parallel lender alongside the commercial banks.
Pricing	The deal is priced at 130 bp during construction of the new section of the road until end - 2005, 120 bp for the first five years thereafter, 130 bp for the next five, 140 bp for the next five and 160 bp for the last 3,5 years.

Tenor	20 years
Mandated lead arrangers	Banco Espirito Santo, WestLB, CIB/Banca Intesa, MFB and EBRD
Arrangers	Banco Espirito Santo (€50m), WestLB (€50m), CIB/Banca Intesa (€79,9m), MFB (€100m), EBRD (€130m), AIB (€18,5m), KfW (€18,5m), Bank of Ireland (€18,5m), Landesbank Hessen-Thuringen (€18,5m), CDC Ixis (€18,5m), Mizuno (€18,5m), Depfa (€18,5m), Natexis (€18,5m), Dexia (€18,5m), OTP (€18,5m), HVB (€18,5m), SMBC (€18,5m), ING (€18,5m), RBS (€18,5m), Islandsbanki (€18,5m), Unicredito Banca Mediocredito (€18,5m) and K&H/KBC (€18,5m)
Co-arrangers	Banca OPI (€12,4m) and IKB (€12,4m)

### **3.1.2 Canada's Anthony Henday Drive SE road PPP**

At the end of January the Government of the state of Alberta reached financial close on the Can\$493 m (US\$ 397 m) Anthony Henday Drive

(AHD) SE road scheme PPP with the Access Roads Edmonton (AREL) consortium, writes Alex Black.

The scheme is part of the province's Can\$2bn (US\$1,5bn), three-year highway construction and improvement programme and was the first DBFO scheme to reach financial close in Alberta.

The other Anthony Henday Drive project – the south west or SW project – is currently under construction. Entirely funded by the Alberta government, it is scheduled to be completed and open to traffic in the autumn of 2006 and will cost around Can\$245m (US\$204m).

Alberta has one of the fastest growing economies of all Canadian provinces and the city of Edmonton is the fifth largest in Canada with a population approaching 1m people.

**Table 2: The Anthony Henday Drive SE PPP road scheme at a Glance**

Project name	The Anthony Henday Drive SE PPP road scheme
Market	Transport/PPP
Sector	Road
Country	Canada
Date of Financial Close	25-th January 2005
Sponsors	PCL Construction Management, ABN AMBRO and LaFarge Canada
Project Company	Access Roads Edmonton LtD (AREL)
Total project value	Can\$493m (US\$397m)
Construction value	Can\$365m (US\$302m)
Total bond issue	Can\$290m (US\$240m) in two tranches (see Bonds table)

#### 4. Conclusion

In February 2005 Ministry of Finance of the Slovak Republic published study on PPP/PPI in Slovakia. This comprises theory of PPP/PPI and gives opinion on it. More important it stipulates that government shall encourages these kinds of investments even though they were not of hundred per cent access in the neighbouring countries – from which – as this study stresses – we should learn our lessons.

There is not much left to comment, probably we should really try to learn how to use this ‘trendy’ instrument for financing of public infrastructure – not only while it has been successfully implemented in the Northern America or also Ireland (not mentioned in this article) which is great example for our economy in many different ways – but also while PPP/PPI in their essence are more efficient and effective than public investment themselves.

Slovak Republic has also very good opportunity – as a member state of the European Union – to combine private resources with EU Cohesion Fund, which would make these investments even more rentable.

## **Abstract**

*The present state of Romanian tourism is also due to the fiscal measure and regulation promoted by the governments that have run the country after 1990. Even if the Romanian fiscal system has been subject to major transformations in the process of adapting to the requirements of the competitive market economy there are still certain problems to be solved, problems which affect all companies, including those which work in the touristic sector. Fiscal policy can have a positive influence on sustainable touristic development if its goals are: the encouragement of those companies working in the touristic sector to make investments and to improve the quality and the competitiveness of touristic services, the encouragement and promotion abroad of Romanian touristic destination, the protection of the environment. The fiscal system that has been introduced after 1990 was very burdensome for the companies working in the touristic sector, reducing significantly their income. We hope that tax relief promoted by the present government will attract more tourists and encourage the investments in the touristic sector*

**Keywords:** *fiscal reform, fiscal policy, sustainable development*

## **1. Introduction**

The complexity of tourism, its social, cultural and economic implications, the interlinking of its distinct components are all reasons for the governments all over the world to pay attention to tourism as they have understood the fact that they can benefit by it.

Tourism is a very complex and complicated industry that comprises many fields. There is no other industry to comprise such a vast group of associated fields as tourism does. It is a combination of industries from all over the world, of the greatest diversity, having a very complicated structure. Taking this as a starting point, it is obvious that the complexity of tourism requires coordination; only governments have the authority and the necessary mechanism to organize such a complex sector.

## **2. Aspects of State's Implication in the Economic Fields**

From the very moment of its coming into being and up to the present, state has had to make a difficult choice: freedom or control? This choice is called by the specialized literature "the dilemma of modern society" and consists in the difficulty of modern society to choose either freedom, giving up on the society's chances to survive or to choose control, in this case giving up on individual freedom.

Therefore, from the economic point of view, the main problem is to choose between the market supremacy and the state's lack of involvement on the one hand, and state's supremacy over the market, on the other. Reality has proved that choosing the individual freedom and the free market has proved to be better than choosing the coordination of the economy by the state. At the same time, it is a well-known fact that individual freedom does not guarantee the support of the citizens, that they need social support and the free market, in its turn needs a stabilizing support from the part of the state. Therefore, from the economic point of view, The main problem is to choose between the market supremacy and state's lack of involvement on the one hand and state's supremacy over the market, on the other. Reality has proved that choosing individual freedom and free market has been better than choosing the coordination of the economy by the state. At the same time, it is a well-known fact that individual freedom does not guarantee the support of the people, that they need social support and, in its turn, free market needs a stabilizing support from the part of the state. Thus, it is a fact that both free market and the state are complementary factors of the economic system, and the boom of the modern economy depends on achieving a balance and sharing the responsibilities between market and state.

Although tourism is an activity supported especially by private initiative, governments play an important part in its development. They have strong reasons to involve in tourism sector. Their involvement is necessary having in view the economic and social importance of tourism and its contribution to the increase of life's quality. At the same time, tourism can have a greater contribution than other fields to achieving some broad goals established by the governments as priorities in the general interest of the citizens: fighting against poverty, improving life's condition, increasing currency chased, intensifying the links between countries and even political goals.

The complex mechanism of interaction between state and market economy requires that the public authority should make use of some means and techniques which are adequate to the difficult role which state has in economy. The allotting, distributive and especially regulator role of the state requires the promotion of the economic policy.

As compared to other economies in the Central and Eastern Europe, the process of transition in Romania has been slow and rather unstable. This state of fact is, in part, due to initial difficult conditions of the previous period of transition when the priorities were the heavy industry, which wasted a lot of energy, the big inefficient agricultural units, the unproductive project and the reducing of imports to allow the prepayment of the foreign debt, to the detriment of the living standards and technological modernization of economy. But, on the other hand, Romania's slow progress regarding transition is caused especially by a not very firm approach and a not very good implementation of structural reform, as well as by a lack of continuity of macroeconomics policies.

### **3. Problems of Romanian Taxation System after 1990**

The present state of Romanian tourism is due to the measurement and fiscal regulation adopted by the governments that have ruled Romania since 1990. In the case of the market economy there is no longer a direct connection between the state than plans and the way of achieving the plan, as it was in the case of the demand based economy. State's attributions are reduced only to promoting financial, fiscal and commercial policies that improve the business environment and are further on applied according to the principle of full autonomy of business in each company.

The reaction of the economy to different policies of the state depends both on the feasibility and adjusting the policies as well as on the degree to

which the economic environment enforces the laws, the efficiency of the democratic mechanism and the inner rules of each enterprise.

After 1989, the Romanian fiscal system has undergone significant changes, adapting to the requirements of the market economy. Today, it satisfies to a great extent the requirements of a competing economy, but there are still a series of problems, both general problems, regarding the entire fiscal system and the way in which it functions, and the problems that are specific for each tax. These problems affect all companies, including those that work in the tourism sector. A main problem identified in the analysis of the evolution of the fiscal system after 1989, is the legislative instability. In time, each of the main taxes has undergone repeated, more or less important changes. Therefore, making long-term business plans is almost impossible, the foreign investors are not encouraged and the internal and external investments are diminished. Another important matter is the way in which fiscal legislation is put into practice and the manner in which the lack of fiscal order is dealt with. In Romania, the taxes and shares owed by the companies do not bring many benefits, this having a negative impact on the economy, as a whole, and on each of its fields. It is very important to keep in mind that only a correct and coherent way of applying the fiscal legislation creates an economic environment that will offer equal conditions for all companies, a fact that will be an advantage for those which are really efficient, thus developing the economy. At the same time, an equal distribution of the fiscal duties might reduce taxation, which will limit the subterranean economy and offer better conditions for firms' development. Another important problem that the Romanian fiscal system has to face is the existence of a strong subterranean economy. This has major negative effects on the economy. Because some firms involved in the subterranean economy do not pay taxes, the fiscal incomes of the state are reduced, which makes necessary a new growth of taxation, which, in its turn, generates an increase of the number of the firms functioning in the field of subterranean economy. This will certainly lead to diminishing the fiscal incomes and to going into a vicious circle. Other problems regarding the fiscal system as a whole are those connected to the value of the taxes. When it comes to the value of the taxes, the Romanian fiscal system is in accordance with what exists at European level and especially in Eastern Europe, but there are still certain steps to be made till the Romanian fiscal legislation will be brought to a balance with that of the European Union.

#### **4. Taxes for Touristic Companies in Romania**

The present Romanian taxation system is the result of many years of transition and, although there have been made many efforts, it contains many regulations that hinder the economic development, and especially the touristic sector, where there is a serious competition in the European continent. The fiscal simplification promoted by the present government is hoped to create a better business environment, to contribute to a durable economic growth and to make the Romanian business environment moiré flexible and predictable. The main reason for which government encouraged the fiscal simplification is that increased values of the taxes can have negative effects on the real economy: they hinder the evolution and the restructuring of the internal offer and a part of the economic activity is not taken into account by the national accountancy.

According to the Plan of Governing for 2005 – 2008, in Romania the fiscal policy will be based on the following principles:

- the principle of fiscal neutrality: the fiscal norm must have the same consequences on every company; fiscal neutrality will be limited only by the situations in which, in order to achieve the goals of the plan of governing, there must be accepted, for short periods of time, unequal fiscal consequences;

- the principle of fiscal effectiveness (performance): fiscal norm must have a strong impact on the respective fiscal behavior; it is not accepted any other fiscal norm that does not change a fiscal behavior;

- the principle of the equality of the fiscal treatment: the companies that have similar economic functions, in an certain lapse of time, will be treated in the same way, from the fiscal point of view, irrespective of the existing differences between them;

- the principle of the sustainability of fiscal norm: the taxes will be established in such a way as the taxable base to be stimulated by the tax itself, the respective taxable material becomes more stable and transparent.

The fiscal system introduced after 1990 has been very burdensome for the companies working in the touristic sector, reducing significantly their incomes.

Local taxes represent the first category of taxes which must be paid by the companies working in the touristic sector. This are paid for the local budget of the administrative-territorial unit in the area of which the respective touristic asset is situated:

- first, the tax on buildings must be paid. This is calculated by applying a quota whose value is situated between 0,5% and 1% from the inventory value of the respective buildings, the quota being established by a decision of the local board. It is a well-known fact that a characteristic of tourism is the unequal distribution of tourists and services in time and space. Many accommodation unit, especially those at the seaside, function only a few months a year; other, have tourists all the year round but there are only few. For a long time, they have paid the taxes for the whole year. The fiscal legislation that has become effective in 2004 provides that the tax on building to be reduced with 50% for those buildings owned by the legal persons, buildings that are used exclusively for offering touristic services for a period of maximum five months in a year. This is a very good idea.

- if touristic companies own means of transportation (cars, coaches, minibuses, boats, yachts, ships or means of entertainment – motor bicycles, scooters, motor boats), they must pay the tax for means of transportation. This is calculated according to the respective type of means of transportation, according to law. For these, the companies working in the touristic sector pay the tax for the entire year, although there are not continuous flows of touristic transports. We can speak of continuous flows of tourists especially in peak seasons. A 50% reduction of the tax on the means of transportation will be beneficial, if they are used in touristic activities only five months a year.

- any company working in the touristic sector that must get a certificate, advice or any other kind of license, must pay the tax for issuing the town planning certificate construction licenses and other similar licenses to the specialized department of the local public administration before the respective certificate, advice or necessary license is released. The taxes for releasing construction licenses, sanitary licenses, licenses for carrying on economic activities are insignificant, but the tax for issuing the necessary license for site organization activities having in view the building of construction is 3% of the authorized value of the site organization activities, and the tax for issuing the license for organizing tent camps, for little houses and trailers or champs is 2% of the authorized value of the construction works. The value of these taxes is rather high even if we take into account the fact that the recovery of the investment in the touristic sector is a long term one and not a short time recovery, as in other sectors.

- any firm that works in the touristic sector and benefits from advertising and publicity services according to a contract or any other kind of agreement with another person, has to pay to the local budget a tax. This tax is calculated by applying the quota of 1 – 3% of the value of the advertising and publicity services. At the same time, any touristic company that use a notice board, poster board or any other kind of board for advertising and publicity in a public place has to pay a tax to the local budget of the local

public administration in the area of which the respective notice board, poster board or other kind of boards are placed.

- some touristic companies organize artistic performances or entertaining activities. They must pay to the local budget the tax on performances. The tax quota is 5%. For a play, ballet, opera or any other kind of musical performances, for the broadcasting of a movie in a cinema hall, or for a performances at the circus, the tax quota is 2%. In case of artistic performances or entertaining activities that take place in a discotheque, the tax is calculated according to the area of the respective building inside of which the respective performance takes place, according to the sum fixed by the local council.

- the local council can levy a tax on the accommodation in a hotel, in a place which falls under its authority. This tax, called the hotel tax, is collected by the respective hotels when the person are accommodated. The tax quota is between 0,5 – 5% and is levied on the accommodation tariff, according to the number of stars of the hotel. This tax is benefic, if it is levied in accordance with its goal: to promote the sustainable touristic development of the respective area.

The profit tax has undergone significant changes during transition. Since the 1<sup>th</sup> of January 2000, the taxation quota of the profit tax has been reduced from 38% to 25%. Even this quota was too high for the touristic companies, because every 3 – 5 years, the touristic structures for accommodation, food or entertainment must be modernized to increase the value of the services offered. A good measure for touristic companies is reducing the value of the profit tax from 25% to 16%, starting with the 1<sup>th</sup> of January 2005. Such a reduced quota, together with the simplification of the present settlements, will contribute to the development of the business of the touristic companies, especially by increasing direct investments in touristic structures.

We must take into account the fact that many of the touristic companies are small enterprises. A small company is a Romanian legal entity with fulfils the following condition:

- it produced material goods; provides services and/or carries on commercial activities;
- it has 1 up to 9 employees;
- the value of its income does not exceed 100.000 euros;
- the registered capital of the respective legal entity is held by persons, other than the state, local authority an public institutions.

For this, in 2001, the profit tax was replace by the tax levied on all those persons' incomes, calculated with a 1,5% quota for all the incomes irrespective of their source. The value of this quota was increased to 3%,

starting with the 1<sup>th</sup> of January 2005. This was a rather controversial measure and some economic analysts criticized it. However, both the measure of levying a tax of the income of small enterprises and that of reducing the value of the profit tax have in view the stimulation of economic activity and fighting fiscal evasion. The former goal seems to have been achieved by the small enterprises that work in the touristic sector, although this is not due only to the taxation system. But the measure taken by Romania's Parliament when adopting this tax as low, to allow the small enterprises to choose between the tax levied on small enterprises and the profit tax are not very good. It allows fiscal evasion.

The Value Added Tax (VAT) has undergone significant changes during the entire period of transition. The enforcing of VAT in Romania was promulgated by law in July, 1992. Although the law had to come into force on the 1<sup>th</sup> of January 1993, it has been enforced since the 1<sup>th</sup> of July 1993. The VAT was the less stable of all the taxes enforced in Romania. Initially, Romania introduced a system with two quotas: a normal one of 18% and the zero quota; shortly after this, a reduced quota of 9% has been added to these, a quota that was also applied to the tariffs in the Romanian touristic industry. In time, the settlements for VAT have undergone many changes, the most important of these being the reduction of the number of products and services exempted by VAT, but also the number and the value of the taxation quotas. Thus, as far as the level of quotas is concerned, these underwent changes of the 1<sup>th</sup> of February 1998, the normal quota being of 19% and, as a result of this, the tariffs in Romanian touristic industry were calculated using this quota.

The present fiscal code, which came into force on the 1<sup>th</sup> of June 2005, has in view a standard quota of 19% and a reduced one of 9%. This reduced quota of 9% is enforced when accommodating in the hotel sector or in other similar sectors, including the hiring of those lands for camping. A low value of VAT can stimulate any touristic company, in a case in which the tariffs of touristic companies are rather high because of the advantage of the price for electric power, water, to which the normal quota of VAT is also applied. The same reduced quota of 9% is applied to the tariffs for entering castles, museums, memorial houses, historical monuments, architectural and archeological monuments, zoos, botanical garden, fairs and exhibitions. But the accommodation, food and treatment services provided by the companies that work in spas or health resort are exempted by paying the VAT, if they have contracts with The National Pension House and Other Rights for Social Insurances.

The 6th Directive of the European Union Council caused the successive changes undergone by the VAT. This process will go on; a series

of fiscal facilities is to be eliminated by the moment of Romania's integration. At the same time, some exceptions stipulated by the 6th Directive which, in the present, are not enforced in Romania, as well as some special treatments for small entrepreneurs, agricultural producers and touristic companies are to be introduced in our legislation.

The present government has in view to keep the present settlements for VAT for a certain period of time; the positive effects of fiscal relief on income and profit will increase the value of VAT up to 16% in accordance with the settlements of the comunitary acquis.

We are going to see if Romania's taxation is burdensome or not (Table no. 1).

**Table no. 1. The evolution of Romania's tax revenue in case of inhabitant in dollars and the general and partial taxation degree as well as that for social purposes in the period 1991 – 2003**

D) Partial taxation degree: (taxes) x 100 / GDP

E) Taxation degree for social purposes: (Contribution to social insurances.x 100) / GDP

Source: *The Reports of the National Bank of Romania, 1991 – 2003.*

It is not my intention to analyze the manner in which the taxation degree (general, partial and for social purposes) evolved in the period 1991 – 2003. It was an oscillating evolution, reflecting the options of the governments that ruled the country during the above-mentioned period. However, the general trend is a decreasing one, being influenced both by the measures of economic and fiscal reform and by the functioning of the economy. My intention was to observe if the taxation is or not burdensome for companies. Having in view the data shown in the above table, we can conclude that the level of taxation is very low in Romania as compared to

that of other countries, especially the European Union countries, where the general taxation degree is between 30% and 55%. This contradicts the opinion of most Romanian citizen.

These low value of taxation are especially due to the fact that the statistics take into account only the tax revenue cashed by the state which, according to some sources, represent only half of the fiscal and social liabilities owed by the tax payers, according to law. Therefore, if they all were collected, the tax degree would be 50 – 60% of the Gross Domestic Product. But in Romania, they are taxpayers that declare and pay all the fiscal and social liabilities correctly, case in which taxation becomes a real burden. At the same time, there are also tax payers that neither declare pay anything or pay only a small amount of the fiscal and social liabilities, and these ones do not feel taxation as burdensome.

Therefore, although the medium level of taxation in Romania is relatively low as compared to that of about 30% of the Gross Domestic Product in other states, taxation is not evenly distributed so that, where as some tax payers pay a taxation of only 10 – 20%, others pay one of 50 – 60%. Most of these are companies working in the touristic sector. At the same time, it is much difficult to take 500 dollars of a 1,800 dollars GDP than taking a sum of money ten times larger of a similar GDP. Although, in both cases, the taxation degree is the same, in the former situation the money remaining after the payment of the respective tax is hardly enough to satisfy personal needs.

## **5. Fiscal Measures for Encourage companies of Touristic Sector**

By introducing the new fiscal policy measures, the present government hopes a tax relief as a means to encourage the business environment, the private initiative and to make legal the underground economy.

Public authorities can use fiscal policy to achieve such goals as:

- influencing the economic processes;
- correlating the economic cycle;
- eliminating the economic dysfunctions.

It is obvious that these goals do not have direct effects on tourism, but they contribute to the process of developing the economy as a whole and to macroeconomic stability; in their turn, these have direct effects on touristic development. A second class of goals has in view the way in which the

measures of fiscal policy influence the activity of companies in general, these, in their turn, influencing directly the companies working in the touristic sector.

Fiscal policy can contribute to economic stability. The fiscal measures compensate the fluctuations of the investment demand eliminating, thus, side effects. Tax abatement, together with the increasing of public expenses is a strategy used, as a rule, during recession, whereas the opposite fiscal measures are used when the aggregate demand tends to become excessive. At the same time, we must take into account the ratio taxation economic circumstances.

On the other hand, the measures taken under certain circumstances can influence the yield of certain taxes, on the other hand these can be used to influence the economy, the fiscal goals being the economic recovery. Beside this, we must have in view the fact that the macroeconomic balance depends on that achieved at the budgetary level. Achieving the budgetary balance requires either diminishing the governmental expenses or increasing the tax values, all these being closely connected to the situation of the economy analyzed in the framework of the fiscal policy of the state.

In order to develop a competing economy, the fiscal policy must correlate the goal of sustainable growth with the requirements of economic stability. Fiscal policy must contribute to encouraging savings and investments by:

- controlling the budget deficit;
- completing the fiscal reform;
- rationalizing the budget options in accordance with the priorities established in the field of expenses;
- ensuring transparency in spending public money.

The most important thing when it comes to the influence of the fiscal policy on companies is its effects on saving and forming the capital. An increase of taxation has as consequence the reducing of savings and of the capital for investments. It is a well-known fact that in tourism, perhaps more than in other fields, upgrading of touristic structures are necessary, in order to enhance the quality of the services provided. So, taxation can hinder the evolution of the companies working in the touristic sector.

Various types of fiscal measures can be used to encourage companies of touristic sector. The most important ones are:

- granting fiscal deductions, for limited periods of time, representing a share of the value of the investments;
- reducing the tax rate for firms for that part of the profit which is ploughed back;

- reducing some of the investment expenses (tax exemption for imported equipments, fiscal reduction for imposing a tax on equipments, etc.);
- granting fiscal reduction for those firm which work hard in the research sector or in professional training or for those which function in disfavored areas;
- granting fiscal reduction, subventions or fiscal incentives for those firms that take measures to protect the environment;
- adopting special fiscal regimes for the groups of companies thus allowing the fiscal integration of the whole results of the group;
- tax exoneration, exemption, reducing or delaying the tax payment;

The budget measures can also influence the touristic development. Among these mention can be made of the financing from the state budget and the local budgets of those touristic activities which encourage the development of any areas and components of touristic offer and promote, in other countries the Romania touristic destination.

## **6. Conclusion**

The fiscal policy can be beneficial for tourism development in Romania if one takes into account the actual state of things in Romanian tourism, the present requirements and future needs; otherwise, if all these are not taken into account, the fiscal policy can hinder the development or even cause the recession of this important field of national economy. Fiscal policy has a positive impact on tourism development only in the case in which public actions are undertaken having in view the priorities in every stage of development, have economic, social effect or other kind of effects correlated with the financial effort, takes into account simultaneously the short-term plans and the middle and long-term plans.

By means of fiscal policy, the development of touristic sector can be protected or encouraged; in such a way, fiscal interventions have in view such goals as: the encouragement of the companies working in the touristic fields to make investments, the improving of the quality and competitiveness of touristic services, the encouragement and promotion abroad of Romanian touristic destinations, the protection of the environment.

## **Abstract**

*The spectacular evolution of the leasing market in Romania has determined the association of leasing companies into professional associations, as well as the emergence of a coherent and professional legal framework. The present study aims at examining the way in which leasing operations, irrespective of their type, influence the financing of the activity performed by both individuals and legal entities. The leasing companies begun to separate based on the services offered, to get to be known by financing objects specific to several market niches. The market's evolution to a superior stage is although conditioned by the sustainability of the economic growth and also by the strengthening of the business environment in Romania. Data in 2004 show that the leasing is a financial product adapted to the Romanian market requests, despite of unfavorable impact of legal background. The increase of leasing companies' portfolios quality, availability of financing sources and the accurate analysis of clients' creditworthiness are considered the main success factors.*

**Keywords:** *financing, through leasing, leasing companies, financial leasing, lease-back, time-sharing, leverage leasing.*

## 1. Introduction

The increase of macroeconomic ratios and especially their contribution to the companies' income, inflation decrease and the necessity of technological upgrade through investments represent just a few of the factors which will impact the leasing market. Moreover, the premise of implementation of the project for leasing regulations' modification shall contribute to the development of such operations. Even if the new regulations will not bring the necessary clarifications, the experience has proven that even with an insufficient legislation, the leasing is considered a very well known activity on the Romanian financial market. Needless to say that by including the software applications among the goods which can be bought in leasing will increase the market share of leasing companies which will assume the additional risks related to such financings.

The development of leasing operations is closely linked to economic development as a whole, therefore, the technological upgrade, production of goods, the sales and circulation, new services are just a few of the important gains for the leasing activity.

## 2. Legal requirements regarding leasing activity

A first legal definition of the leasing process in Europe appears in France, and it is called "crédit-bail", according to the law nr.66-455, from the 2<sup>nd</sup> of July 1966. It included only the real estate leasing, defining the "crédit-bail" process as being a company which can give you real estate stuff for professional use, stuff bought or built by the company itself. The order nr.67-837 from 28<sup>th</sup> of september 1967 made complete the law from the 2<sup>nd</sup> of July 1966, differentiating the "crédit-bail" process for personal goods, from the "crédit-bail" operations for imobil stuff and creating the S.I.C.O.M.I. Status (real estate companies for industry and trade).<sup>1</sup>

As one can notice from the legal regulation concerning the leasing process of the states members of the Leaseurope, many countries in Europe had no specific legal legislation.<sup>2</sup> So, the leasing operations are the subject of the general regulations of the civil and / or commerciale legislation.

---

<sup>1</sup> E.M.Bey, C.Gavalda (1983) – *Le crédit-bail immobilier*, Presses Universitaires de France (PUF), Paris, pag.7

<sup>2</sup> Source : [www.leaseurope.org/pages/Leasing/Legal\\_Aspects/Leasing\\_Legal.asp](http://www.leaseurope.org/pages/Leasing/Legal_Aspects/Leasing_Legal.asp)

As it concerns the regulation procedure of the leasing companies from the countries-members of the Leaseurope, one can notice that the ones that belong to France, Portugal, Hungary, Spain and Italy is under the supervision of the Central Bank, whereas the leasing companies from Luxemburg and Sweden are under the supervision of the Supreme Financial Authority. In Belgium and Germany, the subsidiaries leasing companies of some banks, enter, indirectly , under the supervision of the Central Bank.

In countries like Belgium, Greece, Luxemburg and Norway are necessary special approvals for the setting up of leasing companies. With the exception of Greece and Spain, there is no other country known as a member of the Leaseurope where is made a distinction between the leasing operators from the UE and the ones that are not residents in the UE; but in Spain is also needed an authorization from the Ministry of Finance for the leasing companies that are not resident in the UE.

As it was mentioned above, few countries have a specific legislation in the leasing field, although more and more countries are about to legislate the leasing and the progress made in this field is accelerating. Where such laws were put into operation , these were molded according to the Unidroit Convention on International Financial Leasing.<sup>3</sup> Although the Convention is oriented towards international transactions, it is a useful pattern for the internal regulations from each country that needs a specific leasing legislation.

In Romania, the first leasing contracts have spread out before the existence of a special law intended to the regulation of this operation. As a result, the way of approaching the leasing was more similar to a let out.

The first regulation concerning the leasing appeared in Romania due to the Government's ruling no.51 dated on the 28<sup>th</sup> of August 1997 regarding the leasing operations and the leasing companies, that forecast that the leasing is an operation “ in which a part, also known as lessor, is engaged , following the instructions of a second part, also known as a lessee , to purchase from a third part and to confer the usage and the possession of a

---

<sup>3</sup> The Unidroit Convention regarding the International Financial Leasing, signed on the 28<sup>th</sup> of May 1998 at Ottawa, establishes the juridical backround upon which should take place the leasing operations and should be solved the recent litigations, leaving to the “common law ” the fixing of the competent instances for solving these litigations.

mobile or immobile good, with the purpose of its commercial exploitation or for the final consumption”<sup>4</sup>.

In rule no.90 dated on the 28<sup>th</sup> of April 1998<sup>5</sup> for the approval of the Government’s ruling no 51/1997 some changes have intervened, such as: “the lessor is obliged, at the lessee’s request, to purchase or to take over from a third part, also known as a supplier, a mobile or immobile good and to assign the lessee with its possession or usage, in exchange of a payment called due, with the purpose of exploiting or purchasing the good”<sup>6</sup>.

It can be noticed that in the new exact wording the *employment* of the lessor is transformed into *obligation*, and the user’s indication becomes *request*. As well, the lessor can *overtake* the good, not just buy it. Furthermore, concept of *supplier* appears. The term *to confer* is replaced by the *assigning* of the possession or usage ( here appears or instead of and) upon the good. At the same time, the purpose of the exploitation is no longer reduced to the *commercial* one or to the *final consumption*, the purpose being, according to the new formulation, the plain and simple exploitation or the acquisition of a good.

In January 2000, the Government’s ruling no.51/1997 was republished, on the grounds of art. VII from rule no.99/1999<sup>7</sup>, and the definition comprised in the new regulation is the following: the leasing is that operation “ by which a part, known as lessor /financier, assigns for a limited period of time the right of usage of a good whose owner is the other part, known as lessee, at the last one’s request, in exchange of a periodical payment, called leasing installment, and at the end of the leasing period, the lessor /financier is obliged to respect the user’s right of the option to purchase the good, to extend the leasing contract or to put an end to the relations stipulated by contract<sup>8</sup>.

In the new definition of the leasing operation also appears the term *financier* , and *the due* has been replaced with the notion of *leasing*

---

<sup>4</sup>Government’s ruling no.51/1997, art.1,align.1 ( the initial form of the ruling )

<sup>5</sup> Published in O.M. no.170 dated on the 30 of April 1998.

<sup>6</sup>Rule no.90/1997,art. I, point 1.

<sup>7</sup>Published in O.M. no.236 dated on the 27<sup>th</sup> of May 1999. Rule no.99/1999 also known as “The rule regarding a few measures for the speeding of the economic reform” has six titles, title II being “The modification and completion of the Government’s ruling no.51/1997 regarding the leasing operations and the leasing companies”.

<sup>8</sup>Government’s ruling no.51/1997, republished ,art.1,align.1.

*installment*. In addition, the possibility of assigning the right of possession disappears, the notion of possession being used incorrectly, because, in juridical terms, possession signifies either an attribute of the property law, when the property law is exerted by the owner, or a state of things, respectively a material ownership of a good due to an annullable title, which permits the owner the acquirement of a property through usurpation<sup>9</sup>.

This triple option which is at the user's hand **differentiates** the leasing contract from other contracts and confers **individuality** to it. For example, the location contract does not bring upon any sales obligation, the inhabitant being obliged to return the good in the same condition it was given to him at the very beginning.

The location-sales contract mentions lessee's obligation to purchase the good taken into location, being assigned to him the property over the good which makes the object of the contract at the same time with the payment of the last installment.

The sales contract with the keeping of property until the payment of the price subordinates the transfer of the property to the complete payment of the price. The sales on credit contract transfers immediately to the buyer the property over the good.

### **3. The evolution of leasing in Romania**

Leasing has proved to be one of the most dynamic areas of Romanian economy, its positive evolution being the more important if we consider the difficult conditions specific to the Romanian economy at this point such as the slow privatization process that has determined foreign investors to keep their distance and, most significant of all, the financial scandals linked with the disappearance of commercial or popular banks and of investment funds, all of the above mentioned having a strong impact on the whole Romanian financial system.

The leasing market has thousands of economic agents who fulfill the main conditions requested by law in order to be marketers: the inclusion of the "leasing activity" in the activity object category and an equity capital of 500 million lei.

---

<sup>9</sup> D.Clocotici, Gh. Gheorghiu – *Operations of leasing*, Edition Lumina Lex, Bucharest, pg.32.

### **3.1 Dimensions and degree of concentration on the Romanian leasing market**

There are two representative associations of this industry in Romania: The Romanian Leasing Association of Companies (ASLR) and The Banking Leasing Association (ALB).

**The Romanian Leasing Association of Companies (ASLR)** <sup>10</sup> was founded in 1996 as a professional nongovernmental, nonprofit, nonpolitical and independent organization created with the purpose of developing and extending cooperation and collaboration in the leasing operations area. Beginning with the year 2002 ASLR is a member of Leaseurope.

**The Banking Leasing Association (ALB)** was funded in April 2004 reuniting eight of the leasing companies subsidiary to the Romanian commercial banks, all of them with foreign capital.

Considering the data offered by the ASLR we can conclude that the evolution of the Romanian leasing market has been an upward dynamical one as we see in table 1 .

**Table 1 The value of goods financed in leasing - EUR mln.-**

---

<sup>10</sup> The initial name of this organization has been “The National Union of Leasing Companies in Romania” (UNSLR), it was changed in June 2003 to “The Romanian Leasing Association of Companies” (ASLR).

\*We add that the total value of goods financed in leasing accomplished by ASLR members is only an estimate, as there is no unitary report base for these participants yet.

**Figure 1 The evolution of the Romanian leasing market (regarding value of goods, in million euro)**

*Source: ASLR reports*

The evolution of the Romanian leasing market in the last few years is as follows (table 2):

**Table 2 The evolution of the leasing market (at ASLR level)**

	1998	1999	2000	2001	2002	2003	2004
<i>Number of contracts</i>	6,160	8,746	7,854	14,991	36,093	34,027	49,361
<i>Variation</i>	-	41.98%	-10.20%	90.87%	140.76%	-5.72%	45.06%
<i>Value of goods (million euro)</i>	128.5	202.9	340.0	587.6	624.1	706.3	841.1
<i>Variation</i>	-	57.9%	67.5%	72.8%	6.2%	13.17%	24.63%
<i>Value of contracts (million euro)</i>	-	-	-	-	-	850	1,029
<i>Variation</i>	-	-	-	-	-	-	21.06%

*Source: ASLR reports*

We can observe that, beginning with 1998 the volume of transactions concluded at ASLR level has registered continuous increase, so that by the end of 2003 the value of goods financed in leasing has been of approximately 0.71 billion euro, respectively a total value of contracts (goods, interest rates and commissions) of about 0.85 billion euro. Although the value of goods financed in leasing has grown in the year 2004 by almost 25% compared to the year 2003, the total value of contracts has only grown by 21%, a fact that proves the reduction of financial and non-financial expenses to be stood by leasing users.

By the end of **the first quarter of 2005** the registered value for goods financed in leasing has been 215 million euro and the total value of contracts 265.5 million euro.

In addition to that, the number of contracts has been situated on an upward slope from 6,160 in 1998 to 36,093 in 2002 and 34,027 in 2003 reaching by the year of 2004 the value of 49,361, 45% more than in 2003. In the first quarter of 2005, at ASLR level, 13,477 contracts have been concluded. This evolution can be explained by taking multiple factors into consideration such as the annual increase in the number of members (17 in 2000, 37 in 2004, 33 in the first quarter of 2005), the market development, the clients awareness regarding the importance of leasing transactions as a way to finance their investments.

Considering the distinction between financial and operational leasing, the main direction of leasing contracts carried on by the company members of the ASLR is towards financial leasing. This can be clearly identified from the data shown in table 3.

**Table 3 Financial versus operational leasing (at ASLR level)**

	<i>Financial leasing</i>							<i>Operational leasing</i>			
	2002	2003		2004		Trim.I 2005		2002	2003	2004	Trim.I 2005
	<i>Total</i>	<i>Total</i>	<i>Of which cross border</i>	<i>Total</i>	<i>Of which cross border</i>	<i>Total</i>	<i>Of which cross border</i>	<i>Total</i>	<i>Total</i>	<i>Total</i>	<i>Total</i>
<i>Number of contracts</i>	90.1	92.65	2.16	95.93	0.97	96.54	0.89	9.9	7.35	4.07	3.46
<i>Value of goods</i>	88.4	86.03	5.8	92.96	2.05	96.23	2.8	11.6	13.97	7.04	3.77

*Source: ASLR reports*

The preference towards financial leasing operations can be explained by the much clearer definition of this form of finance compared to operational leasing. The value of cross-border leasing operations (carried on by leasing companies not residing in Romania) was in 2003 5.8% of the total value, about 39.14 million euro, in 2004 their weight dropped to 2.05% of the total value, about 17.22 million euro. Without regard to the type of shareholders, most of the clients of leasing companies are legal entities.

At ASLR level, in 2004, the value of goods financed through leasing represented about 74.90% of the total market, 17.40% being held by the public division the rest of 7.70 concerns legal entities. In the first quarter of 2005 the value of goods financed through leasing in the case of legal entities represented about 63.42% of the total market, 26.78% concern the public division and ONG and the rest, 9.8%, belong to legal entities.

The significant growth of the finance weight for the public division and the ONG by over 9% compared to the statistical data obtained for the year of 2004 is a notable fact. Table number 4 describes the situation of contracts concluded with legal entities in 2004 compared to 2003, reported to the global market for ASLR members, depending on the value of financed goods and the number of contracts.

**Table 4 The situation of contracts closed with legal entities**

	<i>Financial leasing</i>		<i>Operational leasing</i>		<i>Total</i>	
	<i>2003</i>	<i>2004</i>	<i>2003</i>	<i>2004</i>	<i>2003</i>	<i>2004</i>
<i>Value of goods (million euro)</i>	492.5	704.14	32.8	30.06	525.3	734.2
<i>% Of the total market</i>	72.97%	83.71%	4.86%	3.57%	77.83%	87.28%
<i>Number of contracts</i>	28,012	40,963	2,106	1,948	30,118	42,911
<i>% Of the total market</i>	82.32%	82.98%	6.19%	3.94%	88.51%	86.92%

*Source: ASLR reports*

In the “clients of legal entities” category, a distinction between the private and the public division can be made. Thus, of the total 49,561 contracts carried on in 2004, the majority were linked with the private division, that means 84.47%, the public division, other clients division and ONG representing about 15.52%.

We must also notice the awareness of the public division concerning this form of finance, the evolution of leasing finances being, in this case, a spectacular one (from 1% in 2003 to 15.52% in 2004).

The companies belonging to ALB concluded in 2004 a number of 18,200 contracts with a total value of 544 million euro, 81% more than in 2003 when approximately 9,000 contracts with a total value of 300 million euro had been concluded.

From the total number of contracts concluded by the members of this association 95% are finances for corporate clients, 3% for the retail component and 2% belong to the public division.

The legal entities segment has dominated the market represented by company members of ALB with a weight of 96.63%, the quote for legal entities being only 3.21%.

Most of the leasing contracts closed were those with external suppliers: 75.4% and 65% of their value in 2004 for ASLR and respectively ALB.

A classification of leasing contracts made by the ALB depending on the tenor span indicates the fact that 60% of these contracts are between 1 and 3 years, more than 31% are between 3 and 5 years and the rest of 9% have a maturity greater than 5 years.

Parallel to the continuous growth of the market, a tendency of concentrating the leasing operations to a smaller number of companies can be observed. Thus, we find, with a volume of financed goods of about 1.5 million euro in 2004, Porsche leasing, Afin Romania, BCR Leasing, RCI Leasing and Tiriac Leasing – 5 of the 37 companies who have subscribed to ASLR in 2004 – totalizes a market quote of about 36%. Also, the 9 companies belonging to the ALB own another 36.26% of the market.

\*\*\* The numbers were calculated considering the volume of financed goods for the entire market (1,5 billion euro) and the volume financed by each of the companies

Note that bank subsidiaries and captive societies belonging to dealers like Porsche, Iveco or Renault occupy the first positions. Motoractive, TBI Leasing, Romstal leasing and Ager Leasing are the only independent companies who have found a place between the top ten companies of the ASLR.

This polarization is natural because a small sized leasing company as well as a recently funded one cannot overcome the classification, winning a strong position on the market depends greatly on the financial power and the involvement of the shareholders in the activity of the company, simultaneously with an approach of the segments with great development opportunity such as equipment or real estate.

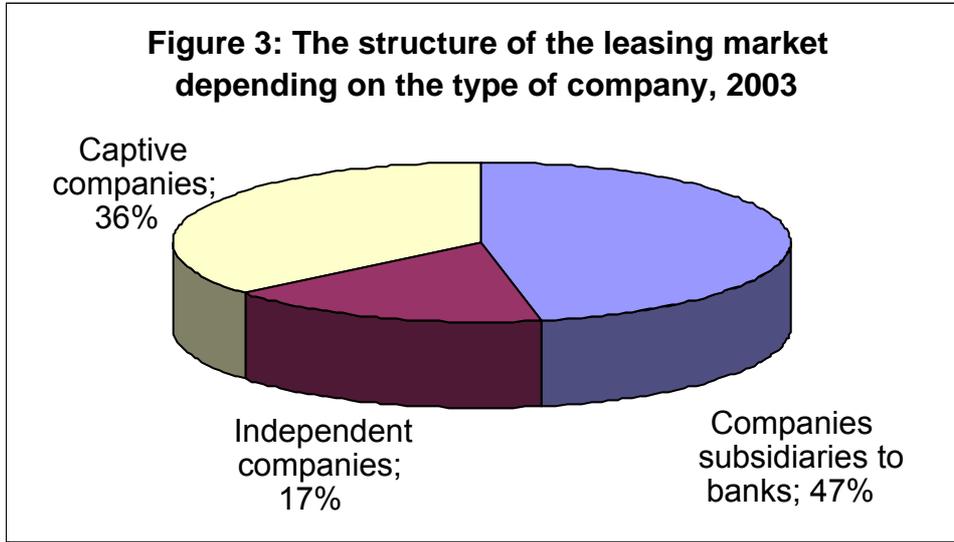

The present configuration of the market is determined not as much by the efficiency of the large companies as by the incapacity of the smaller, especially the independent ones, to raise funds from banks, either due to a weak capitalization or because they weren't able to find a suitable niche on the market. The large weight of companies, subsidiaries to the banks in the market is a consequence of the accessibility to competitive financial resources and a larger clients base.

In the perspective of joining the EU, leasing is expected to evolve in the direction of a stronger structuring of the market between companies affiliated to banks or with a bank status, belonging to manufacturers and independent companies.

The concentration trend of the market is also confirmed by a study of the ALB showing that half of the leasing market belongs to companies subsidiaries to banks, while captive and independent companies have a share of 33% and, respectively, 17%. Together with the nine companies belonging to the ALB, the study has also taken into account the data of BCR Leasing, Romexterra Leasing, Egnatia Leasing, D.R.T. Leasing and Immorent. According to the data of the ALB, contracts that were closed last year by its nine companies represented at the time about 75% of the total volume of contracts financed by all leasing companies affiliated to banks.

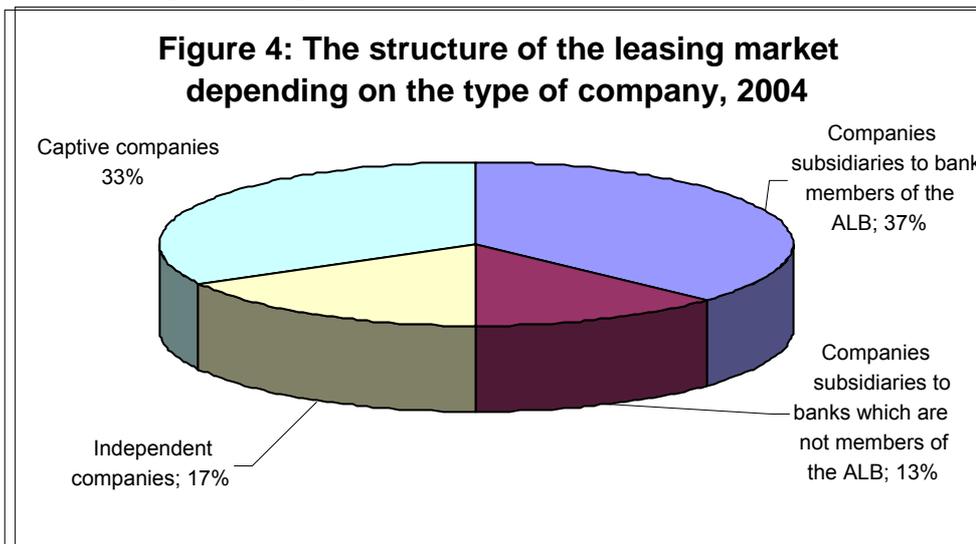

**Figure 3 The structure of the leasing market depending on the type of company, 2003**

- Companies subsidiaries to banks 47%
- Independent companies 17%
- Captive companies 36%

**Figure 4 The structure of the leasing market depending on the type of company, 2004**

- Companies subsidiaries to bank members of the ALB 37%
- Companies subsidiaries to banks which are not members of the ALB 37%
- Independent companies 17%
- Captive companies 33%

### 3.2 The portfolio of leasing companies in Romania

The different shareholder – types bank, automobile manufacturer, or investors – influences the portfolio of financed goods.

The access to considerable and competitive financial resources for periods exceeding three years, the capacity to analyze a good business plan, risk reducing management strategies or the sales policy in the particular case of captive companies all ensure availability for financing well defined categories of goods.

**Table 7 The portfolio of the ASLR and ALB members depending on the financed goods**

	<i>ASLR</i>				<i>ALB</i>	
	<i>2002 *</i>	<i>2003 *</i>	<i>2004</i>	<i>Trim I. 2005</i>	<i>2004</i>	<i>Trim. I 2005</i>
<i>Auto</i>	75.30%	87.84%	92.67%	91.47%	70%	72%
<i>Equipment</i>	23.86%	10.46%	7.07%	7.71%	26%	25%

\* Alpha leasing, BRD Sogelease, HVB Leasing and UniCredit leasing, companies presently reunited in ALB, were in 2002 and 2003 also members of ASLR.

*Source Mediafax – Financial Directory 2005*

At ASLR level, an organization reuniting 33 members at the end of the first quarter of 2005 compared to 37 members at the end of 2004, 75% are independent leasing companies, 15 % are leasing companies affiliated to manufacturers or goods suppliers and 10% are leasing companies subsidiaries of banks. The structure of leasing contracts at ASLR level depending on the object of the contract is shown in table nr 8.

**Table 8 The structure of leasing contracts depending on the object of the contract**

	<i>2002</i>	<i>2003</i>	<i>2004</i>	<i>Trim. I 2005</i>
<i>Vehicles</i>	75.30	87.84	92.67	91.47
<i>Cars</i>	33.70	56.25	61.06	72.02
<i>Auto utilities</i>	41.60	31.59	31.61	19.45
<i>Commercial vehicles</i>

<i>Industrial equipment</i>	10.06	5.90	4.04	5.18
<i>Agricultural equipment</i>	6.40	2.32	0.67	0.21
<i>Planes / ships</i>	-	0.03	-	-
<i>Rolling material - railways</i>	-	0.02	-	-
<i>Other (office materials medical technique)</i>	7.40	2.19	2.36	2.32
<i>Real estate – office</i>	0.84	1.60	0.21	0.57
<i>Real estate – residential</i>	-	0.10	0.05	0.25

*Source: ASLR reports*

In case of companies reunited in ASLR the segment of auto vehicles dominates leasing operations representing 92.67% in 2004. Automobiles have won for themselves 61.06% followed by auto utilities, commercial vehicles and busses with 31.61%. On the following positions we find industrial equipment with a 4.04% quote, farming equipment with 0.67%, while real estate represents only 0.26%. In contrast with the preceding years, a considerable drop of equipment finances can be noticed. The downward trend in this segment at ASLR level can be explained through the fact that companies such as Alpha leasing, BRD Sogelease, HVB Leasing and UniCredit Leasing, presently constituents of the ALB, have been members of ASLR in 2002 and 2003.

**Table 9 The structure of leasing contracts depending on the object of the contract (at ALB level)**

	<b>2004</b>	<b>Trim. I 2005</b>
<i>Auto vehicles, of which:</i>	70.87%, of which:	72.78%, of which:
<i>Automobiles</i>	54%	55%
<i>Heavy auto vehicles</i>	34%	35%
<i>Light auto vehicles</i>	10%	10%
<i>Equipment</i>	25.87%	24.26%
<i>Real estate</i>	3.26%	2.96%

*Source: ALB reports*

In the case of companies reunited in the ALB, the automobile segment owns a smaller share of about 70%. Of these, 54% are automobiles, 34% heavy commercial vehicles, 10% light commercial vehicles and 2% other types of vehicles. Here we can see a diversification of the portfolio, industrial equipment owning about 26% of the total finances and the real estate segment holding 4%. This type of structure reflects the profile of the companies affiliated to banks addressing at the same time all economical branches. The companies members of the ALB have total assets of 645.6 million euro and over 350 territorial branches. ALB leaders estimate a value of approximately 806 million euro for the bank leasing market at the end of 2005.

First quarter operations in 2005 haven't been able to bring about major changes in this direction.

#### **4. Conclusion**

Leasing plays a very important role in the investment conduct, having a significant importance for the economy as a whole and contributing in a positive manner to the general economic situation.

In Romania, the leasing can not be cheaper than the loan, for the simple reason that the majority of the leasing companies are financed by the banks in order to be able to purchase the goods that will make the object of the future contracts. According to LCAR estimations, at present, the banks require, as an average, an interest of 8 - 9% in foreign currency, while leasing companies apply an average of 11 % interest.

The cost of the leasing is influenced by the credit risk of the enterprise. This is the reason why, it is more convenient to make an individual comparison of the cost of the two forms of finance, by taking in consideration the profile of the beneficiary enterprise and, at the same time, the residual value risk taken by the lessor and the credit availability (a rational enterprise can be determined to accept a high price in order to give up its investment project).

As opposed to the financial leasing, in which case the locator presents the value of the leasing installment value, as well as the deducted value of the leasing installments in liquidations and interests, as far as the operational leasing is concerned, the debit installment is rarely known by the beneficiary of the loan, because this information is not made known by the locator through other means but the installment graphic, and not as a interest installment, as the bank creditors do.

Also, the comparison of the costs of the two forms of finance (loan or leasing) has to be drawn up upon the cost after tax. Due to this aspect, the integral deductibility of the leasing installments, an aspect valid in Romania just as far as the operational leasing is concerned, can represent an argument concerning the usage of leasing<sup>11</sup>, unlike the bank loan, in which case just the expanses with interest are deductible (the enterprise has the right to liquidate the good and to deduct the endowments from the liquidations).

Another advantage of the leasing is that it improves the structure of the balance sheet of the enterprise. Even if this argument is often quoted by the lessors to justify the enterprises' motivation in choosing the leasing, considering the present approach of the leasing's accounting. Even if this leasing variant is not registered in the balance sheet of the lessee enterprise, this form of financing is considered as being an indebtedness form and treated accordingly by the financial institutions and by the financial analysts, regardless of the mean of reflection in the financial situations.

Even if the advantages which incite to the usage of the leasing exist, the enterprise can limit the resort to this form of financing and prefer instead the

---

<sup>11</sup> This aspect is applied only if the leasing installments are normal: the residual value shouldn't be too small, because, in this case, the leasing installments grow, thus growing the deductible expenses as well. If the leasing installments are decreasing, they must have a similar value to the fiscal liquidations which would have been used if the enterprise was the owner of the good; the value of the leasing installments paid in the first year must not overcome 50% of the total installments value, if the duration of the contract is 3 years, 40% for a 4 year contract and 38% for a 5 year contract.(A. Maheu, C. Maige(1998)-*Op.cit.*)

bank loan, if the extreme negative effects of the leasing are high. They refer, in principal, to the loss of the operational flexibility of the utilizing enterprise.

## **Abstract**

*The paper deals with the relationship between monetary policy and asset prices. Besides surveying the general discussion, it attempts to extend it to recent developments the New Member States of the EU (NMS), namely in the Czech Republic, Hungary, Poland and Slovakia (EU4). After a brief description of current macroeconomic situation in the NMS, the appropriate reaction of monetary policy to asset prices bubbles is dealt with and the main pros and cons associated with this reaction are summarised. Afterwards, the risks of asset markets bubbles in the EU4 countries are evaluated. Since the capital markets are still underdeveloped and real estate prices boom seems to be natural reaction to the initial undervaluation, the risks are viewed as rather small. The conclusion is thus that for a central bank in mature economies as well as in the NMS is crucial to conduct their monetary policies as well as its supervisory and regulatory roles in a way that does not promote build-up of asset market bubbles. In exceptional times, central banks of small open economies must be ready to use monetary policy steps as a kind of insurance against adverse effects of potentially emerging asset market bubbles.*

## 1. Introduction: Current Developments in New Member States

The new Member States of the European Union (NMS) went through successful stabilization process. With low inflation and pressures for the nominal appreciation of domestic currencies, their central banks lowered short-term interest rates to historically low levels. Figure 1 shows the development of monetary policy interest rates of the selected NMS, namely of the Czech Republic, Hungary, Poland and Slovakia (EU4). There is a significant downward trend in all rates, with the exception of Polish rate during 2000 and Hungarian policy swings during 2003. The lowest rates were always seen in the Czech Republic during the period monitored, which is the only economy with experience of negative interest rates differential against ECB rates.<sup>2</sup>

**Figure 1: Monetary Policy Interest Rates in the EU4 (%)**

*Note: CR=Czech Republic, H=Hungary, P=Poland, SK=Slovakia.*

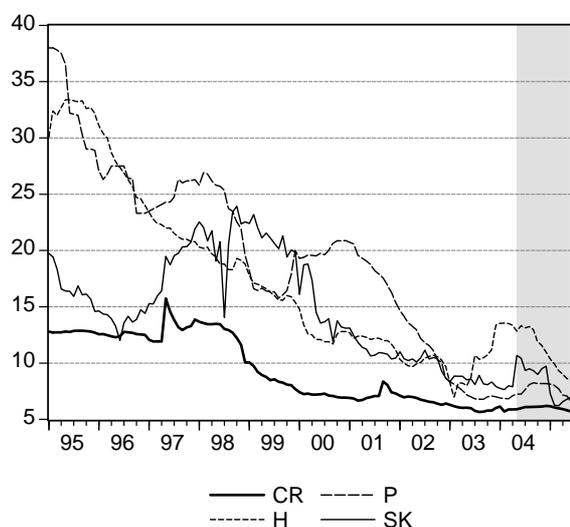

*Source: Eurostat, the EU4 central bank web pages.*

Figure 2 presents the development of the average lending rates of the EU4 countries, which also slope down during the last decade, especially in Hungary, Poland and Slovakia. The Czech lending rates moved to very low levels already in 1999. The long-term nominal interest rates went also sharply down, not only thanks to the expectations of the euro adoption. In addition,

<sup>2</sup> The Czech National Bank was setting the monetary policy rate (2-weeks REPO rate) in three periods below the European (ECB) level: during 26.7.2002–6.12.2002, 31.1.2003–7.3.2003, and 29.4.2005–27.10.2005. The negative interest rate differential was always 0.25 p.p. except for the period 1.11.2002 – 6.12.2002 (0.5 p.p.).

restructured and privatized banks recently began again to extend credit to corporate sector as well as to the households.

**Figure 2: Average Lending Rates in the EU4 (% p.a.)**

*Note: CR=Czech Republic, H=Hungary, P=Poland, SL=Slovakia.*

*Shadow part identifies the EU membership*

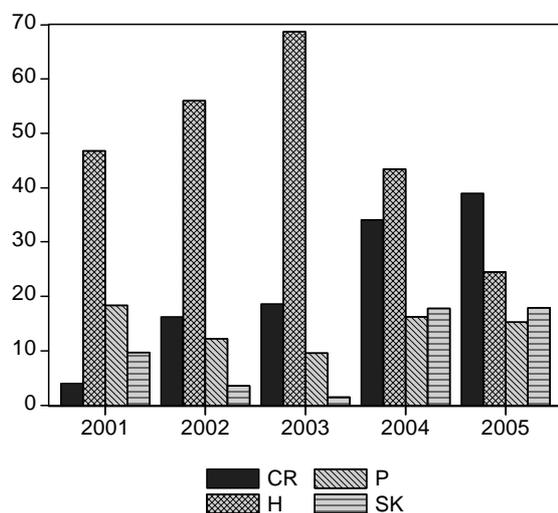

*Source: IMF-IFS CD-ROM.*

The combined effect can be seen mainly in rapid credit expansion in the household sectors, in housing loans segment with yearly increases between 30 to 50% in most countries – see Figure 3. There are fears that the mix of credit boom and optimistic expectations may support investments of a speculative kind and create asset bubbles similar to those experienced by many developed economies in the past. And in the same way, the formation of these bubbles may not be accompanied by visible pressures for consumer prices inflation which is the main focus of central banks. And at the same time, the NMS became part of the worldwide discussion on the impact of low interest rate environment, high liquidity and easy credit availability on the asset markets and on the role of monetary policy in supporting and subsequently taming the asset price inflation.

The central banks in the NMS thus now face the same questions as their counterparts in many developed countries: Are current monetary policies supporting the build-up of asset market bubbles? Should central banks incorporate asset prices into their policy decision process and react by interest rate changes to the asset price inflation? These particular questions have been discussed lively in recent years among central bankers and

academics in the US and many other countries. Our intention is to help to extend the discussion also to the local scene, though it may look premature at least to some observers. For these reasons, we will focus mainly on the mentioned EU4 economies.

## 2. How Should Monetary Policy Respond to Asset Prices?

### 2.1 Importance of Asset Prices for Central Banks

Whether monetary policy should actively seek to encourage asset price<sup>3</sup> stability or even whether monetary policy should seek to prevent or at least reduce asset price bubbles really was one of the key current topics of debate is among central bankers. Despite what media sometimes say, hardly any central banker argues that central banks should completely ignore asset prices and focus only on consumer prices defined in terms of consumer price index (CPI) changes. As stressed for example by Bollard (2004), the economists agree that central banks should take asset prices into account, they disagree on whether they should respond to asset prices drifts.

<sup>3</sup> By an asset price we mean the price of something bought to generate income or to sell for a profit later. Examples are physical assets - like real estate or collectables - and financial assets - like shares, bonds, foreign exchange and other financial instruments.

Central banks automatically take asset price developments into account when setting monetary policy, even if formally they focus on price stability defined solely in terms of prices of consumption. This is primarily because asset price movements impact on CPI inflation and large movements in asset prices can have significant implications for CPI inflation. If prices of real estate, for example, are rising faster than inflation, people try to build more houses. To do it they demand more materials used for building, putting pressure on their prices. In addition to that direct impact, asset price movements also feed into CPI inflation through the "wealth effect". As asset prices rise, people tend to feel wealthier. This can apply with any kind of asset, but in many countries we see this mostly through house prices, due to the high proportion of household wealth associated with housing. The Czech Republic also belongs to countries in which housing has got a major share in household wealth, and at the same time, share of net financial assets is relatively low and does not have a clear tendency to grow. In countries with developed and broad stock markets the wealth effect applies also to share prices.

Asset prices also feed through into spending and hence inflation in other ways. For example, asset price increases improve balance sheets, increasing the borrowing capacity of firms and individuals. Increases in net worth tend to increase the willingness of lenders to lend and borrowers to borrow, facilitating a general expansion in spending as well as an expansion in spending on the investment to appreciating assets. Most of the time asset and consumer prices roughly move together and asset prices present no major problem for monetary policy. There are however times when asset prices move well out of line with underlying economic fundamentals. Sometimes, asset prices can become disconnected from reasonable expectations of future earnings, resulting in speculative bubbles that cannot be justified by economic fundamentals. Sooner or later, speculative bubbles will burst. But a damage they can do to the economy may be quite huge. This brings us to the question of whether central banks should try to constrain asset price bubbles.

## ***2.2 Three Main Opinions on Asset Price Bubbles***

The economists have a variety of opinions on this particular question. We prefer dividing them into three groups. *The first one* is comprised of these who say that central bank should pay attention to asset markets' developments, but cannot and should not try to constrain asset price bubbles on their own. Ben Bernanke, famous academic economist, former Fed governor and a future Fed chairman, seems to serve as the speaker of the group. We will use his words to define the other two groups while explaining

his views on the issue. We will then question his views and explain why more active approach may sometimes be justified.

Bernanke (1999, 2001 or 2002) suggest a very simple rule for central bank policy regarding asset-market instability: Use the right tool for the job. Bernanke (2002) says that the Fed has two sets of responsibilities – maximum sustainable employment, stable prices, and moderate long-term interest rates on one hand, the stability of the financial system on the other. To achieve that, the Fed has two sets of policy tools: policy interest rates and a range of powers with respect to financial institutions. By using the right tool for the job, he mean that the Fed will do best by focusing its monetary policy instruments on achieving its macro goals, while using its regulatory, supervisory, and lender-of-last resort powers to help ensure financial stability.

Bernanke agrees that a central bank must monitor financial markets intensively and continuously. To the extent that a stock-market boom causes higher spending on consumer goods and investments, it may indicate future inflationary pressures. Policy tightening might therefore be an adequate reaction. But the goal of reaction should be to contain the incipient inflation, not the stock-market boom. Central bank cannot be arbiter of security valuation. In other words, a central bank should use monetary policy to target the economy, not the asset markets. He believes that a far better approach is to use micro-level policies to reduce the incidence of bubbles and to protect the financial system against their effects.

To protect financial system, the central bank should use its regulatory and supervisory powers instead. In particular, it should ensure together with other financial sector regulators that financial institutions and markets are well prepared for a large shock to asset prices. To achieve that, commercial banks must be well capitalized and well diversified and they should stress-test their portfolios against a wide range of scenarios. The central bank can also contribute to reducing the probability of boom-and-bust cycles by supporting more transparent accounting and disclosure practices and working to improve the financial literacy and competence of investors. And if a sudden correction in asset prices does occur, the central banks's first responsibility is to do its part to ensure the integrity of the financial infrastructure-in particular, the payments system and the systems for settling trades of securities and other financial instruments. If necessary, the central bank should provide ample liquidity until the immediate crisis has passed.

Bernanke (2002) “sends” the advocates of a more active monetary policy response to asset prices into two broad camps, differing primarily in how aggressive they think the central bank should to be in attacking the

bubbles. *The first group* favours the lean-against-the-bubble strategy. Its representatives agree that the central bank should take account of and respond to the implications of asset-price changes for its macro goal variables. But also, according to this view, a central bank should try to gently steer asset prices away from a presumed bubble path. The theoretical arguments that have been made for the lean-against-the-bubble strategy are not entirely without merit. It seems that it may be worthwhile for a central bank to take out a little "insurance" against the formation of an asset-price bubble and its potentially adverse effects. Bernanke nevertheless assumes that "leaning against the bubble" is unlikely to be productive in practice.

*The second group* comprises those preferring a more activist approach. Bernanke labels it aggressive bubble popping. Aggressive bubble-poppers would like to see a central bank raise interest rates proactively to eliminate potential bubbles. Bernanke views this particular approach as risky and dangerous. He supports this opinion by pointing out to Federal Reserve Policy in the 1920s. When the interest rates peaked in August 1929, the economy was already slowing, though the stock prices were still rather high. The Fed was trying to prick the stock market bubble but succeeded only to kill the economy. It seems to us that something of the sort may also happened in Japan during 1990s. The result was the lost decade of Japanese economy.

We agree that generally there are clear-cut arguments against an activist approach. First, a central bank cannot reliably identify bubbles in asset prices. This seems to be a crucial argument. What we know is that monetary policy response to an asset price increase should depend on the source of the increase. And we agree that central banks should not react to asset prices unless they indicate changes in expected inflation. Unfortunately, it is rather difficult to know at a certain point in time whether the increase reflects fundamental improvements or excessively optimistic expectations. It is thus also difficult to know whether the asset prices changes indicate improved productivity or higher expected prices. But in some occasions we can be quite sure that bubble is on the way because we simply cannot find fundamentals behind asset price drift.

Second, even if a central bank could identify bubbles, monetary policy does not possess appropriate tools for effective use against them. A small increase in policy interest rate can only lead to correspondingly modest decline in the likelihood or size of a bubble. It is unlikely that a small increase in short-term interest rates, unaccompanied by a significant slowdown of economy, will induce speculators to modify their equity or real estate investment plans. Interest rates simply have a limited power to affect the perceptions which move asset prices in the first place. To materially affect some asset prices, such as housing, interest rates might need to move

probably by much more than would be required just to keep CPI inflation comfortably within the target range. Since interest rate changes affect not just house prices, but also the prices of most other assets, goods and services, there would be secondary, unintended consequences, with potentially serious consequences for the economy as a whole.

Third problem is timing of a central bank's reaction. Once a central bank becomes sure that a bubble has emerged, it will probably be too late to act with interest rate hikes. These may conflict with other economic forces that began to act, instead. Given the lag that we think applies between an interest rate move and its effect on the real economy, the risk is high that policy moves would be wrongly timed and only make matters worse. If interest rates are high at the moment that a bubble bursts, those high interest rates will still impact on the economy two years on. This would make the landing harder.

Fourth, pursuing a separate asset price objective could mean having to compromise on normal inflation objective. Seeking to stabilise rising house prices or an overheated stock market might mean having to force inflation lower than otherwise would be required. It might also mean greater variability in the real economy, interest rates and, potentially, the exchange rate.

Does all that mean that Bernanke is right? We would say that in many ways yes. But we would also say that Bernanke ignores some important aspects. First he seems to ignore the question what to do if the bubble is emerging without any signs of inflationary pressures? Inflation measured in terms of consumer prices has not always signalled when imbalances in the economy have been building up. A strong expansion in credit and increasing asset prices have preceded almost all banking crises and the majority of deep recessions in countries around the world over the past one hundred years. In many cases inflation has at the same time been low and stable before the crisis.

Central bank reaction to growth in asset prices is believed to be adequate only when signals exist that economy may become overheated. However, prevailing monetary policy models used to forecast inflation pressures often derive demand pressures (approximated by the output gap) from current inflation pressures. Given that, some signals that inflation pressures may increase in a more distant future may be ignored, especially if monetary policy horizons are too short.

Here we can provide a realistic scenario for a small open economy. It may appear when higher economic growth creates excessively optimistic expectations that lead to nominal appreciation of domestic currency. In such

a situation, a very low inflation can prevail even under a rapid credit growth and asset price acceleration for rather a long time. When the open inflation pressures finally appear, it may be too late for monetary policy to react. Forecasts of resource utilization and inflation can also be systematically inaccurate because the models and assessments used do not take account of the independent role that asset prices and debt can play. Also, as a result of structural changes, historical relationships may have changed, thus causing the central bank, for example, to come to incorrect conclusions about the output gap and potential growth. Nevertheless, the central banks in increasing numbers compile financial stability analyses that should reveal these particular risks.

If these analyses identify the risk of emerging bubble, responding is rather challenging. Nonetheless, the risks of the landing from the build-up and bursting of large asset price bubbles warrants taking some risks in an attempt to moderate the problem. There are cases when the asset price misalignment is sufficiently obvious that one can be confident enough to take the risk. Such situations are likely to be rare. And the risks may be considerable. In such a situation, tightening monetary policy may lead consumer price inflation even outside the target range. Central bank can be then blamed for squeezing growth from the economy. Nevertheless, by raising interest rates at an early stage when asset prices are starting to accelerate and before the expansion in credit has become too sharp, the central bank can indeed achieve somewhat lower inflation than is desirable in the short term, but may avoid a subsequent collapse in asset prices that could lead to considerably lower output and inflation in the longer term. And somewhat tighter monetary policy than otherwise would be able to counter an over-optimistic pricing of financial assets and properties.

### ***2.3 Prudential Measures and Regulatory Features as a Solution?***

Bernanke also seems to forget that micro-policies are also difficult to apply in reality. He is not the only one. The new issue of the IMF World Economic Outlook (September 2005, p. 134) argues that *"in cases where house price inflation remains robust, a combination of moral suasion and if necessary prudential measures could help limit potential risks; over the long term, regulatory features - including those that potentially constrain supply - that may exacerbate price pressures need also to be addressed"*.

Hilbet et. al. (2005) provide an extensive list of such measures and features. Among prudential measures, higher and differentiated capital

---

<sup>4</sup>The recommendations seem to build on recent IMF Working Paper by Hilberts et. al. (2005).

requirements, tighter loan classification and provisioning rules, dynamic provisioning (accounts for the phase of business cycle in calculating loan-loss provisions), stricter assessment of collateral, or tighter eligibility criteria for certain loans are suggested. Supervisory measures include increasing disclosure requirements, closer inspection, periodic stress testing. Some countries also applied administrative measures like bank-by-bank credit limits or mandatory credit rationing. These measures are not generally viewed as "first best option" for taming excessive credit dynamics. This applies especially for the "prudential measures" that should be used only when normal prudential measures (limits) do not work well and when the new ones can move the system towards the "best practice"<sup>5</sup>. All this sounds well, but reality is a bit frustrating. It is rather difficult to find examples of the "prudential measures" or "regulatory features" that would be in use in developed countries. A typical applicant is a developing or transitional country in major problems, though sometimes an attempt to apply them appears in mature economies too.

Can some measures of this kind be recommended to the Czech Republic or other NMS if a housing bubble emerges in the future and at the same time, no problems with price stability exist? Probably not, not only because the framework has been already strengthened and there is hardly any room for further tightening. Besides that, the banking sector is preparing for the adoption of Basel2 rules. These together with international accounting rules make the application of some nonstandard measures not so easy.

The possibility to use prudential measures (in terms of anticyclical action) with the intention to address asset price bubbles was convincingly questioned by Bollard (2004). He finds administrative instruments blunt, harming newcomers to the market, distorting resource allocation and potentially depriving the private sector of sound investment opportunities. Prudential measures are unlikely to be very effective in addressing asset price cycles too. The implementation of policy changes would take time, after which there would be a potentially long and variable lag in the impact on asset prices. The use of such tools for macroeconomic purposes conflict with the objective for which such tools were originally designed - i.e. financial stability. Indeed, the use of prudential regulation to moderate asset price cycles might backfire in some circumstances, creating perverse incentives for

---

<sup>5</sup> This sort of measures was used in the Czech Republic at the end of 1990s. Supervisory authority required the banks to mount up provisions for covering the loss credits collateralized by real estate to 100% value during three years. The reason behind the measure was the evidence that banks during 1990s were lending against rather overestimated values of real estate.

banks to bias their lending into riskier ends of the lending spectrum, which in turn could reduce the stability of the financial system.

### **3. Asset Markets and Risk of Bubbles in the NMS**

Restructuring and strengthening of financial sectors in the NMS increased significantly the access to external financing. This facilitates the development of investments in various asset markets (stock market, housing markets, bond market). Despite remarkable progress, some of these markets are generally still relatively thin and undeveloped relatively to mature economies. Nevertheless, this does not mean that the risks are relatively small. It may rather imply that it is more difficult to analyze these markets and detect potential imbalances. The difficulties are enhanced by the data incompleteness as to the developments of the asset markets in the NMS.

From the point of view of international investors, the foreign exchange and stock markets the most interesting in countries that are of our focus. Domestic investors usually predominate in real estate markets with the exception of some major cities. Naturally, fast growth of domestic credit should have a potential to initiate bubbles in these particular markets. Unfortunately, lack of reliable data on these markets in the NMS prevent us from providing comparisons and deriving conclusions. Besides looking at the EU4 economies, we will comment separately on the Czech asset markets events. This is a natural reflection of a specific knowledge and lower uncertainty as to the data.

Despite rapid growth of credit to private sector, prudential indicators do not indicate a sizable increase in financial vulnerabilities in the banking systems of the EU4 countries and the NMS in general. Banks are well capitalized, they make hefty profits and the share of nonperforming loans in their portfolios is declining. However, these are normally lagging indicators of banking problems. We must therefore pay attention to potential risks of rapid credit expansion. The implications of rapid credit growth to private sector are very often discussed with other the EU4 central banks. We usually agree that the risks are relatively low or even nonexistent. The reason is quite simple – the low base phenomenon.

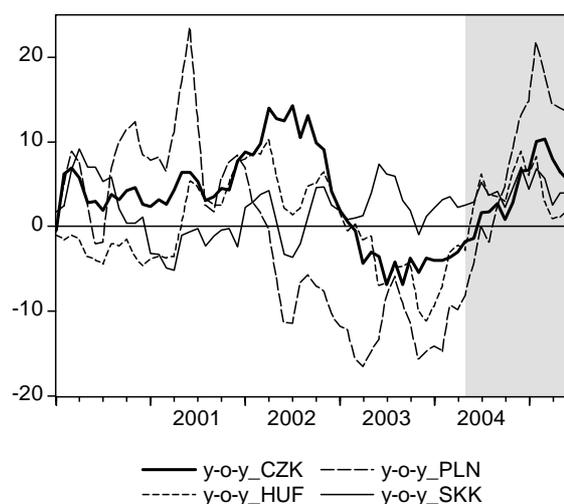

#### ***3.1 Foreign Exchange Markets***

There is an asset price that is a subject to direct reaction of monetary policy of many central banks – exchange rate. This reaction is given by the straight impact of exchange rate on the inflation. There might be disputes whether or not foreign exchange is an asset as well as whether or not monetary policy interest rates should react to exchange rate swings. In

practice, exchange rate is such an important variable that central banks, especially in small open economies, can hardly ignore. Many central banks, which apply the floating regime, therefore adjust their interest rates or intervene when facing significant exchange rate changes (Frait, 2005).

The currencies of the EU4 countries became popular assets among international investors soon after the initial period of transition. The exchange rates of these currencies have been rather volatile in some periods and some swings may be viewed as bubbles. Figure 4 shows year over year changes of the EU4 currencies, which demonstrates relatively high correlation of appreciation and depreciation waves.

**Figure 4: Dynamics of Nominal Exchange Rates of the EU4 against EUR (y\_o\_y, %)**

*Note: CZK=Czech Koruna, HUF=Hungarian Forint, PLN=Polish Zloty, SKK=Slovak Koruna; (+) appreciation, (-) depreciation.*

*Shadow part identifies the membership of the EU.*

*Source: Eurostat, IMF-IFS CD-ROM and authors' calculations.*

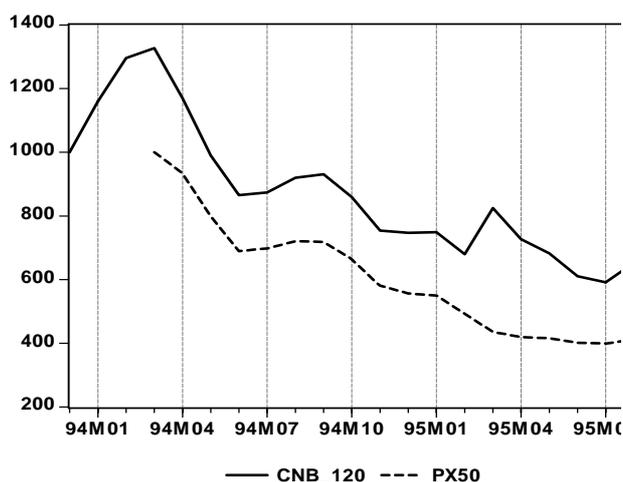

In the Czech Republic, a bubble-like situation was observed in 2002 when the CNB viewed the sharp appreciation of the koruna as unjustified by the fundamentals, labelled it a bubble and responded by interventions as well as interest rates cuts. The CNB was explaining its stance by the supposition that the appreciation was caused by the ill-perceived expectations of massive capital inflows due to privatization sales. The CNB thus tried to spread the correct information among the market participants and acting on top of speaking was necessary to secure credibility of the information content. The fact is that finally the koruna started to depreciate and up to now is still a bit weaker compared to its peak in July 2002 (left hand side of figure A1 in the

appendix). The right hand side of this figure then shows what we can expect from floating exchange rate regime: y-o-y appreciations by 10 to 15% followed by similar depreciation. PLN seems to be even more volatile than CZK: 20% up in 2001, then 15% down in 2003 and 20% up again in 2005. HUF also behaves like this though the focus of the authorities on the exchange rate limits the fluctuations.

### 3.2 Stock Exchange Markets

Probably the first asset market bubble registered during the recent history of the Czech economy followed the voucher privatization in 1993-1995. During this period more than 60% of population obtained shares in hundreds of firms or privatization funds. Despite the initial optimistic expectations, the bubble burst soon since most of the shares were losing the value rapidly. The bust is captured, though only partially, by the decline in the official CNB-120 and PX-50 stock market indices<sup>6</sup> - see figure 5.

**Figure 5: Stock Market Indices in the Czech Republic (points)**

*Note: CNB\_120 = The Czech National Bank monitored trends in the share price movements of 120 issues traded on the Prague Stock Exchange. The component companies were chosen to reflect the economy as a whole and thus all industries*

<sup>6</sup> There were two waves of voucher privatization. The shares from the first one started to be listed in June and July 1993 (622 plus 333 titles), from the second one in March 1995 (674 titles). The CNB-120 index was published from the end of 1993 till 31.12.1999. Publishing of PX-50 began in April 1994 and throughout time changed composition completely. The index is thus rather an imprecise description of the voucher shares performance. Many shares of individual firms as well as privatization funds that were not included in the index lost value completely and were removed from any trading.

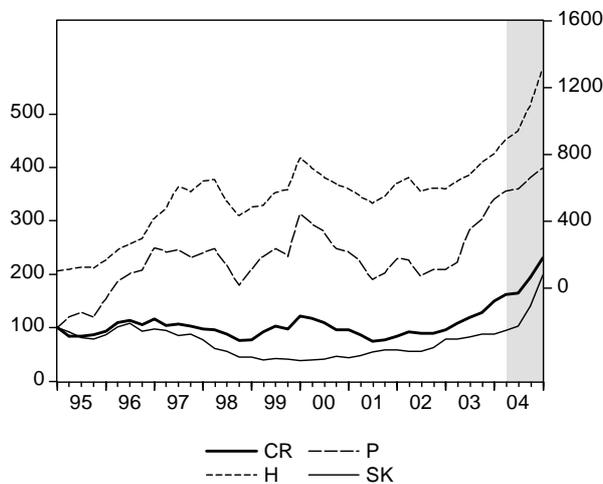

(1<sup>st</sup> March 1995 = 1000 points); PX50 = consists of the most attractive domestic stocks traded on the Prague Stock Exchange in terms of turnover and market capitalization (5<sup>th</sup> April 1994 = 1000 points).

Source: www.cnb.cz

The allocation of the shares among the population surely had a kind of wealth effect which was probably not that strong. Hanousek and Tůma (2002) conclude that the consumers behaved according to the permanent income hypothesis and demonstrate that only a minor part of newly created assets actually lead to an immediate increase in household consumption. Strong growth in domestic demand of the period was thus driven primarily by the corporate credit boom brought about by loose financial constraint of the newly emerged banking sector. It was no surprise that the stock prices bust was followed by the real economy bust later on (Frait 2000). Monetary policy could not react much because its objective during those days was to keep the exchange rate fixed.

How about current stock markets in the EU4 countries? Recent sharp increases in stock exchange indices have already opened debate on potential overvaluation due to purchases of foreign investors searching for some higher yields. Figure 6 displays almost ten years history of stock exchange indices in the EU4 economies. The movement were similar especially among Czech, Hungarien and Polish capital market. Especially from the second half of 2003 we observe clear strong growth of all indices

**Figure 6: Stock Market Indices in the EU4 (1995Q1=100)**

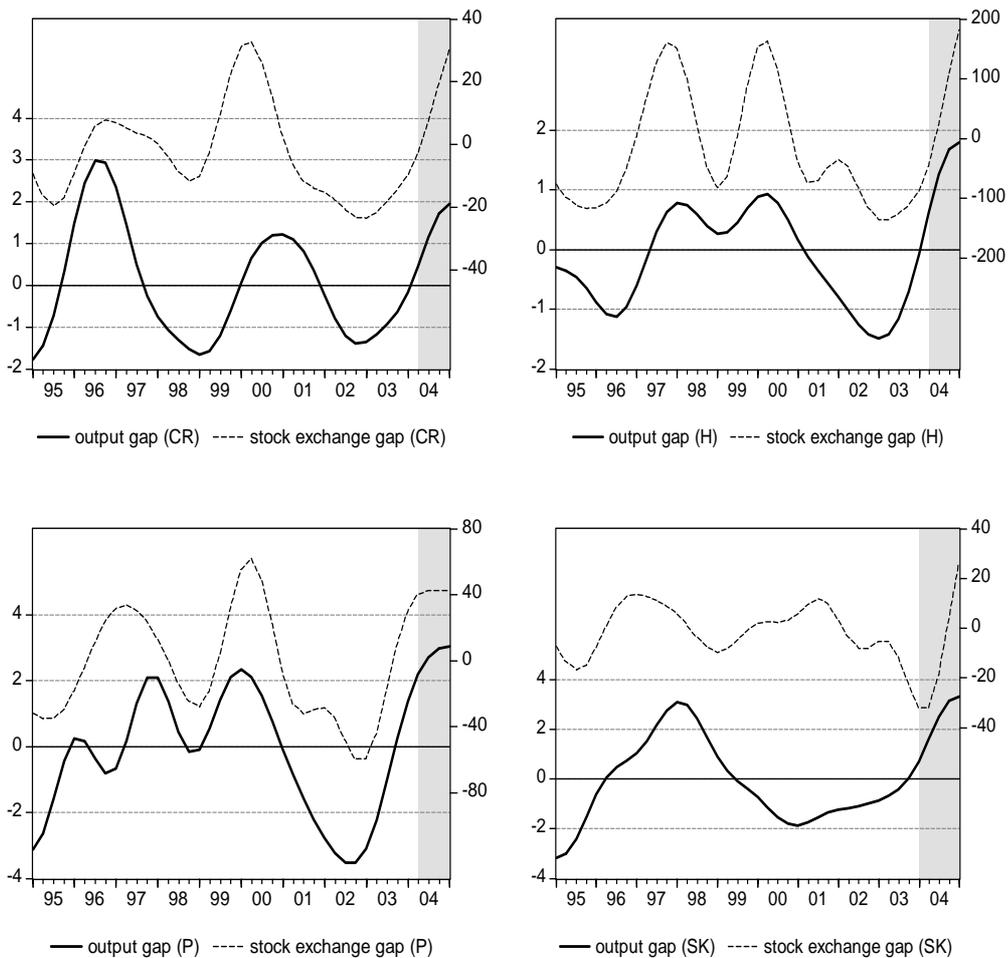

Note: CR=Czech Republic (PX50), H=Hungary (BUX, rhs),

P=Poland, SK=Slovak Republic. Shadow part identifies the membership of the EU.

Source: Eurostat and authors' calculations.

Our ambition is not to add to this particular debate. Instead, we tried to find to what extent the cycles in EU4 stock exchanges were associated with corresponding business cycles. With this in mind, we calculated output gaps and stock exchange gaps by detrending the original series by Band-Pass filter.<sup>7</sup> The final outcomes are presented in figure 7, which also confirms that the development of the Czech, Hungarian and Polish capital market is in accordance with the development of the real GDP. This relationship was not valid for significant period in the Slovak case.

**Figure 7: Output and Stock Exchange Gap in the EU4 (%)**

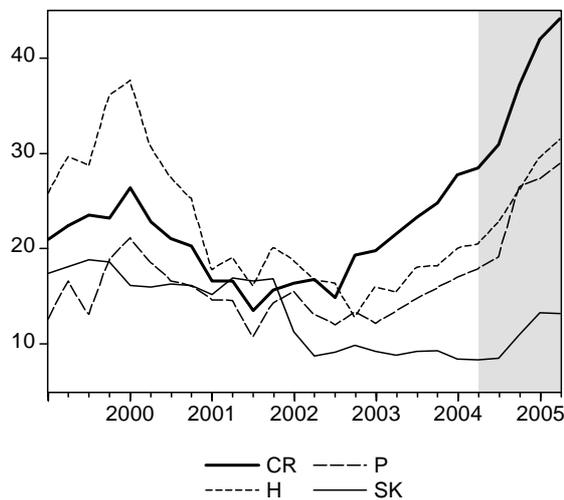

*Note: stock exchange gap on rhs; CR=Czech Republic, H=Hungary, P=Poland, SL=Slovakia. Shadow part identifies the membership of the EU.*

*Source: Eurostat, IMF-IFS CD-ROM and authors' calculations.*

<sup>7</sup> See for example Christiano and Fitzgerald (2003).

The results suggest that stock prices generally reflect economic activity. Positive output gaps would in this case indicate future inflation pressures, the associated positive gap in stock prices would then provide no new piece of information. Reality is a bit different. Standard monetary policy models base their estimations of actual output gap more on the current state of inflation pressures than on the data on economic activity. Monetary policy models in some countries therefore do incorporate stock market data. The inclusion of stock market depends on a country and a structure of model used. However, the features of stock markets in EU4 countries (like limited issuance of quoted equity or a low level of market capitalization) mean that their information content has rather a limited importance. Figure 8 confirms, that the highest market capitalization is in the Czech Republic (from the second half of 2002) and that in all the EU4 countries their levels increase (strongly in the Czech Republic, Hungary and Poland, slowly in Slovakia).

### **3.3 Housing Market**

The growth rates in mortgage markets in the NMS countries in recent years seem to be tremendous. However, the share of mortgages on GDP is still negligible compared to countries like Netherlands or Great Britain. This is captured well by figure 9 plotting growth in mortgage lending between 1998

and 2004 against mortgages stock as a percentage of GDP. All EU4 countries are where they should be as economies in a catching-up process.

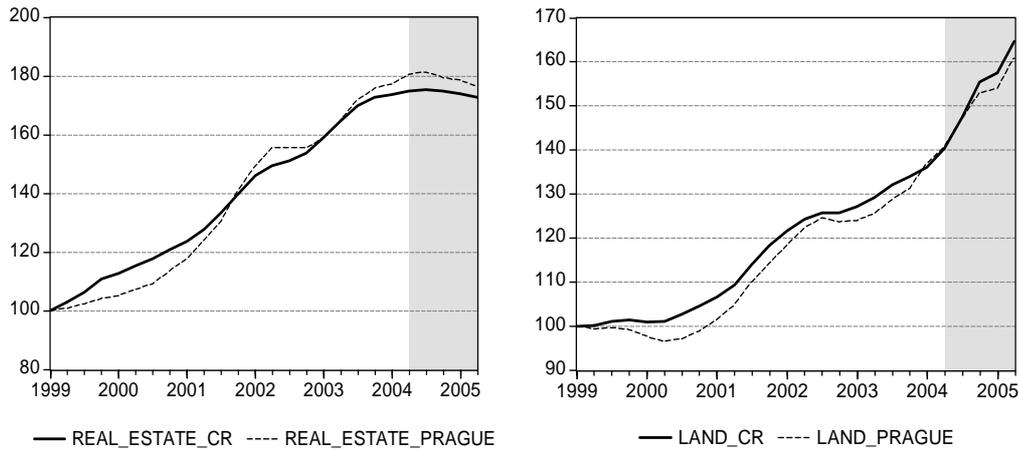

**Figure 9: Housing Market**

Source: ECB.

Housing loans are the fastest growing component of credit in the EU4 countries too. How much should central banks be concerned with potential house prices bubble? It is difficult generally to say because we do not have comparable data series at our disposal. As far as the Czech Republic is concerned, available data presented in figure 10 can hardly be interpreted as a risk of a bubble. Despite remarkable dynamics in land prices, real estate prices seem to be flat in the last two years. Price increases so far must be viewed mostly as movements towards more realistic values.

**Figure 10: Real Estate and Land Prices in the Czech Republic and Prague (1999Q1=100)**

### **3.4 Global Liquidity, Housing Loans and Real Estate Prices**

In the last few years, low nominal and real interests plus high global liquidity were reflected in many countries by relatively high growth in credit and money supply. At the same time, many countries have experienced a real estate prices boom. There is an interesting discussion among economists whether the money supply dynamics causes real estate prices to rise or whether increased money creation is only a natural consequence of increased money demand due to the wealth effect of real estate prices developments. This particular discussion is important for assessing the inflationary potential of current money supply dynamics. If it is a consequence of the above defined wealth effect, the inflation risk may be low since after the real estate price growth slows down, demand for money will slow down too. Money supply growth rates would then tend to much lower numbers.

Of course, money supply growth may add to real estate price expansion. In many countries, credit dynamics is apparently associated with housing loans extension. We could see number of countries with real estate price increase of more than 10% yearly in recent years (France, Greece, Ireland, Italy, Spain, Great Britain, South Africa, New Zealand, U.S.A. or Australia). According to the Economist (that compiles representative indices of real estate prices), relatively to income, the real estate prices peaked historically in 2004 in the U.S., Australia, Great Britain, France, Ireland,

Netherlands, New Zealand and Spain<sup>8</sup>. In some countries, structural changes in financial markets seem to be behind it. In some countries of the euro area, the fall of nominal interest rates to a German level acted as a booster. We plot credit growth and real estate prices in figure 11. We can see a relatively strong correlation. Still, we cannot assign a causal relation to it.

**Figure 11: Correlation between credit growth and real estate prices in developed countries**

Note:  $DOMESTIC\_CREDIT=65.96+0.088*HOUSE\_PRICES$

Source: own calculations based on IMF IFS and the Economist indices (Economic Intelligence Unit database).

Real estate market trends should be of concern of central banks in countries in which real estate prices have a strong impact on consumer spending. This applies primarily to economies with prevailing mortgages with floating interest rate and with widespread “mortgage equity withdrawal” (borrowing that is secured of the housing stock but not invested in)<sup>9</sup>. And these are the same countries that are prone to real estate market bubbles associated with periods of low real interest rates and strong credit expansion.

A dominant view among central bankers is the one that does not associate actual growth in real assets with the inflation because it does not

<sup>8</sup> Currently we can see stagnation or even a decline in real estate prices in some of these countries.

<sup>9</sup> One of the examples is Netherlands where decline in real estate prices growth from 20% in 2000 to zero in 2003 lead to drop in consumption and to recession. It may hardly make a sense to blame the euro.

have influence on value of money expressed in goods and services. The reason is simple - the future inflation should already be embodied in real asset prices. These can be expressed as discounted value of future incomes from holding the assets. The discount factor for real asset valuation can be approximated by real interest rate. If central banks base their decisions on the estimated future inflation, they stabilize in a certain way real interest rate. The prices of real assets then do not constitute a new piece of information. The application of this particular logic to real estate prices is nevertheless questionable. Number of activities linked to real estate influence value of money in terms of goods and services. The changes in real estate prices then have a direct impact on domestic demand via the wealth effect or via the ability to borrow against collateral. Real estate prices change can thus be, under some circumstances, viewed to some extent as new information for policymakers. As far as the EU4 countries are concerned, current credit dynamics does not seem to pose risks to asset markets and financial sectors. For their monetary policies thus “benign neglect” still makes sense.

#### **4. Conclusion**

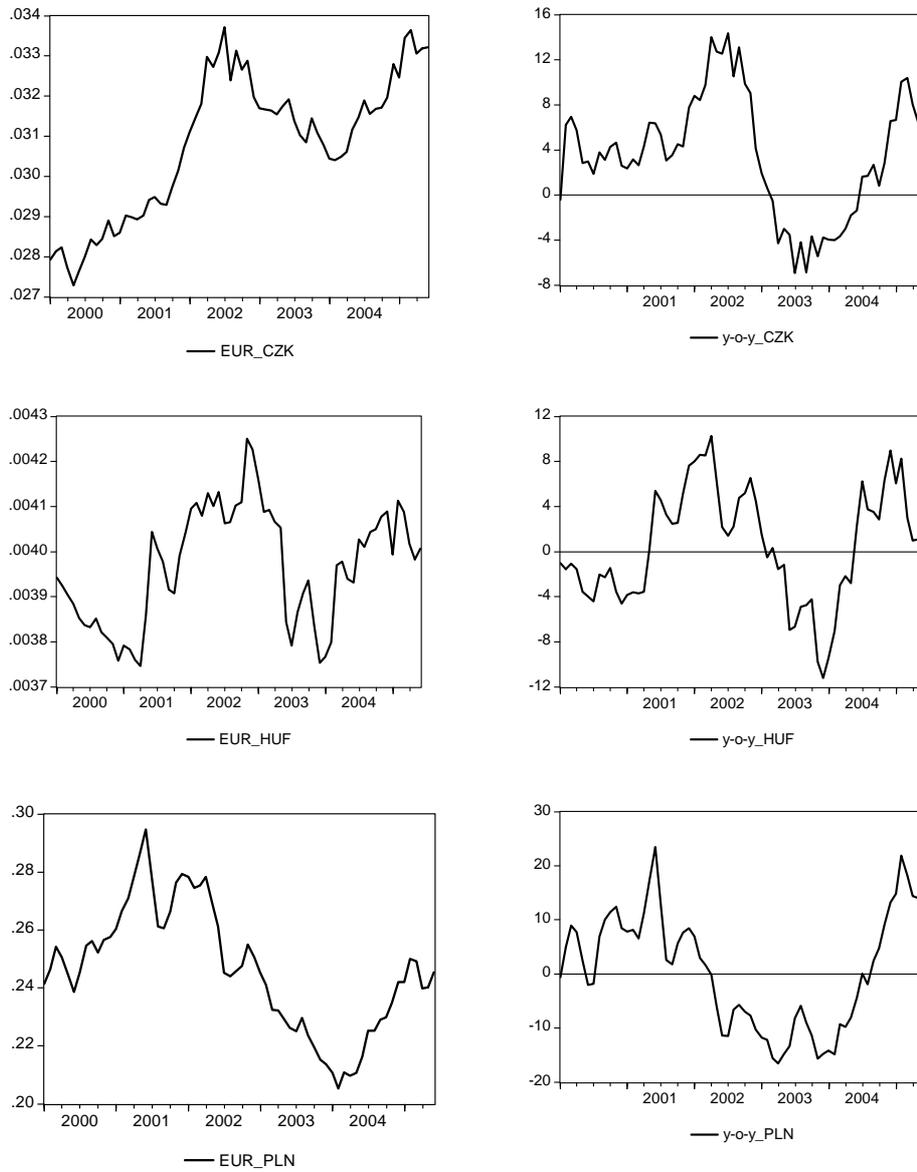

Central banks do have tremendous difficulties in identifying and taming asset price bubbles. Neither monetary policy instruments nor the supervisory and regulatory measures can be much helpful when a bubble occurs. It is therefore crucial for a central bank to conduct its monetary policy as well as its supervisory and regulatory roles in a way that does not promote build-up of asset market bubbles. Monetary policy must therefore be maximally forward-looking. Central banks should not be thinking only in terms of the next two years which is a standard of monetary policy models. Given the potentially long-term nature of asset price misalignments, analyses of financial stability supporting monetary policy making must look at longer horizons while applying risk management approach to financial market developments. In exceptional times, central banks of small open economies must be ready to use monetary policy steps as a kind of insurance against adverse effects of potentially emerging asset market bubble. Reaction to other sort of bubbles should be rate, depends on particular conditions prevailing in a particular moment. As far as EU4 countries are concerned, current credit dynamics does not seem to pose risks to asset markets and financial sectors. For their monetary policies thus “benign neglect” still makes sense.

## **Abstract**

*Currency substitution appears to be an important issue affecting the design of monetary policy, especially in transition economies. Therefore, this paper strives to analyse the particular relevance of the currency substitution phenomenon in the Czech Republic's case. We initially discuss the role of currency substitution in small open economies in transition with some illustrations relating to the Czech Republic. We distinguish and analyse a locally and globally substituting currency from substituted ones and discuss the consequences of euroisation. Further, we estimate a modified Branson and Henderson portfolio model for the Czech Republic. This provides a multi-perspective approach to currency substitution in the broad sense. We attempt to intensify the robustness of our estimations by applying several cointegration techniques, namely the Johansen procedure, ARDL, DOLS and ADL. Finally, we discuss the potential implications of the currency and asset substitution present according to our estimates in the Czech economy.*

**Keywords:** *Currency substitution, demand for money and assets, transition, Czech Republic, cointegration*

## 1. Introduction

Currency substitution is a very important concept in the history of economic thought and one of the most ambiguous concepts in economics. A closer look at the way currency substitution has been defined in the vast literature brings little clarity. There we can distinguish several main areas, problems and incentives of current research. We discuss the idea of a locally (regionally) and globally substituting currency and a substituted currency (the currency being substituted). Further, we deal with these issues by discussing transition phenomena of currency substitution (especially in the Czech Republic) and the problem of *euroisation* (by unilateral or bilateral decision), which is becoming very topical at the end of 2001.

This paper presents an empirical analysis of currency substitution phenomena in the case of the Czech Republic. We introduce the portfolio balance model of Branson and Henderson (1985) which creates the basis for our multi-perspective analysis. This model consists of four equations, two representing the demand for domestic and foreign currency and two describing the demand for domestic and foreign bonds. We modify this model for local Czech conditions and discuss the building of the estimated equations, substituting the variables suggested by theory with their factual equivalents or approximations. Finally, based on our estimates we discuss some of the implications stemming from economic theory and from the experience of other transitional countries.

## 2. Currency substitution in small open transition economies

In most transition economies, the initial conditions and the process of transformation have been similar, i.e. for more than ten years there have been simultaneous periods of internal and external liberalisation and a process alignment with the more developed countries. Internal liberalisation has been brought about by price liberalisation in a higher inflation environment, restructuring of industries, adoption of new tax systems, etc. External liberalisation has been caused by trade liberalisation and, in particular, by external convertibility of national currencies and liberalisation of capital accounts. Generally it can be concluded that the launch of the reform process was coupled with greater economic uncertainty<sup>1</sup> (and in some countries by political instability) and the absence of developed financial markets.

---

<sup>1</sup> This implies a high and volatile nominal exchange rate and inflation, large budget and current account deficits, and the establishment of new national currencies (in the countries of

## ***2.1 Macroeconomic Policy and Currency Substitution***

The implications of currency substitution for macroeconomic policy differ between developed and developing countries and, in two respects, in particular. First are the effects of currency substitution on the efficiency of stabilisation programmes, and second are the effects of currency substitution on the authority revenues received from inflation.

One of the problems of developing countries is the credibility of their stabilisation programmes. The relevant question in this context is: Does dollarisation (euroisation or other -isation) help to stabilise an economy and increase the credibility of its policies? Credibility can increase when foreign currency circulation eliminates the authorities' incentives to manipulate the domestic currency. In the past, many stabilisation programmes have involved fixing nominal exchange rates or establishing crawling pegs. These arrangements have ensured the progressive appreciation of real exchange rates. The other issue relating to stabilisation programmes is the discussion between fixed and floating exchange regimes. Results of currency substitution models and other empirical observations indicate that the presence of a currency substitution exchange rate implies higher volatility, with potentially distribution effects on the economy. These findings lead to the defence of fixed exchange rates (or exchange rate regimes with narrower fluctuation bands) during a "stabilising" period, when currency substitution plays a significant role in the economy.

Inflationary financing of a government deficit poses another relevant question relating to these issues. It can be intuitively said that the higher the substitutability of the domestic currency with foreign currency, the more difficult it is for the government to finance its deficit by printing money. On the one hand, holding foreign currency balances makes it possible to get seigniorage, so that, the demand for foreign currency may act as an inflationary tax. The resulting revenue will be (in the presence of currency substitution) lower for each level of this tax.<sup>2</sup>

Currency substitution also suggests a recommendation for the optimal rate of inflation. The transaction models of currency substitution imply that the marginal rate of transformation (represented by a relative price, i.e. the real exchange rate) between two goods (domestic and foreign) is different

---

the former Soviet Union, the new countries of the former Yugoslavia, and in the Czech Republic and Slovakia).

<sup>2</sup> A discussion of the seigniorage and inflation tax phenomenon, applied in the Czech transition period without considering external influences, is presented by Hanousek, Kubin and Tůma (1995). The influence of currency substitution on revenues from seigniorage in Eastern European economies has been estimated by Aarle and Budina (1995).

from the marginal rate of substitution for these two goods, owing to the costs of liquidity. These liquidity costs are influenced by the rates of inflation in both countries. This model then defines an optimal relative rate of inflation, existing when the marginal rate of transformation is equal to the marginal rate of substitution. If the foreign rate of inflation is known, then the domestic rate of inflation should be set in such a way as to minimise misrepresentation of the aforementioned relative prices.

## ***2.2 Quantification of the Degree of Currency Substitution***

It is useful to look at how we can quantify or measure the degree of currency substitution. Sarajevs (2000) concludes that, ideally, the measure of currency substitution is the value of foreign currency notes circulating in the economy (as a means of payment and a store of value) and all checking accounts and short-term deposits in foreign currency held by residents in domestic banks and abroad. Available data is lacking not only for transition economies, but also for industrial countries. Therefore, most studies generally calculate currency substitution either as (i) the ratio of foreign currency deposits to M2 (broad domestic monetary aggregates), or as (ii) the ratio of foreign currency deposits to broad monetary aggregates, including foreign currency. The next part will show that these two measures of currency substitution have moved together in the case of the Czech Republic.

Which factors can explain currency substitution in the Czech Republic? A number of competing explanations come to mind: (i) The Czech Republic, with its lack of restrictions on capital flows, is a safe place for foreign exchange dealers from many countries. (ii) A lag occurs as financial markets and economic agents adapt to an economic environment with large foreign exchange flows (as individuals and banks get used to dealing with high levels of currency substitution, there are extra costs associated with turning the situation back). (iii) A sharp increase in the openness of the Czech economy increased foreign exchange balances during the transformation.

Another interesting question is: For whom is currency substitution most relevant? In the presence of inflation, poor people suffer more from inflationary taxation than do others. The poor cannot afford to use financial market instruments (including foreign currency) to avoid the inflation tax. Currency substitution can also make it more difficult for the government to renege on its economic stabilisation programme and fall back on the use of the inflation tax.

## ***2.3 Substituting and Substituted Currencies***

In this subsection we distinguish a locally (regionally) and globally substituting currency from a substituted one (the currency being substituted).

The reason for our terminology is as follows. We think that a local and global dimension of currency substitution can generally be found. While the global currencies are definitely the US dollar (USD), the German mark (DEM), the Swiss frank (CHF) and the Japanese yen (JPY), other currencies act more locally than globally. The vast majority of the four global currencies is held by citizens of nations outside the borders of the issuing states. Doyle (2000) presents the relevant research in this area – an estimation of worldwide currency substitution. Using a currency demand equation implied by cointegrating vectors for Canada, the Netherlands and Austria, he estimates for 1996 that only a surprising 30% of USD was held outside the United States, although as much as 69% of DEM was held outside Germany. It must be remembered that foreign holdings of these three main currencies (USD, DEM, CHF) have significantly increased international currency substitution in the world, which roughly tripled between 1986 and 1996.<sup>3</sup>

Of course, several other currencies might qualify to fulfil this role, most notably for historical reasons (the colonisation period). There are at least two candidates: the British pound (GBP) and the French franc (FRF). The best candidate countries for “*poundisation*” include either relatively successful or developed economies such as those of Australia, New Zealand, Canada, South Africa, the Asian tigers (Hong Kong, Singapore and Malaysia) and parts of Middle Eastern territories. The best candidates for “*francisation*” are French former colonies in Africa, which used the Central African franc. This currency was for long time pegged to the French franc. So, we see that worldwide currency substitution is not solely an American or German phenomenon.

Generally, we can specify the reasons for currency substitution, i.e. the reasons why a currency is being substituted: (i) Macroeconomic instability with a sizeable rate of inflation, exchange rate instability and volatility, and a less optimistic country rating. (ii) The existence of a large illegal or underground economy (especially when this sector produces tradable and export goods such as drugs). Examples are to be found in Europe’s former socialist bloc. (iii) A history of financial crisis and risk-averse behaviour by economic agents trying to eliminate this potential risk. (iv) The lack of higher-denomination bank notes issued by the central bank.

The largest increase in currency substitution occurred in the last decade, suggesting that the main reasons for this were the collapse of the former socialist bloc in Europe and the tendency toward dollarisation, especially in South America.

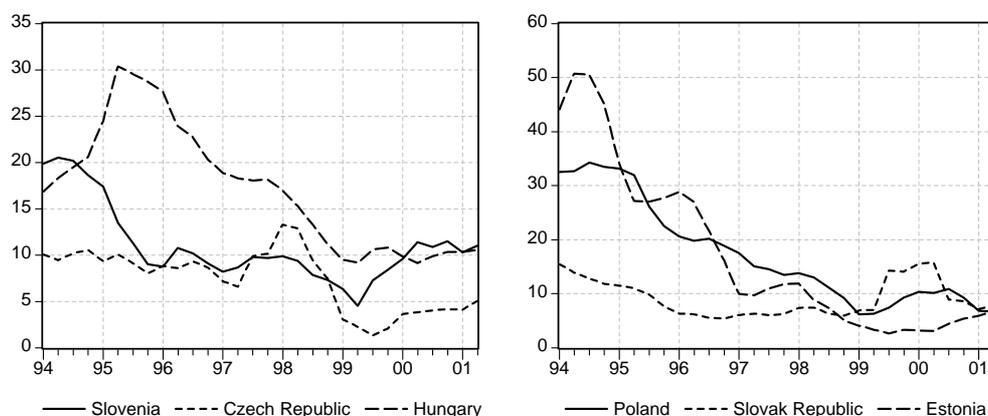

---

<sup>3</sup> These estimations are adjusted for inflation.

## 2.4 The Czech Koruna – A Substituting Currency or Substituted Currency?

We see local substituting currencies as being those which are mostly used in a local environment within a specific economic region. It can be shown that the Czech koruna (CZK) is not only a substituted currency, but has also for several years been the substituting currency for some post-socialist countries. The reasons for this collateral role of the Czech koruna as a substituting currency include the following: (i) Since its inception in 1993, the Czech koruna has remained very stable and not too volatile against the two main currency pairs, i.e. USD and DEM/EUR (Figure 5); (ii) The Czech koruna has not had an inflation rate higher than other transition countries (Figure 1); (iii) The Czech koruna has quite a good general reputation abroad; (iv) The Czech koruna became externally convertible quite soon after 1993; (v) The Czech economy has absorbed a fairly significant amount of post-socialist workers, for whom it is better to hold earned money in Czech koruna (rather than exchanging it for world-wide substituting currencies); (vi) The Czech National Bank issues bank notes with a relatively high nominal denomination of CZK 5000. Conversion from the highest GBP, FRF or USD<sup>4</sup> denominations yields a smaller amount of money than reflected in our highest note.<sup>5</sup> The new EUR notes will have two higher denominations compared to Czech notes and recalculated to CZK: the EUR 200 and EUR 500 notes.

**Figure 1: Inflation rates in transition economies 1994–2001**

Source: Author's calculation based on CNB database (<http://www.cnb.cz>) and IMF-IFS statistics.

<sup>4</sup> Excluding the special issuance of notes between 1914 and 1923, when the FRB issued notes with nominal values of 500, 1,000, 5,000 and 10,000 USD.

<sup>5</sup> See also the work presented by Feige, Faulend, Šonje and Šočič (2000).

## ***2.5 Currency Substitution, Euroisation and Enlargement Process***

The other relevant topic relating to the currency substitution issue (especially from the macroeconomic point of view) is the problem of euroisation in non-eurozone countries, which has become very topical in many transition countries at the end of 2001. Generally, we can distinguish the euroisation process as being based on either a unilateral decision or a bilateral one.

The former (unilateral) decision involves adoption of the euro without the official agreement and permission of the EU/EMU authorities before a candidate country officially joins the Eurozone.

An accession country may generally see various advantages to adopting the euro, namely: (i) the stability of its exchange rate to the Eurozone area is increased (incentives for international investment). (ii) the risk of speculative attacks on the domestic currency is virtually eliminated. (iii) the general necessity of holding foreign reserves is lessened (thanks to lower exchange risk). (iv) lower interest rates and lower inflation. (v) lower transaction costs which are larger for small open economies. (vi) re-establishing the domestic currency and re-creating an independent central bank remain theoretically possible (only for unilateral euroisation).

The general disadvantages (risk and costs) might include: (i) the higher probability of runs on commercial banks in the absence of a “national” central bank acting as a lender of last resort and risk of boom bust cycles, as interest rates become very low and the central bank loses this lender of last resort function. (ii) the general or probable lack of foreign reserves. (iii) the low official euroisation of most first-wave accession countries. (iv) as the independence of monetary and exchange rate policy is lost, these could overburden other policies, especially fiscal policy (plus the possibility of political feuding because monetary policy is much less independent of other countries). (v) non-compatibility of monetary policy instruments with the ECB (though not problematic for those countries in the first wave of accession). (vi) the record of dollarised economies has shown that dollarised nations had a lower rate of economic growth than others. (vii) loss of seignorage income. The European authorities have made clear that unilateral euroisation is not a legally and economically sound option for accession countries on their way to the EU and Eurozone.

The latter (bilateral) decision represents the stage of integration into the Eurozone after accession to the EU and after fulfilment of all necessary conditions. The candidate states: (i) will join the EU, (ii) then they will participate in ERM2 (exchange rate mechanism) for at least two years, (iii) have to fulfil the other four nominal convergence criteria (Maastricht criteria)

and (iv) in a last step, they will introduce the euro as their national currency. This will include a non-trivial process of determination of the euro locking rates for the currencies of transition countries.

The main reason for adopting the euro as late as possible is the modification of the structure of real appreciation accompanying the real convergence process. This process will only be possible through higher inflation and no longer through appreciation (nominal and real) of the exchange rate. This has important implications for macroeconomic policy in the accession (catching-up) countries.

### 3. Empirical Analysis of Currency Substitution In The Czech Republic

Our analysis of currency substitution in the Czech Republic is based on a portfolio model developed by Branson and Henderson (1985), which we further modify to match the conditions in the Czech economy. This portfolio approach enables us to focus on currency substitution phenomenon from several perspectives. It incorporates money demand for both domestic and foreign currencies, and capital mobility, i.e. demand for both domestic and foreign bonds. We consider this approach very useful, since it comprises several independent views on currency substitution analysis, examining the robustness of estimates not only from the perspective of the applied estimation techniques but also from that of different markets (relationships).

We follow Branson and Henderson (1985), without explicit solution of the optimisation problem, and assume that the domestic demand (i.e. that of domestic residents) for assets depends on their relative returns, satisfying the usual wealth constraints:

$$M = M(i, (i^* + e^{ex}), e^{ex}, PY, P^c, W) \quad (1)$$

$$eM^* = M^*(i, (i^* + e^{ex}), e^{ex}, PY, P^c, W) \quad (2)$$

$$B = B(i, (i^* + e^{ex}), e^{ex}, PY, P^c, W) \quad (3)$$

$$eB^* = B^*(i, (i^* + e^{ex}), e^{ex}, PY, P^c, W) \quad (4)$$

The first argument in equations (1) to (4),  $i$ , is the return on holding bonds denominated in domestic currency relative to the return on domestic money (that is minus the rate of domestic inflation). It is assumed that all four assets are substitutes in the portfolio. Hence, an increase in  $i$  raises the demand for domestic bonds but lowers the demand for their substitutes in the portfolio. The nominal return on bonds denominated in foreign currency is  $i^*$ .

Expressed in domestic currency, this return becomes  $i^*+eex$ , with  $eex$  the expected change in the exchange rate. It affects the demand for foreign securities positively and that for other assets negatively. Once again, this second argument is in fact a real return differential, where the return on domestic money is minus the rate of inflation.<sup>6</sup> Similarly, the third argument,  $eex$ , is the return on foreign money, converted into the domestic currency<sup>7</sup>.

The fourth argument,  $PY$ , represents the home currency value of domestic output and affects demand for all assets positively.  $Pc$  is the price of the domestic consumer's consumption bundle expressed in the home currency. An increase in  $Pc$  increases the demand for both moneys and lowers the demand for bonds denominated in domestic and foreign currency. The positive effect on domestic wealth  $W$ , the last argument, reflects the assumption that all assets are "normal assets".

We modify this portfolio approach to the local conditions of the Czech Republic. Specifically, we take account of the institutional features of the Czech economy, which arise from both historical and recent developments in this country. When we go through the portfolio balance approach, the first equation represents the traditional domestic money demand equation which has been estimated in slightly modified form and analysed by several authors with respect to the Czech economy (most recently e.g. Melecký, 2001 and Arlt, Guba, Radkovsky, Sojka and Stiller, 2001). The modification (or difference) lies in the fact that the Czech Republic's broad monetary aggregate (M2) includes foreign deposits. Therefore we will concentrate, as regards equation (1), on M2 adjusted for foreign deposits.

Equation (2) in our case describes domestic demand for foreign currency, i.e. foreign currency in circulation and foreign deposits in the Czech economy. However, monitoring foreign currency in circulation is very difficult and is left for future research. We consider only the demand for foreign deposits. These are probably held in the Czech Republic mostly for

---

<sup>6</sup> Indeed, the real return on the foreign bond in terms of domestic bonds equals the own real rate of interest on the foreign bond plus the expected rate of change in the real exchange rate – the expected rate of change of the nominal exchange rate plus the expected foreign price inflation, minus the expected domestic price inflation. Subtracting the real rate of return, we obtain the nominal return in the equation.

<sup>7</sup> Again, the real return on foreign money expressed in terms of foreign goods is minus the expected foreign rate of inflation. This can be transformed into a real return expressed in domestic goods by adding the expected rate of change of the exchange rate. Finally, adding the expected domestic rate of inflation (that is, subtracting the return on the domestic money stock expressed in terms of domestic goods) we are left with the expected change in the nominal exchange rate.

their store-of-value purpose (although we would not omit the influence of foreign trade), as the Czech economy is not considerably dollarised (or D-markised) and therefore foreign currency is not commonly used as a medium of exchange or unit of account.

The first problem arises when we look at residents' demand for domestic bonds. In the Czech Republic, as a consequence of historical developments, financial intermediation goes largely through the banking sector and the capital markets are generally either inaccessible or illiquid and inefficient. More specifically, owing to the prevalent credit system, the Czech bond market is underdeveloped, so we are left with government bonds and Treasury Bills only. However, these constitute a rather exclusive market that is accessible only to selected large financial institutions.<sup>8</sup> A similar situation exists on the stock market. Furthermore, when considering the demand for credits we face the problem of credit rationing. This has been present in the Czech Republic for, at least, half of our sample period. The above considerations lead us to exclude equation (3) from the portfolio approach.

Although an analysis of the demand for foreign bonds, or foreign portfolio assets generally, may be associated with some inconsistency in data series, we attempt to estimate the function capturing the demand for foreign portfolio assets in the case of the Czech Republic as proposed by equation (4). In addition, the constraints, or rather controls, on capital movement imposed by the Czech National Bank at the beginning of our sample may influence the results, in the sense of increasing the importance of all foreign variables in determining portfolio investment abroad in our case. We take in to account this aspect while estimating the demand for foreign assets.

### ***3.1 Description of the Data Series Used***

We use quarterly data spanning the period from the first quarter of 1994 to the second quarter of 2001. Where a particular variable is of discrete form we use a quarterly average calculated as the simple arithmetic average of the monthly end-of-period values for the three months in the current quarter and the last month of the previous quarter. We use seasonally adjusted data only in the case of the scale variable, which is the only one showing a marked seasonal pattern. (Data source: CNB database, i.e.: <http://www.cnb.cz>.)

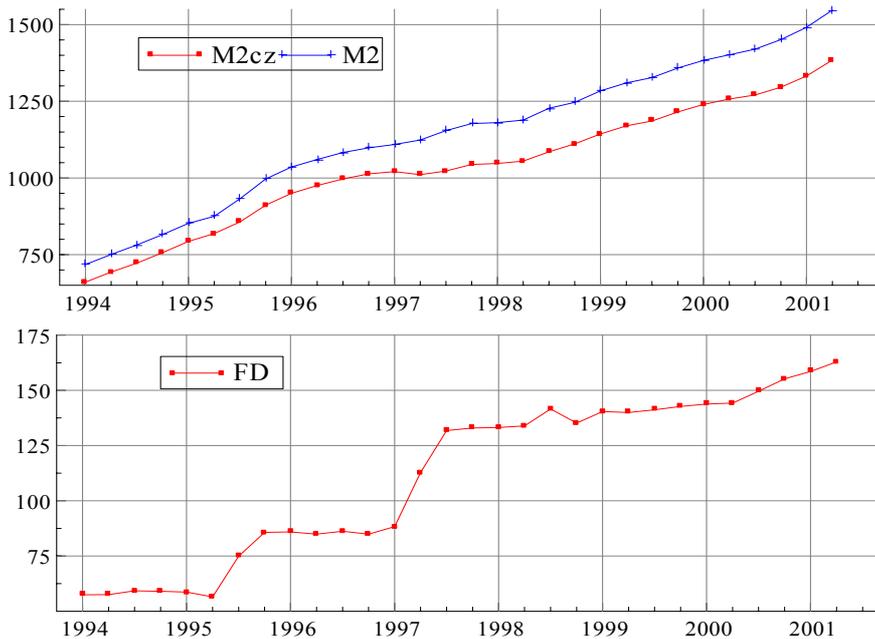

---

<sup>8</sup> A thorough discussion on financial intermediation in transition countries and various aspects of its development can be found in Mishkin (2001).

### 3.1.1 Dependent variables

We first attempt to model the *Mcz* variable, representing deposits in the domestic banking system denominated in the Czech currency. This variable is calculated as the difference between the M2 monetary aggregate and deposits in the domestic banking system denominated in foreign currencies. We further subtract Czech currency in circulation, since we cannot include foreign currencies in circulation in our analysis owing to a lack of data series. Figure 2 depicts the development of the M2 and M2cz series.

**Figure 2: M2cz and M2 Series**

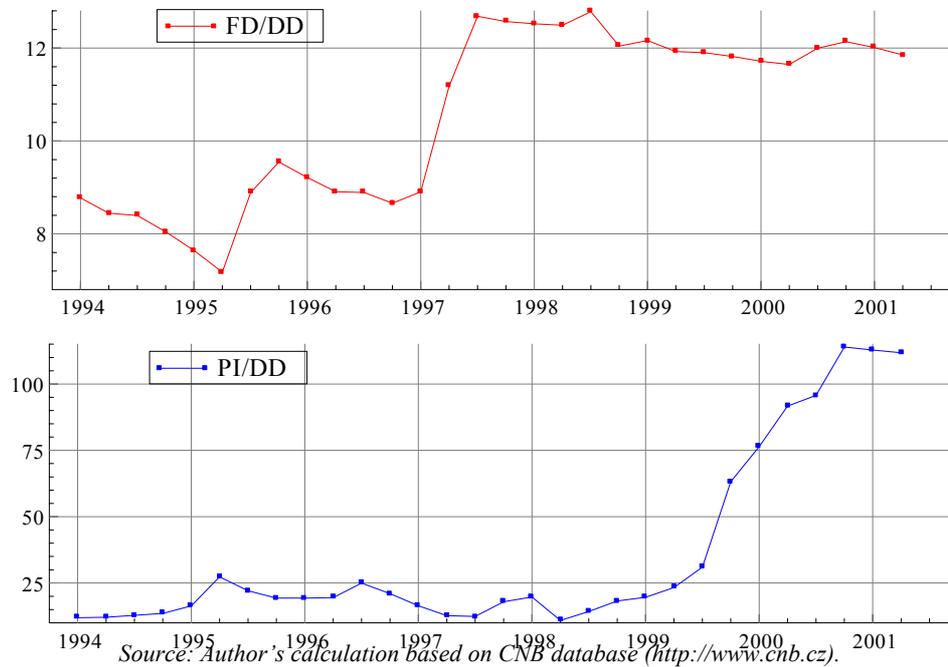

Source: Author's calculation based on CNB database (<http://www.cnb.cz>).

The next modelled variable is the ratio of foreign to domestic currency deposits ( $FD/Mcz$ ); we name this variable the  $FD/DD$  ratio. The modelled variable is similar to those proposed by Feige, Faulent, Šonje and Šošić (2000) in the case of Croatia; and by Mongardini and Mueller (1999) in the case of the Kyrgyz Republic for analogous purposes. We use this ratio to precisely pursue the effect of changing relative prices of assets under consideration on domestic residents' behaviour. We thus differentiate between increases in foreign deposits resulting from an overall increase in wealth and the move from domestic deposits to foreign deposits induced by changes in relative returns. Figure 3 shows a rapid increase in the  $FD/DD$  ratio during the period of currency crisis that seems to be persistent. This may

point to dollarisation of the Czech economy from the store of value perspective.

**Figure 3: FD to DD Ratio (%) and Cumulative PI to DD Ratio (%)**

The last dependent variable, that we attempt to explain, is the ratio of cumulative portfolio investment abroad to domestic deposits. We use this variable to properly evaluate the effect of changing relative prices of foreign assets and deposits in the domestic currency on wealth allocation. Further, we again attempt to eliminate the effect of rising wealth using DD as a denominator. We can see in Figure 3 that domestic agents have only recently extended the use of foreign assets for wealth allocation purposes. However, this extension appears to be highly significant.

### 3.1.2 Explanatory variables

We use the consumer price index (CPI) as an approximation of the variable  $P_c$  in equations (1) to (4). This index should precisely describe consumption basket price development in the Czech Republic and thus correctly deflate nominal variables from the perspective of the domestic agent. Furthermore, we approximate the variable  $P_Y$  in equations (1) to (4)

using domestic absorption (AE), which would measure the amount of transactions in the Czech economy and possibly an accumulation of wealth. We employ this variable, as it is more significant for such purposes according to Sommer (1997) and Melecký (2001). Instead of the return on domestic bonds we use the interest rate on credits, since this seems to be the most significant measure of the opportunity cost of holding money and represents an alternative vehicle for wealth creation. For the purpose of measuring return on foreign money we employ two bilateral exchange rates – CZK/USD and CZK/DEM – since they have experienced a somewhat different historical development<sup>9</sup>. This could result in a rather different relative significance of the two variables. We use current and one-period-lagged values of the exchange rate to approximate exchange rate expectations, since we assume that most agents form their expectations adaptively and the rest base their forecast on the random walk process. This approach is, in our opinion, reasonable since the structure of the economy changes quite considerable during transition. Thus, we do not use purchasing power parity or uncovered interest rate parity to approximate “rational” expectations of changes in the exchange rate. Finally, we consider the return on both USD- and DEM-denominated assets to explicitly consider their relative importance in equations (1) to (4). We calculate this return as the sum of the interest rate and the log of the particular exchange rate, i.e.  $i+e$  (see also Govannini and Turleboom, 1992). Figure 4 describes the development of our core explanatory variables.

Some readers may notice a certain inconsistency between the introduced model and the explanatory variables used. Namely, although the model implies a use of first differences of nominal exchange rates, we use levels of that variable for three particular reasons. First, cointegration techniques comprise or deal with those first differences either implicitly, as in the case of Johansen procedure, or explicitly, as in the case of DOLS. Second, given the I(1) order of integration of nominal exchange rates (see Table 1 below) we would have to find two cointegration vectors when including the change in the exchange rate instead of its levels, as we do. In another words, since the first difference of nominal exchange rate is stationary itself we have to find two cointegration vectors to be able to justify the existence of stationary linear combination of the remaining I(1) variables.

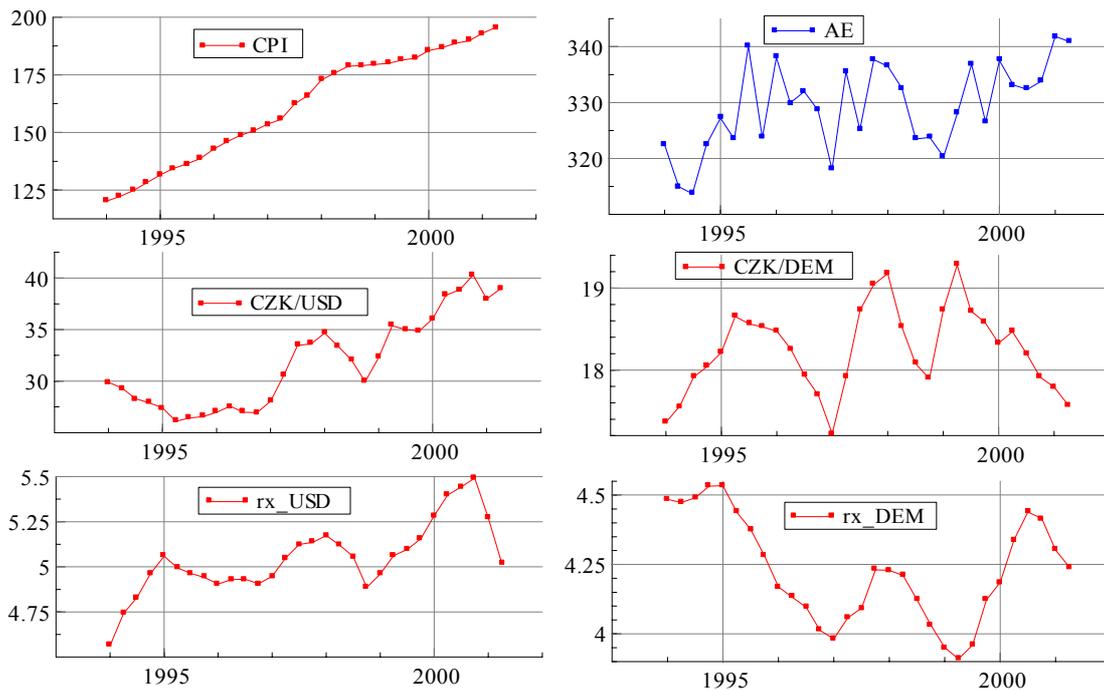

Third, except for these rather technical reasons, there is another one related to the institutional features and historical development of the Czech Republic’s external conditions. Given the identity that express the expected

---

<sup>9</sup> We also check for the significance of nominal effective exchange rate (NEER) to possibly reduce the number of explanatory variables (see below).

change in exchange rate as a result of interaction of capital flows and trade balance (see e.g. Goldberg, 2000) we can accept the following assumption in the Czech republic's case. Given the fact that we have interest rate differential that drives the capital (portfolio) flows already incorporated in the model, it remains to consider the effect of overvaluation of the real exchange rate. The factors responsible for the fluctuation in the real exchange rate have been different between the first and second half of our sample period. In the first half the fluctuation and thus overvaluation of the real exchange rate was nearly exclusively determined by movements in the domestic price level, given the fixed exchange rate regime prevailing at that time. In the second half, these fluctuations have been the result of both price level and nominal exchange rate movements. And concerning the very end of our sample, the real exchange rate movement has been driven mainly by the nominal exchange rate as the Czech Republic adopted the convergence criteria for EU accession and the consequent adoption of euro. Since we have the domestic price level already included in our model, inclusion of the nominal exchange rate would complete our set of explanatory variables, given our small sample of observations.

Figure 4: Explanatory Variables

Source: Author's calculation based on CNB database (<http://www.cnb.cz>).

Conventionally, we first explore the stationary properties of analysed time series, as they are expected to be integrated of order I(1). Results of applied ADF- and PP-tests are summarised in Table 1:

**Table 1: Unit Root Tests of Time Series Applied**

Variable	Unit Root Tests		Likely Degree of Integration
	ADF	PP	
m_cz	3.07 (c,t,3)	2.67 (c,t) !!	Rather I(2)

*\*, \*\* and \*\*\* indicate rejection of the null hypothesis of unit root existence. Numbers in brackets indicate the number of lags included in the ADF test and letters c and t indicate that constant and trend are involved in the particular test. ! indicates violation of the assumption of no serial correlation of residuals.*

Since the dependent variables are integrated of order I(1), as are most of the explanatory variables,<sup>10</sup> we need to use cointegration analysis to

<sup>10</sup> Although there are some indications that certain variables could have been integrated of order I(2), we do not consider this higher degree, since for the case of our small finite sample of observations applied unit-root tests do not have much power and size. Therefore, the higher- order effectiveness of these tests is somewhat problematic.

prevent spurious regression phenomenon. For this purpose we use the Johansen technique (see Johansen and Juselius, 1990); the ARDL procedure developed by Pesaran (see Pesaran, Shin and Smith, 1996); the dynamic OLS estimation, DOLS (see e.g. Stock and Watson, 1993); and the ADL technique (see e.g. Arlt, Radkovský, Sojka and Stiller, 2001).

### ***3.2 Empirical Analysis of Currency Substitution in the Czech Republic from the Demand-for Money Perspective***

We analyse the potential presence of currency substitution in the Czech Republic using the demand for money approach. More specifically, we use equation (1), which describes demand for deposits denominated in Czech korunas. If currency substitution is one of the important techniques of portfolio allocation, then the opportunity costs of holding Czech deposits with respect to deposits in foreign currency and/or foreign assets are to be significant determinants of the demand for Czech deposits.

The procedure for the empirical analysis of currency substitution in the Czech Republic is divided into three stages.<sup>11</sup> First, we explore the existence of currency substitution concerning the effect of exchange rates. In this stage the particular currencies are assumed to compete as a store of value in the domestic banking system. Second, we examine the potential existence of the extensive part of nominal exchange rate elasticity, since the first case considers only the intensive part (see below). Finally, we extend this analysis to include the determinants relating to capital mobility.

Analysing the demand for deposits denominated in Czech korunas we estimate equation (5) of the following form:

$$m_{cz} = \beta_0 + \beta_1 cpi + \beta_2 ae + \beta_3 lr + \beta_4 e^{usd} + \beta_5 e^{dem} + \beta_6 e^{neer} + \xi \quad (5)$$

where  $m_{cz}$  is the M2 monetary aggregate adjusted for deposits in foreign currencies (DFC), i.e. (M2-DFC);  $cpi$  is the consumer price index, measuring price level development;  $ae$  is domestic absorption (GDP-NX), measuring the amount of transactions in the Czech economy;  $lr$  is the lending interest rate, representing domestic interest rates on alternative assets; and  $e$  is, respectively, the CZK/USD and CZK/DEM nominal exchange rates and the nominal effective exchange rate. We thus explicitly test the significance of the alternative approximation of the Czech koruna performance relative to foreign currencies, i.e. the opportunity cost of holding Czech currency.

---

<sup>11</sup> We choose this approach since we want to consider a wide range of possible foreign variables that might be important determinants of currency substitution and we have only a small number of observations.

In the second stage, we consider the possible extensive part of the exchange rate's elasticity, including in the estimated equation two so-called "ratchet" variables that consist of peak values of the CZK/USD and CZK/DEM exchange rates. Following Mulligan and Sala-I-Martin (1996), we assume that when the actual value of the exchange rate hits the peak value during the analysed period, additional agents always decide to adopt financial technology to help them convert the domestic currency into foreign currency. They do so since they are facing the very level of opportunity costs that they consider too high to accept, given current wealth allocation, and that makes them react in this respect (see also Feige, Fautent, Šonje and Šošić, 2000 and Mongardini and Mueller, 1999).

We proceed to the third stage by adding variables that should represent the impact of capital mobility, i.e. the return on foreign assets. We consider returns on U.S. Treasury Bills and German Treasury Bills expressed in Czech korunas, as perceived from the position of Czech residents. The final estimation results using the Johansen's procedure are as follows<sup>12</sup>:

$$m_{cz} = 1.08cpi + 2.52ae - 0.012lr - 0.34e_{t-1}^{usd} - 0.62e_{t-1}^{dem} \quad (6)$$

(0.06)\*\*\* (0.24)\*\*\* (0.002)\*\*\* (0.07)\*\*\* (0.19)\*\*

Summarising our three-stage estimation, we can conclude that the estimating methods applied indicate the presence of currency substitution in the Czech Republic. The important variables accounting for this phenomenon are lagged value of the CZK/USD exchange rate and the lagged value of the CZK/DEM exchange rate. These two bilateral exchange rates seem to be superior to the nominal effective exchange rate. This conclusion may reflect the fact that in certain periods the values of CZK/USD and CZK/DEM evolve in opposite directions, making the NEER less significant (CZK/USD and CZK/DEM are the main components of the NEER).

We find no support for the existence of an extensive part of exchange rate elasticity when using either the Johansen or the other estimation techniques. We can thus conclude that currency substitution performs only through the "intensive" part of exchange rate elasticity.

An inspection of the estimation results gives no support for the existence of significant effect of returns on foreign assets, i.e. capital mobility, on the demand for Czech korunas from the perspective of domestic residents. We can thus conclude that substitution of currency within the domestic banking system (its intensive part) is the only relevant pattern for

---

<sup>12</sup> See table A1 in the appendix for the final estimation results using ARDL, DOLS and ADL.

Czech resident behaviour. Furthermore, in this respect money holdings in Czech currency were substituted by holdings denominated in both Deutsche Marks and U.S. dollars.

Finally, all the domestic determinants are highly significant. The coefficient on the *cpi* variable supports linear homogeneity of deposits in Czech Currency with respect to the price level. The high coefficient on the *ae* variable then points to the wealth accumulation effect. In another words, deposits are perceived to be a luxury good, i.e. as agents reach higher income levels they start to save by holding more of their funds as deposits. In terms of the poorest part of population, it implies that after attaining a certain level of income the impecunious agents not only consume but also start to save.

### ***3.3 Empirical Analysis of Currency Substitution in the Czech Republic from the Perspective of Demand for Foreign Deposits***

In this part, by estimating equation (2) we inspect the presence of currency substitution estimating the domestic demand for foreign deposits. We do not consider the pure stock of foreign deposits in the domestic banking system but rather model the ratio of such stock to domestic deposits.

Using the same set of explanatory variables as in the previous case, we estimate equation (7) of the following form:

$$fd/dd = \beta_1 cpi + \beta_2 ae + \beta_3 lr + \beta_4 e^{usd} + \beta_5 e^{dem} + \beta_6 rx^{usd} + \beta_7 rx^{dem} + \xi \quad (7)$$

where *fd/dd* is the ratio of foreign currency to domestic currency deposit stocks and the explanatory variables are the same as for the money demand. The results of our estimates of equation (7) using the Johansen technique are as follows:

$$fd/dd = 1.03cpi + 0.04lr + 0.74e^{usd} \quad (8)$$

(0.19)\*\*\* (0.01)\*\*\* (0.22)\*\*\*

Given our results, we conclude that agents are concerned with the real value of the *fd/dd* ratio. Thus we can justifiably assume price homogeneity in the case of *fd/dd* ratio demand. The overall insignificance of the scale variable most probably suggests that foreign deposits are held solely for store-of-value purposes. The estimates of the *lr* effect on the *fd/dd* ratio seem to be robust<sup>13</sup> and significant, though it has the opposite sign than was originally expected.

To explain the *lr* effect we recall that *lr* stands for the interest rate on credits. In the case of the Czech Republic this means the cost of financing,

---

<sup>13</sup> See table A2 in the Appendix.

assuming that financial intermediation goes mostly through the banking system. So if  $lr$  increases, agents probably look for an alternative source of financing. In the absence of effective domestic capital markets, this involves borrowing on foreign or international financial markets, resulting in an increase in foreign deposits in the domestic country when the funds are raised. The mechanism described here is relevant for Czech corporations, as these made intensive use of international sources of financing between 1990 and 1997.

When we move to the estimates of the returns on foreign currency, there is general support for the existence of a significant effect on the  $fd/dd$  ratio only from the CZK/USD exchange rate. The higher significance of the CZK/USD exchange rate probably results from the higher volatility of this rate, which has made domestic agents more aware of the opportunity cost of holding domestic currency.

From the perspective of capital mobility or (more precisely, in our case) of portfolio investment abroad, there is generally no support for returns on foreign assets having any effects on foreign currency deposits in the Czech Republic. This inference may result from some capital movement constraints at the beginning of our sample and/or lower incentives from domestic residents to invest abroad caused by a lack of information concerning the international market and only slow adoption of the technology necessary for international investment.<sup>14</sup>

Finally, we also include some additional ratchet variables to inspect various potential aspects of currency substitution. First, we employ the maximum level of the  $fd/dd$  ratio in the history of the estimated sample to inspect the possible dollarisation of the Czech economy. This variable is significant only in the equation estimated by ARDL, leading us to conclude that it is generally not important. Moreover, we again incorporate the historical peak values of the CZK/USD exchange rate to examine the possible presence of an extensive part of its elasticity. Again there is no support for this variable across the estimation techniques used. In the last step, we include historical peak values of inflation to inspect the effect of the creditworthiness of the Czech currency relative to foreign currency. Again, we find no support for such an effect on the  $fd/dd$  ratio.

---

<sup>14</sup> Nevertheless, we may still see this approach as a rather indirect method of estimating the demand for foreign assets. More precise insights concerning the effectiveness of the demand for foreign assets would provide an estimation of equation (4) in the portfolio model.

### 3.4 Empirical Analysis of Currency Substitution in the Czech Republic from the Perspective of Demand for Foreign Assets

This part is concerned with an examination of portfolio capital movement and its determinants. As a framework, we use equation (4) in the portfolio model presented above. We approximate domestic demand for foreign bonds using cumulative gross outflow of portfolio investment. Again, instead of using the pure cumulative value of domestic portfolio investment abroad, we model its ratio to deposits in the domestic currency.

We apply various cointegration techniques to equation (9) in log-linear form:

$$pi/dd = \beta_1 cpi + \beta_2 ae + \beta_3 lr + \beta_4 e^{usd} + \beta_5 e^{dem} + \beta_6 rx^{usd} + \beta_7 rx^{dem} + \xi \quad (9)$$

where  $pi/dd$  is the ratio of cumulative domestic portfolio investment abroad to deposits in the domestic currency and the set of explanatory variables is defined similarly as in the two previous cases. The estimation results using the Johansen technique are presented below:

$$pi/dd = 1.14rx_{t-1}^{usd} + 0.71rx^{dem} - 0.28lr - 1.17e^{usd} \quad (10)$$

(0.38)\*\*      (0.30)\*\*      (0.04)\*\*\*      (0.70)\*

The insignificance of coefficients on  $cpi$  and  $ae$  show that both the real value of foreign assets holdings and the alternative use of such funds for transaction purposes are not important in the determination of portfolio investment abroad. Such a conclusion may reflect the possible lower liquidity of such assets stemming from exchange rate risks and transaction cost. So we may suspect that once Czech residents invest their funds in foreign assets for store-of-value purposes, such funds are no longer used for prospective direct extension of medium-of-exchange stock. We find a highly significant, negative coefficient on the  $lr$  variable entering the decision-making process related to the demand for foreign assets.

Moreover, we can infer that there is significant influence of the return on foreign deposits held in the domestic banking system on the holdings of foreign assets, which would offer domestic agents higher liquidity and lower risks, assuming they are better informed about the domestic macroeconomic situation. However, this effect is not significant at the 5% level. Finally, the significance of the returns on foreign assets is what we are most interested in regarding the determination of capital mobility. According to the estimation techniques applied, the approximations of the returns on both USD- and DEM-denominated assets are highly significant. The effect of the return on USD-denominated assets seems to have its peak at around one lag and that of DEM-denominated assets at around the current value. In the Czech Republic's case, domestic agents perceive investment abroad as one possible

alternative of wealth allocation. We suppose that this pattern will promote itself even more in the close future.

### ***3.5 Summary of the Results and their Implications***

We can conclude from our analysis that both currency substitution (i.e. substitution of deposits in the domestic currency by deposits in foreign currency) and capital mobility effects (i.e. altering of deposits in the domestic banking system by holding foreign assets) are elements of Czech agents' behaviour concerning wealth allocation. When we consider the existence of currency substitution in the broad sense relating to the Czech Republic, we have to take into account several implications suggested by theory and/or experience from other transitional countries.

It is widely believed that allowing a foreign currency to coexist with the domestic one provides an opportunity for greater domestic intermediation, promotes financial sophistication by increasing the number of available assets, and increases credibility by raising the cost of poor monetary discipline. Moreover, the rapid development of foreign-currency denominated operations in the domestic banking system affects the stability of monetary aggregates, the dynamics of exchange rates and the government's revenues from seigniorage. Specifically, the higher the money demand elasticity of substitution between moneys, the larger is the shift from foreign to domestic currency as a result of a fall in expected relative inflation and, thus, the greater is the fall in the nominal exchange rate. Currency substitution also reduces monetary independence, which may then endanger the ability of central bankers to implement stabilisation programmes.

In other words, monetary and fiscal policies, the choice of exchange rate regime and interventions in foreign exchange markets are often undertaken in economies that experience "unofficial" or "*de facto*" dollarisation, i.e. where individuals and firms choose to use a foreign currency as a substitute for some of the monetary services of the domestic currency. Feige, Faulent, Šonje and Šošić (2000) suggest that under such circumstances the effective money supply may be much larger than the domestic money supply and may be subject to endogenous behavioural responses reflecting currency substitution on the part of the public. Similarly, the greater the extent and variability of dollarisation, the weaker is the central bank's knowledge of and control over the effective money supply. Such scenarios are, however, of lesser importance in the case of the Czech Republic. On the other hand, unofficial dollarisation will tend to dampen government efforts to employ inflationary finance to impose implicit taxes on domestic monetary assets. And again somewhat similarly, growing unofficial dollarisation reduces the ability of the monetary authority to earn seigniorage

from its own currency issue. Unofficial dollarisation also reflects citizens' perceptions of the stability of the domestic monetary regime, the credibility of monetary policies and the perceived stability of the domestic banking system.

#### **4. Conclusion**

In this paper we have discussed the possible presence of currency substitution and its resulting potential implications in a transitional country. First, we have analysed the performance of currency substitution in small open transition economies, stating the initial conditions and the process of transformation as similar for the countries considered. The first decade of the transformation process has been associated with simultaneous periods of internal and external liberalisation and alignment with developed countries. We have concluded that the launch of reforms was coupled with greater economic uncertainty, resulting in high and volatile exchange rates and inflation, large budget and current account deficits and inducing the use of foreign money for monetary purposes. In this context we have proposed several explanations concerning the factors determining currency substitution in the Czech Republic's case. These are associated with a relative lack of restrictions on capital flow, early adoption of necessary financial techniques and a sharp increase in openness. Moreover, we have discussed perspectives of substituting and substituted currencies in the global and local context. We propose four reasons for currency substitution: macroeconomic instability, the existence of a large illegal or underground economy, the former occurrence of financial crisis, and a lack of higher-denomination bank notes issued by the central bank. We have shown that the Czech koruna is not only a substituted currency, but has also for several years been the substituting currency for some post-socialist countries. A set of arguments for (and against) unilateral and bilateral euroisation has also been included here.

The last part has been dedicated to an empirical analysis of the currency substitution phenomenon in the case of the Czech Republic during the period 1994–2001. We have based our analysis on a multi-perspective portfolio approach. However, we have first modified, or rather reduced, the system, excluding the equation describing the demand for domestic bonds or alternative assets since the capital market is somewhat underdeveloped or, in the case of bonds, generally inaccessible in the Czech Republic. We have thus been left with three equations to describe the demand for domestic and foreign currency and for foreign assets. In this respect we have modelled the demand for domestic currency in circulation plus deposits denominated in domestic currency; the ratio of deposits denominated in foreign currency in the domestic banking system to deposits denominated in the domestic

currency; and the ratio of domestic portfolio investment abroad to domestic currency deposits. We have used a set of explanatory variables which approximate those suggested by theory, namely: the consumer price index, domestic absorption, the CZK/USD and CZK/DEM exchange rates, and the returns on U.S. and German Treasury Bills expressed in Czech currency. We have detected the presence of currency substitution in the domestic banking system and capital mobility. Exploring the full implication of these for the stability of monetary aggregates and demand for money, the revenues from seigniorage and the changing dynamics of exchange rates is left for further research.

## Appendix

Table A1: Final Estimates of the Demand for Deposits Denominated in Czech Currency

Variable	Estimation Methods			
	JOH(1)	ARDL(1,0,1,0)	DOLS	ADL
$m_{cz}(-1)$	-----	-----	-----	0.80 (0.05)***
cpi	1.08 (0.058)***	2.19 (0.56)***	2.11 (0.11)***	1.30 (0.02)***
ae	2.52 (0.24)***	1.55 (0.60)***	0	0
$ae(-1)$	-----	-----	-----	0.35 (0.03)***
lr	-0.012 (0.002)**	-0.034 (0.008)***	-0.023 (0.003)***	-0.02 (0.001)***
czk/usd	0	-0.80 (0.24)***	-0.44 (0.08)***	0
$czk/usd(-1)$	-0.34 (0.07)***	0	-----	-0.40 (0.03)**
czk/dem	0	0	-0.71 (0.17)***	0
$czk/dem(-1)$	-0.62 (0.19)**	-1.10 (0.65)**	-----	0
neer	0	-1.20 (0.56)**	0	0
rx_usd	0	0	0	0
$rx\_usd(-1)$	0	0	-----	0
rx_dem	0	0	-0.15 (0.04)***	0
$rx\_dem(-1)$	0	0	-----	0
constant	unrestricted	unrestricted	-----	0

\*, \*\*, \*\*\* indicate significance at 10%, 5% and 1% probability levels respectively. 0 denotes an acceptance of zero-restriction on the particular coefficient and ----- indicates that the given variable was not included in the estimated equation. In the case of multi-equation estimation methods (JOH, ARDL) the variables  $m_{cz}$ , *cpi* and *ae* were assumed to be endogenous.

The only dissimilarities compared to the Johansen estimates reported in the main text are the significance of nominal effective exchange rate in the

ARDL estimates and the significance of CZK/DEM exchange rate and return on German assets in the DOLS estimates. Nevertheless, the results presented in the main text are consistent with the results from the other estimation methods.

*Table A2: Estimates of Equation (7) Using Various Techniques*

Variable	Estimation methods			
	JOH(1)	ARDL	DOLS	ADL
fd/dd(-1)	-----	0	-----	0.31 (0.15)**
cpi	1.03 (0.19)***	1.13 (0.14)***	1.48 (0.13)***	1.03 (0.19)***
ae	0	0	-2.05 (0.41)***	0
lr	0.04 (0.008)***	0.04 (0.006)***	0	0.04 (0.007)***
e_usd	0.74 (0.22)***	0.76 (0.14)***	0	0.74 (0.18)**
e_dem	0	0	2.24 (0.83)**	0
rx_usd(-1)	0	-0.18 (0.074)**	0	0
rx_dem	0	0	0	0
constant	Unrestricted	-5.56 (0.52)***	0	-3.01 (0.73)***

\*, \*\* and \*\*\* indicate significance at 10%, 5% and 1% probability levels respectively. 0 denotes an acceptance of zero-restriction on the particular coefficient and ----- indicates that the given variable was not included in the estimated equation. In the case of multi-equation estimation methods (JOH, ARDL) only the *fd/dd* variable is assumed to be endogenous.

We can account for the significant negative coefficient on the *ae* variable in the DOLS estimated equation with following explanation. The increase in transaction amounts in the domestic economy is an impulse for the transfer of foreign deposits into domestic currency sight deposits for transaction (medium-of-exchange) purposes, although this hypothesis has no support from the other estimates.

Although the CZK/DEM exchange rate estimation seems to approximate the own rate of return on FD in the case of the DOLS estimation, this variable is not significant when the other estimation methods are used. We can however conclude that returns on foreign currency significantly affect the demand of domestic agents for foreign-currency-denominated deposits.

Table A3: Estimates of Equation (9) Using Various Techniques

Variable	Estimation Methods			
	JOH(1)	ARDL	DOLS	ADL
pi/dd	-----	0.40 (0.12)***	-----	0.40 (0.12)***
cpi	0	0	2.36 (0.77)***	0
ae	0	0	0	0
lr	-0.28 (0.04)***	-0.27 (0.03)***	-0.41 (0.06)***	-0.27 (0.03)***
e_usd	-1.17 (0.70)*	-0.90 (0.53)*	-2.35 (1.26)*	-0.90 (0.33)*
e_dem	0	0	0	0
rx_usd(-1)	1.14 (0.38)**	1.21 (0.34)***	-----	1.20 (0.26)***
rx_dem	0.71 (0.30)**	0.78 (0.27)***	0.77 (0.28)***	0.78 (0.17)***
constant	Unrestricted	0	0	0

\*, \*\* and \*\*\* indicate significance at 10%, 5% and 1% probability levels respectively. 0 denotes an acceptance of zero-restriction on the particular coefficient and ----- indicates that the given variable was not included in the estimated equation. In the case of multi-equation estimation methods (JOH, ARDL) only the *pi/dd* variable is assumed to be endogenous.

The results in Table A3 supports findings presented in the main text. The only additional finding is the significant positive coefficient on the *ae* variable in the DOLS estimated equation. As expected, this variable approximates the positive effect of increasing wealth on the demand for foreign assets.

# FOREIGN EXCHANGE INTERVENTIONS IN THE CZECH REPUBLIC: DID THEY MATTER?

## Abstract

*This paper studies the impact of daily official foreign exchange interventions on the Czech koruna's exchange rate vis-à-vis the euro (German mark prior to 1999) from 1997 to 2002. Using both the event study methodology extended with official interest rate moves and a variety of GARCH models reveal that central bank interventions, especially koruna purchases seem to have been relatively ineffective from 1997 to mid-1998 compared to the size of the interventions. At the same time, from mid-1998 to 2002, koruna sales turn out to be effective in smoothing the path of the exchange rate up to 60 days. Nevertheless, the event study approach indicates that the success of FX interventions may be intimately related to the coordination of intervention and interest rate policies.*

## **Abstract**

*The paper analyzes the degree of meeting the convergence criteria for adopting the euro in Central and Eastern European countries, spotlighting the particular aspects that characterize this process in Romania. A special focus is placed on the importance of not limiting the convergence process to the nominal criteria, as stated in the Maastricht Treaty, but also taking into account the real convergence degree with the euro zone. We propose a set of indicators to be monitored for assessing the level of real convergence, such as: GDP per capita; the structure of the economy; the degree of openness; the weight of bilateral trade with EU Member States in total trade and calculate their levels in Romania in the period 2000-2004. An important part of the paper is dedicated to assessing the relevance of the Balassa-Samuelson effect in Romania, as part of the catching-up process in order to ensure real convergence with the euro area. In this context, we research whether the exchange rate appreciation is only explained via the Balassa-Samuelson effect or underpinned by several other factors.*

**Keywords:** *real convergence criteria; Romania's integration in the EMU; Balassa-Samuelson effect; euro area; optimum currency area.*

## 1. Introduction

The problematic experience of Greece, Spain and Portugal in the process of ensuring economic convergence with the euro area brought into discussion the importance of completing the nominal convergence criteria with the real convergence ones, whose meeting must precede or at least accompany the meeting of the Maastricht criteria. By real convergence we understand the catching up of the gap between real GDP per capita in Romania and in the EU, as well as the need for implementing structural reforms and finalize the transition towards a functional market economy. Given the fact that economic literature is not overwhelming in providing a set of real convergence indicators, the present paper aims at providing such a set, which is quantified and interpreted for Romania.

For the assessment of the readiness of Central and Eastern European countries to join the euro area, Maastricht criteria can induce misunderstandings, given the conceptual differences, the interpretations and methodology that are used. Adopting the euro must be prudently put in practice and a forced meeting of the Maastricht criteria could generate substantial costs for the real economy of a candidate country to the EMU. The optimum currency area theory must be also taken into account, as well as the warnings addressed by both the European Commission and the European Central Bank on the risks incurred by a country who prematurely adopts the euro, while its economy is not enough convergent with the Western European structures.

According to the optimum currency area theory, states within a monetary union can be in the win-win position after abandoning their national monetary policies and adopting a common currency only when their economic structures have a high degree of real convergence (ensured via flexible prices and wages; integrated labor markets; integrated financial markets; high degree of openness; diversification of production and consumption; political will for integration). Central and Eastern European countries, Romania included, are very sensitive to the occurrence of asymmetric shocks; therefore the incapacity to use their national monetary policies as a stabilizing instrument could cause serious problems. In such a context, it is very important to *ex ante* assess both nominal and real convergence criteria.

According to the real convergence criteria, the successful participation of Romania to the euro area depends upon the capacity to reduce the occurrence of asymmetric shocks and to consolidate the efficiency of the adjustment mechanisms in the absence of independent monetary policy. Four elements are particularly taken into account:

[1] synchronizing business cycles from Romania and the euro zone;

[2] fiscal policy must acquire a stronger role in stabilizing the economy both before and after adopting the euro. The main objective is to ensure a “budgetary field of maneuver” in the event of asymmetric shocks. Moreover, fiscal policy will play a very important part in case of pressure on the current account as a result of constant deterioration in the savings/investment ratio for the private sector;

[3] flexibility of prices and wages should be ensured. In what the flexibility of wages is concerned, the gap to be caught up by Romania is not so large, whereas the situation regarding prices flexibility is still critical. In this respect, competition on the internal market should be consolidated, together with finalizing the privatization process, obeying competition rules, giving up administrated prices, decreasing the regulation burden on the business sector and providing constant support for entrepreneurship;

[4] a certain level of competitiveness must be ensured and maintained. After joining the euro area, Romania could suffer from losses of competitiveness as a consequence of pressures exerted over wages and prices, on the background of increased domestic demand, encouraged by low interest rates.

Taking into account the obvious importance of measuring and monitoring the degree of real convergence between the Romanian economy and that of the euro area, we have deemed useful to draw a grid of real convergence criteria for Romania, based on the optimum currency area theory, to be analyzed together with Maastricht nominal convergence criteria grid.

## **2. Real convergence criteria grid**

The following criteria have been included: real GDP per capita; the degree of labor market integration and labor mobility; the degree of openness of the economy; production diversification; trade intensity and business cycle correlation.

### ***2.1 GDP per capita***

GDP per capita can provide a meaningful image on real convergence among countries, be they member states or candidate countries and can be expressed using nominal exchange rates or the purchasing power parity.

Table 1 and Graph 1 show the high degree of divergence between the Romanian economy and that of the EU. They also point to the fact that the group formed by Romania, Bulgaria and Turkey is characterized by a much

lower level of GDP (both at nominal exchange rate and purchasing power parity – PPP) as compared to the other European countries.

**Table 1 GDP per capita (euro)**

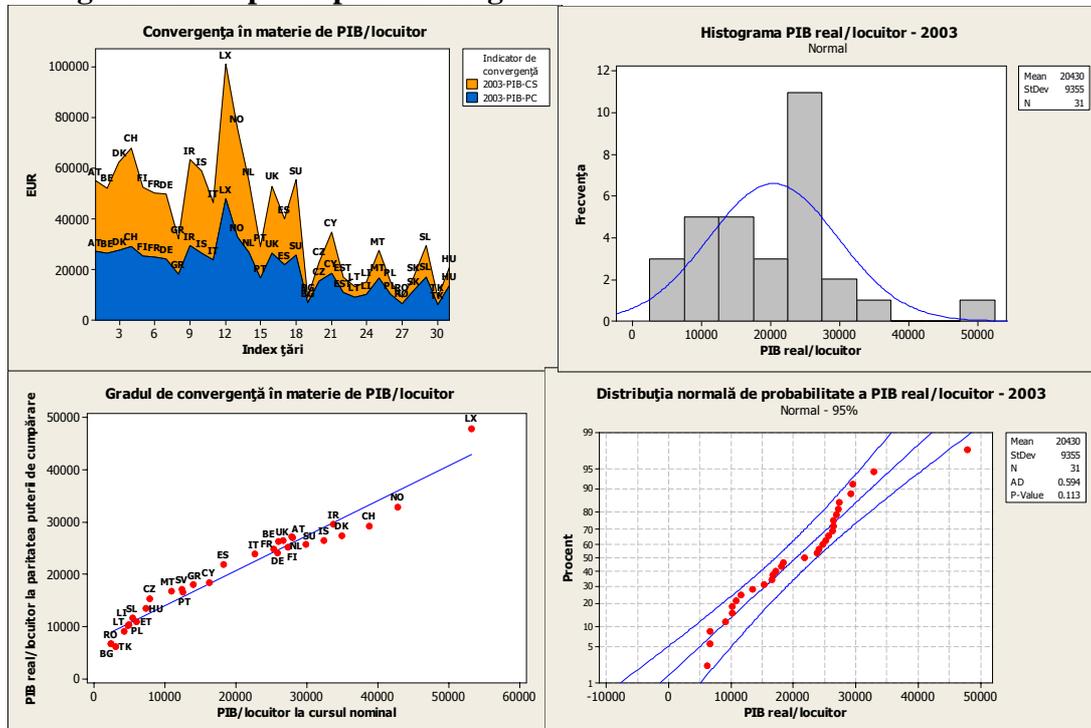

<i>Country</i>	<i>GDP per capita at nominal exchange rates</i>			<i>GDP per capita at PPP</i>		
	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2001</b>	<b>2002</b>	<b>2003</b>
<i>Austria</i>	26460	27444	27926	26140	27072	27272
<i>Belgium</i>	24690	25278	25983	24970	25750	26277
