Scenarios regarding the catching up of this gap are not very optimistic. Supposing a long term differential in GDP growth of about 4%,

the gap might be caught up in about 60 years, without taking into account the appreciation of the national currency in real terms. Forcing economic growth to higher rhythms, for example 8% per annum, would overheat the economy; feed inflation, the current account deficit or a combination of the two.

**Figure 1 GDP per capita convergence**

## 2.2 Labor market integration and labor force mobility

Mundell, Eichengreen, Bentolilla, Thomas, Braunerhjelm, Faini, Norman, Ruane and Seabright, Fatas, Blanchard and Katz point to the fact that production factor mobility is a strategic attribute of an optimum currency area and an adequate criterion for assessing real convergence. Once this criterion is met and asymmetric shocks are met, no adjusting is needed as labor force mobility can act as an automatic stabilizer.

It is likely that EU enlargements would open the perspective of free labor force movements within Europe and further on contribute to an increase in the degree of economic convergence of European economies. As for Romania, we have considered useful to assess unemployment rate per region according to the following judgment pattern: when there is no homogeneity for unemployment between the Romanian regions and taking into account the

fact that distances are small and there are no legislative, language or cultural barriers, it is less probable that labor mobility towards the EU would increase in future.

Table 2 presents unemployment rates for the Romanian regions and Bucharest in december 2003. Statistics show that there is a low propensity for labor force mobility in the North-East, South-East, South and South-West regions, as compared to the Western and North-Western ones.

**Table 2 Unemployment rates in the Romanian regions and Bucharest, 2003**

Region	Unemployment rate (%)
North-East	9,0
South-East	8,1
South	8,3
South-West	9,1
West	7,0
North-West	5,4
Bucharest	2,8

*Source: Annual Statistics of Romania, 2004.*

### **2.3 Degree of openness of the economy**

*Beck, Weber and McKinnon* show that in an open economy, the exchange rate can be easily fixed and the country can become a member of the monetary union, with no important costs associated. We have considered it relevant to measure the degree of openness of the Romanian economy by using as a proxy the degree of trade integration (the ratio of cumulated exports and imports in total GDP).

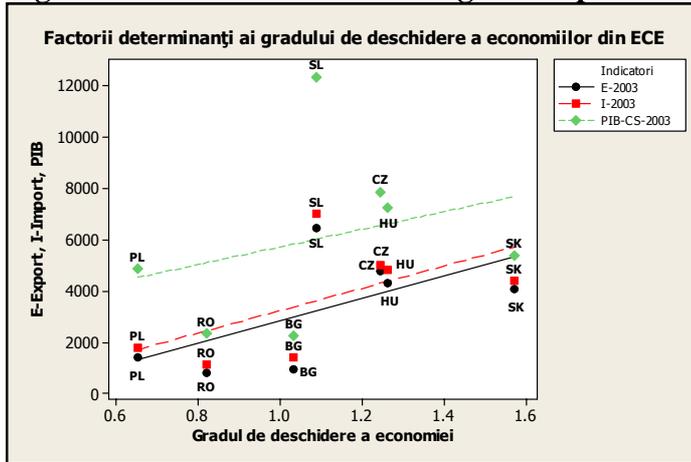

Table 3 and Figure 2 show an average degree of openness for Romania, much lower than for the Czech Republic, Slovakia and Hungary, but higher than that of Poland.

**Table 3 Degree of openness for Central and Eastern European Economies**

	2000	2001	2002	2003
Bulgaria	116,8	118,7	112,9	116,8
Czech Republic	143,0	144,2	132,7	134,4
Poland	63,1	59,8	63,3	72,6
Romania	70,6	74,5	76,5	80,4
Slovakia	146,0	156,5	152,7	157,8

**Figure 2 Determinants for the degree of openness**

#### 2.4 Degree of production diversification

*Bini-Smaghi, Vori and Krugman* show that countries with diversified structure of production should try to take benefit of the advantages generated by a fixed exchange rate given the fact that demand fluctuations and supply shocks would cancel one another at microeconomic level. A well diversified structure of production and exports can protect the economy from the effects of asymmetric shocks or at least disperse these effects.

Within the sectoral structure of GDP in Romania, agriculture has the highest weight, a much too high one, comparable with the one in Bulgaria, as can be noticed in Table 4.

**Table 4 Sectoral structure for GDP**

Table 5 shows a comparison regarding the value added in agriculture, industry and services as percent of GDP in 2003.

Figure 3 points to the fact that Romania is asymmetrically positioned in the inferior side of the distribution interval regarding services and the superior side regarding agriculture.

Figure 3

### 2.5 Business cycles correlation

Business cycle correlation degree can be used to assess the nature of dominant shocks affecting the respective countries. If business cycles are synchronized, countries can form an optimum currency area. We have researched whether the business cycle of Romania is correlated with those of its main trade partners, namely UE as a whole and Germany and Italy as individual partners.

In order to estimate the degree of correlation between the business cycles, we consider that the most relevant indicator is the growth rate of real GDP and we analyze the deviations of GDP growth rates against the trend on the bases of seasonally adjusted Hodrick Prescott data for Romania, Italy, Germany and the EU (Table 6).

**Table 6 Seasonally adjusted real GDP growth rates**

	EU	DE	IT	RO	EU-HP	DE-HP	IT-HP	RO-HP
1993	-0.25	0,2	1,5	1,5	1.599179	2,09197	2,22164	1,67459
1994	2.81	4,1	2,4	3,9	1.739549	2,06901	2,18314	1,52484
1995	2.30	1,9	2,6	7,1	1.861426	2,02713	2,13743	1,37334
1996	1.53	1,4	1,4	3,9	1.957025	1,96773	2,07946	1,24211
1997	2.36	2,2	2,2	-6,1	2.022943	1,89091	2,0088	1,2104
1998	2.70	2	2,4	-4,8	2.051509	1,79113	1,91824	1,38408
1999	2.43	2,05	1,66	-1,2	2.038421	1,66591	1,80247	1,79589
2000	3.30	2,86	3,03	2,1	1.985863	1,51487	1,661	2,41674
2001	1.38	0,85	1,76	5,7	1.899935	1,34148	1,49193	3,18758
2002	0.90	0,18	0,36	5,1	1.799877	1,16265	1,30703	4,04617
2003	0.70	-0,1	0,26	5,2	1.699731	0,99038	1,12076	4,95544
2004	2.10	1,7	1,3	8,3	1.604540	0,82684	0,93811	5,88882

In order to ensure high accuracy to the analysis, we have used a linear function, as well as a quadratic function for the trend. The results can be summarized as follows.

In case of applying the **linear function**, we get the following sets of data for characterizing the trend and residuals, respectively (Table 7 and Figures 4-7).

**Table 7 Linear trend functions**

	LINIAR_ UE	REZ_LIN_ UE	LINIAR_ _DE	REZ_LIN_ _DE	LINIAR_ _IT	REZ_LIN_ _IT	LINIAR_ RO	REZ_LIN_ _RO
1993	1,87692	-0,277744	2,26667	-0,1747	2,38513	-0,16349	0,44872	1,22587

2000	1,99176	-0,0058966	1,51949	-0,00462	1,65361	0,007387	2,42963	-0,01289
2001	1,92871	-0,0287742	1,36462	-0,02314	1,49867	-0,00674	3,10453	0,083045
2002	1,83613	-0,0362496	1,19187	-0,02922	1,32498	-0,01795	3,92509	0,121079
2003	1,71401	-0,0142809	1,00123	-0,01084	1,13253	-0,01178	4,89132	0,064118
2004	1,56237	0,0421750	0,7927	0,034147	0,92134	0,016762	6,00322	-0,1144

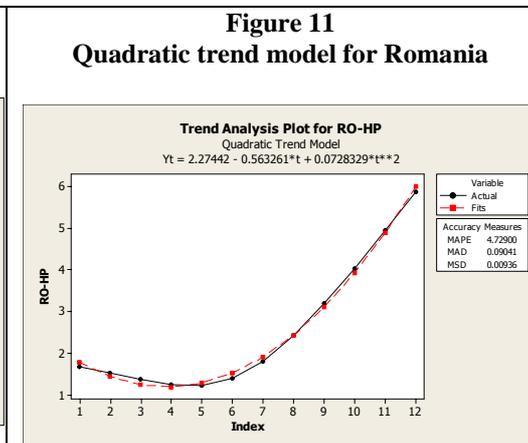

**Figure 8**  
Quadratic trend model for Italy

**Figure 9**  
Quadratic trend model for Germany

**Figure 10**  
Quadratic trend model for the EU

**Figure 11**  
Quadratic trend model for Romania

By comparing the accuracy indicators: MAPE (*Mean Absolute Percentage Error*); MAD (*Mean Absolute Deviation*); MSD (*Mean Squared Deviation*) we can assess that the quadratic trend model is more appropriate for the purpose of the analysis. We then analyze the correlation between real GDP growth rate deviations from the trend approximated by a quadratic function in Romania, Italy, Germany and the EU

Pearson correlation shows the following results with a high trust level (p-value is lower than 0,05):

**Correlations: REZ\_PATRATIC\_IT, REZ\_PATRATIC\_RO**

Pearson correlation of REZ\_PATRATIC\_IT and REZ\_PATRATIC\_RO = -0.932  
P-Value = 0.000

**Correlations: REZ\_PATRATIC\_DE, REZ\_PATRATIC\_RO**

Pearson correlation of REZ\_PATRATIC\_DE and REZ\_PATRATIC\_RO = -0.641  
P-Value = 0.025

**Correlations: REZ\_PATRATIC\_EU, REZ\_PATRATIC\_RO**

Pearson correlation of REZ\_PATRATIC\_EU and REZ\_PATRATIC\_RO = -0.732  
P-Value = 0.007

We can thus notice that there is a high degree of reverse correlation between the business cycle in Romania and those in Italy and the EU, as well as a reverse correlation, but not that intense between the Romanian and the German business cycles.

### **3. The Balassa-Samuelson effect in Romania**

A large part of the economic literature is dedicated to the discrepancy between purchasing power parity and the exchange rate. The Balassa-Samuelson hypothesis links the differential of relative prices (tradables and non-tradables, domestic and abroad) to the differential in labor productivity. Productivity tends to increase faster in the sector of tradables as compared to the non-tradables, which pushes wages upwards in the entire economy. Given the fact that in the economies that follow a catching-up process the increase in productivity is higher than in mature economies, given the imperative to ensure real convergence, the Balassa-Samuelson effect will imply a higher increase in the consumer price index in the candidate countries to the EMU and their real exchange rates will tend to appreciate.

We consider it important to spotlight the weak points and eventual shortcomings of the model pointing to the Balassa-Samuelson effect. First of all, the hypotheses referring to perfect competition on the international markets of goods, perfect labor mobility and the absence of competition in

the field of services are not part of reality. Moreover, it is possible that real appreciation induced by gains of productivity to be diminished or intensified by exogenous factors to the model. Gains in productivity are not limited to the industrial sector, but on the contrary, expand to banking services, insurance, transports, distribution etc. When the gain in productivity is the same in the field of tradables and services, the Balassa-Samuleson effect could be null.

There is no clear evidence of the increase in productivity in Central and Eastern European countries higher than in the euro area. Gains in productivity have been indeed impressive in the 90s, but have been rather exceptional, especially by reducing the artificial employment level from socialism and it would be useful to know if these gains could be maintained (opposite factors such as high energy and labor consumption per product can have a high negative influence, especially in the agriculture sector).

#### **4. Conclusion**

At least for the moment, the initiative of creating a currency union by Romania and its trade partners of the EU would be not appropriate, given the high probability of not being able to face asymmetric shocks. A potential deficit of the approach that we have used is the fact that it is based on historical data and situations can change in future, even as a consequence of the deepening in the monetary integration process. It is nevertheless desirable that Romania would make serious efforts to gradually meet real convergence criteria along with the nominal convergence ones.

In what the applicability of the law of one price is concerned, transition economies are able to align to international prices for tradables, no matter what exchange rate regime they choose. The *de facto* application of the law of one price will be obvious for aligning prices to the EU level and in such a context it is questionable whether Central and Eastern European countries are ready to give up the exchange rate instrument.

## **Abstract**

*This paper studies exchange rate pass-through effect (PTE) on consumer and producer prices in Russia. We find that PTE is significant on most prices and very diverse, but incomplete even in the long run. We also find asymmetry in price reactions to exchange rate appreciation and depreciation. Since the studied period includes Russia's balance of payments crisis of August 1998, we test PTE before and after the crisis and find that PTE was the highest during the crisis and decreased after some structural adjustment of the economy. We also estimate that monetary policy increased PTE during the crisis what pushed prices further.*

**Keywords:** *pass-through effect; exchange rate; inflation; monetary policy*

## 1. Introduction

The term "pass-through effect" refers to the effect of changes in the exchange rate of a domestic currency for foreign currency (or a trade-weighted portfolio of foreign currencies) on the country's domestic prices for traded and non-traded goods. The famous survey of Goldberg and Knetter (1997) defines pass-through effect (or pass-through elasticity) (PTE) as "percentage change in local currency import prices resulting from a one-percent change in the exchange rate between the exporting and importing countries". Other authors (Menon 1995, McCarthy 2000, Hufner and Schoder 2002) understand pass-through effect in a broader sense, as "the process how home prices change in response to changes of exchange rates". Before the end of 1970s academic economists did not pay enough attention to this phenomenon. However, in recent years this topic has become increasingly popular in many countries, perhaps in response to globalisation of the international markets and foreign trade growth. Higher PTE implies greater dependence of an open economy on external shocks in the world market and higher volatility of domestic prices due to changes in the exchange rate. Therefore, the government authorities should know the degree of PTE to forecast domestic inflation and conduct adequate inflationary and exchange rate policies.

This paper is devoted to estimation and analysis of PTE in Russia, measured as the percentage change in Russian prices in response to a 1-percent change in nominal effective exchange rate of rouble (pass-through elasticity). The purpose of our research is to answer the questions: "What is the effect of nominal exchange rate changes onto domestic inflation?", "Does this effect differ across different price categories?" and "What are the factors which determine the degree of PTE?".

This research program is interesting for the following reasons. First, PTE has not been studied properly in Russia: so far there is no single published research paper devoted to this problem. The studies based on other countries' data convincingly show that domestic prices less-than-fully react on the exchange rate fluctuations, implying the PTE is incomplete. Does a similar tendency hold for Russia, and if yes, what are the peculiarities of the Russian experience, and how they can be explained? Second, besides pass-through incompleteness, researchers and practitioners alike are naturally interested in the speed of domestic prices' adjustments. In August 1998, during the currency and debt crisis, the Russian rouble lost more than 60% of its value against US dollar in a week, but this sharp depreciation did not cause a similar and simultaneous burst of the domestic inflation, backed by the expansionary monetary policy, which had an additional effect on domestic

prices. In addition to that, depreciation of rouble has led to great structural changes in the Russian economy and, hence, PTE might have changed as well. Based on this assumption, in this work we study PTE before, during and after the crisis and analyse changes in it.

This research program is related to several theoretical issues and has some practical implications. From *microeconomic viewpoint*, our results may be used by enterprises in different industries to forecast future cash flows and profits, for developing pricing strategies and analysis and management of the exchange rate risk. For example, if PTE in an industry is low, the costs of the imported goods to the Russian firms, expressed in domestic currency, will rise more in case of rouble depreciation, than the revenues which arise from selling these goods on the domestic market, because it is impossible to pass the whole exchange rate change onto output prices. In such case the Russian importer will not only lose a part of its profits, but also might find itself in a situation when it cannot repay its debt to the foreign creditor, which is denominated in foreign currency terms. This exchange rate risk is especially strong in industries with low PTE, which should take care of hedging against it. From *macroeconomic* point of view, this research may be useful for the government and the Central bank for forecasting inflation in Russia on aggregate level and in different industries, as well as for the determination of monetary and exchange rate policies and for industrial regulation purposes. For example, if PTE on consumer prices in a country is large, then in order to maintain the targeted inflation rate and to reduce prices volatility the Central bank should adjust money supply in response to the exchange rate fluctuations, thus reducing PTE. In other words, monetary policy should be endogenous to the exchange rate. Testing this prediction amounts to the estimation of the effects of monetary policy on PTE, which is done in the third section of our paper.

In this paper we estimate and compare different-term PTE on different price categories (the consumer price index (CPI), the producer price index (PPI)<sup>3</sup> and their components) from the beginning of 1995 till the end of 2002. We explain the differences in PTE on consumer and producer prices, on traded and non-traded goods and in different industries of the Russian economy; we analyse the influence of monetary policy on PTE; finally, we study PTE before, during and after the crisis of 1998 and in periods of rouble depreciation and appreciation. To estimate PTE, we apply two-stage procedure of constructing Error Correction Model, which takes into account the long-run relationship.

---

<sup>3</sup> In this paper we do not study PTE on import prices since the import price index is unavailable.

The rest of the paper is organised as follows. The next section describes existing theories and findings of other authors. Section 3 is devoted to estimation and analysis of different-term PTE on consumer and producer prices. In section 4 we study influence of government monetary policy on PTE. Sections 5 and 6 analyse structural changes in PTE after the crisis of 1998 and asymmetries of PTE in case of appreciation and depreciation of rouble respectively. The last section is devoted to conclusions and policy recommendations.

## 2. Literature review and existing evidence

### 2.1. Theories of exchange rate PTE

$$P = P^* \times E$$

where  $P$  – domestic price level,  $P^*$  - foreign price level (assumed to be constant),  $E$  – exchange rate, measured in units of the domestic currency per unit of the foreign currency (indirect quotation – see e.g. Obstfeld and Rogoff (1995, 1998, 2000a))<sup>4</sup>. But even in the simplest models assuming PPP, inter-country differences in PTE of exchange rate on domestic prices may exist. In a *large economy* the inflationary effect of depreciation of domestic currency is counteracted by a decline in world prices (due to decreased world demand), which tends to decrease the observed PTE, whereas in a *small economy* PTE should be complete. However, this theoretical model is based on several assumptions, which do not hold in real world, e.g. the assumptions of perfect competition and absence of transaction costs. Empirical studies show that PTE is not complete in most cases (Isards, 1977; Rogoff, 1996), including that of small economies (Lee, 1997).

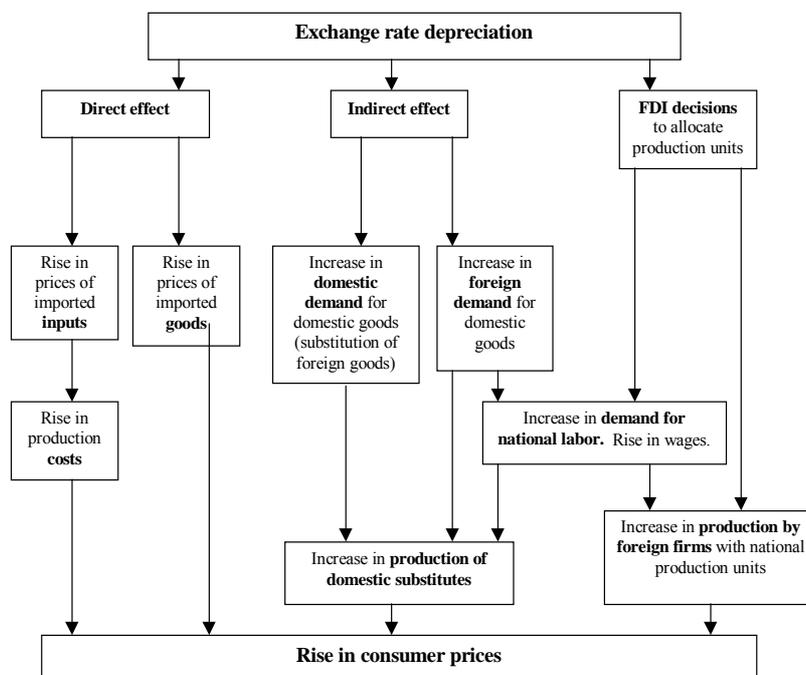

A number of theories were proposed to explain why PTE is incomplete in real life. Obstfeld and Rogoff (2000b) model assumes presence of transportation costs, which increase prices of imported goods and preclude their perfect substitutability for the competing domestic goods. A related argument is that the costs of imported inputs constitute only a small part of the cost of a final good, but the majority of costs being attributable to non-traded services, such as marketing and distribution. Several authors (Bergin and Feenstra, 2001; Bergin, 2001, Corsetti and Dedola, 2001; Bachetta and Wincoop, 2002), argue that PTE may be below 100% even if prices are fully

---

<sup>4</sup> It should be noted that The Law of One Price has an economic sense only for import prices and not for all domestic prices in an economy, since there is no theoretical reason why exchange rate should completely pass through onto the prices of domestically produced goods.

flexible, but markets are imperfectly competitive, which may create incentives for optimal price discrimination or strategic pricing. Finally, if the imported good is an intermediate good, which has locally produced substitutes priced in domestic currency, the local producer may replace the imported input by the domestic one in response to exchange rate changes. Obstfeld (2001) terms this “expenditure-switching effect”, which depends on the degree of substitutability between local and imported goods.

**Figure 1. Mechanisms of PTE**

There are at least three possible chains through which prices of final goods adjust to the fluctuations of nominal exchange rate: direct, indirect and flows of FDI. Lafleche (1996) summarizes them in a diagram, which is adjusted for the Russian experience and presented on Figure 1.

The *direct effect* chain includes direct change in prices of imported intermediate and final goods due to a change in exchange rate, akin to the income effect in demand theory. Empirical literature uses import price index to study this effect separately. Obstfeld and Rogoff (2000) and other authors present evidence that import prices are more sensitive to changes in nominal exchange rate than consumer prices in general. In this paper we do not study the direct effect separately due to unavailable import price index for Russia.

The *indirect effect* chain is based on substitution between foreign and domestic goods. This includes substitution between domestic and imported final goods at home markets (internal substitution), as well as that at foreign markets of our country's trade partners (external substitution). *Internal substitution* can follow devaluation of the domestic currency, which induces "flight from quality" (Burstein et al. (2003)). *External substitution* takes place because devaluation makes domestic goods relatively cheaper for foreigners who increase demand for them. If nominal wages are fixed in the short run, real wages decrease and hence national output increases. However, when real wages adjust to their original level, production costs will increase, the overall price level increases and output falls. In the long run this effect is described by the Marshall-Lerner condition, and confirmed empirically by the Russian current account data.

The *FDI decisions* also are induced by devaluation of domestic currency, which depresses demand for foreign goods and deflated nominal wage in terms of foreign currency. Foreign producers and multinationals then face a dilemma – either to lose the export market or to start production in the devaluing country to exploit comparative advantages of location, cheaper resources and lower wages. This is exactly what happened in Russia after the devaluation of the rouble in 1998, resulting in production boost, increased labour demand and wages, followed by an increase in prices in the longer term.

## **2.2. Empirical evidence**

However compelling are the above explanations, discrimination between them is not straightforward, not least because empirical evidence of PTE is quite heterogeneous. Most part of existing research is concentrated on the effects of exchange rate changes on *import prices* (Goldberg and Knetter (1997) provide a detailed survey). Several works study PTE on *producer and consumer prices* (e.g. Woo (1984), Feinberg (1986, 1989), Parsley and Popper (1998), McCarthy (2000)); some more consider its relationship to the export prices (e.g. Klitgaard (1999), Dwyer, Kent and Pease (1993)). Most authors concentrate on PTE across industries and products, as well as its dependence on macroeconomic policy measures, such as monetary policy, as discussed in the next subsection.

Almost all studies report that exchange rate PTE on national prices is incomplete and varies greatly across countries, industries and other parameters under investigation. Most works are based on the American markets because of their size and superior quality of the data (Menon (1995) describes results of 43 such papers). Quite a few authors analyse PTE on other OECD countries, such as the EU (e.g. Hufner and Schoder (2002),

Fouquin et al (2001)), Australia (Menon (1996), Dwyer, Kent and Pease (1993)), Japan (Tokagi and Yoshida (2001)); as well as developing countries, such as Korea (Lee, 1997), Taiwan (Liu, 1993), Chile (Garcia, Jose and Jorge, 2001), Belarus (Tsesliuk, 2002) and Ukraine (Kuzmin, 2002). Some papers study inter-country differences in PTE for developed countries (e.g. McCarthy (2000), Hufner and Schoder (2002)). Darvas (2001) and Dubravko and Marc (2002) are two of several papers which study PTE in some developing countries, where the effect appears to be larger than for the developed ones. Empirical results also imply that PTE is heterogeneous across countries: thus, Dwyer, Kent and Pease (1993) concluded that pass-through on import prices is higher than that on export prices in short run in Australia, while the tendency appears to be opposite for Japan (Takagi and Yoshida, 2001).

Research on PTE at the *industry level* was mostly concentrated on studying pricing strategies and behaviour of mark-ups (the difference between the selling price and the cost of goods sold) in response to changes in an exchange rate. A theoretical basis for most of these studies was the work of Dornbusch (1987), which appeals to the arguments from industrial organization. Specifically, it explains the differences in PTE by market concentration, degree of import penetration and substitutability of imported and local goods. For instance, if profit-maximizing firms have significant market power in a given industry, PTE is expected to be high in spite of other factors (Phillips (1988)). On the contrary, if firms aim to maximise their market share instead of profits, PTE will be lower (Hooper and Mann (1989), Ohno (1990)). Moreover, if opportunities to discriminate between markets exist, then the situation of “*pricing-to-market*” may occur, which will lead to different PTE in different segmented markets (Krugman (1987), Gagnon and Knetter (1992)).

Goldberg and Knetter (1997) reported that PTE on import prices is lower in more segmented industries, where producers have more opportunities for third-degree price discrimination. Yang (1997) estimated, that PTE is positively related to the degree of product differentiation (i.e. negatively related to the degree of substitutability of goods) and negatively depends on the elasticity of marginal costs with respect to output. Also, PTE is affected by the degree of returns to scale in production of imported goods (Olivey (2002)). On the basis of these principles Feinberg (1986, 1989) concluded that PTE on prices of national producers is higher in industries, which are less concentrated and which have higher import share. These conclusions have been occasionally challenged. E.g. Menon (1996) found that PTE negatively depends on quantitative restrictions (quotas) for imports,

foreign control (presence of multinational corporations), concentration, product differentiation and import share in total sales and positively depends on substitutability between imported and domestic goods.

### 2.3. Influence of monetary policy on PTE

According to the principle of money neutrality an increase in money supply causes a proportional increase in home prices in the long run. This effect co-exists with the exchange rate pass-through. Expansionary monetary policy provokes devaluation of home currency, what make extra pass-through in home prices, but, on the other hand, monetary policy in many countries is aimed at achieving price stability and is adjusted to the exchange rate fluctuations to reduce PTE<sup>5</sup>. Empirical literature on western economies (Parsley and Popper (1998)) concludes that the monetary policy can offset exchange rate changes and reduce pass-through. Is this the case for Russia? This seems quite possible, especially given that monetary policy and exchange rates are interdependent because the exchange rate is not freely floating. Therefore, following economic logic and findings of the other authors, monetary policy should be taken into account when estimating PTE.

Parsley and Popper (1998) demonstrate empirically that omission of this variable results in biased estimates of pass-through, and suggest that monetary policy should be explicitly included into the model. To show the effect of its omission, suppose that the price of a particular good is determined by the following function: in each period,  $t$ ,

$$p_{it} = E\{f_i[e_t, m(g_t), z_{it}]I_t\}$$

where  $p_{it}$  is the price of the  $i$ -th good,  $e_t$  is the nominal exchange rate in terms of foreign currency units per domestic currency unit,  $m(g_t)$ , is monetary policy, implemented using some instruments  $g_t$ ,  $z_{it}$  summarises all other factors that affect the individual price, and  $I_t$  represents the information available when the price is determined.

Then the underlying responsiveness of individual and aggregate prices to the exchange rate can be characterised as follows:

$$\gamma_i = \frac{\partial E\{f_i[e_t, m(g_t), z_{it}]I_t\}}{\partial e}, \text{ and } \gamma = \int_0^1 \alpha_i \gamma_i di$$

When monetary policy is unrelated to exchange rate movements, these parameters,  $\gamma_i$  and  $\gamma$ , can be estimated directly. In practice, measuring the impact of exchange rate changes on domestic prices may be complicated

<sup>5</sup> For example, the European Central Bank has cited the possible inflationary effects of the weak Euro as one factor behind its tightening of monetary policy in 2000 (May 2000 issue of the ECB Monthly Bulletin).

by the actions of the Central bank. The monetary policies of many countries respond to changes in the exchange rate, even if only implicitly. That is, often  $\frac{dm(g_i)}{de} \neq 0$ . This means that monetary policy is endogenous to the exchange

rate. In such cases, the exchange rate affects prices in two ways. It affects prices directly, through the parameters  $\gamma_i$  and  $\gamma$ , and it affects prices indirectly through its influence on monetary policy,

$$\frac{\partial p_i}{\partial m(g_i)} \frac{dm(g_i)}{de} \text{ and } \frac{\partial p_i}{\partial m(g_i)} \frac{dm(gt)}{de}$$

Ignoring the role of monetary policy will bias measures of the underlying responsiveness of prices to exchange rate changes. This problem affects estimates of the responsiveness of both individual prices and the aggregate price index: ignorance of monetary policy during domestic currency depreciation would result in underestimation the effects of the exchange rate on prices.

The same will be true if we assume that monetary policy can moderate price fluctuations not only by offsetting the effect of changes in the exchange rate, but also by influencing the exchange rate itself. In such a case we assume that both monetary policy and the exchange rate are generally endogenous to each other. Such a situation is relevant for Russia, where the Central bank used to maintain the exchange rate in a corridor by changing its reserves and money supply. Again, if monetary policy during depreciation of domestic currency is ignored, the effect of the exchange rate on domestic prices may appear smaller than the true PTE. This would mean that monetary policy is aimed at reducing pass-through and price volatility.

### **3. Estimation of different-term PTE**

#### **3.1. Data**

All data used in this research are time series with monthly frequency and cover time span from the beginning of 1995 till the end of 2002. All indices are transformed to the base period January, 1995 and are expressed in natural logarithms. The main sources of data are Official Statistics of Goskomstat (State Statistical Committee of Russian Federation) and International Financial Statistics (IFS). Data are available from the authors upon request.

Dependent variables:

National Producer Price Index (LN\_PPI). Detailed structure includes indices for the following industries: energy, oil, ferrous and non-ferrous metals, chemical industry, petrochemical industry, machinery, construction materials, textile, food processing and wood industry. The primary data on price indices are taken from Goskomstat Statistical Annual Report, 2003. On aggregate level PPI is presented in International Financial Statistics, 2003, series code 92263XXZF.

National Consumer Price Index (LN\_CPI). Detailed structure of CPI includes food (FOOD), goods (GOODS) and services (SERV). The primary data of CPI and its components are taken from Goskomstat Statistical Annual Report, 2003. On aggregate level CPI is taken from International Financial Statistics, 2003, series code 92264XXZF.

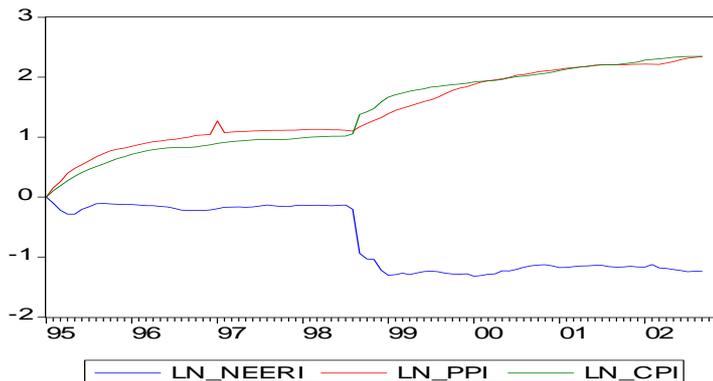

Explanatory variables:

Nominal Effective Exchange Rate Index (LN\_NEERI). The exchange rate is measured as the number of units of trade weighted foreign currencies per unit of domestic currency (Russian rouble). An increase in NEERI means appreciation of the rouble. The primary source of data is International Financial Statistics, 2003, series code 922..NECZF. Figure 2 below demonstrates time profile of the three variables central for our research. The outlier in the 12/97 originates from IFS statistics.

Price of Oil (LN\_OIL). Price of “UK Brent” serves as a proxy for the price of Russian oil “Urals” (which is more relevant for our analysis), since the price of “Urals” is not available for the whole time period, but on the available sample the prices correlate with coefficient 0.96. Monthly time series are provided by International Financial Statistics, 2003, code 11276AAZZF.

Money Supply (LN\_MONEY). Aggregate money supply (M1) from International Financial Statistics 2003, code 92234..ZF..

**Figure 2. Time profiles of NEERI and national price indices**

Real Consumption (LN\_RCONS). Serves as a proxy for real GDP because monthly data on real GDP is not supplied in Russia. The source of data: Goskomstat Statistical Annual Report 2003.

All data have been tested for stationarity. We used ADF test with the specification chosen according to Dolado, Jenkinson'a, Sosvilla-Rivero (1990) procedure:

$$dY_t = \alpha + \beta \cdot t + \sum_{i=1}^p \lambda \cdot dY_{t-1} + \delta \cdot Y_{t-1} + \varepsilon_t$$

Choice of augmentation (parameter p) was done according to “general to specific” procedure proposed by W. Charemza (1997), which starts with reasonably large number of lags and is followed by iterative elimination of insignificant ones until only the significant lags are left in the model. As it was expected, the test rejected the stationarity hypothesis for all data in favour of non-stationary with the level of integration 1 (I(1)). We cannot totally rely on this test since it could confuse a structural break with a unit root. But the Phillips-Perron test for structural breaks confirmed our results. Moreover, the same conclusion about non-stationarity was obtained in the papers described in section 2, which deal with longer and more stable data of western economies.

### 3.2. Methodology and results

To estimate different term PTE we apply two-step procedure of constructing Error Correction Model (ECM). In the first step we estimate the following specification using Johansen cointegration analysis with 3-4 lags as usually the major adjustments occur within this time period in Russia:

$$LN\_P_t = \alpha_0 + \alpha_1 * LN\_NEER_t + \alpha_2 * LN\_MONEY_t + \alpha_3 * LN\_RCONS_t + \alpha_4 * LN\_OIL_t + \varepsilon_t \quad (1)$$

where LN\_P is the dependent variable under investigation: national CPI, PPI or their components in logs. We find that cointegration exists for all price indices<sup>6</sup>, what enables us generate stationary residuals  $\varepsilon_t$ .

In the second step we construct a modified ECM of the following specification using the residuals found above with 1 lag, which takes into account long run adjustments:

$$\begin{aligned} \Delta(LN\_P_t) = & \sum_{i=0}^5 \alpha_{1i} * \Delta(LN\_NEER_{t-i}) + \\ & + \sum_{i=0}^2 \alpha_{2i} * \Delta(LN\_MONEY_t) + \alpha_3 * \Delta(LN\_RCONS_t) \\ & + \alpha_4 * \Delta(LN\_OIL_t) + \alpha_5 * AR(1) + \alpha_6 * \varepsilon_{t-1} + v_e \end{aligned} \quad (2)$$

<sup>6</sup> Results of these and all subsequent estimations are available from the authors upon request.

where  $\hat{\alpha}_{10}$  is the estimate of 1-month PTE and  $\sum_{i=0}^k \hat{\alpha}_{1i}$  with  $k = 2$  and  $5$  are the estimates of 3-month and 6-month PTE respectively. The coefficient of  $\varepsilon_{t-1}$  shows convergence.

The number of NEERI and money supply lags was chosen according to the “general to specific” procedure of iterative elimination of insignificant lags. Lags after the 5<sup>th</sup> for LN\_NEERI and after the 2<sup>nd</sup> for LN\_MONEY were insignificant for all price indices. Also, if we look at the correlation of exchange rate and inflation with different leads, we see that the highest correlation exists with inflation in the following 5 months (see Table 1). Consumer prices in Russia react to exchange rate changes faster than producer prices, and the overall pattern of correlation of consumer and producer prices is similar to that in Brazil and Poland (correlation coefficients of 0.97 and 0.92 respectively (Dubravco and Marc (2002))). In addition, in these three countries the highest correlation exists with inflation in the current period and it is close to one.

Since lags after the 5<sup>th</sup> are all insignificant, we interpret the period of about half a year as long run for price adjustments. Also, we see that consumer prices react to exchange rate changes somewhat faster than producer prices. In terms of this correlation of consumer prices Russia can be compared with Brazil and Poland (corresponding correlation coefficients are -0.97 and -0.92 respectively (Dubravco and Marc (2002))), as in these three countries the highest correlation exists with inflation in the current period and it is close to one.

**Table 1. Correlation of exchange rate with inflation in the current and the following 12 months\***

	<b>CPI</b>	<b>PPI</b>
d(ln_p)	<b>-0.87</b>	-0.20
d(ln_p(+1))	-0.21	<b>-0.21</b>
d(ln_p(+2))	-0.16	-0.16
d(ln_p(+3))	-0.28	-0.13
d(ln_p(+4))	-0.22	-0.19
d(ln_p(+5))	-0.08	-0.18
d(ln_p(+6))	-0.03	-0.11
d(ln_p(+7))	-0.04	-0.08
d(ln_p(+8))	-0.01	-0.09
d(ln_p(+9))	0.01	-0.09

d(ln_p(+10))	-0.03	-0.09
d(ln_p(+11))	0.00	-0.12
d(ln_p(+12))	-0.01	-0.15

\* The highest correlation is in bold.

Since we cannot reject the hypothesis that the first differences of I(1) variables are stationary, we estimate the ECM by Ordinary Least Squares method. We test two sets of hypotheses for all price indices:

*1) Short run PTE (1 month):*

$$H_0: \alpha_{10} = 0 \text{ (No PTE)}$$

$$H_1: \alpha_{10} \neq 0 \text{ (PTE exists)}$$

*2) Long run PTE (6 months by assumption):*

$$H_0: \sum_{i=0}^5 \alpha_{1i} = -1 \text{ (Complete PTE)}$$

$$H_1: \sum_{i=0}^5 \alpha_{1i} > -1 \text{ (Incomplete PTE)}$$

The results of the estimation of PTE on consumer prices are presented in table 2. The statistically significant values are marked in bold. Pluses in the second column stand for confirmed cointegration.

**Table 2. Estimates of different run PTE: consumer prices**

Price index (in logarithms)	Coin- tegratio n	Pass-through elasticity		
		1 month	3 months	6 months
<b>CPI</b>	<b>+</b>	<b>-0.42</b>	<b>-0.40</b>	<b>-0.40</b>
t-statistics		-32.01	-10.06	-5.24
<b>Food</b>	<b>+</b>	<b>-0.45</b>	<b>-0.45</b>	<b>-0.56</b>
t-statistics		-25.43	-8.68	-6.33
<b>Goods</b>	<b>+</b>	<b>-0.55</b>	<b>-0.48</b>	<b>-0.29</b>
t-statistics		-34.88	-10.55	-3.16
<b>Services*</b>	<b>+</b>	<b>-0.05</b>	-0.06	-0.08
t-statistics		-3.15	-1.31	-0.96

\* Insignificant PTE at least in one period

We see that PTE in one month is significant for all consumer prices, what rejects the null hypothesis. This means that the effect of exchange rate

on prices really exists even in one month. To test whether 6-month PTE is complete we perform the t-test of the null hypothesis for the cumulative effect of the six months PTE. The t-statistics are reported in table 3.

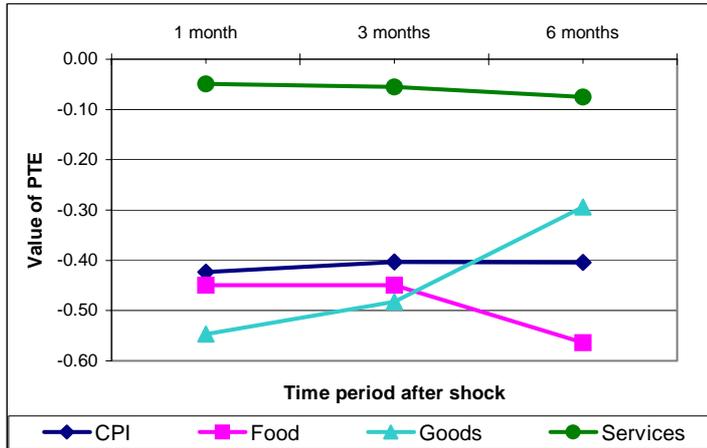

**Table 3. t-statistics for testing long-run PTE: consumer prices**

<b>Price index</b>	<b>t-statistics</b>
CPI	-7.5
Food	-4.89
Goods	-11.83
Services	-11.5

Thus we may reject the null hypothesis about complete PTE in 6 months on all consumer prices, implying that Purchasing Power Parity does not hold in Russia. Further, all consumer prices except those for services are highly exchange rate elastic and the most remarkable adjustment occurs within the first month after the exchange rate change. Prices for services do not highly depend on exchange rate, which is natural for non-tradable goods. The term structure of PTE on consumer prices is presented on Figure 3.

These results suggest a number of conclusions can be made. First, the aggregate CPI adjusts to exchange rate changes for 40% during half a year and the full adjustment (even some overshooting) occurs within the first month. Second, goods prices react faster than others in the first month and adjust for 55%. But the highest pass-through elasticity in 6 months is observed for food prices, which adjust for 56% in half a year. Third, prices for services are exchange rate inelastic and the PTE accounts for only 8% in half a year and is statistically insignificant since services are non-traded goods.

**Figure 3. Term structure of PTE on consumer prices**

These findings come in line with the results for Western economies presented in Table 4 (borrowed from Hufner and Schroder (2002), who use a similar econometric technique).

**Table 4. Estimates of PTE for European countries**

	After 6 months	After 12 months
France	0.01	0,07
Germany	0.07	0,08
Italy	0,06	0,12
Netherlands	0,12	0,11
Spain	0,09	0,08

Tables 2 and 4 suggest that the PTE in Russia is much stronger than in European countries, confirming that Russia is a small economy, which is highly dependent on foreign markets.<sup>7</sup> Stronger PTE in Russia can also be explained by relatively high import share of consumer goods, gradual depreciation of rouble and less competitive Russian economy. If we compare PTE in Russia with that for other developing countries, estimated by Dubravco and Marc (2002), the strength of pass-through on consumer prices is similar to Hungary (-0.54) and Turkey (-0.56). Hence, we can make a general conclusion that PTE in developing countries is stronger than in the developed ones, and Russia is not an exception.

<sup>7</sup> Higher PTE implies more flexible prices. Our results do not contradict the informational theory of financial disturbances expansion, which asserts that in less-developed economies maturities of contracts are shorter, than in developed, so prices are more volatile.

**Table 5. Estimates of different run PTE: producer prices**

\* Insignificant PTE at least in one period

The same analysis applied to producer prices estimates by industries is presented in Table 5. Again, the statistically significant values are marked in bold; pluses in the second column stand for existing cointegration. The null hypothesis for 1-month PTE is rejected for all producer prices except energy prices. Independence of energy prices can easily be explained by monopolization and high regulation of this industry. Although in long run, PTE in this industry is small but significant. It follows that PTE is significant for most producer prices even in one month.

Long run PTE is significant for all producer prices except ferrous metals and fuel industries. Insignificant PTE in ferrous metals can be a result of wide use of long-term contracts in this industry. Absence of PTE in fuel

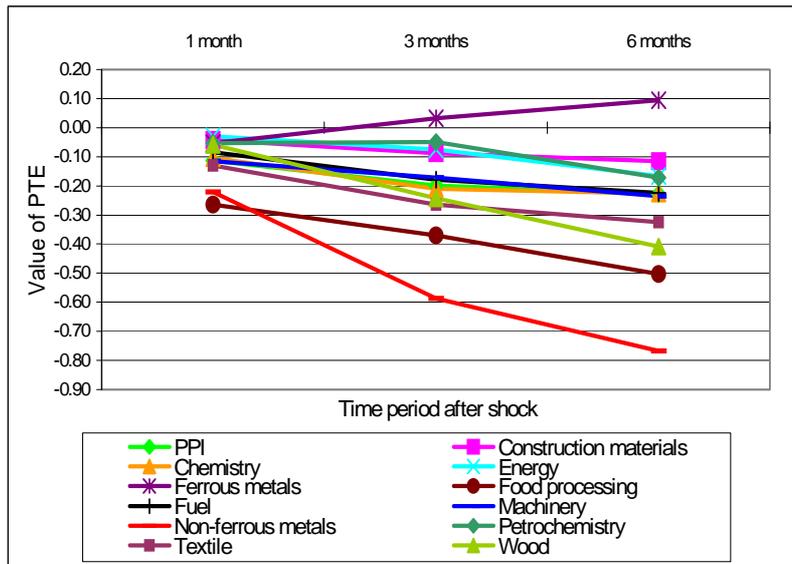

industry is due to monopolization and regulation of prices. To test if PTE in 6 months is complete, we performed another t-test reported in Table 6. This table shows that PTE on prices in all industries is incomplete in the long run., implying that producers are unable to transfer a change in their costs due to a change in the exchange rate to prices fully.

**Table 6. t-statistics for testing long-run PTE: producer prices**

<b>Price index</b>	<b>t-statistics</b>
PPI	-12.83
Construction materials	-17.6
Chemistry	-9.63
Energy	-9.22
Ferrous metals	-11
Food processing	-8.33
Fuel	-4.33
Machinery	-10.86
Non-ferrous metals	-2.88
Petrochemistry	-10.38
Textile	-11.33
Wood	-11.8

Term structure of PTE on producer prices is presented on figure 4. We see that the maximum 1-month PTE is on food prices – 26%, while the maximum PTE in 6 months is on non-ferrous metals prices – 77%. The minimum 1-month PTE is 3% in energy industry, which is monopolized and regulated, while the minimum 6-month PTE is in ferrous metals and equals +10% and insignificant. The remarkable difference between PTE in ferrous and non-ferrous metals industries can be explained by different market structures. Ferrous metals are usually OTC traded using long-term contracts, while non-ferrous metals are traded on an exchange where prices adjust very quickly.

**Figure 4. Term structure of PTE on producer prices**

These arguments imply we can divide all industries into two groups:

- 1) industries with long-run PTE higher than that of PPI (>23%) – food processing, machinery, non-ferrous metals, textile and wood industries. These industries use quite high share of imported inputs.
- 2) industries with long-run PTE lower than that of PPI (<23%), but still significantly different from zero – materials for construction, energy, chemistry and petrochemistry. These industries use local raw materials and are export-oriented.

The conclusion about different PTE for import and export industries comes in line with results of Dwyer, Kent and Pease (1993) for Australian market. They also find that prices in import industries are more exchange rate elastic than prices in export-oriented ones.

It can be noticed that PTE on producer prices is significantly lower than that on consumer prices. This can be explained by the fact that consumer prices include import prices, PTE on which should be significant. Moreover, producer prices adjust to exchange rate changes more slowly than consumer prices, with some time lags.

If we look at food prices, we can notice that consumer prices are more elastic than producer prices. There are two reasons for this. First, consumer prices include prices of imported food. Second, wholesale and retail markets are organized differently.

#### 4. Influence of monetary policy on PTE

As monetary policy in a country is often aimed at targeting inflation, it may decrease influence of exchange rate changes on prices when exchange rates are highly volatile. As argued above, and following Parsley and Popper, we now incorporate monetary policy variable into the model developed in the previous section.

Our test is based on comparison of the estimated elasticities with and without monetary policy in order to determine the influence of this latter on PTE and inflation. In order to estimate PTE without monetary policy we again use ECM of the following specification for CPI and PPI:

$$LN\_P_t = \alpha_0 + \alpha_1 * LN\_NEERI_t + \alpha_3 * LN\_RCONS_t + \alpha_4 * LN\_OIL_t + \psi_t \quad (3)$$

$$\Delta(LN\_P_t) = \sum_{i=0}^5 \theta_i * \Delta(LN\_NEERI_{t-i}) + \alpha_3 * \Delta(LN\_RCONS_t) + \alpha_4 * \Delta(LN\_OIL_t) + \alpha_6 * AR(1) + \alpha_7 * \psi_{t-1} + \xi_e \quad (4)$$

The obtained estimates are compared with the estimates from the previous section in order to determine the behaviour of monetary policy. If the “biased” PTE is smaller than the “true” one ( $\left| \sum_{i=0}^k \theta_i \right| < \left| \sum_{i=0}^k \alpha_i \right|$ ), this will mean that monetary policy is aimed at reducing price fluctuations and PTE in Russia. If the opposite situation is true ( $\left| \sum_{i=0}^k \theta_i \right| > \left| \sum_{i=0}^k \alpha_i \right|$ ), this will mean that monetary policy has some aims other than controlling inflation and it increases PTE and, hence, increases price volatility in Russia.

The results of the estimation are the following. While estimation of cointegration equation (1) produced the coefficient of exchange rate equal to  $-0.61$  for CPI and  $-0.73$  for PPI and monetary policy had a remarkable effect on CPI (coefficient  $-0.40$ ) and almost no effect on PPI (coefficient  $-0.09$ ), estimation of cointegration equation (3) without monetary policy produced coefficient of exchange rate equal to  $-1.03$  for CPI and  $-0.85$  for PPI, what means that PTE increased by absolute value greater for CPI (for which monetary policy is significant) than for PPI (insignificant monetary policy). So we conclude that omission of monetary policy leads to biased estimates of PTE, and that monetary policy in Russia in the long run increases the

exchange rate PTE on prices. This last result goes at odd with Parsley and Popper findings, who found out that omission of monetary policy leads to lowers PTE, implying that monetary policy in the USA is aimed at diminishing PTE.

Short run “true” PTE on CPI and PPI are presented in Tables 2 and 4 correspondingly. The estimates of the “biased” PTE without taking into account monetary policy are presented in Table 7. This table again shows that monetary policy leads to stronger PTE on CPI and PPI, but in periods longer than 1 month. An interpretation is that during the studied period monetary policy in Russia did not smooth exchange rate fluctuations and their consequences on prices.

**Table 7. Estimates of PTE without monetary policy**

Price index (in logarithms)	Coin- tegrati on	Pass-through elasticity		
		1 month	3 months	6 months
<b>CPI</b>	<b>+</b>	<b>-0.42</b>	<b>-0.41</b>	<b>-0.44</b>
t-statistics		-31.40	-9.17	-5.87
<b>PPI</b>	<b>+</b>	<b>-0.11</b>	<b>-0.21</b>	<b>-0.28</b>
t-statistics		-2.03	-3.02	-3.22

What is the aim of monetary policy then? Recall that before the crisis of 1998, government budget deficit was financed by state bonds (GKO) which led to accumulation of government debt to domestic and foreign investors. When the government defaulted on GKO, demand for the national currency from the side of foreign investors fell remarkably, what resulted in sharp depreciation of the rouble on FOREX market. The direct effect of this depreciation was significant rise of domestic prices (high PTE during the crisis). Therefore, Russian economy needed more money for transactions at higher prices and financing the budget deficit, which resulted in money emission reflected in the statistical data. This type of monetary policy (expansion during rouble depreciation) explains why our findings contradict those of Parsley and Popper and others, and why monetary policy in Russia does not eliminate PTE, but, on the contrary, makes it stronger.

## **5. Structural changes after the crisis of 1998**

Before 1998, the Central Bank of Russia followed different kinds of fixed exchange rates regimes, most often the currency corridor. In August 1998, the Central Bank of Russia announced floating exchange rate, but it

hardly implemented this, as the subsequent fluctuations of the rouble/US dollar exchange rate was dependent on various factors, such as the monetary policy goals and oil prices.

These facts pose a question: “Has the exchange rate regime any impact on PTE?” Cuddington and Liang (1999) conclude that “relative price among two categories of tradable goods exhibit greater volatility under flexible exchange rate regimes than under fixed one” – is a similar tendency valid for Russia? Moreover, dramatic changes in the Russian economy (e.g. inflow of FDI, substitution of inputs from foreign to domestic, expanded domestic production, etc.) give reasons for a change in PTE.

To test whether PTE has changed after the crises due to structural changes in the Russian economy we splitted our sample into three periods: before the crises, the crisis and the short-term recovery, after the recovery – by inclusion of two dummy variables:

$$D1 = \begin{cases} 0, & 01/95 - 12/99 \\ 1, & 01/00 - 12/02 \end{cases}$$

$$D2 = \begin{cases} 0, & 01/95 - 06/98 \text{ and } 01/00 - 12/02 \\ 1, & 07/98 - 12/99 \end{cases}$$

The following table demonstrates explicitly which value each dummy takes in each period.

**Table 8. Time periods and corresponding values of dummies**

Dummy	Time periods		
	01/95-06/98	07/98-12/99	01/00-12/02
<b>D1</b>	0	0	1
<b>D2</b>	0	1	0

We test for structural changes in 1-month PTE only, as it is most significant for all prices and testing changes in different-term PTE is not favoured by very short time series. Still we include lagged values of the exchange rate since omission of them will result in a bias of 1-month PTE.

$$\begin{aligned} \Delta(LN\_P_t) = & \alpha_0 + \alpha_1 * \Delta(LN\_NEERI_t) + \\ & + \beta_1 * D1 * \Delta(LN\_NEERI_t) + \beta_2 * D2 * \Delta(LN\_NEERI_t) + \\ & + \sum_{i=1}^5 \alpha_{1i} * \Delta(LN\_NEERI_{t-i}) + \sum_{i=0}^2 \alpha_{2i} * \Delta(LN\_MONEY_{t-i}) + \quad (5) \\ & + \alpha_3 * \Delta(LN\_RCONS_t) + \alpha_4 * \Delta(LN\_OIL_t) + \\ & + \alpha_5 * AR(1) + \alpha_6 * \varepsilon_{t-1} + v_e \end{aligned}$$

We test the following hypotheses using OLS:

$H_0: \beta_1 = \beta_2 = 0$  (No difference in PTE between periods)

$H_1: \beta_1, \beta_2 \neq 0$  (There is a difference in PTE between periods)

If the coefficients of D1 and D2 differ from zero significantly we cannot reject the hypothesis that pass through elasticity has changes after the crisis. Table 9 presents pass-through elasticities in all periods as well as the significance of dummy coefficients (“+” stands for “significant” and “-” stands for “insignificant”), which shows whether PTE is significantly different between periods or not. Statistically significant estimates of PTE are marked in bold.

We can notice that PTE in the period of crisis (column 5) is most closely related in its degree to the whole period PTE (column 7). The null hypothesis about equal pass-through elasticities in all periods is rejected for 6 price indices. Through, PTE is significantly different in all three periods in only two industries – chemistry and wood production. In these industries PTE used to be significantly positive before the crisis, then became significantly negative during the crisis and has become close to zero when the economy recovered from the crisis. For three consumer prices (CPI, food and goods prices) PTE during the crisis differs significantly from that in the other periods. Moreover, it is large and significant in this period only. PTE on energy prices differs in the after-crisis period, when it became significantly positive. But this is probably connected with price regulation in this industry.

For other 10 price indices (services and almost all producer prices) PTE is not significantly different between the periods, what makes us reject the null hypothesis.

It can be noticed that pass-through elasticity of CPI has fallen after the crisis and has become closer to the estimates for European countries. Thus, we can conclude that due to after-crisis structural adjustment of the Russian economy, Russia has become less dependent on exchange rate fluctuations, than it used to be before the crisis.

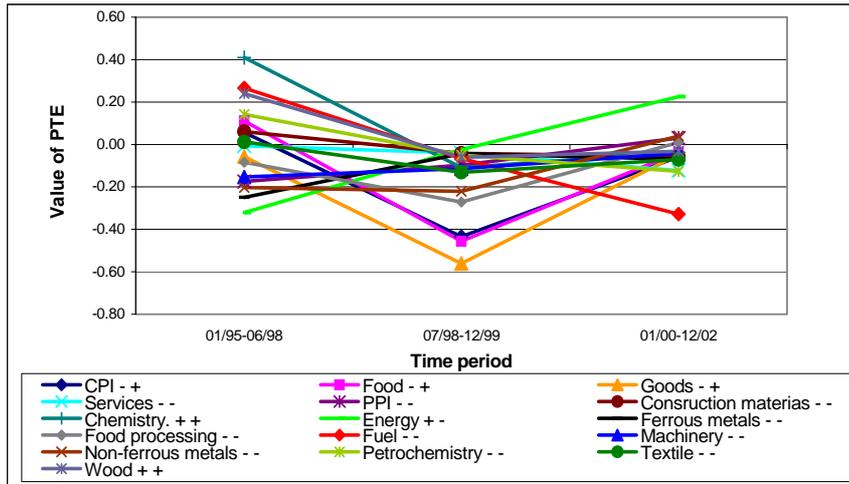

The results are summarised on the Figure 5, where each line shows changes in PTE during the three time periods.

**Table 9. Estimates of 1-month PTE in different time periods**

\* Whole period elasticities are the estimates of 1-month elasticities from Section 2.

**Figure 5. Dynamics of PTE in different periods\***

\*Signs +/-

near price indices indicate significance of the two dummy variables

We can observe the following general tendencies: PTE is rather high and significant for the majority of prices only in the period of the crisis and it is close to the estimate for the whole period. This can be explained by the fact, that since during the crisis the exchange rate fell sharply, most prices were fixed in US dollars. Several papers (Bachetta & van Wincoop (2002), Giovannini (1998) show, that countries with unstable domestic currency tend to fix prices in foreign currencies, what makes PTE close to 100%.

Interestingly, prices of services, which are non-traded goods, were also significantly dependent on the exchange rate during the crisis. This corresponds with the conclusions of Tsesliuk (2002), who finds that if all national prices in a country are expressed in foreign currency, exchange rate will affect all prices including prices of non-traded goods.

Before the crisis, PTE used to be insignificant for most prices, probably, due to the fixed exchange rate regime (a corridor), when menu costs might have overweighed the benefits of changing prices as a result of small exchange rate changes. After after-crisis adjustments, pass-through elasticity almost returned to its before-crisis level. But this may be because the sharp rouble depreciation led to remarkable decrease in real income, measured in terms of foreign currency, and hence, to a fall in demand for foreign goods. This resulted in import-substitution, high foreign direct investment and growth in the domestic production. So, after the recovery of the Russian economy, it became less dependent on the world markets and exchange rate changes.

To conclude, the studied three periods are characterized by different exchange rate regimes and consumption structure and, hence, PTE is also different, although not always significantly. After the crisis, PTE has decreased and become closer to the values for developed countries. Also this may be due to some institutional factors, as some researches find that PTE in many countries has recently decreased for institutional reasons.

## 6. Asymmetry in PTE in cases of rouble depreciation and appreciation

Exchange rate depreciation causes an increase in prices, so, logically, we can expect that exchange rate appreciation will ceteris paribus cause deflation. However, casual observations suggest that prices are downward rigid: depreciation of rouble leads to a rise in prices, while its appreciation does not lead to price fall. The purpose of this section is to compare 1-month PTE in cases of depreciation and appreciation and to determine whether there are any significant asymmetries. To do this, we estimate the following ECM by OLS method:

$$\begin{aligned} \Delta(LN\_P_t) = & \alpha_0 + \alpha_1 * \Delta(LN\_NEERI_t) + \\ & + \gamma_1 * D * \Delta(LN\_NEERI_t) + \sum_{i=1}^5 \alpha_{1i} * \Delta(LN\_NEERI_{t-i}) + \\ & + \sum_{i=0}^2 \alpha_{2i} * \Delta(LN\_MONEY_{t-i}) + \alpha_3 * \Delta(LN\_RCONS_t) + \\ & + \alpha_4 * \Delta(LN\_OIL_t) + \alpha_5 * AR(1) + \alpha_6 * \varepsilon_{t-1} + \nu_t \end{aligned} \quad (6)$$

where  $D = \begin{cases} 0, & \text{if nominal effective exchange rate appreciates} \\ 1, & \text{if nominal effective exchange rate depreciates} \end{cases}$  and  $\varepsilon_{t-1}$  is a residual of

regression (1) with 1 lag. We test the following hypotheses:

H<sub>0</sub>:  $\gamma_1 = 0$  (No statistical difference, symmetric PTE in case of appreciation and depreciation of rouble)

H<sub>1</sub>:  $\gamma_1 \neq 0$  (Statistically significant differences, asymmetry of PTE)

If the coefficient of the dummy variable appears to be significant, then we null hypothesis is rejected in favour of the alternative

**Table 10. 1-month PTE for appreciation and depreciation of rouble**

\* Estimates of PTE for the whole sample from section 2

Table 10 presents the estimates of PTE in both cases as well as significance of the dummy variable (“+” in the second column means “significant”, while “-” means “insignificant”). All significant elasticities are in bold. PTE in case of depreciation is very close to its estimate in the whole sample probably because during the whole studied period the exchange rate

was mostly falling. Significance of the coefficient of the dummy suggests rejection of the null hypothesis for all consumer prices except services and for only one producer price – price of food processing industry. Thus, these prices react to rouble appreciation and depreciation differently: PTE is very strong in case of depreciation (meaning that prices rise), but is positive and insignificant in case of appreciation (meaning that prices do not fall, but may even still rise). This asymmetry is shown on Figure 6, which is a scatter plot, where the coordinates of each point are the corresponding estimated of PTE in both cases.

**Figure 6. Asymmetric PTE in cases of appreciation and depreciation of rouble**

This figure shows strong asymmetry: had PTE been symmetric, all points would have lied in the south-west quarter on a straight line with slope +1. But here most prices are distributed along the horizontal axis, what means that while in case of rouble depreciation PTE is negative and significant for most prices, in case of appreciation the estimates of PTE differ from  $-0.23\%$  (PPI) to  $+0.23\%$  (energy) and are mostly insignificant. But in spite of the visual differences, the estimates of PTE in both cases are not significantly different for most prices.

The four outliers in the lower part of the diagram stand for CPI, prices of food, goods and food processing industry. For these prices PTE in case of rouble depreciation is high (by absolute value) and very significant, but in the other case it is positive and insignificant. Theses differences are probably attributable to short-term contracts (consumer prices) and short production

cycle (food processing industry). Hence we may see that, in general, consumer prices react to exchange rate changes asymmetrically, while producer prices do not.

Similar studies undertaken for European countries find few evidence supporting PTE asymmetry (Gil-Pajera, 2000). Another paper analyzed PTE in period of deflation in some developed countries and found out, that exchange rates did not play a significant role, if any, in explaining deflation (McCarthy (2000)), but it played a significant role in explaining inflation. This means that PTE in case of depreciation of domestic currency (period of inflation) is higher, than in the case of appreciation (period of deflation), what corresponds with our findings.

## **7. Conclusions and recommendations**

In this paper we study exchange rate PTE on domestic consumer and producer prices in Russia and the influence of government monetary policy on PTE for the period from January 1995 till December 2002. We find that PTE on all prices studied in this work is incomplete even in the long run, while even 1-month PTE is significant for most prices.

PTE on consumer prices is quite high and equals approximately 50%, what corresponds to the results for other developing countries and is higher than PTE in developed countries. This characterizes Russia as a small economy, which is exposed to the shocks in the world markets. Therefore, in order to decrease price volatility, monetary policy in Russia should be endogenous and should eliminate the effect of exchange rate changes on prices, if the exchange rate is fully flexible, or the exchange rate should be in a corridor.

Almost all PTE on consumer prices occurs during one month, which supports the idea of flexible prices in Russia. Consumer prices, prices of food and goods are highly exchange rate elastic while prices of services do not react to exchange rate changes. This can be explained by the fact that services can be an example of non-traded goods with rather low level of imports.

PTE on CPI is higher than that on PPI and CPI adjusts more quickly than PPI, which adjusts with some time lags. This is partially explained by presence of imported goods in CPI, PTE on which should be high.

Prices in different industries of Russian economy have different PTE. Low PTE is observed in industries with insignificant import shares (raw materials) and in highly regulated industries (e.g. energy). Companies which work in competitive industries with low PTE and which have high imports are subject to high exchange rate risk, which should be managed properly. High PTE is observed in those industries, which are closely connected with world markets and use a significant amount of imported intermediate goods (e.g. production of food and textile).

Estimation of PTE without taking into account monetary policy would result to biased estimates, while incorporation of monetary policy effects results in stronger effect. This finding goes at odd with the results for western economies, and can be explained by monetary expansion following the crisis of 1998. This crisis itself resulted in structural changes: although for most price indices the hypothesis of symmetric PTE cannot be rejected, four price indices (most consumer prices and food processing prices) react differently to exchange rate changes in different directions, what supports real-life observations. These prices are exchange rate elastic in case of the rouble depreciation, but are not sensitive in case of appreciation, meaning that prices do not fall when the national currency becomes stronger. This phenomenon is probably explained by expectations of price-setters of future depreciation of the rouble.

The results of this paper may be interesting for development of inflation and exchange rate policies as we have shown that it is impossible to manipulate inflation solely through changes in money supply when exchange rate is flexible and has an additional effect on domestic prices. If the aim of the government is to target inflation rate, then monetary policy should be endogenous (should adjust to exchange rate changes) since consumer prices are highly exchange rate elastic during periods of rouble depreciation.

## **Abstract**

*Decisions concerning capital structure and development projects represent the main long-term budget, capital and financial decisions of a firm. These decisions are affected by the choice of both methods and models of the capital structure optimization, economic efficiency of the project evaluation as well as many other factors. Following two factors influencing this decision-making process in Slovak enterprises are presented in this lecture by income tax and cost of capital.*

**Keywords:** *capital structure, development projects, tax shield*

---

<sup>1</sup> The paper has been worked out as part of research in the VEGA Project No. 1/2632/05 *The optimim allocation of capital and management of financial processes in a company and a group of companies (holding)after the accessionto EU.*

## **1. Introduction**

Decisions on the capital structure and company development projects are affected by the choice of methods and models of capital structure optimization, by evaluation of the economic efficiency of projects, economic climate and many other factors. In the paper, we are to present the impact of changes of two factors in the economic climate, namely income taxes and interest rates from long-term credits on these decisions in Slovak companies.

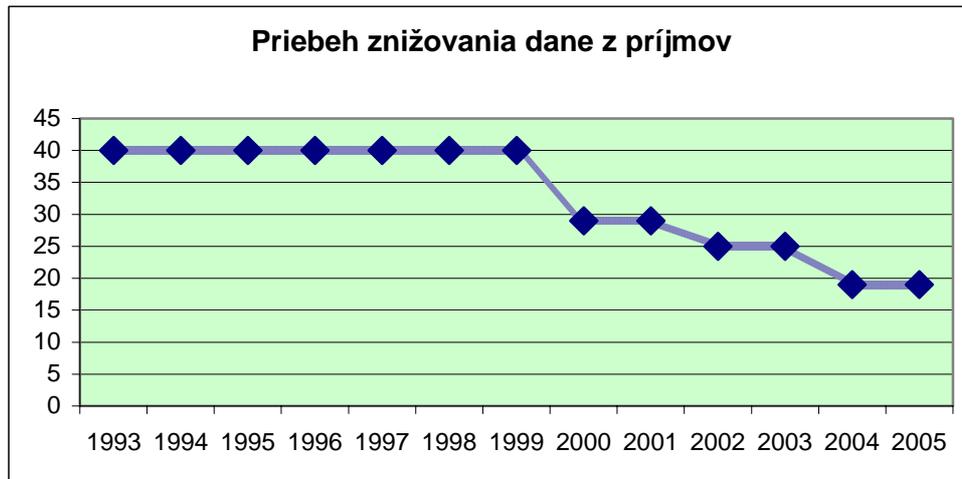

## **2. Development of the Income Tax and Interest Rates**

The transformation process in the Slovak economy made it possible to create space for a gradual decrease of the tax burden of businesses from 1993 (establishment of the Slovak Republic) to 2004 and a decrease of interest rates on credits.

The rate on income tax of legal entities was between 40 and 19 %. The level of 40 % was effective up to 1999, in 2000 and 2001 it was 29 %, in 2002 and 2003 25 %. Since 2004, the rate of income tax valid in the Slovak Republic has been 19 %.

The level of the capital price is also affected by including interests in the company costs. Credit interests included in the company costs decrease the price of the foreign capital (tax shield). The impact of the tax shield in Slovak conditions has recorded a significant change of impact in the past decade. In 1993, the saving on taxes (40 % tax rate from about the 18 % interest rate) was not lower than 7.2 %, in 2004 only 1.3 %, in dependence on the analyzed sector (industries, private sector, etc.). Basically, it moves within the scale 1.0 to 2.0. The decisive fact is that the importance of this factor has gradually declined. Further dramatic fall is not expected in future.

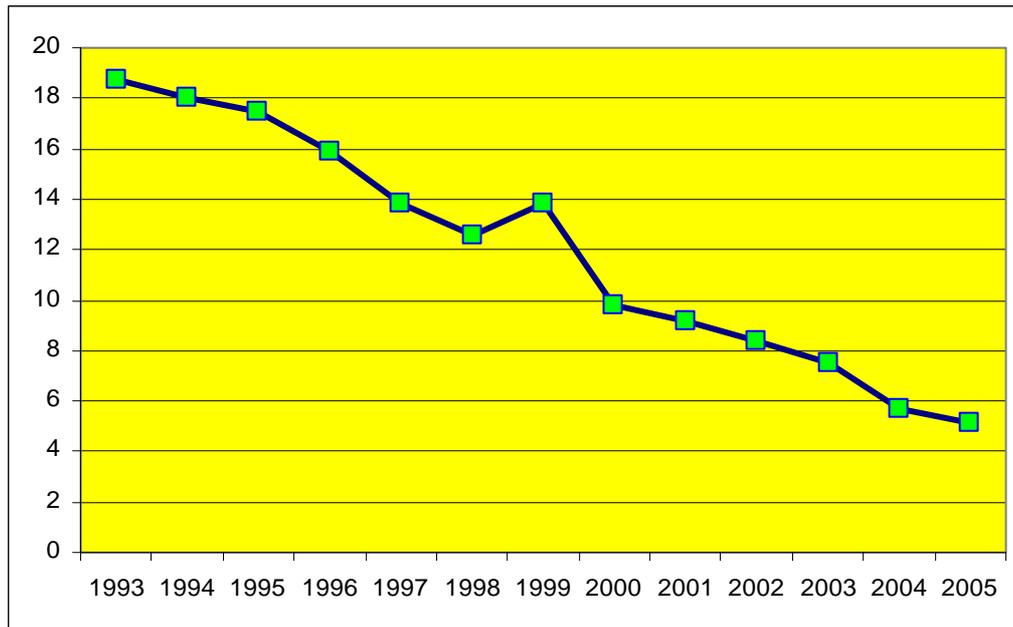

**Diagram 1: Progress of the income tax decrease in 1993 – 2005 (in %)**  
**Progress of the Income Tax Decrease**

Source: *www.drsr.sk*

A significant fall has been seen also in the interest rates on long-term bank credits. Gradually, conditions and prerequisites for their decline have been created. The trend resulting from the Diagram 2 suggests a definite development up to the year of 2005 (till August). Due to the shortage of sources in the past, the interest rates were quite high which resulted in a disproportionate increase in the foreign capital and did not affect a support of company development favourably. At present, the level of the interest rates is much more acceptable. In the analysis, we only assess interests from long-term credits, and do not consider short-term credits part of the capital structure.

**Diagram 2: Development of Interest Rates from Long-term Bank Credits in 1993 – 2005 in the SR (v %)**

*Source: www.nbs.sk*

The income tax rate of legal entities and interest rates from long-term bank credits have significantly changed since 1993 (Diagrams 1 and 2). Their impact must be taken into account, therefore we assess it on a simplified model.

### **3. Impact of Changes of the Income Tax and Interest Rates on the Capital Structure and on Company Development Projects**

By the example of the compromise theory, we are to present how the change (decline) of the income tax and interest rate from long-term credits determines decisions on the capital structure and company development projects. The authors of the compromise theory have linked the M-M access with the real market conditions (they took not only the influence of taxes into account but costs of financial difficulties of a potential bankruptcy as well), and showed the choice of the capital structure as a compromise between benefits of the interest tax shield and costs of financial difficulties.

Their pattern for the company value including debt is as follows:

$$V_Z = V_N + PVITS - PVCFDT$$

in which:  $V_Z$  – value of the company including debt

$V_N$  – value of the company financed by its own capital

$VITS$  – present value of the interest tax shield

$PVCFDT$  – present value of costs of financial difficulties

The optimum capital structure is determined by a mutual relation between the tax benefits and costs of financial difficulties. With the increase of the debt the present value of the interest tax shield increases. At a slight state of indebtedness, the probability of financial difficulties is insignificant and benefits of the interest tax shield prevail. However, at a certain point of debt, the probability of financial difficulties increases fast, and costs of financial difficulties start to reduce a significant part of the company's value. The company reaches the theoretical optimum at the moment when the present value of the tax savings from further debt is compensated by the increase of the present value of the costs of financial difficulties. The costs of financial difficulties caused by a high level of debt (mainly the company's insolvency to settle up interests and debt instalments to their creditors) can be divided between direct and indirect ones. Among direct costs there are various charges and fees to lawyers or specialists the company has to pay when it goes bankrupt. The indirect costs are related to the company's way of management and its consequences. When financial problems arise, managers must usually accept suboptimal decisions. When a company, for example, has to sell part of its assets at disadvantageous prices in order to get liquid money, it must waive carrying out of profitable projects that do not lead to the immediate cash flow. It has to use a less effective but short-term projects instead, and to decrease expenses on training of its staff, on research and development, and reduces stock (it can mean loss of part of sales). Suboptimal financial decisions forced by financial difficulties due to a high level of debt can include necessity to accept other loans even on disadvantageous conditions (e.g. at higher interest rates), to gain other equipment on leasing, although a direct purchase seems to be more economic, to reduce the amount of paid dividends (it gives the financial market unfavourable signals and leads to a decline of the company's prices of shares), etc.

It is very difficult to quantify direct, and especially indirect, costs of potential financial difficulties due to a high level of the corporate debt. In literature, we can find various recommendations. For example, the authors H. Levy and M. Sarnat give a particular example for calculation of the impact

of a company's financial difficulties, and they suppose that a company can insure against bankruptcy (in an insurance company), if they identify the annual amount of the insurance premium with costs of financial difficulties. The same philosophy is used in our example too.

Let us consider three variants of the company capital structure – A, B, C. The company achieves the profit before the interest of SKK 1,500 thousand out of the total capital of SKK 10,000 thousand. The market value of the company at 29 % income tax and 10 % interest rate are shown in the Table 1, line 11, and at 19 % income tax and 5.4 % interest rate in the Table 2, line 7.

**Table 1 Calculation of the Market Value of a Company with Debt and a 29 % Tax (in thousands SKK)**

Line		Variant A	Variant B	Variant C
1.	Own capital	10,000	7,000	4,000
2.	Foreign capital	-	3,000	6,000
3.	Profit (operating)	1,500	1,500	1,500
4.	Interests	-	300	600
5.	Profit before tax	1,500	1,200	900
6.	Tax 29 %	435	348	261
7.	Profit after tax	1,065	852	639
8.	Interest tax shield	x	87	174
9.	Interest tax shield capitalization	x	870	1 740
10.	Market value without debt	10,000	10,000	10,000
11.	Market value with debt	10,000	10,870	11,740

**Table 2 Calculation of the Market Value of a Company in Debt and a 19 % Tax (in thousands SKK)**

Line		Variant A	Variant B	Variant C
1.	Profit before tax	1,500	1,200	900
2.	Tax 19 %	285	228	171
3.	Profit after tax	1,215	972	729
4.	Interest tax shield	x	30.8	61.6
5.	Interest tax shield capitalization	x	308	616
6.	Market value without debt	10,000	10,000	10,000
7.	Market value with debt	10,000	10,308	10,616

The Tables 3 and 4 express the application of the compromise theory. Further to the Tables 1 and 2 we consider three variants of the capital structure – A, B, C, and two companies, X and Y, with a different level of the

economic risk (expressed by probability of financial difficulties in the lines 4 and 8 of the Tables). We also suppose that the company can insure against bankruptcy, and the amount of the annual premium is SKK 1,000 thousand (SKK 710 or 810 thousand after taxes) multiplied by probability of bankruptcy, i.e., the higher the probability the higher the premium required by the insurer. Other information, and the calculation of the present net value of the companies X and Y (lines 7 and 11 of the tables), having taken "costs of financial difficulties" into account, are presented in the Tables 3 and 4.

**Table 3 Application of the Compromise Theory at 29 % Income Tax (in thousands of SKK)**

L.		A	B	C
1.	Company value with capitalisation of the tax shield	10,000	10,870	11,740
2.	Value of debt	x	3,000	6,000
3.	Of own capital value	10,000	7,870	5,740

**Company X:**

L.		A	B	C
4.	Probability of financial difficulties	1	5	20
5.	Insurance after taxes (SKK 710 thousand x line 4)	7.1	35.5	142
6.	Present value of premium (at 10 % discount rate) <sup>2</sup>	71	355	1,420
7.	Company net value (lines 1 – 6)	9,929	10,515	10,320

**Company Y:**

L.		A	B	C
8.	Probability of financial difficulties	5	15	30
9.	Insurance after taxes (SKK 710 thousand x line 4)	35.5	106.5	213

---

<sup>2</sup>Assumption of perpetuity

10.	Present value of premium (at 10 % discount rate) <sup>4</sup>	355	1,065	2,130
11.	Company net value (lines 1 – 10)	9,645	9,805	9,610

**Table 4 Application of the Compromise Theory at 19 % Income Tax (in thousands of SKK)**

L.		A	B	C
1.	Company value	10,000	10,308	10,616
2.	Debt value	x	3,000	6,000
3.	Own capital value	10,000	7,308	4,616

**Company X:**

L.		A	B	C
4.	Probability of financial difficulties	1	5	20
5.	Insurance after taxes (SKK 710 thousand x line 4)	8.1	40.5	162
6.	Present value of premium (at 10 % discount rate) <sup>2</sup>	81	405	1,620
7.	Company net value (lines 1 – 6)	9,919	9,903	8,996

**Company Y:**

L.		A	B	C
8.	Probability of financial difficulties	5	15	30
9.	Insurance after taxes (SKK 710 thousand x line 8)	40.5	121.5	243
10.	Present value of premium (at 10 % discount rate) <sup>2</sup>	405	1,215	2,430
11.	Company net value (lines 1 – 106)	9,595	9,093	8,186

From the results shown in the Tables 3 and 4 are evident the following significant conclusions:

1. The original M-M model adjusted by the income tax leads to an extreme debt policy – the higher the share of debt in the capital structure the higher the company value.
2. Taken costs of financial difficulties also in conditions of the 29 % income tax rate and 10 % interest rate into account, the mentioned extreme solution loses. The companies X and Y have the optimum capital structure at the variant B (lines 7 and 11, Table 3). The variant C, with a higher debt share than the variant B, has a lower net value in both companies.
3. The companies X and Y reach the optimum value when financed by the own capital at 19 % income tax, and 5.4 % interest rate. It is generally true that the decline of the tax and interest rates results in a decline of the interest tax shield, and the optimum shifts to a structure with a lower debt.
4. The decline of the tax rate together with the decline of the interest rate from long-term credits has a favourable impact on debt costs, and when shareholders do not change their requirements, also on the own capital (shareholder's equity) yield and on average costs of the corporate assets (capital), and it affects the growth of the company market value.

As far as decision making on company development projects is concerned, the decrease of the income tax and the interest rate (from 29 % to 19 %, from 10 to 5.4 %) brings the following conclusions (supported by calculations of particular projects):

1. Decrease of the income tax influences favourably decisions on projects, the number of acceptable projects increases, and more space for investments and development is created. The same goes for cases of financing from the company's own sources.
2. Decrease of the income tax and interest rate (if the project is financed from other sources) leads to a decline of the present value of the interest tax shield but this decline does not influence the assessment itself, it is covered by the growth of the net profit as the basic component of the cash flow project.
3. If the primary decision of a company is a decision on the capital
4. structure – the target debt ratio –, decline of the tax and interest rates diminishes space for financing projects through debt.

## 4. Conclusion

Changes in the business climate in the Slovak Republic after 2000, and their impact on the two above mentioned important factors (income tax rate and interest rate from long-term credits) have favourably affected two significant areas of corporate long-term financial decisions and those related to the capital budget – decisions on optimum capital structure and company development projects.

## **Abstract**

*The financial sector, and particularly the banking system played an important role in the process of transition and economic recovery in Central and Eastern European countries (CEECs). The main objective of this paper is to analyze main changes in financing decisions of Estonian companies in the period of economic transition from 1994 to 2004 before joining European Union. Empirical results of Estonian firms' interview study, undertaken annually during 1994-2003, are presented in the paper. The analyze concentrates on informal borrowing and lending in comparison of average interest rate being applicable on official lending from Estonian commercial banks. Firms can finance investment in two ways: with equity—which can be increased by issuing new shares or by reinvesting profits—and with debt. The financial frictions arise because of the following assumptions: (a) there is a cost or premium associated with increasing equity by issuing new shares, compared to reinvesting profits; (b) defaulting on the debt is costly. During the period of transition, availability of financing has changed dramatically. We can observe switch from informal borrowing and lending to the commercial banks and financial intermediaries. However, due to the protection of the shareholders' and creditors rights usage of direct borrowing from owners, including parent company, keeps large share in total financing of companies.*

**Keywords:** *firms' financial behaviour, transition, contractual obligations, payment terms, informal borrowing*

## **1. Introduction**

Restructuring the banking sector was part of the integration programme of the Central and East European transition economies with the European Union. Up to the end of 1980s the transition countries (including Estonia) had a centralised monobanking system. All the banks were owned by the state and through its branches the central bank just opened credit lines for state-owned enterprises. Transition to a market economy involved the introduction of commercial banking and competition. Today the transition period has lasted long enough to enable researchers to make profound analysis and draw conclusions, whereas few years ago the tendencies were for insiders (i.e. Estonians) somewhat politicized and not so easily interpretable.

## **2. Changes in the banking environment**

Together with development of overall economic environment the financing decisions in Estonian firms have changed significantly. These changes have been so quick that sometimes companies do not recognize their own actions to obtain financing, even if reminded now. The current article describes main changes in the financing activities. Estonia is a small country in which banks are the prevalent financial intermediaries, with total assets accounting over 70% of GDP (see Table 1).

In the beginning of 1990-s, Estonia has just become free of planning economy, what efficiently happened in 1989. Although the state has been declared free, the legislative environment and business practice remained comparable to those in other parts of former Soviet Union. Major initiatives from legislative body were related to establishment of monetary system (Law on Estonian Central Bank) and first rules to financial intermediaries. Credit Institutions Act has been approved in 1999, and it has later been modernized several times.

\* incl. branches of foreign banks

Source: Bank of Estonia.

The role of other financial intermediaries is rather moderate. The four largest banks have more than 95% shares in Estonian banks' assets, with two of over 80%. Major shareholders in the four largest banks are Nordic financial conglomerates, which are also active in other Baltic countries. Estonian banking has experienced two system crises, which has significantly decreased the number of banks and has shifted Estonian banking under the control of foreign capital. Similar processes can be observed in all transition countries where in the end of 1999 foreign banks managed 53% of assets. In 1995, the respective number was remarkably lower – 20%. This has also pushed the development of banking regulations and supervision.

Estonia's domestic financial system remains largely dominated by banks, but other institutions are growing rapidly. Banks' domestic credit (excluding loans to other financial institutions—mainly leasing companies) remains by far the largest source of domestic financing, equivalent to almost two-thirds of GDP in 2003 (Figure I.5). The stock market's recent bullish behaviour has boosted market capitalization to 40 percent of GDP, and by a further 8 percentage points in the first quarter of this year, but four-fifths of this is foreign owned. Leasing activities (for real estate, autos, commercial

vehicles, and other items, provided by institutions almost wholly owned by Estonian banks), are unusually prominent in Estonia, and have grown rapidly in recent years. The bond market remains relatively dormant, and insurance premiums grew only somewhat faster than the overall economy. The assets of investment funds (again, largely owned by domestic banks), in contrast, while still relatively small, are surging, in part reflecting the creation of a fully funded second pension pillar. (IMF country report)

Researches on banking reconstruction in Estonia and other Baltic States show that the major banks of transition economy will reach the level of developed countries' banking in relation to the banks' trustworthiness, novelty of products and standards. This is also a claim of global economy for survival, which has been realized generally by the banking of transition economies. But the disadvantage of such development is the extreme concentration in banking, as a result of which competition, which is essential for ensuring stable development and stability of services and prices in the banking market, will gradually decrease.

The Estonian economy has been expanding rapidly, with per capita real incomes rising by 75 percent in the last decade. This was the result of high domestic investment rates; with the average investment share the highest among new EU members in recent years, and sizably above the shares in the old EU and in other large debtors, although recent shares have been temporarily inflated by a number of large, "one-off" projects. The saving rate, in contrast, has been average compared to those in other new EU members, but higher than then those in other high net external liability economies. (IMF country report)

### **3. Changes in financing activities of firms**

In that paper are used some results of the special interview study of Estonian manufacturing firms undertaken annually in 1994-1999 and in 2003. Tallinn Technical University research group, headed by prof. Vello Vensel, has monitored Estonian economical behaviour of enterprises in frames of Monitoring of Business Environment.

The study is one part of larger joint research project of analysis of reforms in financial sector in Central and Eastern Europe transition economies. The study was financed by EU Phare program and Estonian Science Foundation support. The sample has not been very large (being during the period of monitoring from 40 to 68 firms), but it is representative in means of composition from different firms.

The main changes are decreasing share of state-owned enterprises and corresponding increasing share of private ownership due to the successful and rapid privatization process, if we compare distribution of firms by the ownership structure in different years. Share of state-owned enterprises (SOE) decreased from 18.1% in 1994 to 4.1% in 2000 and correspondingly share of domestically owned private ownership increased from 59.2% in 1994 to 73.8% in 2000 we can mention also increase of the share of mixed domestic and foreign private ownership (at an average 16.8%). The average share of foreign ownership in the last group of firms (12 firms responded in 2000) was 68.3%. Most of the sample firms started their business after 1992 and obtained their start-up financing mostly from own savings (at an average 58.1%) because their access to the loan market was limited.

Most of sample firms were medium size firms (at an average 49.6%) with the number of permanent workers 21-200, share of small firms with the number of workers 1-20 was at an average 37.2%. Quite clear trend was increase of the share of small firms (from 20.6% in 1994 to 52.9% in 2000) and respective decrease of the share of large firms (from 23.5% in 1994 to 4.0% in 2000). This phenomenon is result of restructuring the whole economy and start-up of new private small businesses. Average number of permanent workers in sample firms was about 50 in 2000.

As a generalisation, the results show that the sample mostly consists of small (at an average 37.2%) and medium-size (49.6%) domestically owned private (73.8%) joint stock companies (70.4%) or limited liability enterprises (16.5%), which started their business on the basis of own savings (58.1%) after the year 1992 (64.1%), and which are operating in Tallinn (49.2%) and in North-Estonia (28.0%). Although the sample is not very big (at an average fifty firms responded every year) it is representative with respect to different distribution characteristics. As a feedback, more important results of the study and a short financial analysis results (for example, *Altman Z*-score and other financial ratios) on the basis of balance sheet and income statement information was given to responded firms. (Tearu and Vensel, 2001)

An enormously important source of private financing for start-ups and SMEs in both developed and developing countries is the venture capital industry. The availability of risk financing for new enterprises and SME expansion is organized around individuals and firms who seek such opportunities and market them to potential sources of capital. The venture capital industry is particularly important in countries where banks do not make equity investments. However, even under universal banking, banks

often prefer customers with proven track records and shun new enterprises and longer-term commitments and risks that are hard to judge. Thus, the role of venture capital as a source of finance for activities with high risk and potentially large impacts on economic development cannot be understated. (BOFIT discussion paper)

**Table 2. Sources of financing of Estonian Firms in 1994-2000 and 2003, percentage of total**

<i>Source of financing</i>	<i>1994</i>	<i>1995</i>	<i>1996</i>	<i>1997</i>	<i>1998</i>	<i>1999</i>	<i>2000</i>	<i>2003</i>

*Source: Authors' calculations*

Some of the results from the table 2 can be directly attributed to the tendencies in overall economy, e.g. increase of borrowing from relatives and friends in 1999, a year after financial sector has been hit by Russian crisis. Relatively big importance of “other sources” is indicative of increasing share of foreign investments to the Estonian companies.

Not surprisingly, getting a loan from an Estonian Commercial Bank depends on loan guarantees, total assets of the company and the time how long the company has been client of the bank. Because small companies do not have sufficient guarantees at starting the business, it is extremely difficult to access credit resources through bank loans. Many prefer to give direct loan instead of giving additional warranties. This is why the starting capital has been mainly collected from own savings, more than a half of resources of

starting capital every year. Borrowing from moneylenders is not typical and that service does not have significant influence on financial market.

Also, together with increase of availability of formal financing from banks, the importance of lending from moneylenders has decreased. One of the reasons is their higher interest margins; another is their reputation of informal way of debt collection, if the payments were delayed.

Interesting fact is, that despite of increase of availability of formal lending, importance of own savings (including owners' equity) has remained high. It may be related to the "long-term survival" goal of managers. Taking financial obligations is still seen as more risky strategy than having large owners' equity. Somewhat this indicates also confidence of Estonian owners and managements to the economic environment: only small percent of companies have distributed dividends, thus believing that keeping the earnings in the business is more profitable than taking it out.

#### **4. Possible causes of changes in financing decisions**

The current Estonian income tax law supports having more equity in business. Because the income in the company is not taxed, there does not be usual income tax effect on borrowing and the profit of Estonian subsidiary of international group, if consolidated into parents' result, makes groups average income tax level lower. From one side it is disadvantageous to the lenders in banks, but the effect on total economy probably outweighs this disadvantage. The same reason may be behind the aggressive lending by banks to private persons: there simply may not be enough business to whom to lend the funds.

Also, one must note that the improvement in creditor rights protection plays important role in the financing decisions of companies. In the Table 3 below is provided analysis of the creditor rights indices. If transition economies had LLSV index value of 1.4 in an early stage of transition in 1992, the same is increased to 3.23 for 1998. In Estonia, the introduction of the Estonian Commercial Code was the factor mostly changing shareholder and creditor rights.

In CEE/Baltics can trace the formal legal systems primarily to German Law and the countries of South-Eastern Europe to the Ottoman Empire, which in turn was influenced by French law (David and Brierly 1985, Knapp 1972). In contrast the countries of the CIS failed to develop a modern formal legal system prior to a revolution.

**Table 3. Creditor rights in comparison**

	Average of creditor rights (LLSV cr)
<i>World average</i>	2.3
<i>Common law family</i>	3.11
<i>French civil law family</i>	1.58
<i>German civil law family</i>	2.33
<i>Scandinavian civil law family</i>	2
<i>Transition economies 1992</i>	1.4
<i>Transition economies 1998</i>	3.23

Parallel to the reduction of state financing, economic reforms in transition also fundamentally altered the structure of ownership rights through privatisation. Privatisation methods have varied greatly across the region with potentially powerful implications for the availability of external finance. In a few countries, Hungary, Estonia, Latvia and more recently and to a lesser extent Bulgaria and Kazakhstan strategic sales to foreign investors have dominated the large enterprises. In these countries FDI has been an important source of external finance and the catalyst for corporate restructuring albeit concentrated among the top tier of the corporate sector. However, most governments in the region were constrained in a design and implementation of privatisation by the power of incumbent managers who had accumulated implicit control rights as a result of weak state monitoring under central planning. Privatisation often simply led to the explicit recognition of these control rights through the allocation of ownership titles to insiders (EBRD 1997).

Entrepreneurial financing runs the gamut from start-up funds to support the launching of new companies to growth financing for successful small and medium size enterprises (SMEs). Such transactions have important demand and supply components that are hardly unique to transition economies. On the supply side, the riskiness of these ventures is thought to make them unattractive to banks and, hence, these activities will be credit constrained. On the demand side, the adverse selection argument indicates that firms that are successful have no need to access external credit markets so that the only borrowers left seeking outside financing will be 'lemons.' Creditors fearing adverse selection refuse to lend to the entire pool of borrowers and banks maintain below market clearing interest rates and ration credit according to other criteria. These problems are endemic to entrepreneurial finance and various institutions to surmount them have evolved in developed capital markets. In many instances, market imperfections for the financing of SMEs lead to government efforts to

provide subsidized programs for start-up financing and micro lending. Some of the literature on entrepreneurial finance in transition economies indicates that credit market imperfections are not serious impediments and that start-ups have succeeded without any apparent financing difficulties. For example, Czako and Vajda (1993) examined the sources of SME start-up and continuing financing in the early stage of the transition in Hungary and found that only about a quarter of the companies surveyed used either bank or concessionary loans for start-up financing. Furthermore, of the less than 20% of these Hungarian companies that reported the need for subsequent capital, only about 20% used concessionary financing while almost 45% attracted bank financing. (BOFIT discussion papers)

About half of the interviewed companies reported usage of overdraft facilities; most of them received overdrafts from one bank (81%) and others from 2 different banks (see Table 4).

We can not observe clear relationship between the actual average interest rate and the share of companies using bank financing. However, this can be explained by the large share of companies using parent company's or owners' financial support.

The share of "other" clearly indicates that the combination of well-protected shareholder and creditor rights together with the higher market interest rate than in developed countries is driving the tendency of financing companies through equity and owners' direct investment.

According to the IMF country report analysis, the share of FDI earnings reinvested in Estonia averaged 63 percent during 1996–2003, rising to 79 percent in 2003 (IMF report). This again proves that Estonia is exceptionally using large part of the earnings to enlarge the business. Recent data show that Estonia's foreign direct investments per capita are on a solid top 20 positions in the world, and as an indicator we can look at it as one more argument supporting good direct investment climate in Estonia.

**Table 4. Borrowing from Formal Institutions**

	1994	1995	1996	1997	1998	1999	2003
<i>Share of firms (%) using:</i>							
<i>Overdraft facilities</i>	41.9	42.9	45.5	56.3	43.3	45.7	42,7

<i>Insufficient collateral, probably will not be approved for a loan</i>	8.4	23.1	-	29.6	5.5	12.0	10.1
<i>Other reasons (parent firm is helping, already has a large debt etc.)</i>	8.4	-	-	-	16.2	20.0	25,1

*Source: Authors' calculations*

The share of lease financing has had steady growth from 1994 to 1998. That can be explained with general legislation enabling to secure leases in better way than loans. Granted loans have been used more in late 90-s and were even more popular than financial leases in 1999. Lease financing has steadied after 2003 in Estonia, however, Estonian companies have started significant lease activities in CIS countries.

## 5. Informal borrowing and lending

Approximately an half of the companies have requested a loan from bank and nine tenths had received it. Firms, who received loans during the last year or during the last five years, reported more exact terms and conditions of loans. About 2/3 of institutional loans were bank loans, firms received loans also from non-bank financial institutions (for example, from credit unions), from government projects and foundations, from parent firms. The companies what did not apply the loan majority did not need financing outside the company. The second most important reason was lack of security to be pledged as collateral.

23.4% responded firms reported the usage of informal borrowing during last 3 years. The main reasons for informal borrowing (mainly fewer formalities and more favourable interest rate) are presented in the Table 5.

Relatives and friends, also owners and parent firm, were reported as main loan sources, moneylenders and suppliers or clients were also mentioned. To comment informal borrowing the most adequate conclusion is that personal relationship with the borrower is a reason why it is used.

**Table 5. Informal Borrowing and Lending**

<i>Reasons</i>	1994	1995	1996	1997	1998	1999	2003*
<b><i>1. Informal Borrowing:</i></b>							
<i>Share of firms using informal borrowing</i>	18.7	21.2	16.7	24.5	23.9	23.4	20.3
<i>Main reasons of informal borrowing:</i>							
<i>More favourable interest rate</i>	33.3	41.6	12.5	8.3	37.5	36.4	10.2
<i>More flexible repayment schedule</i>	16.7	25.0	25.0	58.4	-	-	-
<i>Less formalities</i>	33.3	-	25.0	-	31.3	54.5	63.9
<i>Collateral is not needed</i>	-	16.7	25.0	8.3	12.5	9.1	12.3
<i>Others (did not got a loan from a bank)</i>	16.7	16.7	12.5	25.0	18.7	-	3.1
<i>Main loan sources/lenders:</i>							
<i>Relatives and friends</i>	50.0	58.3	37.5	50.0	77.4	36.4	61.0

<i>Usage of collateral, %</i>	33.3	28.4	47.4	21.7	38.1	46.1	55.2

*Source: Authors' calculations*

Largest share in money lending have employees. It is probably related to policy of retaining employees in the business when salaries are relatively low. Although loans from banks have become available to many persons, lending from a company is still popular.

An important component of a state's economic policy is its financial policy. The financial sector, and particularly the banking system played an important role in the process of transition and economic recovery in Central and Eastern European countries (CEECs). Banks and other financial institutions are a unique set of business firms which assets and liabilities, regulatory restrictions, economic functions and operations establish them as an important subject for the study, particularly in the conditions of emerging financial sectors in CEECs. Banks and other financial institutions performance monitoring, analysis and control need special analysis of their operating and activities results. It can be done from the viewpoint of different audiences, like investors/owners, regulators, customers/clients, and banking managers.

There are several obstacles hindering the transformation of former centrally-planned economies into well-functioning market economies. The business environment in transition countries is dynamic and dramatically changing.

All these transition activities, such as appropriate institution-building, political democratisation, changes in value appraisal and behaviour of individuals and economic agents, cause rapid changes in the business environment influencing, among others, financing and investment decisions made by firms.

## 6. Conclusion

Small and medium sized enterprises in Estonia have different approaches to the financing. We can notice that large share of financing is provided by either the owners or by the parent company despite availability of different financial products from banks and other financial intermediaries. This tendency may have several reasons: influence of the unusual corporate income tax law, good protection of shareholders and creditors rights, owners' faith to the economic growth in Estonia and relatively good effectiveness of legal enforcement mechanism.

For SME-s borrowing from owners with less transaction cost and less formality is only outweighed by the use of owners' equity, i.e. retained earnings, as a main financing source. Use of own savings, including the equity, is remaining popular for businesses. This can change together with the change in tax system, which is expected after the transition period agreed with EU before accession in 2004 ends.

More profound studies are needed to analyse the reasons behind using of the informal borrowing and lending and the relationship between the shareholders rights and use of owners' equity as a primary source of financing.

## **Abstract**

*The contribution deals with the institutional structure of the support of SMEs in Slovakia. It shows the situation in the field of support of the small and medium -size enterprises in East Slovakia. It also provides a picture of how the small and medium -size enterprises are informed about institutions of support, about using the services of these institutions, about the interest of SMEs to use the services of these institutions, about the interest of SMEs to cooperate with universities. The contribution is a part of the output from the solution of the Grant of the University of Economics in Bratislava, Project of Young Scientific Workers, No. 2330251/04 “Solution of Selected Problems of Regional Forms of Support of Small and Medium-Size Enterprises”.*

**Keywords:** *support of small and medium-size enterprises, support institutions of small and medium-size enterprises, using the services of the institutions for support of SMEs*

---

<sup>1</sup> The contribution is a part of the output from the solution of the Grant of the University of Economics in Bratislava, Project of Young Scientific Workers, No. 2330251/04 “Solution of Selected Problems of Regional Forms of Support of Small and Medium-Size Enterprises”

## 1. Introduction

Small and medium-sized businesses are an important part of the economy. Their development has a positive trend in Slovakia in the recent years. The number of small and medium-size businesses is increasing, the share of employment in small and medium businesses on total employment is growing, the volume of gross production in small and medium-size businesses is increasing but the share of SMEs on total gross production is decreasing.

In spite of this fact the share of SMEs in the total number of companies in Slovakia is comparable with the countries in the European Union.

Joining the European Union means for the Slovak Republic an increasing competition pressure in the markets. In order to maintain the position of SMEs in the competitive markets, the Slovak Republic follows the policy of supporting the development of small and medium-size enterprises and in the effort of improving the entrepreneurial environment by programs of support to small and medium-size enterprise of Ministry of Economy of the Slovak Republic, other Ministries, financial and assistance institutions, interest societies and unions. An important role in this process is played by banks, which take part in co-financing of assistance projects of development of SMEs.

At present, attention to small and medium-sized businesses is given by institutions for support of the development of small and medium-size businesses as well as many scientific and research institutions, among them also universities.

The research project “Solution of Selected Problems of Regional Forms of Support to Small and Medium-Size Businesses” is aimed at examining the current state of SMEs in East Slovakia, analysis of current conditions and possibilities of the access of SMEs to capital for beginning and development of their entrepreneurial activities, determining and solving some of the main problems of supporting small and medium-size enterprises and designing a proposal of measures for improving the situation in this field in East Slovakia.

The aim of this contribution is to present the preliminary results of the research of young researchers and to show the situation in small and medium-sized businesses in East Slovakia.

## **2. Institutional Support of Small and Medium – Size Enterprises in Slovakia**

In spring 2000 at the Lisbon summit, the EU set a new strategic goal: to become the most competitive and most dynamic economy in the world which would be capable of constant economic growth. At the meeting of the European Council in Feira in June 2000, the European Charter for Small Enterprises was issued, which called upon the Member States and the European Commission to support the development of small enterprises. The Slovak Republic officially adopted the European Charter for Small Enterprises at the Conference of CC Best in Maribor on 23<sup>rd</sup> April 2002.

In compliance with the above mentioned Charter and further documents and recommendations of the EU, in Slovakia at present the following institutional framework for support of small and medium enterprises is built up. The guarantor and coordinator of all activities for the field of small and medium enterprising is the Ministry of Economy of the SR which in accordance with the Act of the Slovak Parliament No. 575/ 2001 on organizing the activities of the Government and organization of the central state administration, in the wording of later regulations, participates in the strategy of creating the entrepreneurial environment and supporting SMEs in the fields of industry, power engineering, mining, trade and tourism. The task of the Ministry is:

- creating the strategy of development of small and medium enterprising through state support programs which are carried out through
  - the National Agency for the Development of Small and Medium Enterprises,
  - the Slovak Guarantee and Development Bank, a.s.,
  - the Slovak Power Engineering Agency,
  - the Slovak Agency for the Development of Investments and Trade.
- providing support for establishing industrial parks.

The Ministry of Economy is the Directing body for the Sector operating program Industry and Services through which it is possible since the accession of the SR into the EU to get finances from the European Fund for Regional Development.

The National Agency for Development of Small and Medium Enterprises together with a network of Regional Counseling and Information Centers create the basic institutional tool for support and development of

SMEs which co-ordinate the activities to support them at international, national and local level.

The National Agency for Development of Small and Medium Enterprises was established in 1993 with the common initiative of the EU program PHARE and of the Government of the SR as a foundation. In 1997 it was transformed into an interest association of legal entities of non-profit character. The basic mission of the Agency is to support the development and growth of SMEs in Slovak Republic with regard to the state structural, industrial, technical, regional and social policy. The financial cover for support of SMEs is provided for from the state budget, from funds of PHARE and from funds of the EU.

The National Agency for Development of Small and Medium Enterprises with its financial programs enables:

- Support Loan Program which enables to gain loan funds for setting up or development of a small and medium enterprise, and whose aim is to strengthen the position of small and medium companies, to support their further development and to increase, or maintain employment.
- Micro-loan Program whose subject matter is making loan resources accessible for small entrepreneurs, and whose aim is:
  - to enable establishing/development of small businesses
  - to increase the survival rate of small businesses
  - to contribute to maintaining of employment and creating new jobs in single regions of the SR.
- Capital Starting Fund whose aim is to enable establishing and development of new companies, and to help develop the activities of existing ones in new fields of business by financial investments.

The program enables small and medium entrepreneurs access to capital for starting or development of their entrepreneurial activities through selected banks /Istrobanka, Unibanka, Slovenská sporiteľňa, Tatra banka, Ľudová banka, Všeobecná úverová banka/, Regional Counselling and Information Centers, Entrepreneurial Innovation Centers and Seed Capital Company, s r.o. /established by the National Agency for Development of Small and Medium Enterprises as one of the forms of supporting financial programs – financial investments/.

Besides financial support programs of loan character, the National Agency for Development of Small and Medium Enterprises provides support to small and medium entrepreneurs in the framework of other programs, too, for example:

- additional programs
- counseling and educational programs
- information and institutional programs
- in the framework of pre-accession help of the EU
  - Industry Development Grant Scheme - IDGS
  - Tourism Development Grant Scheme – TDGS
- in the framework of EU help through structural funds – Innovations and Technologies Development Grant Scheme – INTEG
- Sector Operational Program Industry and Services
- and others.

Regional Counseling and Information Centers were established on the basis of partnership of public and private sector as non-profit institutions in the form of association of legal entities with the aim to support economic development at regional level through development of small and medium enterprising. They provide complex counseling, information and educational services, especially for beginning entrepreneurs, or for existing SMEs.

Business Innovation Centers /BIC/ were established with the aim to actively support selected entrepreneurial plans in the region and provide them with long-term care. They are independent legal entities which work out business plans and marketing plans for entrepreneurs , loan applications, accounting, provide services at implementing quality systems, technological and patent counseling, etc.

The above mentioned network of institutions for support of SMESs at regional level is supplemented by:

- Entrepreneurial Incubators which represent places where newly established businesses are concentrated in a limited space, and whose aim is to enhance the survival chance of these businesses, and to support their growth through providing:
  - rent of business premises at the lowest prices in the given location
  - common technical infrastructure
  - specialist counseling services and education.

In Slovakia, Incubators work in Banská Bystrica, Bratislava, Košice, Martin, Prešov, Rožňava, Spišská Nová Ves.

- Centers of First Contact whose services' mission is to contribute to the improvement of the entrepreneurial climate, to support creating new jobs, to increase the competitiveness of target groups, to support cooperation in the framework of the EU, to present and make their regions visible.
- The Slovak Guarantee and Development Bank, a.s. was established by the Finance Ministry of the SR in 1991 as a state money institution, and in 2002 it was transformed into a stock company with 100% stake owned by the state with a special mission aimed at support of financing small and medium enterprises. It is carrying out its support programs for small and medium businesses in the form of providing guarantees, loans and non-returnable financial contributions. It also supports newly beginning small and medium entrepreneurs and self-employed businessmen who, as a rule, are not the target group of commercial banks. Since the end of the year 2000 it has been providing short-, medium- and long-term direct loans to entrepreneurs of operational and investment character. In cooperation with selected commercial banks, SZRB realizes loan products through loan programs.
- The Export-Import Bank supports export activities of exporters mainly into the EU and OECD countries with ensuring return on finances by minimization of risks which arise from insurance, loan, guarantee and financial operations. EXIMBANKA SR performs its functions and activities by financing and insuring export loans with the aim to increase the competitiveness of the domestic products, and support mutual economic exchange of Slovak Republic with foreign countries, especially EU and OECD countries.

Besides the Slovak Guarantee and Development Bank and Export-Import Bank SMEs are supported by the programs of further financial institutions and funds:

- Slovak-American Entrepreneurial Fund
- Fund for Support of Foreign Trade
- Micro-fund Integra
- Innovation Fund

as well as supporting institutions of SMEs :

- Slovak Chamber of Commerce and Industry
- Slovak Chamber of Entrepreneurs
- Slovak Agency for Development of Investments and Trade
- Slovak Agency for Tourism

- Agency for Support of Science and Technology, and many other institutions, associations and societies.

### **3. Research Methods of the State of Support to Small and Medium-Size Enterprises**

The research was carried out in September and first half of October 2005.

Questionnaires which were divided into six parts: Assistance to SMEs, Financing SMEs , Strategy of SMEs, Innovation activity of SMEs, Informatics and General information, were distributed in three ways:

- by sending e-mails with the request of participation in the research with the web site ([www.euke.sk/vyskum](http://www.euke.sk/vyskum)), where the web form was put, which enables anonymous filling in the questionnaire,
- distribution of printed questionnaires by students to small and medium-size businesses, followed by copying the completed questionnaires into the form on the web site,
- distribution of printed questionnaires to small and medium-size businesses through the Slovak Post.

From the database file of small and medium-size businesses provided by the Statistical Office of the Slovak Republic by the method of random selection, enterprises were chosen which sent questionnaires. Companies where e-mail addresses were available were addressed by e-mail, to other companies the questionnaire was sent by post. With both ways of distribution, a quarter of the letters came back because of unknown recipient.

## **4. Preliminary Evaluation of the Results of the Research**

### ***4.1 Legal form of small and medium-size enterprises***

The questionnaires were filled in by 129 companies. The following table 1 shows an overview of the legal form of companies participating in the research.

**Table 1 Legal form of small and medium-size enterprises**

Number of employees	Form of enterprises <sup>2</sup>					
	a.s.	v.o.s.	s. r.o.	š.p.	živnost'	Total
0 - 9	1	0	25	0	57	83
10 - 49	0	1	28	0	5	34
50 - 249	3	0	8	1	0	12
Total	4	1	61	1	62	129

Source: own research

#### 4.2 State of being informed about the assistance institutions helping the small and medium-size businesses

The question “Do you know the institutions which support the development of SMEs?” was answered as shown in Table 2. To answer the question “indicate which” respondents listed institutions: National Agency for the Development of SMEs, regional consulting and information centers, the Ministry of Economy, bureau of labor and others, from which follows that at least some of the companies know the institutions which support the development of SMEs.

**Table 2 Do you know the institutions which support the development of SMEs?**

Number of employees	Legal form <sup>2</sup>	no	yes	total
0-9	a. s.	1		1
	s. r. o.	14	11	25
	živnost'	32	25	57
10-49	s. r. o.	13	15	28
	v. o. s.	1		1
	živnost'	1	4	5
50-249	a. s.	0	3	3
	š. p.	1		1
	s. r. o.	1	7	8

Source: own research

<sup>2</sup> a.s. – stock company, s.r.o. - limited liability company, živnost' – self-employed, š.p. – state-owned company, v. o. s. - public trade company

To the question “Do you use the services of the institutions supporting SMEs?” only 9 respondent gave a positive answer. The question “indicate which” was answered by: the interest association PO Kézfogás, Regional Counseling and Information Centers, courses – counseling – subsidies, mediation of business, state subsidies, working out entrepreneurial plans and grants and information about product promotion counseling, financial contribution for establishing new jobs, grant programs.

The question “Has anybody from your company taken part in an information event on possibilities of supporting SMEs?” was answered positively by only 8 respondents. They stated the following organizers:

- the town Košice
- the town Rožňava
- town authority Veľké Kapušany
- the Ministry of Economy
- the Ministry of Agriculture – 2 respondents
- Regional counseling and information center – directing quality,
- Regional counseling and information center Prešov,
- Regional counseling and information center Košice,
- Integra – course.

From the above mentioned it results that small and medium size enterprises know the institutions which support the development of SMEs but they do not use their services /apart from some exceptions/, and they do not take part in information events about possibilities of assistance to SMEs. However they are interested in using the services of institutions which support SMEs. The interest to use the services of these institutions was expressed by 30 micro-companies with the number of employees from 1 to 9, 14 small companies with the number of employees from 10 to 49 and 5 medium-size companies with the number of employees from 50 to 249.

#### **4.2.1 Support of participation of small and medium size companies in the 6th Framework program of the EU**

The 6<sup>th</sup> Framework program for science and research is an activity by which the European Commission contributes to achieving the aim to create from the EU the strongest economy. The community program is designed to

ensure quick application of new information and technologies in the market especially through small and medium enterprises. For Slovak companies it is a way of gaining access to most progressive technologies and innovations of production.

Special attention is given to SMEs with the aim to support their participation in the activities in single thematic fields, especially in integrated projects. In excellence networks and in target oriented research, it is expected that small and medium size-enterprises will use this form to draw at least 15% of the budget of seven thematic priorities.

Further there are two specific schemes for small and medium size enterprises, which enable them to develop innovations actively without having their own research capacities. These are the “collective research” and the “cooperative research” schemes (CRAFT). Through these schemes can SMEs as well as entrepreneurial groups assign a research task to research institutions (research institutes, universities, etc.), and this way solve their own development and innovation problems.

We wanted to know if the companies know the possibilities offered to small and medium size enterprises by 6<sup>th</sup> skeleton program of the European Union. Only seven respondents answered positively, and they stated the following possibilities:

- support of selected entrepreneurial projects, also financial
- 15% of the budget of the skeleton program is devoted to the participation of SMEs in research, development and support activities from different countries
- micro-loan program
- support from the National Agency for Development of SMEs
- integrated projects
- creation of European research area.

It should be noted that the support from the National Agency for the Development of SMEs and the micro-loan program do not belong to the 6<sup>th</sup> skeleton program of the European Union.

#### **4.2.2 Cooperation with universities**

24 respondents expressed their interest to cooperate with universities in the fields of: research, tourism, quality management, service delivery, production technologies, optimal process directing, power engineering, construction industry, practical accounting, international accounting

standards, market research, marketing, counseling about the possibilities of gaining funds for doing business.

#### 4.2.3 Suitability of sources for gaining information

Our object of interest was also to find out to what extent are single sources of information about support suitable for small and medium size businesses /the more suitable, the higher grade/. Table 3 presents the average of suitability of single resources of gaining information about support to SMEs according to size and legal form of companies.

**Table 3 Suitability of sources for gaining information about support for SMEs**

Number of employees	Legal <sup>2</sup> form	Daily papers	Periodicals	Subject specific magazines	Specialized publications	Internet	Information events
0 - 9	<i>a. s.</i>	7,00	7,00	9,00	8,00	10,00	3,00
	<i>s. r. o.</i>	6,20	6,44	6,28	6,56	8,36	6,24
	<i>živnosť</i>	6,09	4,93	6,00	5,61	8,07	5,50
10 - 49	<i>s. r. o.</i>	5,44	5,70	7,61	6,84	8,89	7,27
	<i>v. o. s.</i>	4,00	2,00	6,00	6,00	7,00	5,00
	<i>živnosť</i>	7,00	4,00	5,40	3,80	8,80	3,40
50 - 249	<i>a. s.</i>	7,33	6,00	9,67	8,00	10,00	6,33
	<i>š. p.</i>	9,00	6,00	6,00	5,00	10,00	10,00
	<i>s. r. o.</i>	6,33	5,00	7,11	7,78	7,56	6,78
<i>Total</i>		6,49	5,23	7,01	6,40	8,74	5,95

*Source: own research and own calculation*

## 5. Conclusion

There are many institutions in Slovakia which support the development of small and medium size enterprises. Small and medium-size enterprises in East Slovakia have information about their existence but as preliminary results of research are showing they do not use their services and do not take part in information events about possibilities of support for SMEs. It will be necessary to look for possibilities of improving this situation in East Slovakia.

## **Abstract**

*Project management and its methods are intended for wide and complicated projects leadership. Useful procedures save time and preparation and primarily cut business costs. Typical way, where to practice project management, is company development by European funds supporting policy. Many people, especially in SME's sector, are specialized only on application form, not for organizing, leadership in time of project realization. In this area you could cut your business costs the best. Second section is dedicated to SWOT projects analysis with pointing out on reasons, why the project wasn't being successful in the competition. Research work was realized in two regions – Moravian-Silesian and Ústí region to be able to compare current situation in Regional Business Centres for SME's support and Employment Agencies. Research presented in this paper was supported by internal grant system of Silesian University, IGS SU Nr. 18/2005.*

**Key words:** *project management; business support; SME*

---

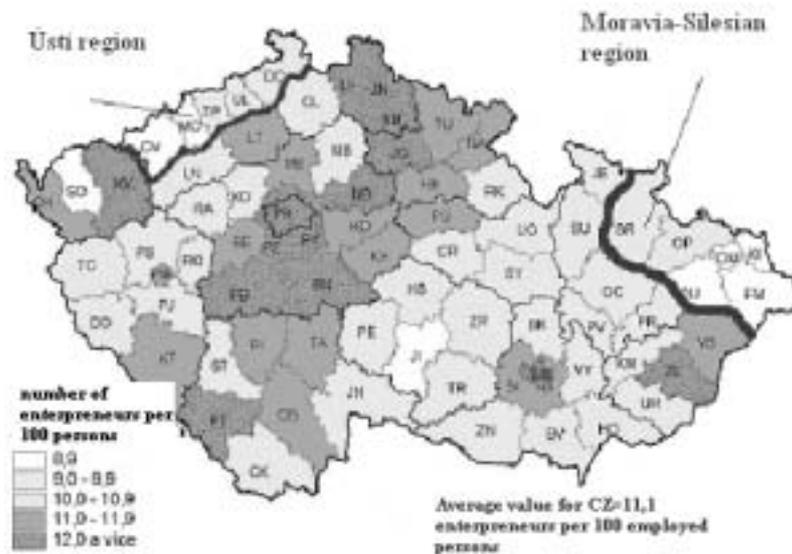

<sup>1</sup> Research presented in this paper was supported by Internal grant system of Silesian University, IGS SU Nr.18/2005

## 1. Introduction

Small and medium sized enterprise (SME) we could characterize as a dynamically growing section of the national economy, especially in number of enterprises. Their importance we could illustrate by the ratio on all subjects on the Czech market in 2004, it was 99.85%. This number says that number of large enterprises decreases strongly too. It means that SME's in the Czech Republic play a big role in regional labour market. Last year it had employed in these sector 61.5 % persons. Their contribution to the economy system is about 34.92 % of GDP; they made 52.15 % of total output and 52.9 % of added value in our republic. SME's are the most important subjects, who increase our foreign trade – 34.3 % of export operations and 52.5 % of import operations.

It was the main reason why is important to promote project management to be more successful in the project competition in Structural funds in the Czech Republic. The activity mainly depends on entrepreneurship intensity ratio. Both mentioned regions – Moravia-Silesian region and Ústí region suffered from high unemployment rate and the lowest entrepreneurship intensity ratio, which is illustrated on the map below.

**Figure 1 Entrepreneurship intensity ratio**

Source: <http://www.czso.cz/csu/edicniplan.nsf/tab/3800373D29>

Czech entrepreneurship is stable growing and developing, by the comparison – three or four subjects are established into one died. The trend you can observe many years. Absolute numbers are represented in Table 1.

**Table 1 Comparison of number of founded and died enterprises**

<b>Year</b>	<b>New founded</b>	<b>Cut-off</b>	<b>Absolute value</b>	<b>Ratio: New founded: cut-off</b>
<b>2000</b>	102 886	27 667	75 219	3.7:1
<b>2001</b>	92 322	30 694	61 628	3:1
<b>2002</b>	64 084	18 413	45 671	3.5:1
<b>2003</b>	99 915	26 781	73 134	3.7:1

Source: *www.czso.cz, own calculation*

Books define project management as an operation limited by time and finance sources, which needs wider cooperation between more departments. Simplified definition says that one team solves one complex object by the most effective way with minimum costs.

When we explain a definition in real life, it means two sides - project description and daily routine. We have to define clearly each work stage and operation sequences. They are existing basic team work rules to be successful. First of all you have to choose a team leader, who has two basic abilities – interpersonal and conceptual and technical skills, than you are able to prepare an implementation timetable and financial plan to be respected by all team members.

Finally all team members have to identify with the project and respect all rules in this time period. The best way to be successful is to support communication activities between all members to solve conflicts and problems during the project. After that you could say that you could the reap harvest the benefits of the project management.

## **2. Research methods and basic hypotheses**

- SME's Analysis in competence of The Ministry of industry and trade 2001-2004, [www.mpo.cz](http://www.mpo.cz),
- Own research, which take place from February to July 2005.

---

<sup>2</sup> Analýza malého a středního podnikání ve Zlínském kraji, srovnání stavu MSP v ČR a EU, definování rozdílů v jeho různých segmentech <http://extranet.kr-zlinsky.cz/vismo/dokumenty2.php?ID=120205>

During above-mentioned period, we made a research between SME's in both regions Moravia-Silesian and Ústi, which was specialized on changes in business environment and main development barriers after the EU accession in 2004. Focus was on the local labour market. It was the reason why we use and compare SME's only from the number of employees view and we abstracted from total balance sheet or turnover, which was new defined by the European Commission from 1.1.2005. Another factor, who changed the research way was the fact, that entrepreneurs was not have a goodwill to write down these figures in questionnaire. It was tested on small entrepreneurship group and the main answer was blank questionnaire. It was the reason to modify main goals and the questionnaire type.

Main goals for the research were following:

- SME's structure in both regions, the capital and size of enterprises,
- Information sources about EU and their supporting policy programmes,
- Education opportunities for SME's,
- SME's Adaptability strategies.

### ***2.1 Hypothesis based on information sources***

Before questionnaire preparation, we have to formulate hypothesis based on previous projects and research, but with one change – now as a European Union member:

- “Micro” structure like self-employment person is dominating in regions mentioned above and in all the Czech republic as a way how to solve the unemployment problem,
- Main specialization is trade because of low request on capital, innovations and education,
- Entrepreneurs not use many supporting programs, they don't know about them and main information source is Internet web sites,
- Low rate of approved projects has influence in low rate of education, no counselling work of Business Centres,
- SME's have a high level of dynamics and adaptability to the new business environment; there is connections wit local labour market.

### ***2.2 Methods of own research***

We contacted 720 entrepreneurs in both regions to be able describe adequately characteristic attributes in their environment. We obtained only 172 responders, 122 from z Moravia- Silesian region (MSR) and 50 from Ústi region (ÚR).

Answers we record into spreadsheet program and we used standard statistical methods. Results of the research are explained into two ways – for each region separately followed by regional comparison, than as all results together by making a model of SME. Finally we use a standard research methods like self-induction and hypothetic deduction based on own secondary data analysis.

### **3. Comparative analysis, modelling project oriented SME**

#### ***3.1 Moravia-Silesian region (MSR)***

The Moravia-Silesia region is located in the north-eastern part of the Czech Republic, internally neighbouring the regions of Zlín and Olomouc. Externally, the outer boundary of Moravia-Silesia marks the Czech Republic's border with Polish Silesia and with Slovakia and the region of Žilina. Though it accounts for 7% (5 554 square km) of the country's area, it is home to 12.4% (1 262 660) of its population.

The region's territory is varied, with the Ostrava-Karviná conurbation at its core. This is a traditionally industrial area with a high proportion of heavy industries – primarily coal mining, metallurgy, heavy engineering and chemicals. Other major sectors include mechanical engineering, pharmaceuticals, electro technical manufacturing, paper, textiles and the food industry. Agricultural production is distributed throughout the region and is represented in the foothills of the Beskydy and Jeseníky mountains by forestry.

Since 1990, the region has undergone extensive economic restructuring, accompanied by lay-offs of tens of thousands of workers. From a nationwide perspective, Moravia-Silesia has been particularly hard-hit by the slump of heavy industry and by soaring unemployment. The region has ripe for the development of tourism; an advantageous geographical location in terms of transport routes; a relatively dense rail and bus transport network; an international airport close by the region's centre with huge development potential.

#### ***3.2 Ústí region (UR)***

The Ústí Region lies in the northwest of the Czech Republic along its northern border with Germany, particularly with the Free State of Saxony. The Region's neighbours are also the Liberecký Region in the northeast, the

Karlovarský and partly the Plzeňský Regions in the west, and the Středočeský Region in the southeast.

The Usti Region has 46 cities, where is living 80.7 % of its inhabitants, and 354 villages. The villages up 500 inhabitants are representing 54 % of all villages in Region, but there is living only 5.8 % of inhabitants.

This location predestines the region a significant position in the international economic and cultural co-operation and seems to be an outcome for a wide range of activities of cross-border co-operation between both these neighbouring regions. The position of the Region is, in terms of its gradual integration into European structures, along with the close vicinity and accessibility of Prague and other regional centres, a significant factor of its development. In addition, the main European roads and railway lines on the axis from **Berlin to Vienna via Prague**, together with the Labe waterway, go through this Region. The concentration of industry and population is representing, in terms of the Czech Republic, important market, good accessible from Prague and from neighbouring Saxony. The Ústí Region is varied as for natural conditions as well as from the point of view of its economic structure, density of settlement and condition of the environment. Historically, economic importance of the Region is based on its raw materials, especially large deposits of brown coal, which lie close to the surface. The brown coal basin stretches under the hillsides of the Ore Mountains from the town of Ústí nad Labem to Kadaň. There are also other important raw materials in the Region, e.g. quality glass and foundry sands and building stone. Industrial activity from the past had and still has an unfavourable influence on the quality of the environment. Strongly developed surface mining distinctively damaged the natural face of the landscape, which gradually recovers only thanks to a costly re-cultivation. Well-known are also problems with the emission situation in the Region and high unemployment rate for many years.

### ***3.3 Regional comparison***

The questionnaire was sent to 720 entrepreneurs, from which we get only 172 responds. The main reason for their cooperation was a “help to somebody to make some thesis research” not for better cooperation with the university.

**Table 2 Research sample in both regions**

	MSR		ÚR	
	Amount	Share per total	Amount	Share per total
<b>Fill-in Questionnaires</b>	<b>122</b>	<b>30.5%</b>	<b>50</b>	<b>15.6 %</b>
<b>Blank Questioners</b>	<b>46</b>	<b>11.5%</b>	<b>34</b>	<b>10.6 %</b>
<b>Without response</b>	<b>232</b>	<b>58%</b>	<b>236</b>	<b>73.8%</b>
<b>Total</b>	<b>400</b>	<b>100%</b>	<b>320</b>	<b>100%</b>

*Source: own research*

Regional contrasts are not deep full. By the table comparison, we could illustrate the current situation in the business environment.

Actual figures (30.6.2005) said, that average number of entrepreneurs is on the low level in the Czech republic, because average number is 190 subject per 1 000 citizens and both regions have about 150 per 1 000 citizens. In average, we could say, that one entrepreneur have registered two and more specializations – two licenses. However, from own research in “Moravia” is only 1.1 licenses per 1 entrepreneur and 1.12 in “Ústí”.

We made our research in Business centres too. We were able to make some simplified SME’s definition (which use project management) from questionnaire data. The successful SME, financed by supporting EU funds isn’t the same structure as “common SME” form second part of our research. You could compare it in two tables below.

**Table 3 “Common” SME’s model**

	Moravia-Silesian region	Ústí region
Year of founding	<b>1992</b>	<b>1990</b>
Type of SME	<b>1-10 employees</b>	<b>1-10 employees</b>
Main specialization	<b>Trading company</b>	<b>Trading company</b>
Structure	<b>58% man 42% woman</b>	<b>69% man 31% woman</b>
Education		
<b>Primary school</b>	<b>11.3%</b>	<b>34 %</b>
<b>Secondary education – practice schools, vocational schools without school leaving exam</b>	<b>36 %</b>	<b>38 %</b>

<b>Secondary education- colleges and other schools with the final exam</b>	<b>40.7%</b>	<b>21%</b>
<b>University degree</b>	<b>12%</b>	<b>7%</b>
Language skills	<b>English and Polish</b>	<b>English or German</b>
Capital dominating	<b>95% Czech</b>	<b>90% Czech</b>
Form of cooperation	<b>70% nothing, 30% trade chains</b>	<b>80% nothing, 20% trade chains</b>
Foreign trade	<b>As a third SME</b>	<b>As a fifth subject</b>
EU Funds		
Money utilization	<b>New technology</b>	<b>New technology, development</b>
Funds contribution	<b>increase on market position</b>	<b>increase on market position</b>
Information source	<b>Internet</b>	<b>Internet</b>
Projects preparation	<b>By their self</b>	<b>Consulting company</b>
Main reasons for cut off the business	<b>Lack of capital, competition growth</b>	<b>Lack of capital, competition growth</b>
IT and utilization		
Internet connection	<b>87%</b>	<b>86%</b>
E-learning agreement	<b>41%</b>	<b>62%</b>
Main sections for education	<b>Law, accounting, marketing</b>	<b>Law, accounting, languages</b>

*Source: own research*

**Table 4 „Innovative“SME’s Model**

	<b>MSR</b>	<b>ÚR</b>
Type of SME	<b>11-49 employees</b>	<b>11-49 employees</b>
Main specialization	<b>Industry</b>	<b>Building industry, industry</b>
Structure	<b>70% man 30% woman</b>	<b>82% man 18% woman</b>
Education		
<b>Primary school</b>	<b>10%</b>	<b>15%</b>
<b>Secondary education – practice schools, vocational schools without school leaving exam</b>	<b>10%</b>	<b>10%</b>
<b>Secondary education-</b>	<b>70%</b>	<b>50%</b>

**colleges and other schools  
with the final exam**

University degree	10%	25%
Age	26-50 years	26-50 years
Money utilization	New technology	New technology, development
Information source	Internet, consulting companies	Friends, Internet
Projects preparation	consulting companies	consulting companies
Main reasons why project isn't accepted	Many "similar" projects	Standing of a firm, many "similar" projects
Main barriers	Growth of administrative costs, minimum tax rate	Lack of capital, competition growth
How many projects are successful?	65%	90%

*Source: own research*

We could say that model of "common" Czech SME is not corresponding with "innovative" Czech SME, as being represented by Business Centres. Successful project is mainly prepared with cooperation of the consulting company. Finally, we could say, that main way to get financial support from EU funds is to take advantage of project making specialists, who knows more about program objectives, rules, logical framework, feasibility study and actual law and regulations on the each markets and specializations.

#### **4. Useful project management strategies**

All projects, mainly for developing and growing SME's need a lot of preparation work, which includes analysis of pre-conditions a problem analysis, logical framework and dependence on actual business environment. Useful strategy application includes adaptability on new European environment after the enlargement in May 2004. So, we could talk about as a main used tool called "Euro strategy".

##### ***4.1 Euro strategy Application***

Unified Euro strategy application needs more and more project management approach, which is a result of company department's

cooperation in wide business environment. “Survival problem” is spread into wider array of factors in *European problem format*. If you are a businessman and you want to or not, European globalization trend and changes in business environment could catch you in the most underdeveloped region.

First step to use and prepare Euro strategy is classical SWOT analysis of the common SME in the unified European market approach. We could say the main strongness in this analysis is good knowledge about new EU members, but Czech is still oriented on old EU members. New members have one big advantage – more dynamical harmonization of EU standards and rules.

**Table 5 SWOT analysis of the CZ business environment**

STRENGTHS	WEAKNESSES
<ul style="list-style-type: none"> <li>✓ The Government approval of the <i>Industrial Policy Concept of the Czech Republic</i> including various support possibilities applicable to SME’s</li> <li>✓ Rapid adaptation to market demands</li> <li>✓ Introduction of new technologies</li> <li>✓ Creation of new jobs with low capital costs</li> <li>✓ Contribution to quicker development of towns and villages through entrepreneurial activities</li> <li>✓ Support to structurally affected and economically weak regions</li> <li>✓ Sound infrastructure network for SME’s promotion – 7 Euro Info Centres, 29 Regional and Information Centres, five Business Innovation and Science and Technology Centres.</li> </ul>	<ul style="list-style-type: none"> <li>× Bureaucratic legal and administrative procedure of registering enterprises</li> <li>× Lower economic power than large enterprises</li> <li>× Lack of legal, economic, technical and managerial capacities</li> <li>× Higher sensitiveness to law enforcement and to administrative problems and lengthy process of business disputes</li> <li>× Insufficient orientation at foreign market</li> <li>× Lower awareness of negative impacts of production on environment</li> </ul>

## OPPORTUNITIES

- ✓ Development of industrial production and industrial services
- ✓ Development of business relations with TNC's and wholesalers to become their suppliers
- ✓ Application of a innovative potential as a generator for added value production
- ✓ Creation of enterprise clusters
- ✓ Participation in the Multi-annual Programme for SME's could strengthen infrastructure of supporting capacity

## THREATS

- × Higher competition as a result of market globalization
- × Conservative approach of enterprise managers to introduction of certificated systems of management, including production quality management
- × Lack of capital for development of entrepreneurial activities

*Source: SMALL AND MEDIUM-SIZED ENTERPRISES IN COUNTRIES IN TRANSITION, UNITED NATIONS New York and Geneva, 2003, ISBN E.03.II.E.43, p.66*

Then you are able to analyze your own company situation, main specialization and competitiveness on the market. You have to find original idea, which makes you more different from others.

All components and factors we could illustrate on picture below to be able analyze all factors and identify main goals of our Euro strategy.

### Figure 2 Euro strategy components

**MAIN GOAL:** To increase SME's output by the growing profit from the turnover and growing market

**IMMEDIATE GOAL:** Maximalize chance and minimalize risks from the EU entrance

*Source: Vývoj průmyslu a podnikání, OHK Brno, available from [www.ohkbrno.cz](http://www.ohkbrno.cz)*

After factors description we could make next step in Euro strategy application – a strategy definition by step by step method. Each step covers inside factors which could make it unsuitable for the company, this factors in each group we could include into risk strategy components. We need a lot of adaptability and dynamics in making strategy changes.

**Table 6 Step by step Euro strategy formulation**

Implementation procedure	Strategy type , main problems to solve
<i>Step 1</i>	<ul style="list-style-type: none"> <li>• <b>Research in the new external business environment and conditions on the unified European market.</b></li> </ul>
<i>Step 2</i>	<ul style="list-style-type: none"> <li>• <b>Business sector analysis – analysis of the firm’s market (closer external environment),</b></li> </ul>
<i>Step 3</i>	<ul style="list-style-type: none"> <li>• <b>SWOT analysis from the point of unified EU market view,</b></li> <li>• <b>Firm’s Opportunities and strongness comparison adapted on the new conditions,</b></li> <li>• <b>Firm’s threats and weaknesses comparison adapted on the new condition,</b></li> <li>• <b>Find strategy opportunities,</b></li> <li>• <b>Validity test of strategy opportunities.</b></li> </ul>
<i>Step 4</i>	<ul style="list-style-type: none"> <li>• <b>Strategy choice – competitive strategy formulation</b></li> </ul>
<i>Another steps</i>	<ul style="list-style-type: none"> <li>• <b>Adaptability strategy implementation on the new conditions with standard methods.</b></li> </ul>

**4.2 Project management cycle**

The project cycle follows the life of a project from the initial idea through to its completion. It provides a structure to ensure that stakeholders are consulted, and defines the key decisions, information requirements and responsibilities at each phase so that informed decisions can be made at each phase in the life of a project. It draws on evaluation to build the lessons of experience into the design of future programs and projects.

**Project Cycle Management** we could define as a methodology for the preparation, implementation and evaluation of projects and programs based on the principles of the Logical Framework Approach.

**Figure 3 Formulating Project Elements**

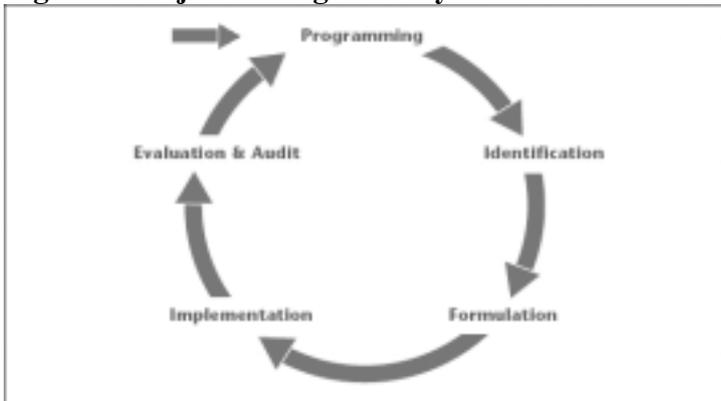

Source: *Project cycle management guidelines, available from <http://europa.eu.int/comm/europeaid>, page 38*

The idea of project cycle management is cooperating with Euro strategy implementation, which could improve SME's competitiveness on the big European market. We could say that this moment is another step to be successful in projects supported by EU.

Project management cycle procedures we could simplify into figure below.

**Figure 4 Project management cycle**

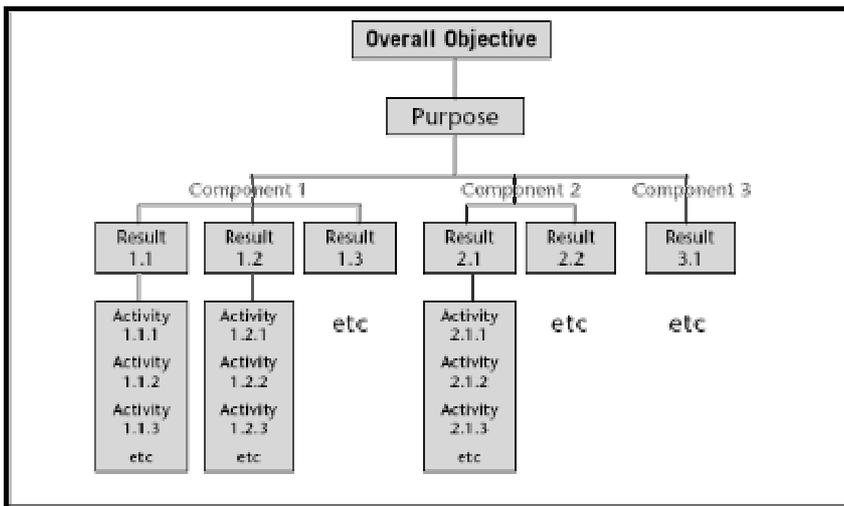

Source: *Project cycle management guidelines*, available from <http://europa.eu.int/comm/europeaid>, page 16

We could see five important stages in this approach. First of all we need to choose appropriate supporting program, which fits the best on our entrepreneurship conditions. Then we have to identify our strategy goals (what will be the benefit of this type of financing support), prepare implementation program step by step and prepare pre-financing study for first phase, because in many cases SME's obtain loans or guaranties after that.

Very important thing is time to do auditing our effectiveness in this project. Is recommended to plan doing project in 1 – 1,5 year and make some time “fund” to make changes and administrative tools for project evaluation. It is the result from EU funds statute, that one project is time limited by the rule “ $n+2$ ”, what means “*You have to complete your project into two years from the project confirmation*”.

The problem could be solved by another tool – objective tree, you could plan your goals and activities which you need to get the biggest effect. This method we call MBO (management by objectives).

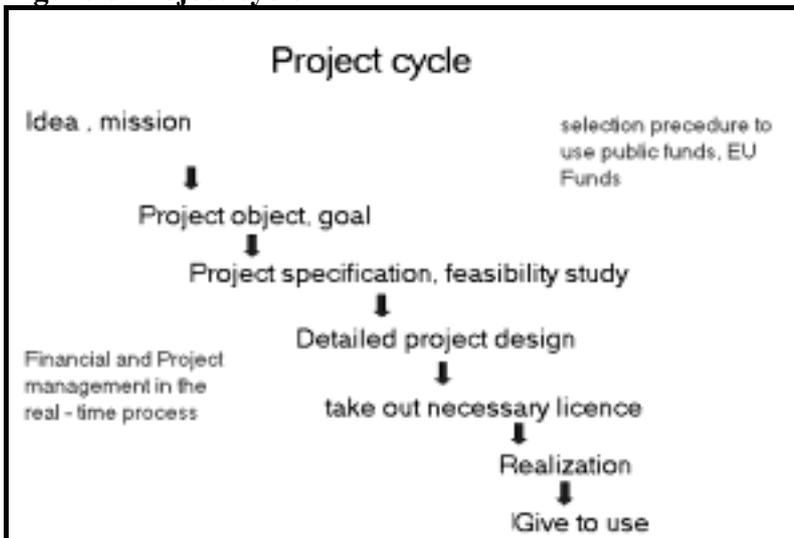

**Figure 5 Objective tree**

Source: *Project cycle management guidelines*, available from <http://europa.eu.int/comm/europeaid>, page 78

If we summarize our knowledge about preparing Euro strategy with project cycle management, we are able to define some “break points” on the way to our “project”. It is illustrated on the Figure 6.

**Figure 6 Project cycle**

Source: *Příležitosti veřejného financování ze strukturálních fondů EU*, PBA Group, Praha, [www.jzp.cz/PrezentaceSFEU012004.ppt](http://www.jzp.cz/PrezentaceSFEU012004.ppt)

It consists on external and internal procedures, which include many managerial skills as a project and financial management, influence of EU policy and development strategy. They are connected with each other and have big or small influence on our project. All the factors are in real time, so another factor which could make our project unsuccessful is “time lag”, when some new legislative regulations could change market conditions and we have to be dynamical to implicate it into project as a “business risk”.

## 5. Conclusion

Preparing a good project need to take a care about all document parts and choose a suitable supporting program not only for getting money, but the main reason must be a company development.

Successful project covers inside many types of analysis, the main points, which we could point out are:

- **Strategy, project goals** - we have to find answers for these following questions: Which is the main project goal and possibilities to fulfil it in the time? Is my project useful? (benefit analysis/ project’s profitability)
- **Financial management** – Which are our main costs? Which are the main cost items? Are we prepared for pre-financing project phase? (Considering *ex-post* EU funds financing) ? Which are the main risk sections?
- **Cooperation , project benefits** – Who is our project partner – does he help us or threaten us? Will be our project supported by the local government?

Finally, each project includes following sections:

- Financial and economical evaluation,
- Economical effectiveness analysis,
- Feasibility study (cost-revenues analysis, social-economic analysis of project benefit, marginal and risk analysis),
- Business plan,
- Environmental impact.

Projects prepared for EU financial support are very useful for SME’s development, but disadvantages are project parameters or program conditions, which could make our project work like lost labour on it.

## **Abstract**

*An increasing number of new small and medium-sized enterprises uncovers a long-term problem concerned with their financing. According to a literature seed-up and start-up firms have many possibilities of raising capital from different external sources. Reverse is true. On the one hand, many innovative business ideas and quality business plans, but without any collaterals or experiences on the other hand, do not fulfill desired conditions and so they are doomed to failure. In this bearing is maybe more actual than anytime before a question of private informal investors. One kind of these investors represents business angels. They are private investors who provide both financing and managerial experience, which increase the likelihood of start-up enterprises to survive. The aim of this paper is represented the most interesting findings of research which we carried out with the aim to show an importance of the business angels as informal investors offered a venture capital with a higher added value for small and medium-sized enterprises in a country with a long-term history of the active business angels – in Germany. Findings of our research are very similar to the findings of other researches. In generally we can say that business angels can influence a next development of firms with a good combination of a monetary and a non-monetary investment.*

**Keywords:** *small and medium-sized enterprises; business angels*

## **1. Introduction**

The latest survey notes that 18 % of European small and medium-sized enterprises (SMEs) regard the cost of finance, and 19 % the availability of long-term finance, as a barrier for their next expansion. This problem is worse particularly for seed-up and start-up firms. These young enterprises feel during early phases of their enterprising lack of the experiences, own capital and the collaterals. If a beginning firm cannot use any loans from the banks or other venture-capital associations due to these reasons, private investors in a form of business angels represent the perfect partners for them.

## **2. Business angels as a financial resource for small and medium – sized enterprises**

Business angels (BA) are individuals who invest capital in, and bring entrepreneurial know-how and experience to enterprises with growth potential. Business angels can overcome the information problem plaguing banks and venture capital funds. They can make investment decisions using their knowledge of the field, and their appreciation of the potential of the firm they are investing in. Business angels' investments can be both early stage and expansion, and they can have a leveraging effect for other sources of funding, including bank loans and formal venture capital. They come from experienced businessmen, managers and solvent bank clients.

A term - business angel was used for the first time in USA in first middle of 60.<sup>th</sup> years. It was connected with a movie industry. Its importance has increased together with an importance of an informal capital for last 25 years. The terms - private investors, informal investors and business angels were used as the synonyms at the beginning. It had a crucial impact on economists not only in USA but in the Great Britain and Europe as well. In German-spoken area a term business angel is used when we talk about the private investors offering an added value not only in a form of finance but in a form of business consulting as well.

### ***2.1 Types of business angels***

Due to an increased importance of this kind of private investors and their variety there are the efforts to classify them in a literature and in a practice too.

The business union from Germany (Neues Unternehmertum Rheinland e.V.) differentiate these three types of business angels:

- perfect business angels (offering capital, know-how and experiences),

- active business angels (offering more know-how, experiences and less capital),
- silent business angels (offering only capital).

According to the different sources we can business angels sort into these two groups:

- potential business angels:
  - virgin angels (complying with all conditions, but they still do not invest),
  - latent angels (have experiences with investments, but they are passive now),
- active business angels:
  - entrepreneurial angels (are business oriented and experienced),
  - income-seeking angels (seeking only a regular income),
  - corporate angels (through an investment they follow interests in own firms),
  - silent angels (offering only capital),
  - management angels (they are not really entrepreneurs but they offer managerial experiences and know-how)
  - consulting angels (offering only consulting services and contacts).

In practice it is often very difficult to sort business angels positively into mentioned groups. They mostly have characteristics of more type of them. Particularly according to these characteristics we should be able to recognize an original business angel from a false business angel / business devil.

## ***2.2 Business angels in Europe***

Informal investment has been around in Europe for a long time. These long-term experiences pointed out one problem. There was an information gap between private investors on one hand, and firms looking for potential financial resources on the other hand. A good solution to this problem represent a phenomenon - business angel networks. Business angel networks are organizations that are set up primarily to facilitate the matching of angels and entrepreneurs. Due to existing business angel networks the entrepreneurs find angels that would be interested in them, and the angels find enterprises

that would fulfill their criteria. Established business angel networks make the matching process more efficient.

The pioneer among European national networks has been the National Business Angels Network (NBAN) in the United Kingdom, which has been the model for several other national networks. The development of business angel networks in Europe has accelerated since the establishment of the European Business Angel Network (EBAN) in 1998. The number of active business angel networks in Europe has grown rapidly in the last few years. Most countries have a national network and several regional ones. Most business angel network activity in Europe is concentrated in the United Kingdom, Germany and France.

**Table 1 Business angel networks in Europe**

<i>Country</i>	<i>1999</i>	<i>2000</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>Mid 2004</i>
<i>Austria</i>	1	1	1	1	1	1
<i>Belgium</i>	2	6	6	7	7	5
<i>Czech Republic</i>	0	0	0	0	1	2
<i>Denmark</i>	0	1	4	6	8	8
<i>Finland</i>	1	1	1	1	1	1
<i>France</i>	3	13	32	48	48	40
<i>Germany</i>	1	43	36	40	40	40
<i>Greece</i>	0	0	0	0	0	1
<i>Hungary</i>	0	0	0	0	0	1
<i>Ireland</i>	1	1	1	1	3	1
<i>Italy</i>	0	5	12	11	10	12
<i>Luxembourg</i>	0	0	0	0	0	1
<i>Malta</i>	0	0	0	0	1	1
<i>Poland</i>	0	0	0	0	0	1
<i>Portugal</i>	0	0	1	1	1	1
<i>Spain</i>	0	1	1	2	3	11
<i>Sweden</i>	1	2	2	2	9	28
<i>The Netherlands</i>	1	1	2	2	3	3
<i>United Kingdom</i>	49	52	48	48	51	101
<i>Total</i>	60	127	147	170	184	258

*Source: European Business Angels Network (EBAN), Statistical compendium, October 2004.*

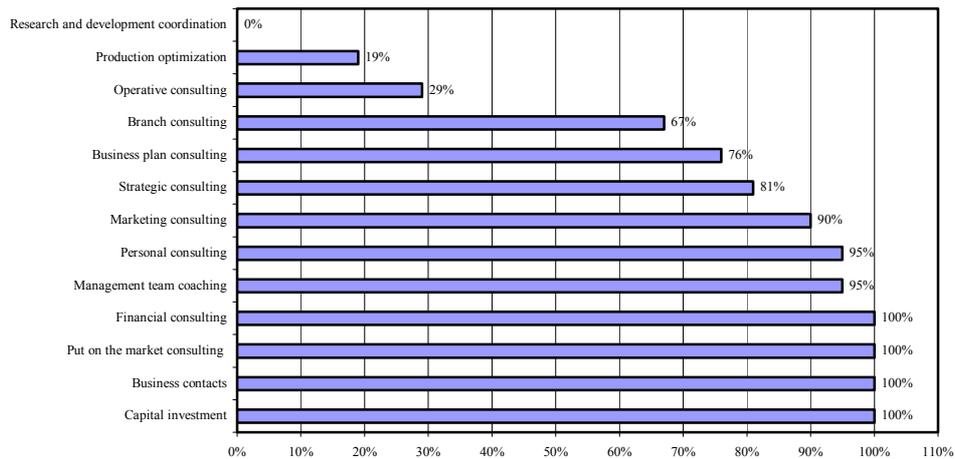

The sizes and methods of the national and regional networks vary between countries reflecting different local conditions. The rapid increase in the number of networks indicates that there has been a need for them, and that they are serving a purpose.

### **3. Business angels in Germany**

We carried out a research with the aim to show an importance of the business angels as informal investors offered a venture capital with a higher added value for small and medium-sized enterprises in a country with a long-term history of the active business angels – in Germany (Emscher-Lippe Region). It was conducted in a form of a questionnaire from January to March 2005 on a research sample of 21 business angels. The questionnaire consisted of 10 semi-opened, 1 opened and 3 closed questions divided into three parts: activities of business angels and their potential impact on economic prosperity of SMEs, a profile of target SMEs, a profile and a motivation of business angels. We present the most interesting findings from our research in this paper.

At the beginning, we were interested in the activities, which BA offered to help SMEs. Every from the questioned BA had some experience with a small-size beginning enterprise and at least once invest capital in. According to a literature, a financial investment does not present an unambiguous determinant indicating private investors - business angels. All the questioned BA (100 %) had experiences not only with a capital investment but with the non-monetary character activities such as business contacts, put on the market consulting, financial consulting (see Figure 1). They are followed by other activities such as management team coaching and personal consulting (95 %).

**Figure 1 Business Angels Activities**

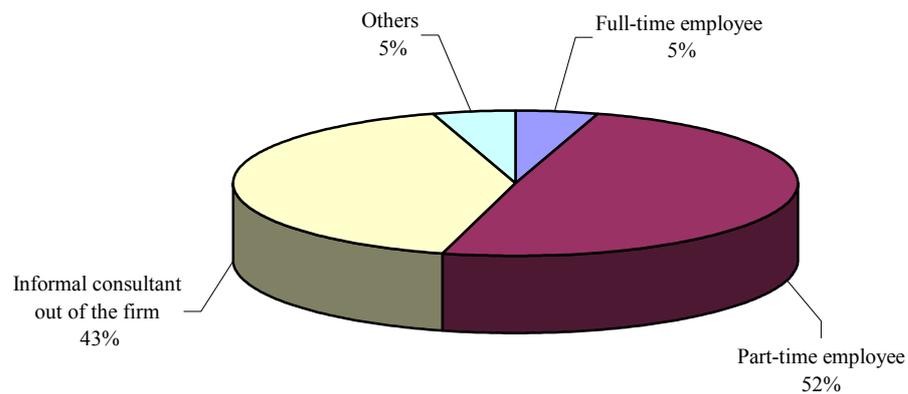

*Source : data from the own research*

As other important activities were mentioned marketing consulting (90 %), strategic consulting (81 %) and business plan consulting (76 %). These results are consequences of the fact that business angels come from a variety of the experienced businessmen and managers.

On the other hand, a relative small share of business angels' activities belonged to the activities such as research and development consulting (0 %), production optimization (29 %). This finding can be caused by a small number of production enterprises with which questioned BA had experience or a low intensity of their activities in that kind of firms. A marginal business angels' activity presents an operative consulting (29 %) too. It can indicate a trend that for business angels it is more significant to play a role as a consultant or coach for strategic management than for operative management who deals with every day problems and existing details of the firm.

Another interesting finding was a way of which business angels participate in the firm (See Figure 2).

**Figure 2 Business Angels Participation**

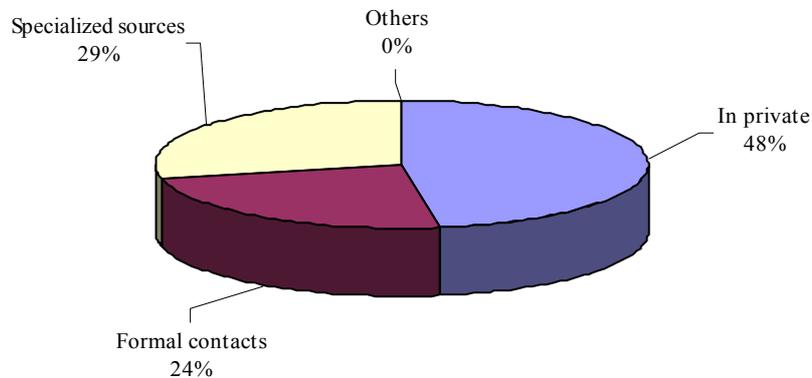

*Source : data from the own research*

Most of the questioned BA participate in the firm as a part-time employee (52 %). 43 % of them work as an informal consultant outside the firm. The reason for these results is predominate consulting character of these private investors' activities. Only one of the questioned BA participated in the firm as a full-time employee and one of them used a different way of participation, but he did not state it.

A particular form of making contact between the business angels and the firm varied (See Figure 3).

**Figure 3 Contact Between Business Angel and Firm**

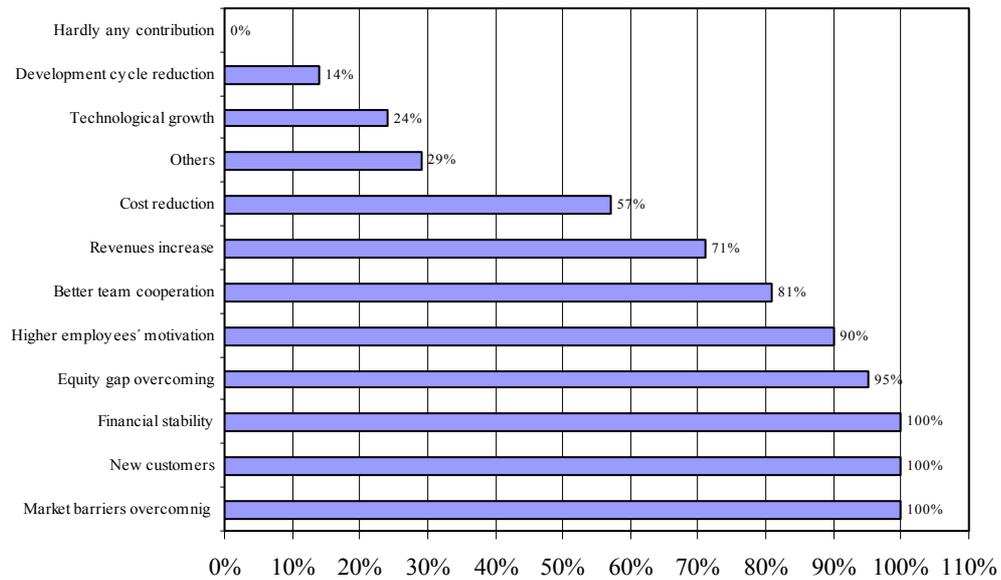

L

*Source : data from the own research*

Almost in a half of all cases, the first contact between the business angel and the firm was made in private (48 %), it means by private contacts or acquaintance's recommends. 29 % of respondents used services of institutions specialized in an electronic or personal matching of the private investors on one hand and the resource finding beginning firms on the other hand. A form of these institutions differs in practice it can be BA stock market, BA organization, forum etc. In 24 % of all cases, the first contact was done by a way of formal contacts at banks, consulting, investment or business associations, universities etc. All of these institutions and centers represent places, where new enterprising ideas meet together with financial resources waiting for their relevant market opportunity.

Business angels activities developed in each firm can be considered to be potential sources of firms' success. Business angels contributions to firms should be something more than only finance, coming from passive private investors waiting for their profits. It is particularly a case of various non-monetary contributions of business angels working in firms (See Figure 4).

**Figure 4 Business Angels Contribution**

*Source : data from the own research*

All of the questioned BA highlighted among their biggest advantages for firms:

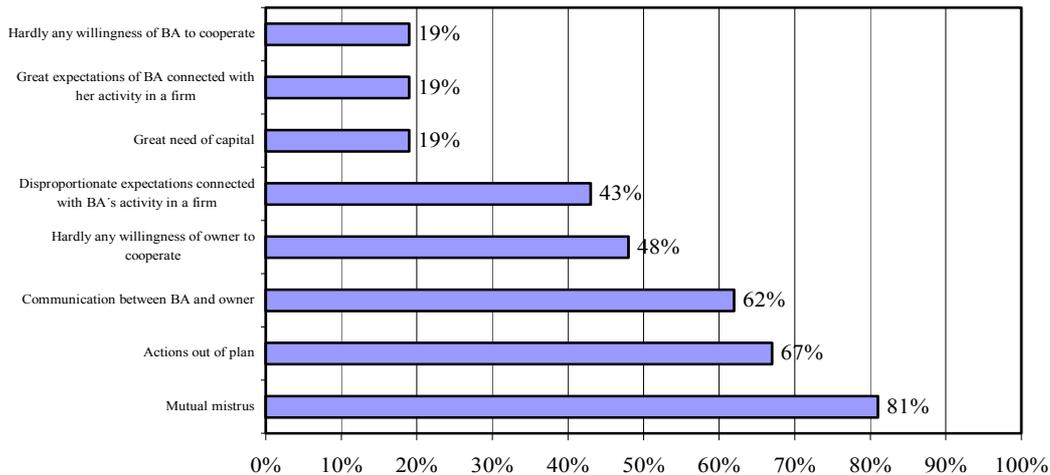

- overcoming early barriers connected with a market entrance,
- gaining new customers,
- increasing financial stability.

These contributions stem not only from their managerial and business experiences, but from their sector knowledge and large numbers of contacts as well.

To a frequent advantage belongs overcoming equity gap (95 %) using external resources in a form of formal venture capital, bank loans and another loans and grants.

A mutual cooperation between business angels and firms is equally as every human activity often connected with many problems, misunderstandings and barriers (See Figure 5).

**Figure 5 Cooperation Barriers Between BA and Firms**

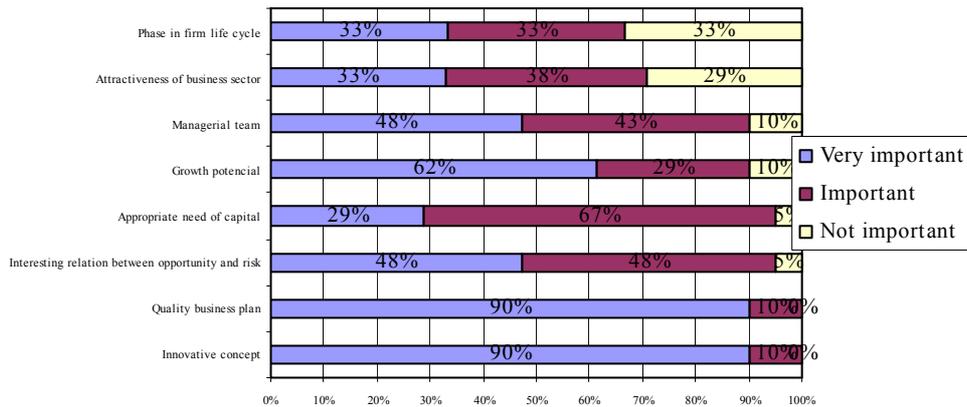

*Source : data from the own research“*

The biggest barrier is concerned with a lack of trust between involved sides (81 %). Every investment is a risk project that needs a mutual trust of both. This trust must last not only during an opening matching process but it must hold on during a whole cooperation as well. Other barriers are activities carried out of plan (67 %). A business plan plays a significant role in every firm as an instrument for controlling. Every activity out of it does this role impossible. Communication problems (62 %), hardly any willingness of interested firm's owner to cooperate (48 %) or disproportionate expectations connected with BA's activity in a firm (43 %) appeared as other barriers.

Among last but not least important barriers were mentioned a great need of capital, great expectations of BA connected with its activity in a firm and hardly any willingness of BA to cooperate (every 19 %). Particularly last one - hardly any willingness of BA to cooperate could represent potentially big problems connected with a new phenomenon – business devils. Business devils are private investors with a risk capital, which try to enforce their own opinions and ideas in the firm. These activities very often lead to a negative development of firm out of all plans.

In third part of our questionnaire we were interested in a motivation of business angels to help seed-up and start-up firms (See Figure 6).

**Figure 6: Motivation of BA**

*Source : data from the own research*

Innovative concept together with quality business plan belonged to the most important motivational criterions of BA to invest or not to invest. Another crucial criterions were an interesting relation between opportunity and risk, an appropriate need of capital and a growth potential. On the other hand, a phase in firm life cycle and an attractiveness of business sector were indicated as not important motivational criterions.

#### **4. Conclusion**

Findings of our research are very similar to the findings of other researches among active business angels. In generally we can say that business angels represent informal investors who can influence a next development of a seed-up or a start-up firm, with a good combination of a monetary and a non-monetary investment. They are very often the last and the only possibility of the firms to survive. To the most important forms of business angels' support belong a support by coming onto market, marketing and other consulting, establishing business contacts or raising additional external financial resources.

All these activities bring many contributions to small and medium-sized enterprises such as overcoming equity gap, easier coming onto market, gaining new customers, increasing financial stability etc. Their contributions are visible among employees and their motivation too.

These results can give with a wrong interpretation impression of the business angels as a cure-all for all problems existing and appearing in firms. The reverse is true. Their wide and various knowledge are consequences of their previous and long-term experiences in business. According to European Union particularly business angels with their experiences and expanding the financing opportunities of entrepreneurs business angels contribute to growth and employment, and make European culture more entrepreneurial.

## **Abstract**

*Venture capital is a financing method to provide funds for entrepreneurs to establish new ventures. Venture capital firms and venture capitalists provide funds and consulting to entrepreneurs to develop new ideas, make innovations, establish new ventures and grow their ventures. Venture capital firms and venture capitalists receive the shares of these new ventures for financing and consulting that they provided. The fastest growing sector is high technology for venture capital financing in the world. This study first summarizes the concept, financing stages and global practices of the venture capital. Secondly, it explains venture capital practices in European Union member countries. Then, it focuses on venture capital practices in Turkey. It also provides recommendations for the future of venture capital funding in Turkey.*

**Keywords:** *Venture Capital, Venture Capital Firm, Venture Capital Practices in Turkey*

## 1. Introduction

Venture capital is a financing method to provide funds for entrepreneurs to establish new ventures. It is an important financing method for new ventures. Venture capital firms and venture capitalists provide funds and consulting to entrepreneurs to develop new ideas, make innovations, establish new ventures and grow their ventures. Venture capital firms and venture capitalists receive the shares of these new ventures for the financing and consulting that they provided. It is an investment to ventures that could have high growth potential.

Venture capital is defined as a professionally managed pool of money raised for making actively-managed direct equity investments in rapidly-growing companies with a well defined exit strategy. It has grown in most of the capital markets of the world. The fastest growing sector is high technology for a venture capital financing.<sup>1</sup> American National Venture Capital Association defines venture capital as a source of financing that is provided by professional who made investment to new and fast growing ventures.<sup>2</sup>

Venture capital is a partnership of entrepreneurs, venture capital firms and investors who provide financing for venture capital funds. Entrepreneurs are new business owners who get attention and expect high growth potential and profits for their ideas and products. Venture capital firms provide financing and expertise to entrepreneurs and ventures to get high profits. Investors can be rich people, large industrial enterprises, banks, institutional and foreign investors. They have financial expectations to get high profits.<sup>3</sup>

Venture capital firms are established as limited partnerships in which managers are unlimited responsible parties whereas investors are limited responsible parties. Most of the venture capital firms are management companies that represent different partnerships and have responsibility to manage different pools of funds. Unlimited responsible partners working as professional teams in these management companies, manage partnership

<sup>3</sup> BULUT, H. İ. Sermaye Piyasalarında Finansal Araçlar Olarak Risk Sermayesi Şirketlerinin Rolü, *İMKB Dergisi*, 2000, sayı 4, pp. 31.

funds provided by investors as their representatives to structure and manage the new investments for fees.<sup>4</sup>

Companies that are supported by venture capital firms are more prestigious in a IPO stage. Investors believe that they can trust the company and buy its shares. Venture capital firms share risks of entrepreneurs. They are experts in their areas and good at portfolio management. The following issues related the venture capital firms are important for the pricing of ventures in IPO stage: Investors trust ventures that convinced many venture capital firms to use their funds. These ventures are controlled by venture capital firms for a long time to be succesfull and they are more expensive for investors. Investors prefer ventures when venture capital firms are in their board of directors for a long time. They trust ventures inwhich venture capital firms have prior experiences in other ventures for IPO stage. Investors prefer ventures that used funds provided by large venture capital firms. They also trust ventures inwhich venture capital firms have big shares. It shows that venture is leaded for a long time and less risky for investment<sup>5</sup>

The quality of venture capital firm to observe and lead investments can be evaluated by following criterias: Venture capital firms need to focus on promising sectors that will offer the maximum values.<sup>6</sup> They provide financing to ventures based on their success to use the funds. They can motivate ventures to follow the milestone schedules and be succesfull while they are using funds.<sup>7</sup> They provide other services besides financing such as development of good image and business relationships with other companies, motivation and business training to ventures.<sup>8</sup> They need to establish investment consortiums with other venture capital firms to delegate risks, find more financing and get the advantage of their expertise.<sup>9</sup>

SAHLMAN, W.A. The Structure and Governance of Venture-Capital Organizations, *Journal of Financial Economics*, 1990, vol. 27, pp. 473-521.

<sup>5</sup> BULUT, H. İ. Sermaye Piyasalarında Finansal Araçlar Olarak Risk Sermayesi Şirketlerinin Rolü, *İMKB Dergisi*, 2000, sayı 4, pp. 47-50.

<sup>6</sup> BYGRAVE, W.D. *Venture Capital Investing: A Research Exchange Perspective*. Unpublished Phd Thesis. Boston University. 1989.

<sup>7</sup> GOMPERS, P.A. Optimal Investment, Monitoring and The Staging of Venture Capital. *The Journal of Finance*. L (5), 1995, pp. 1461-1489.

<sup>8</sup> FRIED V.H. AND HISRICH, R.D. The Venture Capitalist: A Relationship Investor. *California Management Review*. vol. 37, no. 2, 1995, pp. 101-113.

<sup>9</sup> LERNER, J. The Syndication of Venture Capital Investing. *Financial Management*. Autumn 1994, pp. 16-27.

The differences between venture capital and private equity are not very clear. Venture capital firms usually provide funds for new ventures that have high growth potential for seed capital, start-up capital and early stage financing. On the other hand, private equity firms usually provide funds for ventures for expansion investment, bridge financing, late stage financing, management buy-out and leveraged buy-out financing.<sup>10</sup> Private equity firms also provide management consultancy for formulating strategy, recruiting and developing relationships with stockholders such as financial institutions, customers and suppliers.<sup>11</sup>

Kuratko and Hodgetts define venture capitalists as valuable sources for equity funding for new ventures. Venture capitalists provide capital for ventures during start-up and expansion phases. Entrepreneurs can consult venture capitalists for market research, strategy formulation, management audit and risk management. Venture capitalists can contact with customers, suppliers and other stockholders of the company. They can provide assistance in negotiating technical agreements. They can also help establishing accounting and management controls.<sup>12</sup> Venture capitalists focus on large returns on their investments to provide capital to new ventures.

According to one study surveyed over 100 venture capitalists, 28 criterias were determined to evaluate new venture proposals and they were grouped in six categories: Entrepreneur's personality, entrepreneur's experience, characteristics of the product or service, characteristics of the market, financial considerations and nature of the venture team. Ten essential criterias to evaluate new venture proposals are as follows: capability of sustained intense effort, familiarity with market, at least ten times return in 5-10 years, demonstrated leadership in past, evaluating and reacting to risk well, investment can be made liquid, significant market growth, track record relevant to venture, articulating venture well and proprietary protection. According to the same study venture capitalists could reject proposals when two of the mentioned criterias were missing.<sup>13</sup>

<sup>13</sup> MACMILLAN, I. C., SIEGEL, R. AND NARASIMHA, P. N. S. Criteria Used By Venture Capitalists to Evaluate Venture Proposals. *Journal of Business Venturing*. 1985, vol.1, issue 1, pp. 119-128.

According to another study, venture capitalists decide to make investment in 6 minutes on initial screening and 21 minutes on the overall proposal evaluation. The requirements of the venture capital firm, long-term growth and profitability of the proposed venture are the critical factors for initial screening. The background of the entrepreneur and the characteristics of the proposal are other critical factors for initial screening.<sup>14</sup>

According to one study, characteristics of the request (including business plan and amount), sources of advice (including technology, places to seek funding), characteristics of the enterprise (including location and industry) and characteristics of entrepreneurs (including experience and education) are factors that affect the success of entrepreneurs to acquire funds.<sup>15</sup>

The business plan need to include the following sections: summary, business description segment (includes description of the venture, industry, products and services), marketing segment (includes research and analysis related to market and marketing plan), research design and development segment (includes design and development plans, technical researches, research assistance needs, costs), manufacturing segment (includes location analysis, production requirements and costs, information related to labor supply, suppliers and transportation), management segment (includes information related to management team, board of directors, consultants and legal structure), critical risks segment (includes potential problems, risks and alternative solutions), financial segment (includes financial forecast, sources and use of funds, budgeting plans, stages of financing), milestone schedule segment (includes timing and objectives, deadlines and milestones, relationships of events), appendix and/or bibliography.<sup>16</sup>

The business plan is an important element to evaluate new ventures. Five aspects of the plan to be analyzed are the size of the proposal, financial projections, recovery of the investment, competitive advantage and management of the company.<sup>17</sup> The steps of venture capital financing are as follows: initial screening, evaluation of business plan, oral presentation, final evaluation (evaluation of the feasibility of the project and visiting suppliers,

<sup>17</sup> Kuratko and Hodgetts, p. 421

customers and consultants), signing the investment contract, realisation of investment and exit from the investment.

Entrepreneurs need to evaluate venture capitalists as well. They need to choose the venture capitalist that will add value to the new venture beyond the financing especially for high-innovation ventures.<sup>18</sup>

Although, venture capital is also defined as a long term investment that is made by investors who have excess capital to SME's with high growth potential, investors prefer new ventures that could be profitable in short term to make investment. Venture capital investment can be risky because the investee company may not have enough experience and financing may not be sufficient for operations. Risk factors of venture capital are as follows: technological risk, management risk, financial risk, production risk, marketing risk and risk related to products and services be out of date before reaching to required profits.

## 2. History of Venture Capital

Venture capital is an important financial instrument for the effects of knowledge era on the financial system both in Anglo-American countries and in the countries of the European Union. Venture capital provides funding for the development of new technology oriented companies not to be restricted due to the lack of risk capital. Venture capital fund raising is growing fast in US and Western Europe compared to most developing countries. This growth is expected to continue in the near future as well.<sup>19</sup>

Venture capital became popular in US, U.K., France, Japan, Germany and Holland after the World War 2.<sup>20</sup> The first modern venture capital firm, "American Research and Development" was established in 1946. Digital was one of the firms that American Research and Development made investment. It received \$70.000 funds at the beginning. The market value of Digital reached \$10 billion after its merger with Compact in 1998.<sup>21</sup> Apple Computer, Federal Express, Intel, Sun Microsystems are other companies that received venture capital at the beginning and became global leaders.<sup>22</sup>

Venture capital funds help entrepreneurs to develop new and innovative ideas for technological improvements to be leaders in global markets.<sup>23</sup>

### **3. Types of Venture Capital Firms**

#### ***3.1. Private Venture Capital Firms***

They are institutionalized private partnerships to provide venture capital. They were family businesses in the past. Venture capitalists are in the board of these companies. Partners in the management get 2.5-3% of capital as a management fee and 20% share from profits. Vakıf Risk is a private venture capital firm in Turkey.

#### ***3.2. Venture Capital Firms as a Subsidiary of Financial Institutions***

They are established by commercial banks and insurance companies to provide financing to profitable companies that do not fit their credit requirements. Commercial banks and insurance companies are limited responsible partners of these venture capital firms that are not established in our country yet.

#### ***3.3. Venture Capital Firms as a Subsidiary of Nonfinancial Institutions***

They are established by large industrial enterprises. Their goal is to develop new products to be strong and competitive in the market.

#### ***3.4. Small Business Investment Companies (SBIC)***

There are almost 400 public and private SBIC in US. There are two types of SBIC: Lending Oriented and Equity Oriented. They are established with at least 1 million USD capital. Equity Oriented SBICs are established with 2 million USD capital. They use government resources intensively. SBICs can use 33% of their portfolio for real estate investments. They can't make investments abroad. They can take on debt 3 times of their equity from Small Business Administration (SBA) so they focus on giving credits instead of venture capital financing. SBICs are private capital institutions that provide credits to small businesses. Kobi Yatırım A.Ş. established by TOBB,

<sup>23</sup> SARIASLAN, H. *Orta ve Küçük Ölçekli İşletmelerin Finansman Sorunları, Çözüm İçin Bir Finansal Paket Önerisi*. Ankara: Türmob Yayınları, 1994, p. 66.

TESK, Halk Bank, KOSGEB and 16 chambers of industry to provide financing to SMEs in Turkey is an example of SBIC in Turkey. Its goals are helping development and economic activities of SMEs, improving their contributions for industrialization, providing capital, consulting and training to SMEs, encouraging investment projects of SME'S by establishing partnerships.<sup>24</sup>

The fund resources of venture capital vary in different countries such as US, U.K. and Turkey because of different financial systems used. R&D applications that cause high uncertainty and risk affect venture capital investments of companies. Long term investments with negative cash inflows in the first years affect fund resources badly.

## 4. The Financing Stages of Venture Capital

### 4.1. Seed Capital

Venture capitalist provides funds for new venture projects after its feasibility study. The research and development of the project is usually financed by venture capital.<sup>25</sup> The idea of the new venture is developed but its business plans are not prepared at this stage. Professional venture capitalists do not usually prefer seed capital because it is a very risky

<sup>24</sup> <http://www.kobinet.org.tr/hizmetler/bilgibankasi/finans/003d.html>

<sup>25</sup> VERMA, J.C. *Venture Capital Financing in India*, New Delhi: Response Books, 1997, p. 28-29.

investment. Although, there is a high uncertainty related to the application of the project, high profits can be received. Seed capital usually starts 2-3 years before the start-up of the venture and it requires 10 years at average to liquidate the investment of the venture capitalist.

#### ***4.2. Start Up Capital***

It is a stage where an investment idea is started to be implemented, a firm is established and a venture capitalist tries to make the new venture successful. The business plan of the entrepreneur is scanned carefully by venture capitalist. The real information related to market, targeted market share, growth of business and management of new venture need to be gathered at this stage. The venture capitalist helps the entrepreneur with its knowledge and skills. The start up capital is usually 5 years in average.<sup>26</sup>

#### ***4.3. Early Stage Financing***

The firm reaches to a substantial size at this stage. It has some products and services but does not have a brand image and big market share. The venture develops its prototypes but it requires funds for production and marketing of its products. Ventures do not usually gather funds from banks because of not having enough caution money. Ventures do not usually gather funds from the capital market either at this stage. Ventures may have some managerial problems that can be solved with the financial and managerial support of the venture capitalist.<sup>27</sup>

#### ***4.4. Expansion Investment***

The venture can market its products and services at this stage successfully but it requires additional financial resources to develop new products, to have effective distribution channels and competitive strength.

#### ***4.5. Bridge Financing***

Ventures that plan to go public in 6 months and a year require the bridge financing.

#### ***4.6. Late Stage Financing***

It is a financing to save the unprofitable venture to be profitable again. It is also used to sell the shares of partners before going to public.

---

<sup>26</sup> Övek, p. 38

<sup>27</sup> Ibid., p. 39.

#### 4.7. Management Buy-Out

It is a financing to help the managers buy out the company not to be bankrupted. It is profitable and less risky investment.

#### 4.8. Leveraged Buy-Out

The venture capital firm provides financing to entrepreneurs who do not have enough funds to buy a business. The venture capital firm prefers entrepreneurs who have required skills, education and work experience to be successful.

#### 4.9. Exiting From Investment/Divestment At Cost

It is the final step to end the venture capital investment. The purpose of the venture capital firm is to sell its shares in venture when they reach to the profitable level. The venture capital firm gets profits when the venture ends its technological and economical growth and reaches to a substantial size. The types for exiting business are as follows:

1. Going public (Selling stocks of the company to public)
2. Selling venture to another company
3. Selling the shares of the venture capital firm to the venture
4. Selling the shares of the venture capital firm to another company
5. Restructuring the venture
6. Liquidation of the venture<sup>28</sup>

Venture capital financing instruments are share certificates, founding share certificates, shares without voting rights and convertible bonds.<sup>29</sup>

## 5. Venture Capital Practices in US

Venture Capital financing model started in US in 1946 for the first time by establishment of American Research and Development Corporation of Boston.<sup>30</sup> U.S. government also encouraged venture capital financing. Small Business Investment Company (SBIC) established in 1958 is a venture capital firm. Its capital was provided by government. It is managed by private sector. It encourages investors to invest in small businesses. Its funds are used to give credits to small businesses. Venture capital firms can receive financing from the government and private sector. Government finances 1/3 of funds that are more than 15 million USD and 1/2 of funds that are higher than that amount. Government gets 2% fee for the funds used. Companies that purchase stocks from venture capital firms are tax free. The largest source of venture capital firms are pension funds and partnership shares. Small Business Administration (SBA) also guarantees 75% of credits of small businesses up to USD 500.000 to get from commercial banks. The credit term can be up to 25 years. Small businesses pay 2% of guarantee fee to SBA.<sup>31</sup>

SBIC (Small Business Investment Companies) that are public-private partnerships, provide venture capital financing in US. They provided long-term credits with interest rates to ventures at the beginning. Since, this financing method was not successful, SBIC focused on venture capital financing.

The growth of venture capital financing caused the growth of stock exchange markets in US. US Congress asked "US Securities and Exchange Commission" to start NASDAQ Stock Exchange Market and helped the growth of venture capital financing in US. Companies that received the venture capital financing start to trade their stocks in Stock Exchange Markets in the growth stage. Pension funds are also important to form venture capital funds in US. Nowadays, US venture capital firms acquire half of their funds from pension

funds.<sup>32</sup> The pension funds can buy stocks of venture capital firms and this helps the growth of venture capital financing in US. The successful growth of venture capital financing in US led to implement it in other countries.<sup>33</sup> Small Business Investment Law, tax discounts and incentives caused the shift of private sector funds to venture capital financing. Modifications in FRSA laws in 1978 and usage of 2.5% of pension funds for venture capital supported the growth of venture capital financing.<sup>34</sup> Venture capital financing was structured in US. Almost 80% of venture capital investments were managed by venture capital firms that are limited partnerships.<sup>35</sup> Venture capital investments focus on software, biotechnology, telecommunications, networking and equipment, medical devices and equipment, semiconductor sectors.<sup>36</sup>

## 6. Venture Capital Practices in The World

Venture capital firms acquire funds from financial institutions, industrial enterprises and public. They provide management and marketing support besides capital to companies.<sup>37</sup> Venture capital investment partnerships are experts to make investments in most industries in the world. The establishment of stock exchange markets for SME's caused the success and widely usage of venture capital financing in the world. NASDAQ in US is the best example for stock exchange market for SMEs. The deals are made electronically for SMEs. ESDAQ in Europe, JASDAQ in Japan, Alternative Investment Market (AIM) in U.K., Neue Markt in Germany, Nouveau Marche in France and Vancouver Stock Exchange Market in Canada are other examples of stock exchange markets for SMEs.<sup>38</sup> There are tax discounts up to 100% for venture capital investors to encourage them to make investments in Australia.<sup>39</sup>

Japan was not as successful as Western countries and US about venture capital financing model at the beginning. There are larger companies instead of SME's in Japan and they provide financing for their technology improvement investments. Their work ethics encourage Japanese to work in their first job in the rest of their lives instead of starting their own business. Venture capital financing focus on companies that operate in electronic and

<sup>37</sup> <http://www.dto.org.tr/bilgi/kaynak/risksermayesi.html>

<sup>39</sup> Övek, p. 71.

IT sectors in Japan.<sup>40</sup> The government gives guarantees to long term bank credits that are taken by new ventures during the start-up phase in Japan.<sup>41</sup> The secondary markets were established to trade stocks of companies to provide venture capital financing in 1985.<sup>42</sup> Venture capital firms were established with the support of government institutions at the beginning. Banks and stock broker companies started to establish venture capital firms afterwards.<sup>43</sup> Venture Enterprise Center was established in 1974 to encourage the establishment of small companies and provide financing to new ventures.<sup>44</sup> It goes bail for 80% of investment credits of SME's given by banks. Japanese venture capital firms focus on late financing whereas US venture capital firms focus on early financing.<sup>45</sup>

## 7. Venture Capital Practices in European Union Member Countries

U.K. has the most established venture capital practices in Europe. Holding companies, banks and local organizations are sources of venture capital in U.K. Banks become partners to SMEs with growth potential by buying their stocks to provide the required capital.<sup>46</sup> Private and government organizations support the growth of venture capital financing in U.K.. Investment in Industries was established by Bank of England after the World War 2 encourage industrial enterprises to improve their technology. Equity Capital for Industry is a private venture capital firm that provide funds to new ventures in U.K.. There are many private venture capital firms in U.K..<sup>47</sup> The legal format was prepared for "Stock Exchange of The Unlisted Securities Market" in 1980 in U.K. to ease the trade of stocks of small companies in the capital market.<sup>48</sup> The funds of venture capital consist of pension funds, foreign private companies, insurance companies, public, industrial enterprises and British Banks in U.K..<sup>49</sup> Business Start-up Scheme and Business Expansion Scheme are private venture capital funds established by British

Government. British Technology Group was established in 1981 to provide credits and support to small ventures that operate in high tech industries<sup>50</sup> British Venture Capital Association and a magazine called Venture Capital Reports act to improve venture capital in U.K. They publish promising business plans to attract venture capital firms and improve the venture capital model.<sup>51</sup> The investments made by British private equity companies increased 5% to 1566 in 2004 in the world. The total value of worldwide investments also increased 52% to £9,679 million. The number of companies financed increased 2% to 1301 in UK and investment in the UK increased by 31% to £5,336 million in 2004.<sup>52</sup>

Banks usually provide venture capital financing in France.<sup>53</sup> There is a tax discount up to 25% on revenues from investments in stocks in France. There are also tax discounts to public and companies for their revenues of stock investments in Belgium. Ventures in high-tech industries do not pay corporate taxes in Belgium. There are also tax discounts for investors who provide venture capital in Belgium. Revenues from investments in stocks are tax free in Denmark.<sup>54</sup>

Governments also encourage venture capital in European Union Member Countries. Investment Company Flanders established by Belgium government in 1980 is managed by private sector that has 25% share. It provides financing to high tech projects in Flaman region. Three funds were established to finance high tech projects in 1996 in Holland. The partners of the funds are Holland government (25% of shares) and regional development companies. SOFARIS that 42% of its capital belonged to French government was established in France to finance SME's. It guarantees 50% of credits that SMEs get from banks. The maximum credit guarantee limit is 5 million FF. TBG that makes technology investments is supported by German Government Bank in Germany. BTU was established in 1995 to provide financing to small businesses in high tech sector by German Government. It provides financing to companies that have more than 50 workers and have been established less than 10 years ago. German Development Bank provides long term credits with low interest rates. ERP that is a subsidiary of Federal Ministry for Education and Research also provides credits to small businesses in technology sector. German Economic Development Agency guarantees

<sup>54</sup> Övek, p. 71.

90% of credits that venture capital firms get from commercial banks. Venture Capital Trust, Enterprise Investment and Business Expansion Scheme (BES) were established to provide financing to ventures in U.K. by the support of government. BES encourages investors to invest in small businesses. Enterprise Investment Fund (EIF) lets investors not pay taxes up to 20% of their investments. Revenues from investments to EIS stocks are tax free for 5 years. Bank of England also guarantees 70% of new credits that are more than £100.000 and taken by ventures. European Commission is responsible for credit programs of venture capital firms in European Union. European Seed Capital Fund Scheme (ESCF) gives credits to ventures for start up capital and early stage financing. Ventures get interest-free credits for 10 years up to 50% of their business costs for 5 years. The capital of European Investment Fund is provided by funds of European Commission, European Investment Bank and other banks. It encourages stock investments in small businesses. It also guarantees credits taken by small businesses from financial institutions. Credits can cover 50% of investment, portfolio credit insurance and late stage financing. Also, 10% of regional development bank resources are used to finance small businesses.<sup>55</sup>

Venture capital is also provided by banks in European Union member countries. Banks usually provide debt credits instead of receiving the stocks of the venture for not taking risks. Start-up investment increased 13% and reached €2.2 billion in 2004. The amount invested in high tech companies increased 6.5% and reached €7.4 billion. Funds allocated to funds increased 32% and reached €8.8 billion in 2004. In terms of total amount of invested, buyouts, expansion and start up investments all increased. Buyout is the largest proportion with 70% or €25,7 billion. Investment in expansion stage is second with 21% or €7.9 billion and start up investment is third with 6% or €2.2 billion. On the other hand, seed investment is 0,4% with €148 million. When looking at number of investments, expansion is first with 45%, start up investment is 30% and buy outs is 18% of total number of investments. The UK has the largest share of amount invested interms of country of management with 52%, France second at 14%, Germany third at 10% and Spain fourth at 5%.<sup>56</sup>

The UK accounted for 26% of the amount invested in terms of country of destination, with France and Germany achieving larger proportions of investments with 17% and 14% respectively. The Netharlands is fourth at 9%. Consumer related businesses is the highest proportion of

amount invested at €8.5 billion (23%), followed by other services with €5.1 billion (14%) and communications with €4.9 billion (13%). The average investment size reached €3.6 million. The average size for buyout investments rose to €14 million, the expansion stage investments reached to €1.7 million and start-up investments rose to €733,871. On the other hand, the average size for replacement investment decreased to €2.5 million and seed investments to €364,867. The majority of investments, 86% by number and 65% by amount of investment, were made in local country. Cross border investments within Europe by number were down to 10%. The fundraising is between €25-28 billion. The funds for buyouts decreased to 65% whereas the funds for venture capital increases 32% of total funds raised. Exits were €19.6 billion with 5917 exits. Trade sales is one fourth of all divestments by amount at €4.6 billion. Divestments by public offering (IPO and sales of quoted equity) increased to €2.3 billion.<sup>57</sup>

## **8. Venture Capital Practices in Turkey**

Although there are efforts to accelerate venture capital practices in Turkey since 1980, these efforts are not enough for the time being. The legal arrangement for venture capital practices have been made concerning venture capital investment companies based on Capital Market Law since 1993. The last Communiqué on Amending the Communiqué Regarding The Principles About Venture Capital Investment Companies Serial: VI, No:16 was published in the Official Gazette dated 7 January 2004, numbered 25339. Its details are presented in Appendix 1. It sets principles regarding the founders and formation procedures of venture capital investment trusts, registration to the board and public offering of venture capital investment trusts' shares, management and the required qualifications of the managers, scope of activities, portfolio restrictions and disclosure requirements of venture capital investment trusts.

The requirements for foundation are as follows: Venture capital investment trusts should be formed in accordance with the foundation procedure. Besides, companies with different activities should be transformed into venture capital investment trusts by amending their Articles of Association pursuant to the provisions of the Law and this Communiqué. For the approval of foundation of or conversion to venture capital investment trusts by the Board the following requirements must be fulfilled: In case of immediate establishment: must be incorporated as a registered capital corporation, initial capital should not be less than TL 5 trillion, shares must

---

<sup>57</sup> Ibid.

be issued in return for cash, the trade name of the company must contain the "Venture Capital Investment Trust" phrase, the Articles of Association must comply with the provisions of TCC, the Law and this Communiqué, board members of the legal entity shareholders which have more than 10% of the shares of the corporation shall meet the requirements specified under Article 5 of this Communiqué, application must be made to the Board for dealing with activities listed under portfolio operations specified in subparagraph (f) of first paragraph of Article 30 of the Law and at least one of the founders must be a leading shareholder.<sup>58</sup>

According to this Communiqué, the investments to be made in venture companies by corporations shall be made under the framework of an agreement to be executed by and between the parties. This agreement shall have provisions mainly about the management of the venture company and rights and obligations of the venture company. The venture companies must aim to manufacture or develop, vehicles, tools, material, services or new products, methods, systems and production techniques having industrial and agricultural application potential as well as marketing potential or have the capacity to realize the specified objectives with management, technical or capital support. The corporations can be shareholders of venture companies or may purchase debt bonds to be issued by venture companies. The corporations may make investment into securities issued by other venture capital corporations within the framework of the provisions in this article.<sup>59</sup>

Venture capital financing are provided in Turkey since 1991. Banker Trust and Turk Petrol made an agreement in 1991. Then, the financial politics of Banker Trust changed and 50 million USD was returned as a result of this agreement. Some banks established venture capital firms in 1993 because of the support of government. Vakıf Risk A.Ş. is the only company that survived in these companies. Sparx Asset Management invested 40 million USD in 7 ventures in agriculture, textile, packaging, banking, leasing, electronic and biotechnology sectors in 1995. It exited from 2 companies via IPO after two years. One of the investment was unsuccessful on the other hand. Fiba Holding established Girişim Holding as a private equity fund that made only one investment to Gima supermarkets by buying its majority shares from Dedeman Holding. Merrill Lynch made investment to Termo Teknik that was a steel radiator manufacturer. It then sold its shares to a double price to British Caradon Company. Lehman Brothers made 70 million USD investment to Superonline that was a ISP and online services provider.

---

<sup>58</sup> <http://www.cmb.gov.tr>

<sup>59</sup> Ibid.

İşbank established İş Venture Capital to provide financing to medium size enterprises that had growth potential.<sup>60</sup> Venture capital firms focus on SME's and companies that operate in IT, software, biotechnology, medical technology, energy, telecommunication and service sectors to make investments.

There were 40 venture capital investments between 1996-2003 in Turkey. They provided 200 million USD funds to companies. There have been few private equity investments in Turkey. Some of the private equity investors were Sparx Asset Management, Merrill Lynch+Bank of America, Safron Capital, AIG Blue Voyage, EMEA, Citicorp and Lehman Brothers. Private equity investors are still partners in some of these investments. Some of the companies that used private equity are as follows: GSD Holding, Biomar, Rant Leasing, Eka Elektronik, Aba Ambalaj, Termo Teknik, BIM, Jumbo, Galatasaray Sportif, AFM Movie Theaters, Gorbon Işıl, Merko Gıda, Işıklar Ambalaj, Superonline.

Venture capital financing are provided by few Turkish venture capital firms in Turkey. Most of the entrepreneurs and owners of SMEs are not aware of and not using venture capital financing. Turkish SMEs focus on receiving credits from commercial banks, government incentives, credits and incentives provided by KOSGEB.

KOSGEB is a non-profit, semi-autonomous organisation responsible for the growth and development of SMEs in Turkey. KOSGEB's Board consists of more than fourty members from the Government of Turkey and half of them are from the private sector representative organizations. The primary objective of KOSGEB is to improve SMEs share and efficiency in Turkish economy and enhance their competitive capacity. In order to accomplish this objective KOSGEB has assumed responsibility for the following functions; developing SMEs' technological skills, improving their training and information level, providing appropriate financial mechanisms and improving their managerial infrastructure.<sup>61</sup>

Venture capital firms have limited funds and hesitate to take risks. They do not want to grow the venture capital market. They just evaluate ventures that applied to themselves. They prefer to invest in very promising projects. They do not try to attract entrepreneurs and owners of SMEs to provide venture capital financing. They do not have experts in their

<sup>60</sup> <http://www.kobinet.org.tr/hizmetler/bilgibankasi/finans/003d.html>

<sup>61</sup> <http://www.kosgeb.gov.tr/KOSGEB/Index.asp>

organizations to evaluate the growth potential of ventures from different sectors. Some of the venture capital firms focus on corporate development projects not to take risks. As an overall evaluation, Turkish venture capital firms are behind of other venture capital firms in the developed countries. The venture capital firms in Turkey and their limited practices are as follows:

### ***8.1 İş Venture Capital***

İş Venture Capital was established in 2000 by İşbank Group with advisory support of World Bank. Current partnership capital of the company is as follows: 39,92% Public, 20,08% İş Investment, 16,89% TSKB, 11,11% TTGV, 6,67% Anadolu Insurance, 4,44% Milli Reassurance, 0,89% İş Factoring. Its goal is to support and help entrepreneurs build their companies into market leaders. İş Venture Capital seeks out companies from most promising sectors with the highest growth and return due to the dynamic nature of the Turkish economy. It has USD 60 million funds. It usually invests from \$1 million to \$6 million. It invests up to 10-15% of their investment assets in any one company. İş Venture Capital prefers to have a minority stake with shares having special rights on operational and strategic decisions. It requires to be represented on the Board of Directors of the investee company. The expected holding period for investments is 2-5 years. The preferred exit options of the company is a strategic sale, IPO or sale back to the original shareholders. İş Venture Capital is interested in equity and fixed income investments. It focuses early stage, expansion stage and privatization investments. Although bridge stage, management buyout and workout/turnaround investments are rare in Turkey, İş Venture Capital considers them as investment alternatives. İş Venture Capital evaluates new ventures based on their business plans. It invested in Probil, ITD, Nevotek, Cinemars, and Step companies. Probil is in a IT sector providing technology and business focused solutions to companies. ITD is in a IT sector focusing on voice and payment products and solutions with e-business in Middle and Eastern Europe. Nevotek conveys dynamic and value-added solutions for Cisco IPT infrastructure. Cinemars is a chain of movie theaters in Turkey. 3-D movies can be shown in its movie theaters. Step is a carpet, home textile and accesories retail company that has stores in Turkey and abroad.<sup>62</sup>

### ***8.2 Vakıf Venture Capital***

Vakıf Venture Capital was established in 1996 as a subsidiary of Vakıf Bank. It is the first venture capital firm in the sector. More than half of

---

<sup>62</sup> [www.isrisk.com.tr/English](http://www.isrisk.com.tr/English)

its stocks are traded in İstanbul Stock Exchange. The objective of the company is proving venture capital financing to projects from different sectors to convert the technology based knowledge into a commercial product or service. It has provided financing to three companies: Teknoplazma, Inova Biotechnology and TR.Net. Teknoplazma locates in Technopolis in Ankara manufactures a coating reactor that is used to make high calibre coatings of cutting tools and moulds for the first time in Turkey. Inova Biotechnology produces metallic nanoparticles, antigens, antibodies and conjugation of them to manufacture rapid diagnostic tests for the determination of pregnancy and infectious diseases like HIV. TR.Net is the first internet service provider (ISP) set up in Turkey. It is still the biggest corporate service provider.

### **8.3 Esas Holding**

Esas Holding established in 2000 has strong financial structure, good market reputation, management and industrial experience to provide assistance to the investee companies. It provided venture capital financing to 6 companies in 3 industries namely food, transportation and health care. It evaluates feasibility, growth potential, competitive strengths, characteristics of entrepreneur and management team of investment projects to make investment decisions. It invests to ventures in a start up stage as well as other stages. It considers company size, financial structure, market position of the venture. It also considers capital requirements and usage to achieve goals for growth of the venture.<sup>63</sup>

### **8.4 İLAB**

İlab Holding is an investment company that focuses on providing financing to companies that make business via internet. It targets playing a major role in a digitalizing process in Turkey. It has made investments in 7 companies in chemical-plastic, iron-steel, insurance, human resource consulting, e-buiness consulting and software sectors. All of these companies use internet technologies to make business and provide value added services in their sectors. İlab Holding establishes new ventures in its holding group as well as it provides financing to other ventures out of its group that need venture capital. Sigortam.net (gives service as first Turkish insurance e-market), BesOnline.net (personal retirement system expert providing information and solutions about retirement ), Treda (expert on E-business

---

<sup>63</sup> [www.esas.com.tr](http://www.esas.com.tr)

projects to provide solutions), Chem Orbis (chemical and plastic e-market for companies) and Steel Orbis (Iron steel e-market for companies) were established by İlab Holding. Kariyer.net (the most improved Turkish human resource web site) and Kariyerakademi.net (first Turkish reservation web site that helps the meeting of training companies with people and companies that want to get training). İlab Holding targets to be a reliable business partner that has the same rights with other co-partners instead of playing operational role in investee companies. It transfers its experiences in areas such as strategy formulation, management and marketing.<sup>64</sup>

### **8.5 Koç Information Group**

Koç Information Group has provided financing to 12 companies that are in Koç Holding. These are Koç Sistem, Ultra Kablo TV Koç.net, Bilkom, Koç Bryce, GVZ, Biletix, Promena, Kangurum, Kotonline and. Tanı. Koç Information Group focuses on corporate development instead of venture capital financing for the time being.<sup>65</sup>

## **9. The Financial Problems of SMEs in Turkey**

The source of capital is usually savings in SME's and they are added to equity. SMEs hesitate debt financing. They prefer deferred payments provided by their suppliers or customers. They can not use the banking system efficiently because the current system can not provide financing urgently. The lack of financing is the main problem of manufacturing companies. Finding short term early financing is a problem for entrepreneurs that provide their own capital for their ventures. There are problems to get credits from banks. Costs of long term credits are high. Banks require caution money from entrepreneurs as the same amount of credits they provide. Most of SMEs are not institutionalized to receive financing from capital markets.

İstanbul Stock Exchange Market established The Regional Market and The New Companies Market for SMEs. It is important to attract investors to these markets by improving their trusts. Venture capital financing is an important financial instrument to develop new financial stock exchange markets for SMEs. The growth of venture capital financing in Turkey will help the growth of new stock exchange markets.<sup>66</sup> The Regional Market was designed for SMEs to find financing in capital market. SMEs

need to have profits in the last two years and paid capital of €470.000 to be traded in The Regional Market. The New Companies Market was designed for technology companies in information technology, computers, internet, high technology and telecommunication and related sectors to find financing in capital market.<sup>67</sup>

## **10. Conclusion and Recommendations**

Private equity is an industry that attracts professional risk takers. They invest directly rather than lend money and target privately owned companies. As a result, these transactions are privately negotiated and they receive an equity stake for their investments. Of the different types of private equity, the most publicized is that of venture capital. Venture capital firms tend to focus on technology related companies, with some specializing in biotechnology.

Venture funds are usually set up as limited partnerships that use money from corporations and from traditional institutional investors such as insurance companies and pension funds to fund start-ups. The VCs who run these funds are the general partners who receive a management fee based on the size of the fund. Venture capital clearly serves as an important source for economic development, wealth job creation, and innovation. Venture-backed companies grow more quickly and create far more value than nonventure-backed companies. Similarly, venture capital generates a tremendous number of jobs and boosts corporate profits, earnings, and workforce quality. Finally, venture capital exerts a powerful effect on innovation

Good investment strategies should utilize; detailed due diligence and deal screening based on intensive industry knowledge, syndication of investments to gather more information and diversity risk, equity ownership and incentive compensation for senior management to directly link the interests of investors and the entrepreneur, carefully thought out boards of directors that provide oversight, strategic advice, and credibility to the company. Venture capitalists help entrepreneurs start businesses and then sell those businesses to the public market in an initial public offering or to more established companies wishing to buy the start-up.

Exit possibilities for investors is a critical issue. Sufficient exit opportunities are fundamental for private and institutional investors prior to investing in new companies. In Turkey, although the national stock market in Istanbul offers some exit possibilities, the impact has generally been limited.

---

<sup>67</sup> <http://www.imkb.gov.tr/halkaarz/bolum10.htm>

The exit market is immature, and the industry has experienced only few successful exits, where most of the trading takes place in very large issues. Similar to other emerging markets, IPO has hardly been the most likely exit route in Turkey.

The most important obstacles for Turkey in the previous years were the lack of capital and high interest rates. Due to the political instability and lack of confidence, the government was borrowing short-term and at high interest rates. In this environment, domestic capital invested in high interest government bonds or transferred their capital to international markets. Turkey has always attracted very low inflows of FDI relative to other comparable countries. Several reasons for this low performance can be listed as structural barriers, heavy bureaucratic requirements, macroeconomic and political instability.

Turkish Government has made reforms since 2002 to attract foreign investors, improve investment environment and provisions for foreign and domestic investors. Subjects handled within the reform framework include Company Establishment, Employment, Sectoral Permits, Investment Location, Taxes and Incentives, Customs and Standards, Intellectual Property Rights, Investment Regulation, Investment Promotion and SMEs. During next few years with the wind of the EU membership, Turkey should reach the level of venture capital funding seen in Eastern European countries. More ambitious target could be pursued if Turkey decides to adopt a program to develop the industry.

SME's constitute 99,5% of total companies in Turkey. They have financial problems. They are lack of capital for their equity. Being lack of capital cause not to get the advantage of leverage affect for SME's. There are investment instruments for SME's such as leasing, short and long term bank credits. On the other hand, venture capital is an alternative investment instrument especially for Turkish SME's. It helps entrepreneurs to share their financial risks with venture capital firms and investors. Venture capital financing need to be used extensively in Turkey. Entrepreneurs need to be aware of it and do not hesitate to get the advantage of it. New venture capital firms need to be established and investors need to be encouraged to make investments in ventures in every stage. Our study is important to emphasize the importance of venture capital financing for Turkish SME's. The new stock exchange markets need to be developed for Turkish SME's. They will help legal arrangements for venture capital financing that will expand financial markets and cause financial deepening in Turkey.

companies (securities / venture capital / real estate), brokerage houses, banks, insurance companies, special finance institutions, portfolio management companies, pension and aid funds, foundations, institutions founded based on Provisional Article 20 of Law Numbered 506, associations, other investors which will be considered by the Board as similar to these mentioned ones, and the investors that have at least 1 trillion Turkish Liras of securities at the time of public offering of venture capital investment trust's shares.

## **SECTION TWO**

### **PRINCIPLES REGARDING FOUNDATION AND CONVERSION**

#### **Requirements for Foundation**

ARTICLE 4- Venture capital investment trusts should be formed in accordance with the foundation procedure. Besides, companies with different activities should be transformed into venture capital investment trusts by amending their Articles of Association pursuant to the provisions of the Law and this Communiqué. For the approval of foundation of or conversion to venture capital investment trusts by the Board the following requirements must be fulfilled;

A- In case of immediate establishment,

- 1) Must be incorporated as a registered capital corporation,
- 2) Initial capital should not be less than TL 5 trillion,
- 3) Shares must be issued in return for cash,
- 4) The trade name of the company must contain the "Venture

Capital Investment Trust" phrase,

5) The Articles of Association must comply with the provisions of TCC, the Law and this Communiqué,

6) Board members of the legal entity shareholders which have more than 10% of the shares of the corporation shall meet the requirements specified under Article 5 of this Communiqué,

7) Application must be made to the Board for dealing with activities listed under portfolio operations specified in subparagraph (f) of first paragraph of Article 30 of the Law,

8) At least one of the founders must be a leading shareholder,

B- In case of conversion,

1) Must have adopted the registered capital system or have applied to the Board for this purpose,

2) Paid-in (or initial) capital must be at least 5 trillion TL,

3) Application must be made to the Board for amending the trade name of the company so that it contains the "Venture Capital Investment Trust" phrase,

4) Application must be made to the Board for amendment of the Articles of Association according to provisions of TTK, the Law and this Communiqué,

5) Board members of the legal entity shareholders which have more than 10% of shares of the corporation shall meet the requirements specified under Article 5 of this Communiqué,

6) Application to the Board for dealing with activities listed under portfolio operations specified in subparagraph (f) of first paragraph of Article 30 of the Law,

7) At least one of the current shareholders must be leading

shareholder,

The requirements listed in sub article (a)/6 and sub article (b)/5 shall not be relevant for public institutions and other institutions which are considered to be like public institutions. (This provision is added by the Communiqué numbered Serial: VI, No: 16)

All amendments in the Articles of Association after foundation or transformation of the company will also be also subject to the Board's approval.

#### **Qualifications of The Founders**

ARTICLE 5 - At venture capital investment trusts;

a) Founders, and other shareholders who directly or indirectly hold 10% or more of the corporation's shares shall not have due debts to the taxation authority and the public pension system.

4

b) Founders who will have 10% or more of the corporation's shares, shall obtain the required financial resources through their own commercial, industrial or other legal activities without any disputes.

c) Shareholders who are natural persons;

1. and the institutions of which they are general partners must not be insolvent,

2. must fulfil the requirements listed at sub article (d) of first paragraph of Article 9 of the Communiqué Regarding Intermediary Activities and Intermediary Institutions.

#### **Special Requirements for the Leading Shareholder**

ARTICLE 6 - Leading shareholders shall have the financial strength, reputation and experience necessary to be founder and shareholder of a venture capital investment trust.

If the trade name of the corporation contains the name or trade name of natural or legal persons or if it contains a phrase which denotes that the corporation has a relation with those natural or legal persons, then those natural or legal persons are required to be leading shareholders.

Leading shareholder shall have at least 25% of the total shares of the corporation and those shares shall be registered to the name of the leading shareholder.

#### **Foundation and Conversion Procedures**

ARTICLE 7-The corporation requesting foundation or conversion shall apply to the Board with the foundation/conversion application form and the documents mentioned at the form.

The application package shall include a feasibility report which contains information on the target industries, the planned periods when the capital will be increased and shares will be offered to public, amount of planned capital increases, consultancy services which will be provided by or for the corporation, the investors targeted for public offering of shares.

The Board inspects the application in terms of compliance to provisions of the Law and this Communiqué and in case no contrary matter is found out, foundation or conversion request shall be approved.

In case the Board approves the application, then an application for approval of foundation or approval of the amendments at the Articles of Association and the certificates proving that the capital has been paid in accordance with the provisions of this Communiqué and other required documents shall be submitted to the Ministry.

The corporation established according to immediate foundation, shall be incorporated upon registration to trade registry pursuant to related provisions of TTK following foundation approval of the Ministry.

5

The companies to be converted into venture capital investment trusts shall convene general assembly of shareholders or if required, general assembly of preferred shareholders pursuant to provision of Article 389 of TCC in order to obtain approval of general assembly for amendment of the Articles of Association following approval of the Ministry. Upon approval of the amendments and registration to trade registry, conversion procedures shall be completed.

#### **License for Portfolio Management Activity**

ARTICLE 8 - While licensing the corporation for engaging in portfolio management activities, the Board evaluates the existence of sufficient physical space, hardware, employees, organization and managers, and finally if it becomes sure that the corporation can successfully engage in portfolio management activities, the Board gives the license to the corporation.

Within fifteen days, licenses shall be registered to Trade Registry and disclosed at TTSG. Any amendment related to the license shall also be registered and disclosed in the same way.

The corporations that didn't submit the application for portfolio management license within six months after the registry of foundation or amendments to the Articles of Association of the corporation, and the corporations of which the Board rejected the application, shall not operate as a venture capital investment trust anymore.

Following the end of the six month period or the date when the corporation is informed about the Board's rejection decision, the corporation shall apply to the Board to amend its Articles of Association so that it can not operate as a venture capital investment trust and to exit the registered capital system within three months. In case the corporations do not apply for these amendments, they will be considered annulled as stated in the second and sixth sub articles of first paragraph of Article 434 of TCC.

### **SECTION THREE**

#### **Principles Regarding Registration of The Shares By The Board Application for Registration**

ARTICLE 9 - Within three years from the registry of portfolio management license to Trade Registry, a corporation that is founded as a venture capital investment trust or converted into a venture capital trust shall compose its portfolio and apply to the Board with the request of having its shares registered so that they can be offered to public.

The corporation that didn't submit the application for registration of its shares to the Board within three years after the registry of portfolio

6

management license to the Trade Registry, and the corporations of which the Board rejected the application, shall not operate as a venture capital investment trust anymore.

Following the end of the three year period or the date when the corporation is informed about the Board's rejection decision, the corporation shall apply to the Board to amend its Articles of Association so that it can not operate as a venture capital investment trust and to exit the registered

capital system within three months. In case the corporations do not apply for these amendments, they will be considered annulled as stated in the second and sixth sub articles of first paragraph of Article 434 of TTK. On the other hand, upon the request of the corporation, the Board can grant a one year extension for the three year period in case of significant problems that occurred in the market where the shares of the corporation are supposed to be offered to public.

#### **Public Offering**

ARTICLE 10 - In public offering of shares, the Board's general regulations on public offering and sale of shares shall be applied, where there is no relevant provision in this Communiqué.

#### **Registration by the Board**

ARTICLE 11- The Board shall evaluate application for registry of shares in terms of public disclosure, in particular whether the offering documents contain the information required under the regulations about the corporation and the shares.

In case the Board gets the opinion that the offering documents are not sufficient and do not reflect the truths and therefore cause abuse of the public, then the registry of the shares to the Board may be rejected. Registry of the shares to the Board does not mean that issued shares and the trust will have been guaranteed by the Board and cannot be used for advertisement purposes.

#### **Quotation to The Stock Exchange Market**

ARTICLE 12 - The corporations shall apply to the Board for issuance of certificates required for quotation of issued shares to Stock Exchange Market within 15 days from end of sale period. Within 15 days following the date of these certificates, corporation is obliged to apply to stock exchange market with the request of quotation of the shares.

#### **Notification to The Board**

ARTICLE 13 - The corporations shall be obliged to notify the following to the Board within six business days subsequent to:

7

- a) the announcement date of Articles of Association of the Foundation, one copy of TTSG,
- b) the publishing date, statement, circular, announcement regarding sales and advertisements about public offering,
- c) the end of sale period, the information about new shareholders structure and sale results occurred after sale,
- d) the signing date, one copy of agreement about investment to venture firms,
- e) end of the quarter, quarterly portfolio table containing investments in trust portfolio.

In addition, the resolution of the board of directors about investment to venture firms shall be notified to the Board and the Stock Exchange Market where the shares are under transactions through the fastest communication means until 9:00 of the next business day.

#### **Transfer of Shares**

ARTICLE 14 - Before public offering, transfer of shares shall be subject to the permission of the Board regardless of any ratio. Transfer of shares within the framework of the provisions in this article the new shareholders must fulfil the restrictions of the founders.

**Issue of Preferred Shares**

ARTICLE 15 - The corporations cannot issue any securities providing privileges other than privilege to nominate 2/3 of candidates for members of the board of directors or privilege for dividend. If the number of 2/3 of board of directors is not an integer, the closest integer will be taken into account. After public offering, no privilege, including nominating members for the board of directors and dividend, can be created.

**SECTION FOUR****Principles Regarding the Management of the Corporation****Member of the Board of Directors and General Director**

ARTICLE 16 - The members of the board of directors and the general director must have the qualifications specified under article 5, paragraph (a) and (c) of this Communiqué.

**Scope of Activities**

ARTICLE 17- The corporations,

8

- a) can be shareholders of venture firms within the framework of the provisions in this Communiqué,
- b) may take part in the management of venture firms, may offer consulting service for the mentioned firms,
- c) may make investments in securities being transacted in secondary markets in order to have varieties in their portfolio,
- d) may use short term credit, which have a maturity of less than 1 year, in the amount of half of their equity capital, long term credit, which have a maturity of more than 1 year, in the amount of two times of their equity capital.

**Investment Restrictions**

ARTICLE 18 - The corporations,

- a) can not make investment into firms where the shareholders with more than %10 of the capital or the voting rights, members of board of directors and general director separately or collectively have more than 10% of the capital or the voting rights of corporation,
- b) can not invest more than 50% of its portfolio value on securities other than the ones issued by venture firm and the being operated at secondary markets, investment to venture firms are considered as this kind of investment after ten years since the investment date,
- c) can not invest more than 10% of its portfolio value on securities issued by one firm specified under subparagraph (b) above.
- d) can not have more than 5% of voting rights or capital of one single firm specified under subparagraph (b)
- e) can invest in securities appropriate with their investment objectives with the purpose of hedging of portfolio against currency, market and interest rate risks provided that their articles of association have a provision in this line, this issue mentioned in disclosure documents, and approved by the Board, for hedging purposes invest in forward, options and futures contracts.

**Obtaining Consulting Services**

ARTICLE 19 - The corporations can obtain consulting services from specialized persons and foundations in connection with the matters related to their activities provided that their articles of association have a provision in this line and a resolution for this purpose has been taken by the board of

directors.

One copy of contract with specialized persons and foundations must be notified to the Board within six business days following the signing date. If no staff will be assigned to the related departments within the period of contract, the contract must be approved by the Board.

9

#### **Investment in Venture Firms**

ARTICLE 20 - The investments to be made in venture firms by corporations shall be made under the framework of an agreement to be executed by and between the parties. This agreement shall have provisions mainly about the management of the venture firm and rights and obligations of the venture firm.

The venture firms must aim to manufacture or develop, vehicles, tools, material, services or new products, methods, systems and production techniques having industrial and agricultural application potential as well as marketing potential or have the capacity to realize the specified objectives with management, technical or capital support

The corporations can be shareholders of venture firms or may purchase debt bonds to be issued by venture firms.

The corporations may make investment into securities issued by other venture capital corporations within the framework of the provisions in this article.

The corporations can make;

- a) Contracts that give to the corporations the option to sell the shares of venture firms to the shareholders or the employees of venture firms,
- b) Contracts that give the option to the shareholders or the employees of venture firms to buy the shares of venture firms,
- c) Contracts that give the shareholders the option to buy the shares of venture firms,
- d) Futures contracts regarding the sale of shares of venture firms to the shareholders or the employees of venture firms,
- e) Futures contracts regarding the sale of shares of venture firms to the corporations by the shareholders or the employees of venture firms, and other options and futures contracts regarding the investment activities of the corporations.

These kinds of contracts are considered as venture capital investments.

For these kinds of contracts corporations must obey the rules determined by the Board regarding the obligations of the parties, valuation principles of investment on venture firms, the scope of public disclosure, investment amount and etc.

Sufficient information about options and futures contracts must be disclosed in the disclosure documents.

10

#### **SECTION FIVE**

##### **OTHER PROVISIONS**

##### **Principles Regarding The Sale of Shares To Sophisticated Investors**

ARTICLE 21 - If the shares of corporations will be sold only to sophisticated investors provided that their articles of association have a

provision in this line and this issue mentioned in disclosure documents, the following principles would be valid.

- a) Corporations have to obtain and keep regularly persuasive data and documents about the investors proving that they meet the sophisticated investor criteria within the framework of this Communiqué.
- b) All the shares must be written down on its behalf. These shares can only be sold to the sophisticated investors. Corporations must obtain persuasive data and documents about the investors proving that they meet the sophisticated investor criteria. The sale of shares to the investors that does not meet the sophisticated investor criteria can not be registered to the share register.
- c) In case of foundation and conversion the paid-in or initial capital must not be less than 1 trillion TL.
- d) Corporations are not obliged to have a leading shareholder and the provisions regarding the leading shareholder are not valid for these corporations.
- e) There is no need to have an investment portfolio prior to registration to The Board however the corporations that does not meet the specified criteria under article 18, paragraph (b) of this Communiqué within one year following the registration can not operate as a venture capital investment trust. Following the end of the one-year period, the corporation shall apply to the Board to amend its Articles of Association so that it can not operate as a venture capital investment trust within three months. In case the corporations do not apply for these amendments, they will be considered dissolved as second and sixth sub articles of first paragraph of Article 434 of TTK.
- f) Article 12 and the last paragraph of article 13 of this Communiqué are not valid for these corporations.
- g) In case of public offering paragraph (b) of article 5 and third subparagraph of article 6 of Communiqué On Principles Regarding Registration With The Capital Markets Board And Sale Of Shares Serial: I, No:26 published in Official Gazette dated 15/11/1998 and numbered 23524, second subparagraph of first paragraph of article 3 of Communiqué on Principles Regarding the Sales Methods of Capital Market Instruments Through Public Offering, Serial: VIII, No: 22 published in Official Gazette dated 27/10/1993 and numbered 21741 are not valid for these corporations.
- h) There is no need of auditing, notification to the Board and disclosure for the six-month results of the corporations. However, year end financial statements and audit report must be submitted to the Board and disclosed at TTSG within one month following the date of annual general assembly.

Board can differentiate the public disclosure requirements of these corporations.

#### **Being Subject to Related Regulation**

ARTICLE 22 - The corporations shall be subject to regulations of the Board in connection with the matters such as financial tables and reports, profit distributions, announcements and advertisements. In case this Communiqué does not have any provisions about a specific matter, then the regulations of the Board about publicly-held firms and other regulation provisions shall be applied.

**The Fee to Be Deposited to The Fund**

ARTICLE 23 - Before the registry of the shares of corporation, the registry fee under Article 28 of the Law shall be deposited to the account of the Board in advance.

**Documents Determined By The Board**

ARTICLE 24 - Board can determine the format, scope and principles of notification to the Board of prospectus, articles of association, application forms and portfolio tables mentioned in this Communiqué.

**Amounts Determined By The Board**

ARTICLE 25 - Board can determine the amounts mentioned in the articles 3,4 and 21 of this Communiqué.

**Evaluation of The Applications By The Board**

ARTICLE 26 - Documents regarding the application must be submitted fully to the Board in order to evaluate the application. Other documents and information to be requested must be submitted within the period determined by the Board.

**Repealed Provisions**

ARTICLE 27 - "Communiqué Regarding the Principles About Venture Capital Investment Corporations" Serial: VI, No: 10, published in Official Gazette dated 6/11/1998 and numbered 23515, being in effect before this 12

Communiqué has been terminated.

Temporary Article - The principles regarding the leading shareholder and minimum paid-in capital will not be valid for the corporations founded before publishing date of this Communiqué.

**Entry into Force**

ARTICLE 28 - This Communiqué shall enter into force on the day of its publication.

**Execution**

ARTICLE 29 - The provisions of this Communiqué shall be executed by the Board.

# PRIVATE EQUITY AND VENTURE CAPITAL – THE NEW IDEA FOR GAINING CAPITAL IN CENTRAL AND EASTERN EUROPE<sup>1</sup>

## **Abstract**

*In the contemporary world, the capital market in Central and Eastern Europe (CEE) is spreading further and further. Young and emerging enterprises not only need but also acquire capital for developing themselves and entering new markets. Following this path the assets class grows and matures, and at the same time the number of transactions on the secondary market obviously keeps increasing. Due to this reason, we should take into consideration the subject of private equity and venture capital. Private equity and venture capital are the forms of investing in unquoted securities of new, small or medium-sized enterprises. After a certain period of investing equity the shareholders could sell back their shares in order to maximise yield or minimise losses. The goal of this working paper is to present the market of private equity and venture capital in Central and Eastern Europe countries (especially in Poland, the Czech Republic) as well as its possibility for the future development in Europe.*

**Keywords:** *Private equity; venture capital; Central and Eastern Europe*

## 1. Introduction

When we look at companies such as Euronet, Computerlan, Google, or Hewlett Packard, it is usually easy to indicate in what market sector they operate or what their main product is. However, it is not commonly known just how they managed to gain the leader position in their fields. The key to their success was the intriguing way of acquiring external capital in the form of Venture Capital (VC). The form that focused on the human factor, his creativity and will to take up risk. Unfortunately, this does not mean yet that the mentioned source of financing is available for everyone, at least not yet in the CEE countries.

The beginning of VC dates back to the '80, when the USA faced an extreme increase in the financing of investments in infrastructure using this method. The value of VC investments in the USA has risen since 1980 from USD 5 billion to USD 180 billion in 2000.

This study acquaints the reader with the main definitions of PE/VC as well as presents the development of PE/VC in Europe. However, the most interesting part is about the changes being introduced in this field in the CEE countries. Surely, the accession into the EU will cause the VC market in the CEE countries to be regulated, and therefore will give a chance to develop and become competitive to many small and medium-sized enterprises.

## 2. Main aspects of private equity and venture capital

### *2.1 The nature of PE/VC funds*

Today, private equity and venture capital funds are one of the specific forms of financing the development of enterprises. The idea of private equity and venture capital is very simple. There are always two sides of a transaction: wealthy investors (a sponsor or moneylender, who finances a new idea or project) and originators (who know how to improve the financial state of the company to acquire a huge profit). Nowadays, even very expensive projects or ideas can find a moneylender willing to take a risk in return for a high reward – the future profit. This is the reason why such forms of financing are very often called high risk capital. However, not only does the moneylender contribute his money to the company, but also his know – how, high –tech, low – tech and no- tech as far as the management of the company is concerned. This transfer of capital helps investors to manage the company as well as to enter the market with a specific product. This kind of private investor, who not only provides the company with capital, but also with business expertise, is known as **business angel**. [TAMOWICZ P.,

*Venture Capital – Kapital na Start*, PARP Publishing, Gdańsk 2004, pp. 66 – 67. ISBN 83-88802-90-9]

**Private equity (PE)** is a medium or long-term form of financing investments. This form is provided to an unquoted company in return for an equity stake in potentially high growth of such company. Moreover, the term “private equity” is used to describe the industry as a whole that is “venture capital” (the seed to expansion stages of investment) as well as management buy-outs and buy-ins.

Private equity backed companies usually grow faster than other types of companies. The private equity firms will seek to increase a company’s value to its owners, without taking day-to-day management control. Although the company may have a smaller “slice of cake”, within a few years the same „slice” should be worth considerably more than the whole “cake” was before

As far as the idea of **venture capital (VC)** is concerned, it should be stressed that this is the same form of financing as private equity. However, venture capital is provided to a company, which is very new and is just starting to position itself on the market. Due to this fact, the risk of putting up capital to such an enterprise is higher. Following this path, there is a popular belief that the future profit from such companies is also higher, but this is not a rule. Moreover, venture capital provides capital to companies, which are not listed on the stock market. Venture capital refers mainly to management buyouts, management buy-ins, replacement capital as well as venture purchase of quoted shares.

Investments are usually carried out by acquiring shares, but their amount depends on individual agreements between originators and investors. Thus the investor becomes the company co-owner. After financing the proper project the investor withdraws his capital and sells his stocks and shares. This is also a very important feature of venture capital (VC), which concerns companies that are not listed on the stock exchange. Therefore, VC is recognized as a part of the nonpublic or private capital market. [The Polish Private Equity Association, Yearbook 2003, pp. 41 – 45]

In fact, venture capital (VC) is an element of private equity, which is contributed to the company by an external investor to a small or middle-sized enterprise for the period from five to ten or even fifteen years. This period depends on the time, which is necessary to obtain appropriate development in the early stage of the venture (speed and start-up phases) or expansion of the business.

Taking the PE/VC structure into account, it seems to be very interesting that some collaterals (like mortgages), which are usually required

in the credit procedure, are not needed in this form of financing. According to this statement, the only collateral in the PE/VC form is only the share of the company's equity as well as the rights, which results from this share.

These are:

- Voting rights;
- Access to financial information;
- Control system.

In most cases, the investor resigns from taking the monthly profit margin in order not to charge the budget of the enterprise. Actually, PE/VC is an award itself for the company and a proof of its success. Hence the more company is worth, the more investors earn from shares.

As far as the idea of PE/VC is concerned, there are two kinds of investments in this structure. They differ from each other in legal requirements as well as in their structure. These are:

- **Direct investment in PE/VC**
- **Indirect investment in PE/VC**

Direct investment in PE/VC takes place when an investor buys shares of a company. The investor is a private person or group of people, who might come from among a circle of families or the entrepreneur's friends. However, it should be taken into account that the financial possibilities of friends or family are limited, and can not bankroll all phases of production. Therefore, the possibility of direct investment runs out, when the company starts to produce goods on a large scale. Overall, the direct form of investment was once very popular in the private equity structure, but now it is not as popular as the indirect form.

The second form of investment is indirect investment in PE/VC. Such a form of financing the process of investment is by far much more complicated as well as profitable than the direct form. The idea of indirect investments relies on using specialized institutions -private equity investment funds. This is a special legal structure, which symbolizes the accumulated capital managed by experts, called **fund managers** or **investment managers**. The fund manager is responsible for researching and selecting markets, sectors and industries to invest in, deciding how much to invest in each sector, when to buy or sell etc. In other words, the private equity investment fund is a vehicle that enables raising capital from several investors, and then invest this capital in equity-related securities of companies - **investee companies**. These are usually private companies not listed on any stock exchange. Nevertheless, the fund could also take a form of a company or an unincorporated entity such as a limited partnership. [CIEJPA-ZNAMIROWSKI, K., *Zagrożenia i perspektywy rozwoju polskiego rynku*

*kapitałowego*, KUL Publishing, Lublin 2002, pp. 14 – 16. ISBN 83-228-0821-6]

The legal structures needed to establish these funds might be different in various countries due to the differences in tax systems or legal regulations.

Entities that are mostly interested in setting up venture capital funds are:

- Pension funds,
- Banks,
- Insurance companies,
- Huge corporations.

The above mentioned entities have large capital resources. For this reason, they want to invest their capital in the fund and at the same time achieve better profits from this transaction. On the one hand, the type of investors in a fund is not significant, but on the other hand it truly could be. For example funds, which are established by banks, might be much more aware of investing in better-positioned and more secure companies. Obviously, investments in such companies will take less time, than in companies in the speed stage.

## ***2.2 The idea of fund of funds***

As the idea of private equity and venture capital develops, the case of the fund of funds should not be avoided.

In the developed financial markets, local institutional investors are typically providers of private equity capital. In most European Union countries (like the UK, France, Hungary, Austria) more than half of all private equity capital is provided by banks, pension funds etc. However, not all counties in Europe are so lucky...for example Poland. In comparison with European countries, the Polish private equity (PE) market is characterized by a low level of financing from local, domestic sources. Despite this fact, the Polish institutional investment market is rising quickly. Polish pension funds currently control a capital of PLN 58 billion. Moreover, the value of the assets of insurance companies in 2004 exceeded PLN 61 billion and market investment funds accounted for a further PLN 32 billion.

Unfortunately, in spite of such a considerable capital, Polish financial institutions are not allowed to invest in the local private equity market. In fact, the local private equity market is effectively cut off from sources of local financing. The reason of this situation is quite simple – the Polish law system. Due to the regulatory constraints, pension funds can not invest

directly into non-listed foreign investment entities. Under these circumstances, this form of investment includes private equity funds, which use the non-listed foreign investment entities to maximize their tax efficiency. Actually, foreign pension funds, banks as well as insurance companies are still one of the leading PE investors in Poland.

However, there is a solution to this problem in the Polish legal regulation. This solution is called the **fund of funds**.

Today, funds of funds are quite a popular form of investment vehicles on the private equity market. At the end of 2003, there were approximately 125 funds of private equity that managed around USD 130 billion all over the world. In other words, globally, funds of funds account for about one fifth of the overall private equity capital. Taking into consideration the European market, this ratio is slightly lower and reached around 14% in 2003. This situation makes funds of funds the fourth biggest provider of private equity capital on the European market.

The idea of the fund of funds is really simple to explain. A fund of funds is an investment vehicle that pools money from investors to invest in a selected portfolio of private equity funds. Particularly, a fund of funds usually acquires a portfolio including from 10 to 20 selected PE funds. When the life of these selected funds ends or if the funds expire, cash from divestments is transferred to the fund of funds and returned to its investors. Therefore, a **divestment** is a point at which the private equity fund ends its involvement in a business and takes its profit. [The European Private Equity and Venture Capital Association (EVCA), Yearbook 2005, pp. 202 – 203]

There are many advantages of the fund of funds:

- **Access to the best funds (top-tier funds)** – funds of funds want to generate the best return from the selected best private equity funds (e.g. funds from the top-quartile funds like these, which have a return on investment at the level of 25%). The demand for these top-performing funds is very high on the market, and may even exceed supply. As a result, not all investors can take part in such profitable funds. However, due to the power of funds of funds, for example its management skills or market expertise, it may provide access to the leading private equity funds.
- **Cost effectiveness** - An institutional investor, who would like to allocate for example 10% of his assets to private equity as well as wants to reduce his risk by investing that capital in a number of funds, should bear the costs of employing a team of private equity professionals, to construct and manage a portfolio of private equity funds. Investing into a fund of funds allows the investor to outsource

all mentioned tasks, and at the same time save time as well as money. In fact, a selection of investment opportunities or tasks to be performed, which are connected with monitoring and reporting the portfolio, requires both the investor's knowledge and constant monitoring of the investments. Therefore, the choice of a fund of funds is the best solution for an institutional investor.

- **Diversification** – investment risk in the fund of funds substantially goes down through portfolio diversification. Thus the fund of funds diversifies its portfolio across:
  - Funds,
  - Sectors,
  - Strategies

The reason of this solution is to diversify portfolio risk. As a recent research of the PE shows, funds of funds are the least risky form of allocation in private equity. Whereas the risk of capital loss in the case of a direct PE investment in a business is 42%, the risk of a loss going up from an investment in a single private equity fund (whose portfolio may consist of shareholdings in 10 – 20 companies) is substantially reduced, but still significant at around 30%. When investing through a fund of funds the risk of capital loss is just 1%. Moreover, the risk of total loss of capital during investing through a funds structure was found to be zero.

- **The possibility of investments with limited capital** – a potential investor in a private equity fund should provide a substantial threshold. Consequently, if the investor wants to build his own portfolio of PE funds, he must have a significant sum of money to enter into several funds. Investing via a fund of funds has the advantage of allowing an investor with relatively limited capital to gain access to a large spectrum of private equity funds. An institutional investor who allocates less than EURO 500 million for investments in private equity will participate only through funds of funds vehicles.

### ***2.3 Stages of financing investments***

The financial quotation of a venture capital fund is very diverse. In practice, VC funds could finance all phases of business development as well as some specific situations, that may exist in the enterprise e.g. a turnaround (restructuring), or a buyout (a transaction, in which a business unit or company is acquired from the current investors).

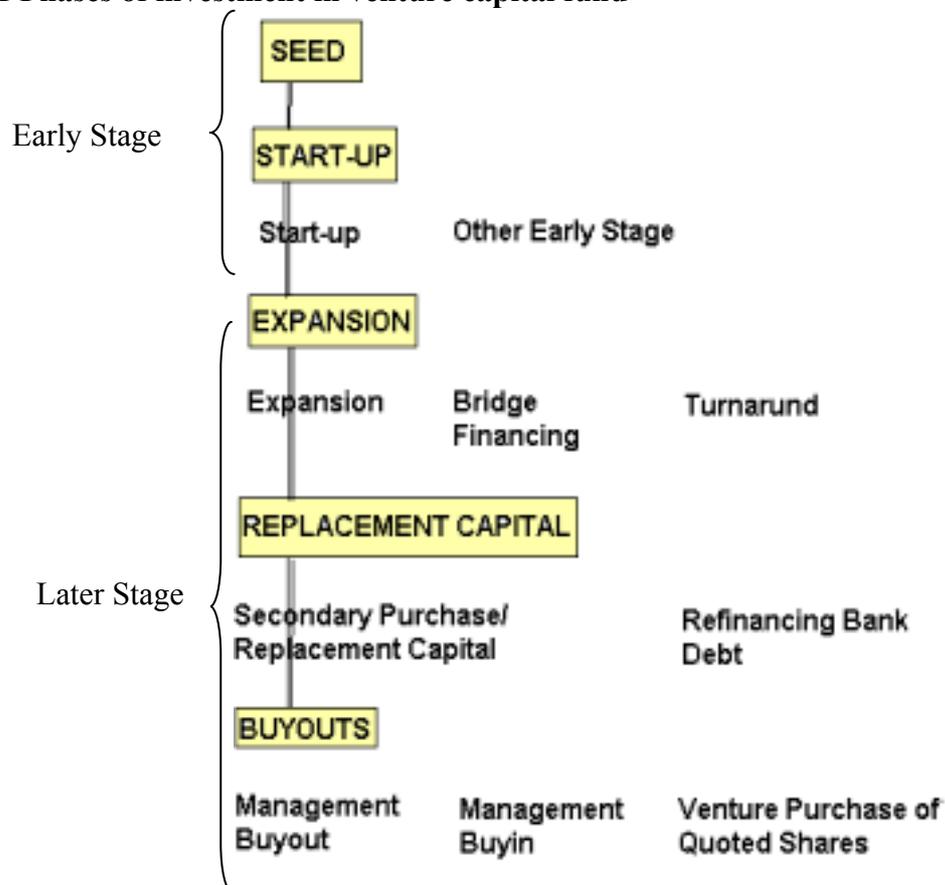

In fact, there can be distinguished many phases in the financial offer of VC funds. Seed and start up phases should be diversified according to the

business, which will be operating in the future. Therefore, both of these phases are used to finance the early stages of the investment project's development. Clearly, this advance financing involves projects from several to several tens of dollars.

The seed stage includes financing, which is important to investing in promising and profitable ideas, research or concepts, before a business has reached the start-up phase.

The start-up stage should take into account companies, which are in the process of being set up or have been in a business for a short time, but have not sold their product commercially yet. In fact, this stage of financing should be acquired by enterprises that must invest in product development as well as in initial marketing. [COMPERS P., LERNER J., *The Venture Capital Cycle*, MIT press, London 2000, pp. 33 – 45. ISBN 0-262-07194-0]

**Figure 1 Phases of investment in venture capital fund**

*Source: Personal elaboration*

Because of the experience of the company and the position on the market, the investment risk as well as financial return from investment is playing an important role for the fund. In practice, financing ideas and entering the market are by far the most risky as well as expensive investments for the VC funds. This is the reason why funds expect very high rates of return. Unfortunately, there are few companies, which could accept such conditions and provide so profitable rates of return. In fact, the VC funds are not very interested in financing seed and start-up phases. However, the initiative of governments can be a good solution for this problem. In some countries, for example Great Britain, Netherlands, Slovakia or Poland, governments aid the developing funds that invest in seed or start-up stages.

In practice, there are much more early stages. These stages focus on companies that have completed the product development stage and require further funds to initiate commercial manufacturing and sales.

**The expansion capital stage** is also called the development capital phase. In this phase all funds are allocated into the growth and expansion of the company. The capital may be used to finance increased production capacity, develop and market the product as well as provide additional working capital. An interesting phase in this stage is bridge financing. Such form of financing could be a good solution for companies in the period of transition from being privately owned to being publicly quoted. Another interesting phase that belongs to the expansion stage is turnaround. The turnaround is one of the forms of PE/VC financing, which helps companies to exist within a branch, while financial problems or insolvency start to occur. Due to this solution, enterprises have a new chance to re-establish prosperity.

The replacement capital stage (secondary purchase) concerns the purchasing of existing shares in the company from another private equity investment organization, or from another shareholder or shareholders. Another phase, which is called refinancing bank debt, rarely takes place. This phase is used, when the company's level of gearing must be reduced.

The last stage of investment includes management **buyout, management buy-in and venture purchase of quoted shares**. The management buyout (MBO) is a buyout in which the target company's management team acquires the business from the current shareholders, with the support of private equity investors. The management buy-in (MBI) is a buyout in which external managers take over the company. However, the group of managers or a manager could not have enough money to carry out such a target. In fact, financing from PE/VC investors enables them to reach this point and buy the company. The last phase is connected with de-listing

the company, which could go bankrupt or which one of the products was withdraw from the list of production. It is a purchase of quoted shares with the purpose of rebuilding or de-listing the company.

#### ***2.4 How to choose the best fund***

To explain the below case, it could be a good idea to assume that the form of financing of a new investment has just been chosen, but not a concrete venture capital fund. Moreover, the situation is much more complicated, because there are many available VC funds in a country.

However, the investor should take into consideration five features:

- Branch specialization,
- Financing specification,
- Investor's requirements for investment limits,
- Localization of a fund,
- Reputation of a fund

The first criterion is by far the most important. Most of the funds describe themselves as universal, which operate in all branches. However, there is a group of branches, which are avoided by venture capital funds. These branches are usually regarded as dangerous, because of political, social as well as economical reasons. To the most crucial branches belong sectors, which produce and trade arms, tobacco, high percentage alcohol, means of abortion or drugs. Furthermore, due to the fact that VC funds admit responsibility for the activities they invest in, they do not invest in companies that destroy or poison the environment. That is why there are many funds, which invest only in the internet technology, communication or commodity food processing industry.

**Table 1 The most popular Polish investment offer of PE/VC funds in 2004, regarding brands.**

<b>PE/VC fund</b>	<b>Sectors</b>	<b>Amount of investment (million PLN)</b>
<b>3TS Venture Partners</b>	Electronics, IT, Internet, media, telecommunication,	9 - 27
<b>Advent International</b>	Media, IT, telecommunication, chemistry, food processing industry	40 – 120
<b>Argus Capital International</b>	No preferences	20 - 100
<b>Dresdner Kleinwort Capital</b>	Telecommunication, media, IT, logistics, medical services	12 - 100
<b>Enterprise Investors</b>	Production and services for industry, IT, telecommunication, health care, environment protection	12 – 120
<b>DBG Eastern Europe</b>	Consumer goods, media, IT, services, telecommunication, transport	13 - 54

*Source: The Polish Association of Capital Investors, <http://www.psik.org.pl>*

Another important feature, which has a huge influence on choosing a PE/VC fund is its financial specification. It means that the investor should check first, whether the VC fund specializes in financing projects that are in the early stages of investment development. There is a possibility that the VC fund majors in management buys-in or turnarounds. In fact, if the fund does not finance the seed stage, sending documents about the project is just a waste of time.

Speaking about the selection of funds, the case of investment limits must be taken into consideration. The limits of investment are strictly connected with the size of the PE/VC fund. The larger the fund, the higher value of investment is required by such a fund. In other words, if we have a project, which is worth PLN 2 million, we should only choose funds that finance projects from approximately PLN 1 to PLN 5 million. As it is, the value of investment as well as investment limits required by PE/VC funds must be known in detail.

The last two features are much easier to understand. The localization of the fund is not a very influential matter in the contemporary times, in

which telecommunications are so well developed and keep expanding even more. In practice, the cooperation between the fund and originator, even at a long distance, is currently unimportant. However, if the entrepreneur wants to realize a small and locally situated project, this factor could be meaningful

The reputation of a VC fund is a quite interesting case, when the originator wants to eliminate unfortunate surprises. Reputation means both experience as well as knowledge how to manage a fund and cooperate with the originator. Such cooperation may last even several years. As a matter of fact, it is better to gather information about the chosen fund e.g. on web sites.

## ***2.5 The structure of investment process***

The whole process of investment, which begins from the first contact with the project and ends when the shares of the company are sold, is called the investment cycle. This cycle may be divided into three parts:

- Preparation of investment, when the capital is contributed,
- Cooperation with the company to increase of investment's value,
- Completion of investment and the withdrawal of involved capital.

These phases consist of specific operations and objectives, which are taken up in both the VC fund (its managers, financial advisers etc.) as well as originator of the project.

First phase focuses on a detailed analysis of the prepared project. When the project is be acceptable and viable to perform, the stages of negotiating and settling the conditions of the agreement are sign. However, to the most significant and influential factors of this phase belong the in-depth analysis due diligence. This kind of analysis makes a detailed and careful assessment of the financial, commercial, legal and technical fundamentals of the business targeted for investment. After that, the VC managers prepare a term sheet and finally establish such terms of the transaction, which will satisfy both parties. In this phase the originator is obliged to present the project, business plan as well as all negotiation or problem areas. At the same time, the VC fund has to prepare an in-depth analysis of the company and law records.

The time of preparation of all conditions depends on the size of the project as well as its level of problematic areas. Usually, the time needed to finish the first phase of the investment process takes from 3 weeks to even 5 months. By far the most time-consuming and at the same time most expensive is the due diligence process. [TAMOWICZ P., *Venture Capital – Kapital na Start*, PARP Publishing, Gdańsk 2004, pp. 9 – 10. ISBN 83-88802-90-9]

Another stage concentrates on the effective process of carrying out of the project. It is the longest process among all the mentioned phases, which can last from three to seven years. Considering this stage, it is very hard to separate concrete phases or activities. Nevertheless, there occur special sequences of cooperation between the fund and entrepreneur in order to reach a high rate of return from invested capital.

The last stage starts, when the VC managers feel that the company is close to reaching its agreed ceiling of value. This stage lasts from 2 to 11 months. To the most important functions belong:

- Preparing the company to withdraw from the fund,
- Searching a purchaser,
- Implementation of the transaction.

This stage is as expensive as the first stage of financing the investment, because the VC specialists have to prepare an assessment of the company as well as its informational memorandum for future investors or clients.

### **3. The world of PE/VC funds in Europe**

#### ***3.1 The region of changes***

Over the last decade Central and Eastern Europe (CEE) has undergone major structural changes. Due to this process, especially new EU members have become an attractive source of private equity investment opportunities. The rate of improvement as well as the level to which opportunities for investment have increased is surprising and striking. Under any circumstances, CEE is exceptionally positioned to reach significant returns for investors in private equity that may outshine performance in the more mature markets of the old EU members.

As far as the private equity is concerned, the roots of PE development in CEE have a lot in common with the development of Western Europe. Twenty years ago, the private equity industry in most of Western Europe countries was still in its infancy. However, thanks to the meaningful changes in taxes, business climate or other regulations in the west, the PE forms could be established. The situation in CEE countries was similar; the process of harmonization with the European Union has provided structural changes that have in turn improved private equity opportunities.

Structural changes, reforms as well as willingness to develop the PE industry since the early 1990s in Western Europe have accelerated the development of the PE industry in the CEE region.

According to the Baring Corilius Private Equity report, investments in Europe have reached the record level of EUR 36.9 billion in the end of 2004 in comparison to EUR 29.1 billion in 2003. Moreover, that was an even better result than in 2000, when the level of investments reached the point of EUR 35 billion. Experts predict that in the end of 2005 the level of investments in Europe will go up to approximately EUR 42 billion. The largest amount of funds was in the UK in 2004 with EUR 10.1 billion, or 37% of the European total, although this was down a third from 2003, when UK funds represented 55% of total European funds. The second position was taken by Sweden with EUR 3.7 billion and the third by The Netherlands with EUR 3.2 billion. It is a very interesting fact that the amounts increased, in each individual country, very significantly from year to year. This was especially easy to observe in some smaller markets, where only a few new independent funds may be raised each year. [SOBIŃSKA K., *Nasz Rynek Kapitałowy, Coraz bliżej unijnego poziomu*, vol. 6, no. 174, pp.40 – 43]

The most influential deterrent of PE development in Europe (in the last 20 years) was the process of privatization as well as law changes. Considering only the CEE market, the privatization process has played also a meaningful role in building up roots of a stable economy. The financing of turnaround processes was for a long time one of the most typical activity carried out by private equity funds. On the one hand such process were a strong catalyst for PE funds, and on the other hand could aid privatized companies to come into the reality of free market economy.

In any case, in the beginning of 1990s privatization has played the most important role for the establishment of the private equity market in the CEE region. However, this impulse did not overheat in the end of decade, because new factors, which support growth and development of PE funds, have appeared

To present all structural or legal changes in Europe that have influenced the contemporary situation of PE/VC funds, another written assignment should be taken. However, the table on the next page can help understand the most influential points.

**Table 2 Comparison of factors affecting PE development in Western Europe and CEE**

<b>Countries</b>	<b>UK</b>	<b>France</b>	<b>Germany</b>	<b>Central Europe (CE)</b>
<b>SUPPLY OF OPPORTUNITIES</b>				
<b>Need to solve the problem of family succession</b>	Moderate need	High need	High need	Low need
<b>Need to restructure diversified groups</b>	Established patterns throughout period	Became established in 1990s	Becoming established from mid-1990s	Increasing established in early 2000s
<b>Need to privatize state-owned companies</b>	Well established program from 1980s; now complete	Less extensive than in UK	Former GDR apart, relatively little	Bulk of privatizations completed
<b>Scope for going-private transaction</b>	Large stock market; few initial deals, now significant	Steady flow but often complicated by family control issues	Relatively small number of quoted companies	Many candidates; specific opportunities must grow
<b>Development stage of merges and acquisitions (M&amp;A) markets</b>	Highly developed	Relatively active	Becoming active	Relatively active
<b>DEMAND FOR PRIVATE EQUITY</b>				
<b>Attitude to entrepreneurial risk</b>	Became very positive from early 1980s	Moderate	Traditionally cautious, changing slowly	Positive and growing
<b>Willingness of managers to buy</b>	High	Moderate	Starting to develop	High, but lacking financial means
<b>INFRASTRUCTURE TO COMPLETE DEALS</b>				
<b>VC market</b>	Grew rapidly from early 1980s	Grew from late 1980s but many small players	Traditionally small & not MBO-oriented	Small but developing
<b>Supply of debt</b>	High	Moderate	Tradition of high leverage	Low but growing
<b>Favorability of legal framework</b>	Favorable	Favorable	Moderately favorable	Favorable
<b>Favorability of taxation regime</b>	Favorable	Favorable	Reforms in progress	Moving to favorable with EU reforms
<b>Intermediaries</b>	Highly developed	Moderately developed	Fragmented	Highly developed

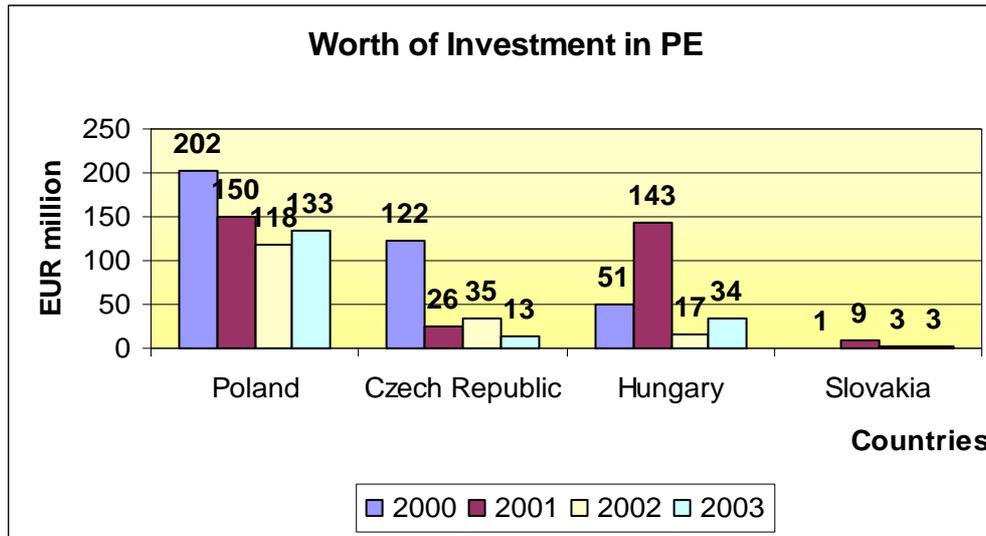

<b>REALIZATION OF GAINS</b>				
<b>Stock markets</b>	Receptive to PE companies from mid-1980s; now more difficult	Development of second market	New issues sparse	Growing domestic capital pool and appetite(demand)
<b>Trade sales</b>	Highly active	Becoming more active, especially for partial sales	M&A market developing	Highly active
<b>Secondary buyouts/turnaround</b>	Increasing interest	Favored exit route	Possible exit route	Possible exit route

*Source: SOBONSKA K., Nasz Rynek Kapitałowy, Coraz bliżej unijnego poziomu 2005, pp. 44*

Nowadays the possibility to access the European Union has played the main role in developing the PE/VC market in Central and Eastern European Countries. Due to the harmonisation and implementation of the EU law to the CEE region, the new EU members could develop conditions to enter the PE/VC market. To the most influential features, which helped to open and intensify the development of private equity in CEE belong:

- Deal flow that is adequate to the size of PE funds,
- Supply of educated as well as capable managers, who understand the motivation of establishing PE funds,
- Access to professional legal and consulting services,
- Infrastructure, which support the development of capital market,
- Expansion and diversification of the PE fund divestment (exit) from a business

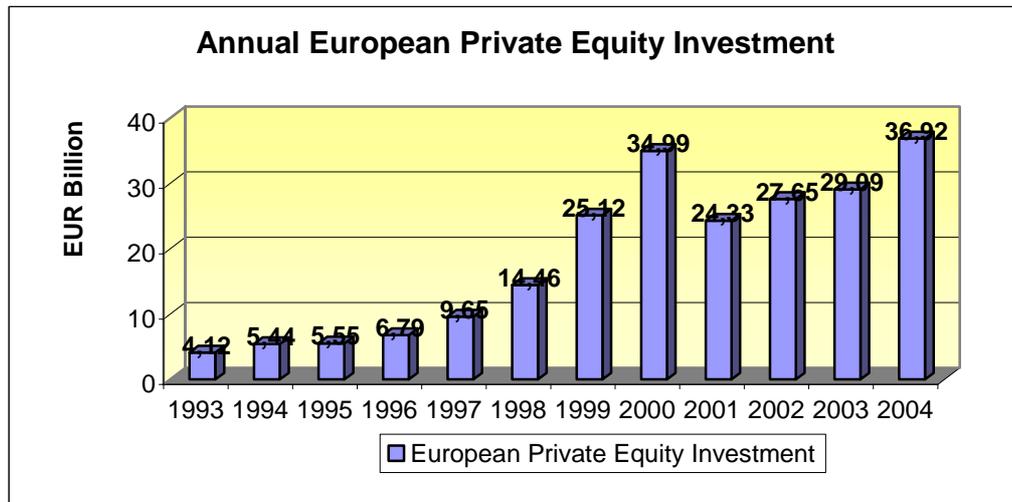

**Figure 2 The worth of investment in private equity in CEE**

Source: *The Polish Private Equity Association, Yearbook 2003, pp. 57 - 59*

The view of CEE countries as a real market of possibilities for PE funds has developed in 2004s. The accession to the EU has opened great opportunities for new members to become not only an emerging market for PE, but to approach, in the short run, the average level of the old EU members. The eight new members from CEE are populated by 73 million people. Their total Gross Domestic Product (GDP) is approximately EUR 420 billion and their average GDP growth rate is 4%. It is much higher than the average growth rate in the old EU members (1.6%). According to A.Sormani from *European Venture Capital Journal*, new countries that accessed EU in 2004s have markets, which could be classified in the low-and medium category. However, such markets have so huge and dynamic financial potential that may push away countries like: Greece, Portugal or Spain. The accession made the CEE markets much more mature, no more exotic for potential investors.

**Figure 3 Annual European Private Equity Investments**

Source: *EVCA 2004, pp. 43*

Total amounts invested by European private equity firms reached a record number of EUR 36.9 billion in 2004. This result reflects a 27% increase compared to the amounts invested in 2003, when the amount of investment reached EUR 29.1 billion. This is a surprising new record, which was at first set in 2000 when the level of PE investment boom reached EUR 35 billion. The number of investments declined slightly to 10,236 from 10,375 in 2003. The average investment size therefore increased to EUR 3.6 million from EUR 2.8 million in 2003. These investments were made in 6,985 portfolio companies so that the average financing per company grew to EUR 5.3 million (comparing to EUR 3.9 million in 2003).

### ***3.2 Previous and future tendency for the PE/VC development in Europe***

The CEE region is by far the fastest growing and developing area in Europe. Moreover, most analysts are sure that the level of growth in this region will outperform the rest of Europe. Considering the matter of PE/VC funds, the situation seems to be similar. As a rule, economy growth as well as the communists' heritage cause capital scarcity. Following this path, a big demand for PE/VC will be generated in the following years

The fall of the Berlin Wall has unleashed a boom in entrepreneurship's development as well as established a new generation of

managers, which are very often much more open to new ideas for businesses than their colleagues from the west. Furthermore, teams are currently much more valued in supporting private equity than individuals. For example in Poland, foreign direct investment exceeded USD 65 billion between 1990 and 2002. Leading investors include GE, Volkswagen, GATX, Tesco, France Telecom, Citibank, Deutsche Bank and Rodamco. Investments generated by these entrepreneurs have been backed by training management teams, which operating today and represent both a vibrant exit route as well as source of new deals.

To meet such a big demand, the mature private equity industry is evolving. Thus local banks (foreign-owned) start to offer specialized leveraged finance capabilities for mid-market deals. Team work gives better possibilities to activate mezzanine debt for a larger part of investors. Mezzanine finance is a quite new element in CEE markets. Its procedure consists of loan finance, but includes elements of both equity and secured debt. However, generally, it is usually unsecured and requires a higher interest rate than secured loans. Moreover, it often carries an option to give the lender a stake of equity.

In fact, the development of debt market (especially mezzanine finance and junk bonds) in the CEE region has begun the buyout activity not only in such region, but also in Western Europe. Moreover, the continuing harmonization with EU regulations is creating an increasingly positive environment for investment, and at the same time for private equity.

As it was earlier mentioned, banks are still the largest single source of capital in Europe, at approximately EUR 5.1 billion in 2004. Pension funds contributed an amount of EUR 4.5 billion in 2004, down by 8% at 19% of total funds raised. Funds of funds reached the value of EUR 3.2 billion, which was 14% of all funds, down by 24%. The fourth largest source were funds from insurance companies at 12%, up by 27% from EUR 2.2 billion in 2003.

Some 57% of the funds raised in 2004 came from domestic sources, at EUR 15.7 billion. Funds raised from other European countries represented 19% of funds raised at EUR 5.2 billion. Funds from non-European countries also went up in 2004 and contributed 24% at EUR 6.6 billion.

Table 3 shows that banks are the largest group, which provides capital in the CEE region. In 2004, banks reached the level of EUR 180.7 million, compared with approximately EUR 114.3 million in 2003 in this region. In fact, this tendency is strengthening in the CEE countries, contrary to the Western countries. The second position in 2004 was taken by pension funds, which contributed the amount of EUR 162.5 million, in relation to EUR 6

million a year earlier. The situation of the fund of funds seems to be very surprising. In 2003, the fund of funds reached the level of EUR 11.2 million, while in 2004 it did not provide any such capital in the CEE region.

**Table 3 Private equity raised by type of investors**

	CEE		European Union (15)		CEE/EU(15)

\*Amount in EURO x 1,000

Source: Author's calculation, using EVCA and CMBOR Reports from 2004

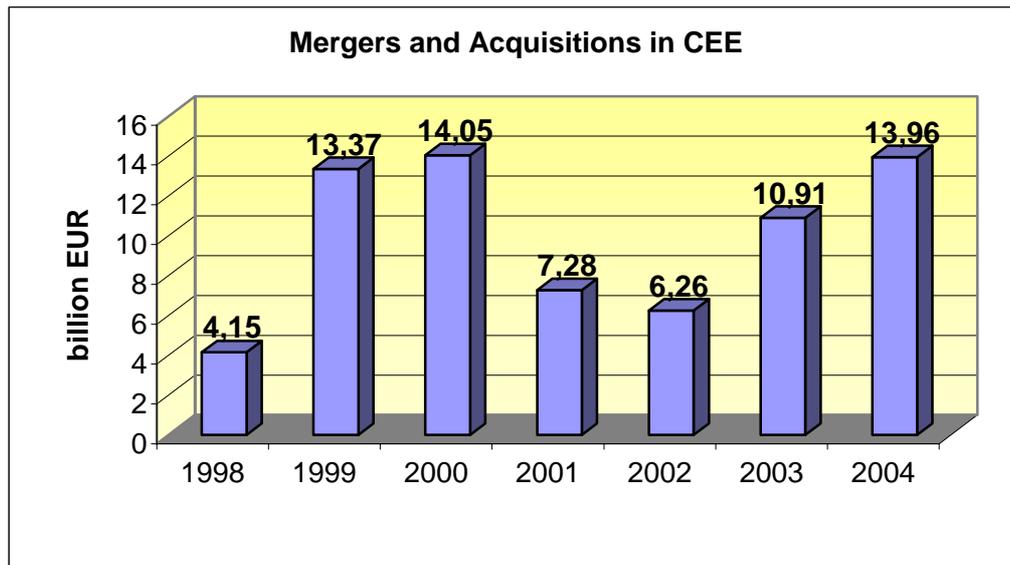

As it results from the above shown table, the share of CEE pension funds in the pension EU funds total is increasing. In 2003 it was only 0.121%, while in 2004 – 3.585%. The role of CEE banks is also rising, from 2.104 % of the total amount contributed by the European Union banks in 2003 to 3.549% in 2004. The third greatest player on this market were the insurance companies of the CEE region. Although in 2003 they have not generated any capital for private equity, in 2004 they covered 1.012% of the total value for European Union insurance companies.

Speaking about tendencies in CEE, the subject of mergers and acquisitions (M&A) must be mentioned, due to the fact that it represents the side of deal opportunities, which are by far the most important factor of the PE/VC development. In the last two years, M&A activity has shown stronger

resilience in CEE than in many other Western European markets. Moreover, it a slowdown in the world trend can be observed in this sector. In 2004, there occurred steep falls of even 30% worldwide and 40% in the USA. This is additionally a reason, why CEE may be proud.

As the figure 4 shows, there is an upswing in M&A operations. In 2004, M&A generated approximately EUR 14 billion, which was 22% more than in 2003. Nevertheless, this result did not exceed the level reached in 2000, when there was a boom on the M&A market.

**Figure 4 M&A in Central and Eastern Europe**

*Source: SOBIŃSKA K., Nasz Rynek Kapitałowy, Coraz bliżej unijnego poziomu, vol. 6, no. 174, pp. 43*

According to the CMBOR prediction, this level, however, should be outperforming in the end of 2005. Clearly, the activity growth for the M&A market is significant especially in Poland, the Czech Republic and Hungary, and could reach approximately USD 22.5 billion in the medium term, based on US levels of activity. Besides, countries like Poland and the Czech Republic are poised to enjoy further significant economic forecasts in PE investment as they will catch up with Western Europe. If, for instance, Poland reaches the levels in PE investment comparable to Italy or Spain, the value of M&A activity will double the recent level. Let's go further, if Poland achieves a PE investment matching the EU average, such activity will perhaps triple... Such optimistic forecasts can be made as the EU accession

increases opportunities for buy- as well as build-strategies. Moreover, companies and management teams have established proven track records, in which investment risk in the CEE markets is sharply going down. At the same time, opportunities to realize gains in the CEE region are developing. The amount of exits is increasing. As the M&A market grows, **trade sales** remain the dominant exit route. It should be taken into account that regulatory, logistical as well as administrative problems are solved much faster than e.g. five years ago, this contributes also to increasing the rate of realizing gains and transactions.

As far as **local strategic buyers** are concerned, they become more and more active. Due to the fact that PE exits can be strictly local affairs, which is the new way of exits opportunities in this region. Today it amounts to the highest value among all PE/VC exits. However, as far as domestic capital bases grow and the liquidity of the institutional investor base expands the **public market** begins to play the main role in exits. As it is predicted, this market can generate the highest capital from PE/VC exits.

### ***3.3 The Polish Private Equity market***

Today Poland has one of the most developed PE/VC markets in the CEE. There are 34 fund managers active on the Polish market. Most of the capital is managed by regional funds with investments involved in (almost only) large transactions.

The crucial point for the Polish PE market, as well as the ones of the other seven CEE countries, was the day of 1<sup>st</sup> May 2004. Thanks to the accession to the European Union, Polish legal and regulatory environments could be harmonised. Following this path, new established rules have improved conditions for investments as well as exits in the Polish PE market.

Everything has started to focus on the number of 19%...The overall business and investment climate has improved significantly, because of reducing the corporate income tax from 27% to 19%. The same 19% flat tax rate is also applied to personal tax of small business owners. Moreover, profits from investments are taxed with the same 19% flat rate. On the whole, this rate is used for the capital gains tax, tax from dividends and interest income.

Furthermore, all new law regulations have made the overall business environment much more attractive for foreign investors. The most meaningful changes include:

- The establishment of the one-stop-shop facility (the first professional contact point for small and medium sized businesses), which simplifies the process of setting up a company, reducing the annual number and duration of tax inspections etc.,
- The Polish government initiative to support venture capital that will be able to finance the seed and start-up companies, by offering the establishment of a government-supported investment vehicle, which is called **the National Capital Fund**. However, the initiative of setting up the NCF is still in a beginning phase.

The focus of attention on larger investments is visible throughout Europe and Poland is following this trend. Unfortunately, only large and profitable investments...The early stage transactions, which are signed by young companies, are not able to attract private equity investment because of a lack of credit liability or adequate means. A young company may have a great project to introduce a new technology in order to improve management of the enterprise, increase production, and at the same time achieve better profits. However, a bank does not have permission to finance such projects because of banking law, which guards the bank from the possible entrepreneur's insolvency. According to this statement, the bank is not able to grant a credit or bank loan, due to the high rate of risk from such a transaction. In fact, a capital gap appears on the market. In rich countries, the business angels (capital angels) are one of the best solutions for this situation. These are private investors with a large capital that can be invested directly into the company even if the project seems to be risky e.g. Bill Gates is one of the most powerful business angels. Actually, there are fewer business angels in Poland and that is the reason why VC funds are much more popular from placing capital. Nevertheless, Polish VC funds invest only in operations over EUR 10 million. Obviously, young enterprises do not have any possibility to develop and become competitive on the Polish market.

Due to this reason, the government wants to establish a fund of funds, called the National Capital Fund (NCF). The works on setting up the NCF are just in the beginning phase. Recently, the government is putting forward a bill to enact the NCF. A mission of the Polish fund of funds is to improve the situation and image of small- and middle-sized enterprises (S&M). Today, approximately 3.5 million S&M Polish firms have been established, half of them are very active on the market, and generate 49% of the GDP. Moreover, these enterprises employ 67% of all people in working age. However, according to the Lisbon strategy this situation must be improved and incentives should be made for S&M companies to generate a higher rate of

return as well as invest into know-how and some innovating financial or technical solutions. As some of analytical experts have estimated, the preparation of an investment of PLN 1 million requires the same costs as the preparation of a project worth PLN 9 or even PLN 10 million. Consequently, VC funds are more interested in financing bigger enterprises. [The Act dated on 4th March 2005 about the National Capital Fund, which is available on: [http://ks.sejm.gov.pl/prock/ustawy/3226\\_u.htm](http://ks.sejm.gov.pl/prock/ustawy/3226_u.htm)]

According to the bill about the NCF, the NCF is to be set up by the Bank Gospodarstwa Krajowego, which is the main shareholder and operates in agreement with commercial law. The authorized share capital of this fund is set on the level of PLN 20 million. The role of an advisory board will be held by the Investment Committee. The NCF is going to secure VC funds by putting a project out to tender. As it is assumed in the bill, the country's budget as well as structural funds will be the main sources of supporting the NCF. However, contributions from the budget are going to include only the period from 2005 to 2008. In 2005, the Polish government has invested PLN 23.300 million into establishing this fund of funds. Till the end of 2008 the NCF should accumulate a total amount of PLN 450 million. This will be PLN 370 million from the budget and PLN 80 million from the structural funds.

However, many economists are against the fact that the budget will be giving subsidies only till the end of 2008. They argue that the accelerated sum of capital is not enough to make this fund profitable. On the other hand, opponents of this view are convinced that the NCF should generate PLN 2.400 billion from investments into S&M enterprises to the end of 2013. Moreover, they add that all simulations as well as economical forecasts have been carried out using the most pessimistic calculations. They have also calculated that one zloty from the budget gives 28.50 zloty of return. In fact, this is a very high as well as profitable financial leverage. Following this path, thanks to the NCF and new investments the amount of new workplaces should fluctuate from 18.000 to 50.000.

All small- and medium-sized enterprises, which are situated in Poland and settle their incomes no matter where they were acquired, may receive aid from the NCF. However, firms, which intend to invest into new solutions, technologies, and then implement them, have the biggest possibility to use the NCF.

Fund-raising activity in Poland is still being maintained at a high level. Total funds raised reached the amount of EUR 303.88 million in 2004, compared to EUR 25.74 million in the previous year. This situation resulted from investments made by both Polish- and foreign-based private equity investors.

Polish-based private equity firms invested EUR 130 million in 2004, which is 2,4% less than in 2003 (EUR 133,2 million). Foreign-based private equity investors located EUR 48.27 million in 2004. The average value of transactions was on the level of EUR 3 million in 2004, in relation to EUR 2.1 million in 2003.

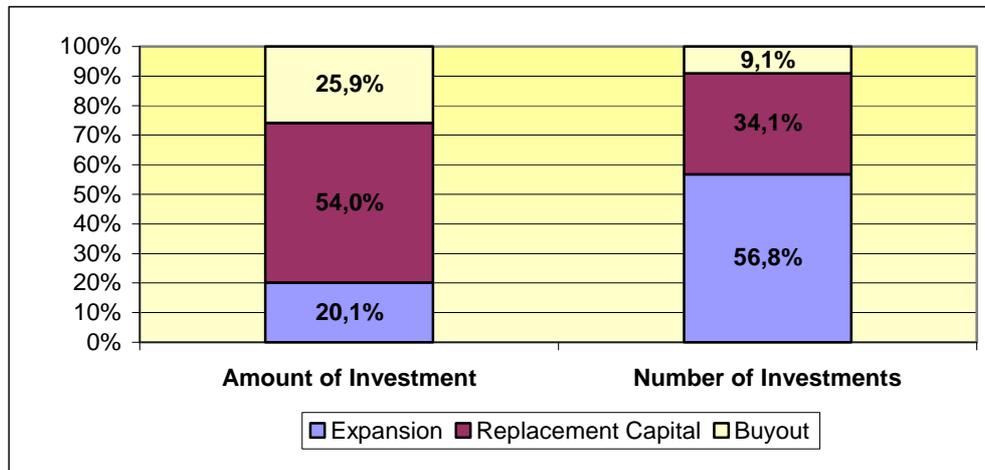

Initial investments generated EUR 93.8 million in 2004, which was 72.1% of the total investment amount (that was EUR130.03 million), compared to EUR 122.4 million (91.9%) in 2003. [*Krajowy Fundusz Kapitałowy – jako uzupełnienie systemu wspierania rozwoju sektora MSP*, Published by Ministry of Economic Affairs and Labour, <http://www.nsrr.gov.pl>]

The largest volume of investment in Poland was made in the later stages of their development. According to this statement, buy-out and replacement capital transactions generated the greatest amount of capital. These later stage investments increased in total investments and achieved 79.9% in 2004, compared to 68% in 2003. There was a decline in seed and start-up investments, and in the end of 2004 there were no VC shares in this area. In fact there were two results of this situation:

- The lack of seed transactions assigned to the limited number of funds, which were focused on this segment;
- The limited supply of seed capital investment opportunities.

However, this situation may change, because of the setting up of the National Capital Fund (NCF), which will perhaps reduce this equity gap.

**Figure 5 Stage distribution of investments in Poland in 2004**

Source: EVCA, Yearbook 2005, pp.2004

In 2004, the most popular group that invested in PE were pension funds. These funds generated EUR 159.24 million in 2004, which was the first year of making profits by these entities. The second position was taken by banks, which invested an amount of EUR 109,49 million in 2004, up by 1262% compared to 2003 (EUR 8.04 million). Next position was dominated by insurance companies, which invested 9.5% (EUR 28.47million) of total investments by amount in PE in 2004.

As far as the patterns of sectoral investment is concerned, the Polish-based PE fund managers invested approximately EUR 43.96 million in 2004, which was 11.2% more than in 2003 (EUR 39.51 million). Another attractive investment sector in 2004 was the construction branch, at EUR 22.73 million, in relation to EUR 1.99 million in 2003. In fact, the amount of investment in this sector was 11.4 times more than in 2003. The third position in the sectoral distribution of investments was taken by financial services with an amount of EUR 21.56 million in 2004, compared to EUR 31.53 million in the previous year. The high-tech sector attracted 33.8% of total investment in 2004, which was 9.4% more than in the previous year.

**Table 4 Sectoral distribution of investments in year**

<b>Sectors</b>	<b>Amount of Investment in 2003 (EUR million)</b>	<b>%</b>	<b>Amount of Investment in 2004 (EUR million)</b>	<b>%</b>

*Source: International Investment Position – annual data, the National Bank of Poland, Warsaw 2005, <http://www.nbp.pl>*

The subject of exiting from business should also be mentioned. There is a decreasing tendency of divestment in Poland. The amount of total divestment reached the value of EUR 88.69 million in 2004, which was approximately 23% less than in 2003, when divestment amounted to EUR 115.16 million. The most popular form of divestment in 2004 was trade sale, which accounted for 30.8% of the total divestments. Divestment through buy-back reached EUR 8.7 million (9.9%) in 2004. The level of write-offs went up by 21%, from EUR 14.12 million to EUR 17.10 million in 2004. The role of public equity market has also increased significantly. Actually, exit through IPO (Initial Public Offering) is the new idea on the Polish private equity market. As a consequence, the role of the Warsaw Stock Exchange for local IPOs is increasing. Moreover, due to a steady inflow of foreign capital, the liquidity of the Warsaw Stock Exchange can be strengthened. Considering the number of IPOs, the Warsaw Stock Exchange was ranked on the second position in Europe, after the London Stock Exchange.

Overall, the markets of many sectors in Poland are fragmented. It may be predicted that as their structure is currently different to the one of the old EU countries, in the future strong consolidation trends may be observed (after taking the local development conditions into consideration). Due to these trends, the Polish market may be able to catch up with the old EU countries. Even now, the beginning of the foreseen consolidation trend is visible in the CEE countries.

### ***3.4 Some aspects of the Czech Republic private equity market***

Due to the fact, the Czech Republic joined the European Union on 1 May 2004, the new Act on Collective Investment has been signed on this date. The new Act has regulated the activities of VC funds in the Czech Republic. According to this Act, VC funds are represented by special funds, which may be set up as closed- (open-) end unit funds or closed-end investment funds.

An open-end fund is a fund, which is operated by an investment company. Such a company raises money from shareholders and invests in a group of assets, in accordance with a stated set of objectives. Open-end funds raise money by selling shares of the fund to the public. Then the funds take the money they receive from the sale of their shares (along with any money made from previous investments) and use it to purchase various investment vehicles, such as stocks, bonds and money market instruments. In return for the money, they give to the fund (during purchasing shares), shareholders receive an equity position in the fund and, in effect, in each of its underlying securities. For most open-end funds, shareholders are free to sell their shares

at any time, although the price of a share in an open-end fund will fluctuate daily. This depends on the performance of the securities held by the fund. Benefits of open-end funds include diversification and professional money management. Open-end funds offer choice, liquidity, and convenience, but charge fees and often require a minimum investment

Closed-end funds generally do not continuously offer their shares for sale. Funds sell a fixed number of shares at one time (in the initial public offering), after which the shares typically trade on a secondary market. Actually, funds are not obligated to issue new shares or redeem outstanding shares as open-end funds are. The price of closed-end fund shares is determined by the market and may be greater or less than the shares' net asset value (NAV). Moreover, close-end funds are those whose portfolios are still owned by earlier investors and are still actively managed as always, but they no longer sell shares at NAV rates to new investors.

A difference between an investment fund and unit funds, is that the first manages its own assets, while the unit funds assets are managed by a separate Czech management company or by a management company with a European Union passport.

The Act on Collective Investment has assumed that the minimum share value of a VC fund should be CZK 1 million at the issue date as well as the minimum investment of the entity should amount CZK 2 million. . [The American Chamber of Commerce in the Czech Republic, the Czech Republic Report 2005, pp.5-8, <http://www.amcham.cz>]

Dividends, profit distribution, the sale of funds' share in companies or liquidation of companies are the parts, from which VC funds realize their income. It is an interesting fact, that Czech VC funds are not visibly used in fiscal policy. For instance, revenues achieved by funds are subject to tax at the level of the fund, (not the level of revenue). Furthermore, dividend income from a Czech company is excluded from the tax base of funds. Additionally, there is no separate capital gains tax in the Czech Republic. In fact, the capital gains from the sale of shares are subject to 5% tax rate, which is the standard corporate tax rate for funds.

Due to these mentioned legal and fiscal facilities, the Czech Republic is one of the most attractive and active PE markets in the CEE region. However much must be still done to develop this emerging market. There was a significant decline of total fund raised in 2004. The total funds raised amounted to EUR 4.84 million in 2004, which was 19.4 times less than in the previous year. Investment made by Czech PE/VC companies went up by 51% from EUR 13.3 million in 2003 to EUR 20.1 million in 2004, while the number of investments dropped from 13 to 10 in the same period. At the

same time the number of firms investing in PE/VC funds decreased by 20%, which was from 10 to 8.

**Table 5 Sectoral Distribution of Investments in year**

Sectors	Amount of Investment	%	Amount of Investment	%
	2003		2004	
Communications	5,63	42,2	12,84	63,8
Biotechnology	0,62	4,6	0	0
Consumer Related	6,5	48,7	7,27	36,2
Financial Services	0,59	4,5	0	0
<b>Total Investment</b>	<b>13,34</b>	<b>100</b>	<b>20,11</b>	<b>100</b>
<b>Subtotal High-Tech</b>	<b>6,24</b>	<b>46,8</b>	<b>12,84</b>	<b>63,8</b>

*Source: EVCA, Yearbook 2004*

As table 5 presents, communication and consumer related companies were ranked as the best position in all sectors. The situation in biotechnology as well as financial services also seems to be interesting. Almost 4.6% of all investment went into biotechnology companies in 2003, while there were no investments in this area in 2004. A similar situation occurred in financial services, which generated 4.5% of total investment in 2003, and 0% in the next year.

#### **4. Conclusion**

Due to deep and dynamic structural changes, CEE has become an attractive place for PE/VC investments. This refers mainly to countries, which have recently entered the EU. Despite a certain level of risk, PE investments in CEE have a great chance to give better results than investments in the old EU. The possibility to utilize means from structural funds opens an enormous chance for development for these countries. The question is, whether they will be able to effectively use this help.

The data presented in the study allows to come to some basic conclusions concerning the future development of PE/VC funds in CEE:

- The increase in the number of CEE managers with international experience, which positively influences the demand factors of VC funds;
- The higher experience in running privatized and new companies during the last 10 years;
- The development in the field of investment risk management, which has an impact on the ability of effectively locating capital;

- The prediction of the future increase of the PE/VC market in Hungary and Poland.
- The outlook for the increase of the M&A market

During the recent years, several CEE countries noted a considerable rise of their GDP. The prospect of a GDP increase makes the country more attractive for investors. It was particularly high in Poland, 4.7% in 2003 and 5.8% in 2004. The EU membership may bring a further increase of this indicator. Investors are also drawn due to the prospect of acquiring cheap and increasingly better educated labor force, not only to Poland, but to the whole CEE region.

The bill about enacting the NCF in Poland seems to be a very interesting idea to not only multiply the value of VC funds, but also to develop the investments in small and medium-sized companies. The fund will be aided by structural funds as well as the country's budget.

Currently there is a trend in the CEE countries that favors the rise of PE/VC funds. In spite of this fact, many questions about PE stay unanswered. The most important seem to be: How long will this tendency be maintained in the CEE countries? Can the statement wrote by W. Shakespeare "Men that hazard all, do it in hope of fair advantages." be true?

## **Abstract**

*The paper presents the pace of venture capital market development and barriers for its further growth. Venture capital funds exhibit much higher dynamics in Poland than in other CEE countries. However, when venture capital investments are expressed as the GDP percentage, Poland is still lagging behind other European countries. The main impediments for venture capital market development are: low quality of management, low innovativeness of Polish economy, administrative and legal barriers, taxation of capital gains, supply barriers and no support from the government.*

**Keywords:** *venture capital, venture capital market in Poland, development financing*

## **1. Introduction**

Choosing the financing sources always gives rise to the enterprise's problems and is dependent on many factors, like - among other things – a type of goals to be achieved (operational, investment ones), the enterprise development level, its financial status, capital costs. Big enterprises have more freedom in choosing their financing sources and are able to issue stocks and bonds, to use credits, loans or leasing. For small companies only starting their operation, getting the capital is not easy. The capital suppliers are not convinced by a good business philosophy and growth prospects. Such companies burdened with a greater risk have no credit reliability; thus, the banks either are not eager to credit them or the credit offered is expensive and substantial securities are required. Furthermore, the current service of credits within the initial period of the company operation may be difficult. A good financing source for such companies can be the venture capital fund.

Such funds have a long standing history in the United States and in the developed EU countries. In Poland, the funds appeared after 1990 only. Although the development level is higher than in other Central and Eastern Europe countries, they still face various barriers to their growth.

The paper shows the rate of and the barriers to the growth of venture capital funds in Poland.

## **2. Venture Capital nature and features.**

Venture Capital is invested in the companies at the early stage of their growth or just starting their market operations.

J. Węclawski (1997) describes VC as the own capital to be - for a limited duration – contributed by outside investors to small and medium-size enterprises having an innovative product, manufacturing method or service, such companies not having yet been verified by the market and thus bearing risk of the investment failure. The high risk is in contrast to the expected higher than average profits to be gained by selling the company shares.

The investments described as VC are for the companies just being set up or at the early stage of their growth, very innovative ones, but risky, which - with the manager and capital support – promise a high return rate on the invested capital (Schofer, Leitinger 2002).

VC is one of private equity investments, i.e. a medium- or long-term investment, based on shares, usually on a non-public market. The above definitions are in compliance with the American Venture Capital standard

suggested by the National Venture Capital Association (NVCA) wherein VC function is to finance the early stages of enterprise operation and growth, and the funds called Venture Capital are involved in the business concepts being commercialized and in supporting the growth of new companies, specially in the highly innovative areas (Sobańska, Sieradzan 2004) .

In Europe, there is no clear differentiation between the Venture Capital and the Private Equity financing. By the definition of the European Private Equity and Venture Capital Association (EVCA) it is assumed that VC funds are to supply the start-up capital to start business operation, to finance the early stage of enterprise development, its further expansion, or even to finance the projects related to the enterprise restructuring or ownership transformations. This might include financing a new product, technology, working capital increase or labour reduction (EVCA 1995). Actually, the funds are sometimes involved in financing the mature enterprises too. In the statistics, VC/PE funds are presented together.

In order to understand better the nature of VC, the characteristic features of such investment process are worth showing. These include:

- investment risk high
- medium– and long-term investments, 3-7 years
- funded project highly innovative
- return rate on the investment expected 36-60 per cent
- investments in companies with big growth potential, non-listed on the stock-exchange
- investor (VC fund) being a participant in the company management, not only the capital supplier
- capital contributed being of proprietary nature
- current capital costs non-existing, the funds waiving their dividends and re-investing the profits.

VC are being directed mainly to companies with a chance for higher than average growth and a dynamics increase in their value. Frequently, these are high-tech companies initiating new solutions in various areas of industry and economy, but also companies which are not related to the area but have an innovative solution, product or service. Such companies are flexible enough to be able to implement even the most unconventional projects in an effective way. VC funds support such companies in the management, supply financial, organization or marketing know-hows. VC have wide contacts with business and with financial institutions, they know consulting companies and lawyers, and thus are able to provide full assistance and to add to the company's reliability. Moreover, they are monitoring the company operation

financially, which enables to identify the problems just in time and to look for their solutions together.

### **3. Venture capital market in Poland.**

Venture capital funds appeared after 1990. The Polish economy opening and the system transformations resulted in the inflow of both the government capitals and aid capitals from other countries.

According to the history of their growth and to the ways the VC funds are set up, three main market segments can be singled out (Tamowicz 2001):

- 1) funds based on the aid institutions' capitals or on the government resources (foreign ones mainly);
- 2) funds based on the domestic and international private institutions' capitals:
  - a) funds set up by the banks
  - b) funds based on the general privatization program
  - c) funds continuing the ones operating since 1994 – Enterprise Investors Group, Renaissance Capital, Innovo,
  - d) funds arisen in the wake of interest in Internet: MCI Management, Internet Investment Fund
- 3) transregional funds investing all over Eastern Europe, Poland included.

In VC market arising and growth in Poland, the key part was played by foreign resources, both public and private ones. Due to them, many investments have been implemented, both on local and on national level.

VC and Private Equity sector in Poland and in the neighbor countries (Czech Republic, Slovakia, Hungary and Baltic countries) is now growing very fast. According to EVCA estimation, within the period of 1990-2004 there was an inflow of nearly 7 billion Euro to the countries of Central and Eastern Europe, and over 60 equity type funds have been set up, while out of the 900 investments funded over 400 have been completed (EVCA 2002).

In 2004, the said funds' investments in Poland reached 9000 million PLN which is 15 per cent more than in the preceding year. As shown by Table 1, in 2001 the investments amounted to 386 million PLN (105 million EUR).

**Table 1. Amount of VC/PE investments in Poland within 2001 – 2004.**

Specification	2000	2001	2002	2003
Investment volume, million PLN	386	529	779	900
million EUR	105	137	177	213
Dynamics, per cent	100,0	130,4	201,8	233,2

Source: EFCA & Polish Association of Foreign Investors, Yearbooks 2004, p.24

Within the subsequent years, the commitment of funds in the Polish economy was quite strong. In 2003, there was a growth in the funds' investments by 47,2 per cent as compared to the preceding year, while in 2004 the increase was over 15 per cent as compared to 2003.

As compared to other East European countries, the VC market in Poland is best developed. The capital inflow to this market is higher than to other EU regions. It is illustrated by Table 2.

**Table 2. VC/PE investments in the Central and Eastern Europe countries within 2002 – 2003 (million EUR)**

Countries	2002	2003
Czech Republik	27,4	39,4
Hungary	75,7	110,8
Poland	137,2	177,2
Roumania	18,0	82,0
Slovakia	4,7	4,5
Baltic countries	2,9	10,0
Other countries*	7,7	24,6
Whole region	273,7	478,4

\* Bulgaria, Croatia, Slovenia

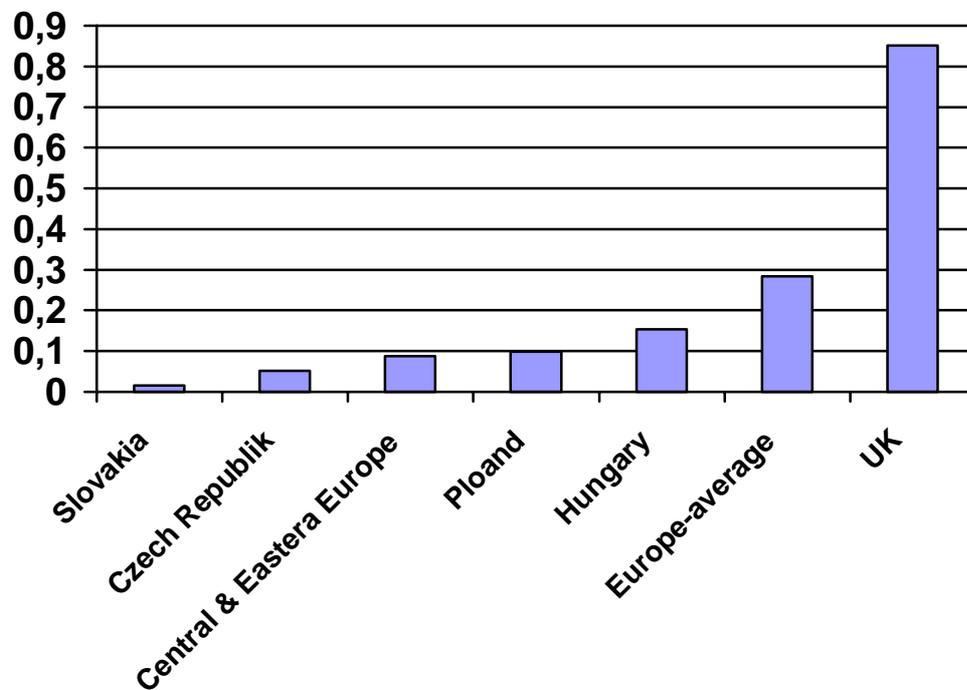

Sources: EVCA Special Paper 2004, Central and Eastern Europe Success Stories, [www.evca.com](http://www.evca.com), p.7

The total volume of investments was in 2003 increased by 75 per cent as compared to the preceding year. The biggest – by as much as 4.5 times – increase was in Romania. The highest value of investments was in Poland. However, the comparison of amounts of funds made use of is not a complete illustration of their commitment in the economy. They have to be referred either to GNP or per capita. (Graph 1).

In Poland, the correlation of venture capital funds to GNP is much lower than the European average, but higher than in other Central and Eastern Europe countries which followed the transformation path similar to Polish economy. The higher ratio is in Hungary. It is emphasized by the

bibliography that the direct reasons for this are a lack of legal solutions suited to the specifics of high risk investments, the complex administration procedures, as well as tax incentives missing.

**Graph 1. PE/VC investments referred to GNP in the selected European countries, in 2003.**

*Source: EVCA Special Paper 2004, Central and Eastern Europe Stories. [www.evca.com](http://www.evca.com)*

One reason seems to be the specifics of projects to be funded. In Poland, the VC/PE investments are in privatization, in restructuring and in reform projects, and only next in the most up-to-date projects in the area of telecommunication or internet. In the developed countries, the VC/PE funds are oriented on new technological and biotechnological solutions at the early project stages.

#### **4. Company financing stages.**

The bibliography differentiates between several stages of company financing, depending on the company development level. Most often, they are:

- Seed capital.
- Start-up capital.
- Development stage, initial growth.
- Expansion stage.
- other VC investments.

Seed capital are the resources needed to finance the very early development stage of a new project. Frequently it happens that scientists or technologists with a good idea of an innovative product or service are unable to get funds from conventional financial institutions because of a high risk related to such project. However, such risk is acceptable for specialized investors who manage a Venture Capital. Such investors' operations are described as "incubation", i.e. reducing the time needed for the product to enter the market. A Venture Capital is a supplier of resources for the activities prior to set up the company, i.e. to study the market potential, the legal solutions and restrictions, the competition level in the relevant area, acquisition of patents, licenses, etc. Within this stage, a probability is determined of the specific business to be accepted by the market, while the resources spent are reasonable.

The start-up capital is used to break the barriers faced by the company when entering the market. Within this stage, the expenses are related to a test batch of goods and services being prepared, to the trade mark recognisability being created. Venture Capital makes the resources needed at this stage available only when the project is attractive and high rate of return from the invested capital can be anticipated. The investor is striving to participate in the management so that his risk is limited.

Within the Company development stage, the VC funds enable it to create a solid basis for expansion or to get the market share as big as possible, to diversify its production pattern, to get contracting parties, to strengthen the managing staff. It is all very capital consuming. The staff tries to get VC funds even on the expense of losing some of their shares to the benefit of such funds. Using credits within this stage could result in the loss of financial liquidity.

Within the expansion stage, companies search for VC capital to fund their key action for further development. Included in such actions are (Sobańska, Sieradzan 2004):

- to outdistance the competition, and to maintain the position of market leader or one of the leaders in the relevant line.
- to extend the range of products or services offered, as well as the distribution network and the geographically new sales markets,
- to strengthen the managing staff, to create a solid executive level and to delegate specific functions to them
- to raise efficiency of the company employers through a proper motivating system.

It has to be emphasized that within the expansion stage VC funds are obtained by such companies which either are profitable or reach the break-even point, while their main goal is to outrun the competition.

VC funds are involved also in other investment types. Usually, these are, projects related to ownership and organization restructuring of the companies, etc.; and particularly:

- Management Buy-Out
- Management Buy-In, MBI
- bridge financing
- restructuring of enterprises facing financial problems (turnaround, recovery)
- Venture Management
- enterprise financing by means of hybrid securities, mezzanine capital.

The structure of company financing, by VC/PE funds at various stages is illustrated by Table 3.

**Table 3. Value of investments at various stages of the company development in Poland, within 2003-2004, millions PLN.**

Company development stages	2002	2003
Seed capital	38	1,0
Start-up	38	12,0
Dynamic development	244	176
Refinancing (Buy-out)	209	590
Total:	529	779

*Source: based on the Yearbooks of Polish Association of Capital Investors, 2003 & 2004.*

In 2003, the highest percentage of funds (46%) was committed in the companies at their dynamic growth stage, and in the mature companies

(nearly 40%). The widest interest of the funds in 2003 was in the mature companies needing capitals for their further market expansion. 76 per cent of the total resources were spent for such companies, while 23 per cent for the companies at the stage of their dynamic growth. By such way of financing, the risk is reduced with the rate of return being relatively high and the resources being recovered sooner. The share of VC/PE funds in financing companies at their initial growth stage fell from 38 down to 1,0 million PLN, while for the ones at their start-up stage from 38 down 12 million PLN. It shows an obvious drop of interest in the young companies to the benefit of fund investments in mature companies. According to A. Kornasiewicz (2004), there are several reasons for such trend:

- VC funds, specially the big foreign ones, are involved in the process of enterprise privatizations and restructuring, where great chances of fast and higher profits are existing, with the risk being lower,
- at the big, well-known and successfully restructured companies, the disinvestment process is more efficient than with small companies of no renown and with chances to establish their market position after years only.
- low qualifications of the management staff at small companies, their mistrust towards outside investors and reluctance to share their profit do not add to the aura which would foster popularization of VC funds at such group of enterprises.

VC type financing is of strategic importance at the initial stages, when a company is starting to grow, when capital and manager's support are needed. Later on, it is easier to get financing from the conventional financing institutions, i.e. banks.

## **5. Barriers to the Venture Capital development in Poland.**

Despite the relatively high increase in VC/PE funds investments as discussed earlier, many barriers restraining their development can be identified in the Polish economy. The factors directly affecting the Venture Capital market growth in Poland and restraining it are mostly considered to be institutional, supply, legal and tax factors, as well as the ones related to the investing aura. The Funds' top managers, when asked about the barriers, most often state the following impediments:

- poor quality of the manager staff
- low innovativeness of the Polish economy
- separate legal regulations on high risk funds missing
- legal and administration barriers
- tax system solutions

- supply limitations
- poor support from the national authorities.

Apart from the above restraints, what the funds miss on the Polish market is an aura fostering VC funds popularization; what they are hindered with is a poor information and difficult access to technical solutions which might be interesting for VC fund, as well as the problems with backing out of the investments.

The main barrier to the growth of the Venture Capital market in Poland is the poor quality of the manager staff at the enterprises looking for financial support. The entrepreneurs willing to make use of new technical solutions commercially are usually not prepared to get the resources from Venture Capital Funds. Frequently, they do not understand the principles being the basis of the funds' operations; only rarely they have experience in operating their business in the way which would be expected by the funds. After a certain stage of the company growth is reached, ownership should be separated from management; the company owner having to search for a professional manager. Such manager will be more than the owner himself eager to finance by means of a share capital; he would understand that the funds expect a particular return rate on the capital and are willing to supervise its getting.

Another barrier restraining the growth of Venture Capital funds is low innovativeness of the Polish economy. Usually, VC funds are involved in the initial stages of the enterprise development – in creating its project, solid operation basis, gaining the market position. Thus, the investors search for innovative companies wherein the risk will be compensated by the return rate being high enough. In Poland, the main problem is that there is no supply of such projects, the expenditures on research and development which would result in such project arising being too low. Thus, the country innovativeness and economic competitiveness are adversely affected. In Poland, the expenditures on R&D are as low as less than 1 per cent (0.7) of GNP, while in OECD countries the average accounts for 2.3 per cent. Higher expenditures for research and development are in Czech Republic (1.3%) and in Hungary (1.0%).

The developed countries assign relatively much for R&D; thus, in reference to GNP it is: 4.3% in Sweden, 3.4% in Finland, 3.1% in Japan, 3.0% in South Korea. The biggest amounts to this purpose are assigned in the United States; in 2002, 285 billion US \$ were spent (2.8%GNP); and in Japan – 104 billion US \$ (OECD 2003).

The structure of expenditures on research and development works in Poland is very unfortunate. The majority, ca two thirds, are the expenditures

from the national budget, while in the developed countries a big percentage of funds is from the enterprises (e.g. 90% in Luxembourg, 70% in Sweden, c. 65% in Ireland, Germany, Belgium and the USA). Due to such structure of R&D financing, what is prevailing in Poland is basic research, not related to enterprises and not usable practically. Even such projects which would be possible to be introduced are not initiated in practice, because of the managing persons' marked reluctance to any risk. In the developed countries, the research and development projects financially supported by the companies are better suited to their needs, and they are sooner introduced at the enterprises raising their competitiveness. It is noteworthy that a substantial portion of scientific and research organizations is owned by the State.

In Poland, we have no separate legal regulations on high risk funds, which would contain stipulations on – among other things – the conditions to set up various types of PE/VC funds, the requirements on the structure of their share portfolio, or on the criteria of access to the public resources. Such solutions appear worldwide, their goal being a better transparency and security of the fund operations (Rogoziński 2003).

Along with the financial market growth, the situation in this area is changing too. In 2004, the new law on investment funds has come into force (Journal of Laws of 2004) ; however, it provides no solution for the problems of high risk subject functioning. Now types are introduced, like the non-public capital fund and the fund of funds (FoF). FoF's are a popular form of investing resources in the West Europe countries. Their difference from the ordinary funds is that the main portion of their portfolio are not shares, bonds or bills, but participation units of other funds. The Private Equity fund of funds collects capital from the investors and is then investing it in the private equity funds of choice. Due to this, a client – despite of having purchased a single fund only – becomes a shareholder of many, thus limiting his risk. Most often, the FoF portfolio is composed of 10-20 PE funds. When any of them cease to operate, the resources got from the portfolio of companies being disposed are transferred by them to the fund of funds, which returns them to its investors.

The inhibitor to the growth of the Venture Capital market in Poland are considered to be the existing legal solutions. They incorporate the regulations of the commercial partnership code, of the bankruptcy law and of the civil code. Among other items, the regulations are on the limitations in granting the shareholders rights in connection with the preference shares, share redemptions on request, raising target capital, or regulations of the stockholders' share in the event a company is liquidated. The limitations on the preference shares prevent the share preference construction which would

entitle the holder to get a specific amount of dividend to the company status notwithstanding, which is frequently done by private equity funds abroad. An important limitation of leverage (debt supported) transactions are the regulations of commercial partnerships code barring the stock companies from financing acquisition or from assuming the stock issued by them (Sieradzan 2004).

An indispensable condition to be met in order that funds are willing to be committed in the investments on VC market is the law enforceability, specially the enforceability of ownership titles or debtor's claims. Now in Poland, the time needed to recover the receivables is c. 1000 days which is the lengthiest in Europe. Quite often, an outcome of ambiguous, hardly enforceable legal solutions are the administration barriers from the conduct of administration workers who delay the administrative decisions.

Legal restraints to VC/PE fund operations in Poland are closely related to the tax barriers. A lack of incentives and the current fiscal solutions are the reason that some funds operating in Poland are registered abroad. This is due to a lack of explicit regulations making possible that the income is taxable only once. When this would be the case, a private equity fund would be exempt of income tax, taxation taking place at the investors. This is the case with investment funds, but only with those buying into securities in public circulation and getting their resources from individual investors. Because of strict information duties and of the supervision by Securities & Exchange Commission, such solution is unacceptable by the VC/PE funds.

The funds expect such legal solutions with tax exemptions and write offs or high risk investments taken into account in order to avoid dual taxation. Privileges might be enjoyed both by the fund itself as well as by the investors depositing their assets therein.

One important limitation of the growth of VC/PE funds market are the supply limitations. Worldwide, the Venture Capital funds are a significant part of the asset portfolio of many investors. Those are pension funds, investment funds, banks, financial institutions. In Poland, capital supplies from the pension and the investment funds are actually nonexistent. The major portion of domestic capital is from banks and financial institutions, as well as from manufacturing companies. It has to be noted here that the domestic capital accounts for as little as 3 per cent only of the Venture Capital funds' resources.

The bibliography shows three groups of reasons restraining the share of the Open Pension Funds (OPF) in the high risk capital, and namely:

- investment quotas,
- - reference index,

- information policy – track record.

The range of allowable OPE deposits is strictly regulated by Polish law, and it is very different as compared to the way such funds are functioning on the European or American market. Pension funds can deposit their assets only in the stock partnership stocks in public circulation, in the National Investment Funds' (NIF) stocks, in participation certificates and in the investment certificates of investment funds. There are, however, some restrictions. Thus, for example, they can possess in their portfolios 40% max of stock-exchange listed stocks and NIF shares, 40% max of municipal bonds not in public circulation, 10% max of deposit receipts or investment certificates. Such restrictions do not allow any meaningful involvement of pension funds in the private equity market.

An important factor discouraging the pension funds from investing on the private equity market is the measuring method of their investment results and the mechanics of the bonus for results. Such techniques enable to compare and – to some extent – to control the results of various OPF's. The techniques accentuate good results to be achieved within a short time. Thus, the managers tend to avoid the risky – but in long-term more effective – investments, the ones related to Venture Capital included.

Till 1<sup>st</sup> April 2004, the funds were obliged to calculate the return rate for the last 24 months by the end of each quarter and to report it to the Supervision Committee for Insurance and Pension Funds, as well as to make it public. Now, the benchmark of pension funds is the 36-month weighted average return rate to be calculated twice per year. The rate is an average rate of return achieved by various funds, a weighted arithmetic mean of the given fund share in the market as of the day preceding the 36-month period and as of the day the said period is ended. The focus on good results to be achieved within short period is enhanced also by the method of rewarding for the results. The managers are given resources from the bonus account as of the moment the ranking prepared according to the return rate is constructed. Hence, they are not motivated to diversify the risk. They are rather interested in presenting good results as of the moment the examination is made.

The growth of Polish private equity market is also obstructed by the information policy of many funds. The managing companies are quite reluctant to show their results achieved. They do not make available at all any information on their investments, even the ones successfully completed. By the lack of information, the potential capital suppliers are deterred. The potential investors would like to be sure their resources entrusted to the managers will generate a return rate higher than average. Confidence can be gained provided the information is complete.

Supply restraints as a barrier to the Venture Capital market growth are also related to poor commitment of banks. In the countries with a developed equity market, the important capital suppliers for VC/PE funds are – apart from the pension and the investment funds – the banks. In Poland, their share of the market is marginal. There are many reasons for it. Nearly all banks in Poland are listed on the stock-exchange, which means a pressure on short-term results. On the other hand, commitment in VC/PE funds means that in short-term there is a drop in the investment portfolio value, by which the bank's result is directly affected.

In Poland, restricted supplies of the high risk capital is best perceivable at the sector of small and medium-size enterprises, where the venture capital is to finance the “sowing” and the start-up phases mainly. The high risk of committing the resources into such phases results in the funds being involved in the initial phases of the companies' growth to small extent only. The source of insufficient financing of small subjects by the high risk capital is the limited role of the State in supporting such funds.

In the developed countries, the tremendous role of VC/PE sector as a driving force of the economic growth, of raising the innovativeness level and of export stimulation had been understood long ago; also, the venture capital funds are an important instrument for old enterprises restructuring. Therefore, the growth of VC/PE market in those countries was stimulated by the legal, the tax and the promotion solutions. In Poland, due to the existing barriers to the Venture Capital market growth, active involvement of the State is absolutely needed as well as, support of such growth through due initiatives by the Government.

In conclusion, it has to be emphasized that within the recent years the growth of VC/PE investments is fairly strong as measured both in the absolute values and in reference to GNP. However, the gap between the equity funds market in Poland and in the developed countries still remains wide. This is for various reasons. The most important one seems to be the low innovativeness and competitiveness of Polish economy against the Western countries, the managing staff not being prepared as appropriate, and a lack of special regulations on the equity market operation in Poland. Many barriers inhibiting the enterprise growth are still existing (red tape, corruption, instability of the law, etc.). There are no motivation systems, no relieves or preferences which would encourage a risk of having an own company.

However, along with the economic growth, the barriers will be removed and they will less and less concern the investors on VC/PE market.

## **Abstract**

*The development of SMEs is essential for the future of Romania despite the background of economic, social and political changes. This sector is needed to ensure continued economic growth and thereby to enable economic development, employment and improvement of living standards. Romania has made considerable progress over the past decade in setting up an extensive policy framework to support the SME sector. A range of institutions, policy instruments, regional tools and resources exist, all of these assisting Romanian SME development. In fact, Romania is involved in discussions concerning fundamental problems and coherent strategies, emphasizing the support that European Union gives to Romanian SMEs, but also the self-efforts that have to be done. One of the main problem for Romania is the foundation of entrepreneurial abilities specialized on SME sector definitely, measured by the growth in input ratios and output ratios of firms on the market. But these rates should face the birocracy and the conservativeness which can be associated with a state of inadaptability. The most important accomplishments are in the legislative domain, and the hardest problem remains the problem of enterprising, financing, fiscality and training population in order to do small business.*

# 1. Revitalization of SME Sector after 1990 in Romania

## 1.1. Macroeconomic trends

Romania's transition, starting in 1990, was in many respects more difficult than in the other countries of Central and Eastern Europe. This was partly because by the late 1980s, the country's economy was on the verge of collapse after 40 years of rigid central planning that emphasized self reliance, an excessive focus on heavy industry and large, uneconomic infrastructure projects. Over the past ten years, the Romanian economy has been characterized by a series of stop-and-go reform attempts that have resulted in a highly cyclical growth pattern. Like most transition countries, Romania experienced a sharp recession during the early 1990s, followed by a period of steady growth and declining inflation from 1993 to 1996. Against all expectations, the Romanian authorities averted a liquidity crisis in mid-1999 and adopted a new set of economic policy measures to stabilize the economy as part of a three-year, Stand-by Loan Arrangement (SBA) with the IMF.

After three years of negative growth and rising unemployment, the policy corrections resulted in GDP growth of 1.6% in 2000 (Figure-1). The recovery was led by high industrial output growth (up 8.7% in 2000 compared to 1999) and exports, stimulated by a large devaluation of the ROL. GDP growth accelerated in 2001 (to 5.3%), thanks to a rebound in domestic demand. Real GDP growth slowed to 3.5% in 2002 from an estimated 5.3% in 2001, as a result of a more severe global slowdown post-September 11th and a domestic policy correction.

**Figure 1. GDP Growth (percent)**

*Source: National bank of Romania, Yearly Report 2003*

In an attempt to minimize the social costs of transition the Romanian government initially hesitated to impose tight fiscal constraints and privatize

large loss-making enterprises. In the late 1990s, attempts to impose macroeconomic stability without full structural support led to negative economic growth, and poverty increased sharply, doubling from 20 percent in 1996 to 41 percent in 1999.

Since 2000, the Government has implemented macroeconomic policies which are supportive of growth. A disciplined fiscal policy, which complemented a tight monetary policy and was augmented by strong advances in structural reform, led to improved financial discipline in the enterprise sector and has placed public finances and the financial system on much firmer footing.

This resulted in GDP growth for three consecutive years. In addition, inflation and interest rates declined steadily, the fiscal deficit was brought under control, foreign exchange reserves increased to historic highs, and the external balance was held to comfortable levels. Export growth remained vigorous, fuelled by private investment and the initial competitive depreciation of the currency. The competitiveness of the enterprise sector was boosted by productivity gains. Romania is now a visible and attractive destination for international investors as a result of better sovereign ratings and improved access to international capital markets.

The country is comprehensively reforming and restructuring its economy with a view to joining the EU in 2007. As part of this, the Government seeks to build institutions and design and implement public policies to fundamentally transform Romania's economy and society. This requires strong political commitment, considerable expertise and resources, as well as popular and external support.

Despite economic growth in the past three years, important challenges remain. Further structural reforms are crucial to build a competitive market economy capable of withstanding the pressures of EU integration.

### ***1.2. Trends in Private Sector Development***

Romania, like most transition economies, inherited from the communist regime an industrial sector dominated by large state-owned enterprises, in particular in the petrochemical and mining sectors. The trade and service sectors were underdeveloped and the financial sector was unable to respond to the needs of the enterprise sector.

A central issue of importance during the transition process has been the restructuring of the large, unprofitable and uncompetitive state-owned enterprises. Since the start of the transition, various administrations have taken a cautious approach with respect to restructuring because of the fiscal

and social costs that this process would entail. To offset the social costs, these governments have followed the strategy of fostering the development of the private sector by accelerating privatization and promoting FDI and entrepreneurship, in particular new SMEs. Under the guidance and with the support of the IMF and the World Bank, the Romanian Government has taken a new approach to industrial and financial restructuring. The State Ownership Fund was dissolved and replaced by the new Authority for Capitalization the State Assets (AVAS) in 2000. An agreement with the World Bank was reached on a second Private Sector Adjustment Loan program targeting the restructuring and privatization of 18 State-Owned Enterprises.

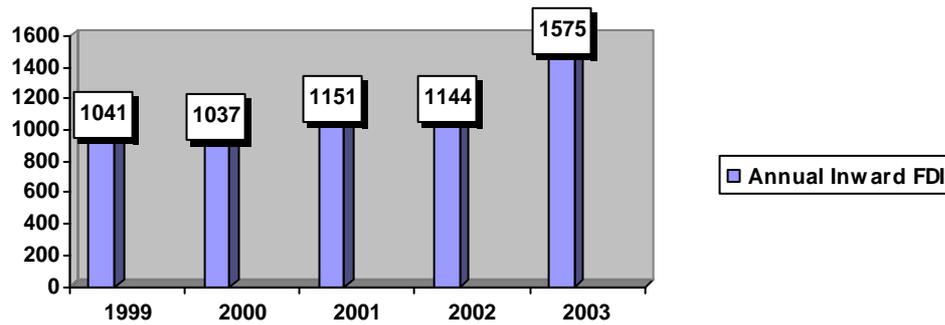

The privatization process has encountered setbacks in the past. The subsidies to loss-making enterprises have acted as a drag on national finances and hampered the development of the SME sector. The vast majority of privatizations completed have involved smaller enterprises and the process has been complex. Some contracts have had to be cancelled due to the low quality of the strategic investor and, in some cases, the process has not been entirely transparent. There is a very large number of disputes associated with past privatizations, with about 15,000 court cases still pending.

Starting with 2000, the government renewed its commitment to the privatization process. So, it tried to improve the transparency and speed of the privatization process, together with the monitoring of the post-privatization developments. Also, the government, transferred the responsibility of selling state shares in large utilities and key public companies to the relevant ministries.

Over the last years Romania has made significant progress towards macro-economic stabilization and has achieved high rates of economic growth. As a result of greater political and economic stability and of the implementation of economic reforms, the investment climate has started to improve and international investors are looking at the region with a much more positive attitude, seeing Romania as a possibility for increasing their trade on the regional market.

According to the statistical data provided by the National Bank of Romania, in 2003 the inward FDI reached USD 1575 million, compared to the same period last year, when the inward FDI registered the value of USD 1141 million (Figure -2). The figures reveal an increase of 37.6 % of FDI inflows in 2003 against the value reached in 2002, practically 2003 being the first year since 1999 when the FDI inflow registered a significant increase.

**Figure 2. Annual Inward FDI in Romania**

*Source: Romanian Statistical Yearbook 2003*

FDI evolution in Romanian economy emphasizes the positive trend Romania is on, the improvement of Romanian business climate, as well as our country attractiveness to foreign investors. In addition, it's worth mentioning finalizing land restitution process supporting Greenfield projects development, solving utilities network legal situation, developing industrial parks, granting incentives to foreign investors, elaborating policies for local authorities aiming at attracting and encouraging foreign investment, as well as developing domestic capital as a significant element in attracting new investment through economic relations development.

Due to all favorable shifts, the foreign investors started to change their position towards Romania, perceiving it as a more friendly business environment and becoming more confident in the Government's investment policy. The increased interest of foreign partners towards Romania as a destination for foreign investments is revealed as well by the number of commercial companies registered during 2003 (6594), according to the data provided by the National Trade Register Office - Ministry of Justice.

Romania has been relatively successful in attracting small and medium-sized foreign investments, particularly in labour intensive sectors located in the north-western part of the country. These investments are driven mainly by location and relative labour cost considerations. They have contributed to the rebalancing of the industrial structure and to the reorientation of trade flows towards the European Union.

### ***1.3. Small and Medium-Sized Enterprises***

The main impediments to business development in Romania are considered to be as follows: inflation, taxes and regulations, political instability and access to financing. These are the conclusions of a survey conducted by the European Bank for Reconstruction and Development (EBRD) and World Bank, which confirm the results of similar surveys and studies.

The conclusions of the survey of Romanian enterprises, consisting mainly of SMEs, are basically accordingly with those of other SEE countries. Overall, Romanian enterprises appear to be more concerned about inflation and policy instability compared to the overall SEE average. Also, lack of financing is marginally less important than the tax and regulatory constraints.

**Table 1. Main impediments to business development in Romania**

Micro Environment	Macro Environment	Law and order
Finance	Political Instability	Functioning of the Judiciary
Taxes and Regulations	Inflation	Corruption
Anti-competitive Practices	Exchange Rate	Organized Crime
Infrastructure		Street Crime

*Source: EBRD (1999) and <http://www.worldbank.org/ru/survey/front2.htm>*

The emerging private sector is responsible for a significant share of the economy. Its contribution to GDP has increased annually from 15% in 1989 to 65% in 2001, according to the EBRD studies.

The SME sector has grown very rapidly during the years of transition. The period 1990-1995 can be characterized as having witnessed rapid increases in the number of registered companies. The recession of 1997 to 1999 affected the SME sector (Table 2). In 2000, the SME sector accounted for 57% of the number of employees within the private sector and 46.9% of the total number of employees within the national economy.

**Table 2. Evolution of Private SMEs (1992-2002)**

Years	Active SME	Weight of staff in active SME	Weight of SME turnover in the turnover of total enterprises
1992	126549	12.3	30.9
1993	214349	17.8	33.8
1994	283697	20.1	41.3
1995	301781	23.9	46.7
1996	309454	29.1	48.3
1997	314183	32.9	45.2
1998	315970	37.8	52.8
1999	316593	42.5	54.0
2000	306073	46.9	55.9
2001	309303	48.5	57.2
2002	313159	50.7	55.9

*Source: Romanian Statistical Yearbook 2003*

At the end of 2002 the total number of small and medium enterprisers was of 313159 with 1.,1% more than the previous year (309303). The birth ratio of SMEs was 5.6% in 2000, 5.6% in 2001 and 7.5% in 2002, and the mortality ratio dropped from 1.2% in 2000 to 1% in 2001; in 2002 it was registered a spectacular growth of the mortality ratio to a value of 19%, due to the great number of SMEs erased in 2002, which didn't increase the social capital within the limits of legal term. The trends are dropping for the mortality ratio and increasing for the birth ratio.

At the beginning of the year 2004, statistic data show that other many SMEs should be erased due to not presenting on time the annual financial situations. This shows the difficulties that Romanian SMEs still confront with.

In general, the micro-enterprises dominate the SME sector. This is not dissimilar to other countries. Ninety-three per cent of all firms in the EU are micro-enterprises, and 99.8% of all firms are SMEs, accounting for 90% of all employment.

The high concentration of SMEs in the trade sector (65.7%) reflects the fragmentation of the distribution and retailing industry in Romania (see Table 3). The data also suggest that the service sector, although still relatively underdeveloped, has a good deal of potential for development.

**Table 3: SME Industries and Size Categories (2002)**

Sector	SME distribution	Micro	Small	Medium
Industry	11.2	79.8	16.1	0.4
Agriculture	1.7	82.5	14.1	3.3
Construction	2.9	71.7	20.9	7.4
Trade	65.7	95.6	4.0	0.3
Tourism	0.5	83.5	11.7	4.9
Transport	2.9	92.4	5.7	1.9
Services	15.1	94.0	5.1	1.0
Total SMEs	100	92.5	6.3	1.2

*Source: Romanian Statistical Yearbook 2003*

Regarding the SMEs distribution on domain of activity; the situation is:

- trade is the area in which most SME are involved 65.7 % in 2002;
- the second area was the one of services, with 15.1% in 2002;
- industry is area in which 11.2 % in 2002.

These three sectors concentrate more than 90% of total SMEs, situation resembling with the one in EU countries.

Concerning the form of ownership, the next data were registered:

- most of SMEs (99.3%) have integral private capital;
- SME with public capital and mixed capital represent less than 1%, thus SME are based on private capital in great majority.

***Analysis on the territorial distribution of SMEs brings more new information about their development; the statistic data presented are focused on the eight Romanian regions of development.***

Firm's development distinguishes significant disparities between the eight regions of development in Romania concerning density, turn over, profitability and economic results.

**Table 4. The repartition of private capital SMEs on regions of development - %-**

	<i>Regions of development</i>	2000	2001	2002
1	North-East	11.6	11.7	11.7
2	South-East	13.2	13.3	13.0
3	South-Muntenia	11.8	11.4	11.5
4	South-West Oltenia	9.5	9.0	8.3
5	West	8.4	8.7	9.0
6	North-West	13.6	13.7	14.0
7	Center	11.8	12.1	12.6
8	Bucharest-Ilfov	20.1	20.0	20.0
9	Total sector SMEs	100.0	100.0	100.0

*Source: Processed by the Romanian Statistical Yearbook 2002, page 353-355 and data offered by www.mimmc.ro*

It is observed that the highest density of SMEs is registered in Bucharest-Ilfov region, and the lowest in South-West Oltenia region (where the firms' density is 170% lower than in Bucharest-Ilfov region). Approximate 18% of medium firms spotted in Bucharest-Ilfov region, while in South-West region their number represents 6,7% of the total.

The statistic situation registered in 2002 indicates a relented economy, being also the positive evolution in the dynamic of private sector. Thus:

- the growth of working places in SMEs sector from 1797206 in 2000 (38% of the total number of employees in Romania) to 1844312 in 2001 (40% of the total number of employees in Romania), respectively 1876938 in 2002 (50.48% of the total number of employees in Romania);
- the growth of SMEs in the service field; in the industrial sector and in the construction field;
- SMEs generate around 60% of the gross internal product of Romania.

#### ***1.4. Results Obtained by SME's in Romania***

##### **1.4.1. Turnover**

Regarding the turn over the greatest number of SME's with a turn over higher then 2000 billion lei is registered in Bucharest Ilfov region, 35%

of the total, the South West region gain a percentage of 5.7% (the lowest value at national level).

The statistic situation registered in 2002 shows the growth of SME's turnover from 634250.4 billion lei in 2000 to 916014.3 billion lei in 2001 (44%), respectively 1513528.6 billion lei in 2002 (65%).

**Table 5: The structure of turnover achieved by SMEs sector with private capital by size and development regions - %**

Development regions	2001				2002			
	Total	Micro	Small	Medium-sized	Total	Micro	Small	Medium-sized
North-East	10.2	9.9	9.7	11.4	10.0	9.7	9.8	11.0
South-East	11.0	11.9	10.3	10.5	10.8	11.7	10.2	10.3
South	10.4	10.2	9.8	11.5	10.3	10.3	9.7	11.1
South-West	6.0	6.9	5.6	5.0	6.0	6.6	5.7	5.3
West	8.3	7.4	8.7	8.9	9.0	8.0	9.5	9.7
North-West	12.0	11.1	13.0	11.9	12.6	11.6	13.6	12.8
Centre	11.5	10.5	12.2	12.2	11.4	10.5	11.7	12.5
Bucharest-Ilfov	30.7	32.1	30.8	28.4	29.9	31.7	29.8	27.1

*Source: Processed by the Romanian Statistical Yearbook 2001-2002 and data provided by [www.mimmc.ro](http://www.mimmc.ro), National Agency for SMEs and Cooperatives*

Also as regards turnover, Bucharest-Ilfov scores the highest number of SMEs with turnover higher than ROL 2.000 billion – 20% in total, with South West region scoring for a modest 6.75% (the lowest value at national level).

#### **1.4.2. Profitability indicators obtained by SME's in Romania**

Profitability indicators obtained by SME's in Romania are presented on regions of development in Table 6.

**Table 6. Profitability indexes at SME on regions of development**

	Regions of development	Commercial profitability ratio		Economic profitability ratio		Financial profitability ratio	
		2000	2001	2000	2001	2000	2001
1	North-East	0.92	2.01	3.35	4.68	6.74	14.70
2	South-East	2.14	2.01	6.22	5.44	27.79	27.29
3	South-Muntenia	1.85	3.04	5.52	7.28	14.02	23.57
4	South-West Oltenia	0.44	1.93	2.69	4.78	4.49	15.00
5	West	1.94	1.47	4.85	3.63	14.08	12.31
6	North-West	2.11	3.39	5.90	7.48	18.45	28.93
7	Center	2.09	3.13	5.22	6.53	15.39	24.18
8	Bucharest-Ilfov	-0.37	2.56	1.24	4.89	-5.00	35.81
9	Total SMEs	1.09	2.53	3.45	5.47	10.33	24.26

Source: Processed based on data provided by [www.mimmc.ro](http://www.mimmc.ro)

It is noticed the commercial profitability ratio (Profit/Turnover), economic profitability ratio (Profit/Assets) and financial profitability ratio (Profit/Equity Capital) have registered upwards evolutions along the two years, and as regions, South-Muntenia, North-West and Center regions stand out. Higher profitableness rates registered SMEs from services and constructions sectors.

Economic profitability of micro-enterprises is 9 times higher than national average in South Muntenia region and 162 higher than in South West. While Bucharest-Ilfov accounts for the largest number of companies in retail trade, construction and research, North East is strong in the textile sector. South West in tourism and waste recycling. North West region scores the relative highest number of companies in transport and metallic production. South in agriculture, Centre region for wood processing.

### ***1.5. The financing of SMEs in Romania***

In the most cases, Romanian enterprises perceive financing as an important compulsion concerning the start or development of their business. To fight-back this situation, a series of measures and financing instruments, like communitary programs and credit access, were elaborated.

For the growth of the SMEs access at financing, financial-banking and administrative institutions have to actively cooperate for identifying and promoting the most adequate actions at microeconomic level. Also, a higher priority has to be given to the needs of new and small firms through traditional means, reducing interest rates and securities, and encouraging the micro-credit.

New instruments of improving access to financing were proposed, like *capital grant scheme*- that takes into analysis the following issues:

- the lack of bank credit due to the lack of securities or to the incapacity of getting more than one credit at once;
- the necessity of taking rapid decisions concerning financing;
- the necessity of finding means of control for the grey market, especially concerning turnover and occupation.

The scheme of capital granting will represent, partly, at the same time, a *pilot scheme for future accessing of Structural Funds*. Thus, it will have the following characteristics: specific co-financing from the beneficiary; transparent selection criteria; clear and countable objectives; relatively short period paying capacity; a clear auditing process and capacity of avoiding fraud.

### **1.5.1. Financing Through Communitary Programs**

In the 2000-2006 period, 16 billion Euro of structural funds were allocated for the financing of SMEs oriented projects. Approximate a third of this amount was allocated for a consulting and a business services, like incubators, networks and clusters. In the candidate countries also, an important part of the pre-aderation funds was oriented toward SMEs. Many other programs, such as LIFE (the financial instrument for environment) and Eco-label, are mostly addressed to small firms.

In 2001, the Phare contribution for all candidate countries was 104 million Euro and 54.7 million Euro in 2002, going through more than 19 programs. The overall of communitary programs had a number of 29, which weren't all opened to the participation of candidate countries. National co-financing is different from country to country, being determinate by the effective moment of entering these communitary programs.

It is noticed that Romania has been the beneficiary of many communitary programs, but its participation at these programs is varied. thus, for frame programs specific to certain domains, the sums allocated by the EC are smaller, as compared to Research and Development Frame Programs and Leonardo da Vinci and Socrates Programs, at which allocated amounts are a lot bigger, considering the scope of the actions taking place in these programs.

Table 7 presents Romania's participation in communitary programs, which reveals that in the year 2001, the national contribution represented

more than half of total allocated budget, and in 2002, the national contribution reduced at less than half.

**Table 7. Participation of Romania in communitary programs** mil. Euro

	Participation of Romania in communitary programs	Total Budget	National Contribution
1	2001 - 8 programs	35,6	20
2	2002 – 16 programs	38,5	16,7
3	2003 – 15 programs	in progress	in progress

*Source: Processed based on data provided by www.mimmc.ro*

Romania concentrated its effort for sustain the SMEs sector through the specific programs which are financed by the budget and external funds.

- In order to support this sector, in 2002-2003, the state budget allocated over 3158 billion lei and brought a contribution of 24.02 millions Euro, representing the co-financing from the Romanian state of a Phare component with a budget of 75.07 millions Euro (for investment, the access to the consulting and training services, for the export promotion);

- Increase the efforts to gather external financing sources for the SMEs which represent over 100 million Euro, in the period 2002-2003, from BERD, BEI;

- The development of the component „SME facility” in Romania gathered over 1050 millions EURO;

- The diversify of the multiyear national programs financed by the state budget.

### **1.5.2. Financing through credit**

There is a significant and hard to satisfy demand for financing SMES trough credit. Thus, is necessary to continue and supplementary extend the present credit lines at which SMEs are aiming, by using the example of different financing schemes implemented so far, (especially through MIROBANK, BERD credit line, USAID help for credit and KfW credit line).

In order to support the SME’s for demanding credits, it is recommended the possibility of practicing attractive interests credits granted from the unemployment insurance budget, by the National Agency of Work Force Occupation (Ministry of Work, Social Solidarity and Family) as well as granting such credits for other categories of potential enterprisers that could initiate and develop business, as, for example, students.

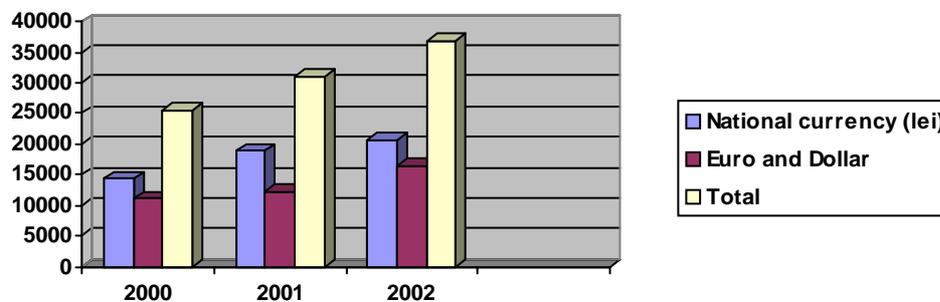

From the banking sector view, the SMEs represent a strategic sector towards should be focused, from the following reasons:

- the SMEs insure a good risk dispersion;
- the SMEs accept the standard costs (interests, banking fee and commissions) insuring a high efficiency in this sector.

Even the SMEs represent an attractive market with a high potential for the banks, there are some factors which act against the SMEs credit, such as: the low offer of the banks for this kind of credit, the lack of the SMEs training regarding the credit documentation, the lack of the customer (SMEs) financial information for the banks; the lack of a regional network for the banks.

In this circumstances, the credits for SMEs got in 2002 just to up 36.51% from the total corporate credits.

**Figure-3. The credits granted to SMEs (2000-2002)**

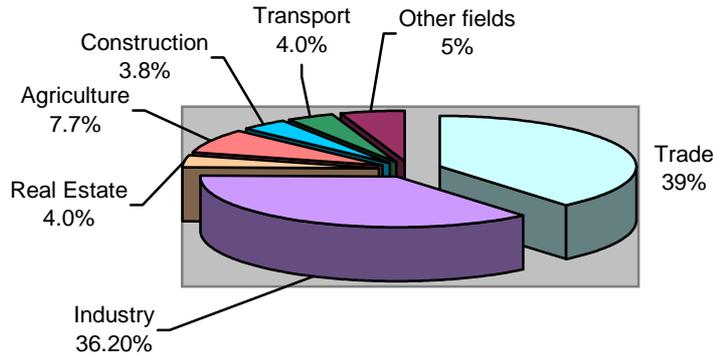

*Sursa: Study National Bank of Romania, "Creation of the necessary frame for development of some banking product and services" (2003), pg. 67*

Even in the analyzed period, there was registered an increase of the SMEs credits from 26743.2 mil. lei in 2000 to 36966 mil. lei in 2002, this increase did not satisfy the market demand. Regarding the credit distributions in function of the enterprises size, there was a reorientation of the banks towards the medium firms, and the micro-firms.

Concerning the destination of the credits granted to the SMEs the situation in 2003 is presented in the figure-4.

**Figure-4. The destination of the credits granted to the SMEs (economic fields)**

*Source: Romanian Statistical Yearbook 2003*

The weight of the credits for SMEs are directed towards the trade (39%) and industry (36,2%) from the total credits for SMEs.

The distribution of the credits granted to the SMEs by regions of development reveals the credit concentration at the Bucharest area where in 2002 were placed 37% from the beneficiary firms, which is much higher than the other counties (with an average of 4% from the credits). The main reason which determined this situation is the low level of development for the banking infrastructure the regional level.

**Table 8. The distributions of credits granted to private capital SME's by size classes and regions of development**

	Regions of development	2001			2002				
		Total SMEs	Micro	Small	Medium	Total SMEs	Micro	Small	Medium
1	North-East	6,7	5,9	6,8	7,1	7,5	5,4	8,5	9,1
2	South-East	8,3	9,0	8,0	7,9	8,4	9,7	6,9	8,2
3	South-Muntenia	7,8	7,3	8,4	7,7	8,1	5,9	10,0	8,9
4	South-West Oltenia	4,5	4,7	4,4	4,5	4,6	4,2	4,4	5,2
5	West	7,7	5,9	6,7	10,0	11,1	10,9	9,1	13,1
6	North-West	8,0	6,9	10,4	6,8	9,2	6,5	12,2	9,8
7	Center	11,8	6,7	10,4	16,8	11,0	6,9	13,6	13,7
8	Bucharest-Ilfov	45,3	53,6	44,9	39,3	40,1	50,4	35,4	32,0
9	Total SMEs	100	100	100	100	100	100	100	100

*Source: Processed based on data provided by www.mimmc.ro*

Concerning the distribution of credits granted to SMEs on regions of development, the SMES in Bucharest-Ilfov region have obtained an average of credits four times bigger than SMEs in other regions.

Considering the high present level of interest rates on credits, it will also be considered the possibility of interest subsidizing for certain domains of activity.

For the improvement of SMEs's access to financing, the following *actions* will be taken:

- the continuance of obtaining financial allowances for SMESs, from the state budget and external sources, for the development and implementation of multi-annual financing instrument of the SMES sector at national level (credit and granting schemes for supporting the investments of start-up firms and of the existing ones, promotion of export, investments in priority economic sectors, innovation, transfer of technology and Know-how, sub-contracting);
- promotion of Multi-annual Program, with national applicability which corresponds to the firms development stage, by: implementing multi-granting schemes; implementing scheme of granting associated with; promoting schemes of micro-credit;
- the continuing of apply the credit program for SMEs and its monitoring;
- promotion of setting-up and developing risk capital funds;
- the development of a permanent system of monitoring and periodic evaluation of the way of finance use and fiscal facilities received by SMEs;
- the efficient promotion of present financing programs;
- the assurance of Romania's participation - in the community programs, - within Financial Instruments component of the Multi-annual Program (2001-2005) for Firms and Enterprises, especially for SMEs, with the support of EC;
- creating a database with information on financing opportunities for SMEs, unrepayable financially, guarantee funds; commercial banks, risk capital funds;
- the elaboration of the action plan for improving the SME's access to financial services, as a part of the Technical Assistance - Institutional Construction program, financed through Phare 2001 program;
- the elaboration of banking settlements due to encourage SMEs financing by the financial-banking institutions, the opening of special departments within banks which can offer such services.

## **2. European integration and the Romanian SME sector**

One of the main economic policies within European Union is to develop as rapidly as possible the SMEs sector, because it is considered that small enterprises are the “back-bone” of the future integrated economy. It is emphasized the idea that united Europe’s efforts will reach success only if small business will be brought to number one within theory and economic practice.

EU shows a special attention to small and medium firms, in present member states of EU, as well as in the rest of the European countries that sooner or later will be integrated within the union.

At the EU executive level there were already adopted a series of documents establishing key domains for supporting and encouraging small business. The most important is The European Charter of Small Firms, adopted at the European Council in Santa Maria Feira in June 2000, establishing 10 key domains.

Romania is involved in discussions concerning fundamental problems and coherent strategies with impact on SMEs sector, starting from the support that EU gives to Romanian SMEs.

### ***2.1. Theoretical Fundaments***

I. The European Charter for Small Enterprises calls upon Member States and the Commission to support small enterprises in ten key areas:

- Education and training for entrepreneurship;
- Cheaper and faster start-up;
- Better legislation and regulation;
- Availability of skills;
- Improving online access;
- Getting more out of the Single Market;
- Taxation and financial matters;
- Strengthening the technological capacity of small enterprises;
- Making use of successful e-business models and developing top-class small business support;
- Developing stronger, more effective representation of small enterprises’ interests at Union and national level.

These ten key areas demonstrate the difficulties for SMEs to take many political measures and full advantages for economy

We consider that these domains are connected with the rethinking of the optimal dimension concept of all business, on the founding of present phenomenon which cannot be ignored anymore, such as:

- the stressed dynamic of all economic activities;
- the danger of some natural resources' exhaustion;
- the necessity of quick finding some innovative solutions for humanity, in terms of decision transparency, without subjective interventions which can distortion normal evolutions.

Experience has proved that only in states with a great mobility and diversification of small business (the best example are still the US) can be reached the selection and affirmation in maximum objectivity conditions of truly useful and efficient activities for human society. Because of that, above the appreciations that SMESs are the locomotive of present society or very sensitive barometers of economic, social or political evolutions, we consider that it will far more correct the idea according to which the small firms' high "birth rate and mortality" phenomenon represents a true economic test of objective selection for enterprisers. This test is less expensive, talking about low resources, but has essential effects on identifying and expanding some efficient activities.

SMEs development is closely in connection with enterprising problems, starting from the premises that enterprising is the engine of economic growth, of competitively and of the creation working places, as well as from the discrepancy which still exists in the field of enterprising between Europe and the United States. In this context, European Union has decided to support the force of enterprising in a most efficient way, identifying those priorities that can affirm the enterprising initiative. The European Commission has published in January 2003 The Green Book of Enterprising in Europe, discussing people's attitudes concerning enterprisers or the actual number of enterprisers, dynamism within enterprising activity and enterprisers' performance.

The analysis of the SMEs sector has to emphasize the advantages, as well as the disadvantages, especially through a comparison with advantages and disadvantages of big firms.

The advantages of SMEs sector are connected to present trends of globalization, hard competition and mobility within the economic process, thus:

- SMEs have a great flexibility and adaptability, practically under all aspects (financing, production, marketing, human resources), when

economic circumstances modify rapidly, especially when these become unfavorable;

- SMEs need more reduced financing resources (based mostly on equity capital), using more efficiently the resources that they can rely on;
- SMEs are much more active on the work market, creating very rapidly working places, often in new areas, the costs connected to creating a working place being much more reduced than the ones registered by big firms;
- SMEs influence the efficiency of internal markets, these finding or creating quicker or easier or market shares for certain products or services;
- SMEs are perceived as an element of economic growth and stability, through the assertion of the trends of a healthy long term economic growth.

The disadvantages or week points of SMEs sector appear in front of big firms, as well as because of extra economical reasons, like:

- SMEs have a reduced access to local and international capital markets, involving a vicious circle, meaning that small enterprisers are often excluded because they are small, but cannot become bigger and they disappear, because they can't cover the high costs of making their projects;
- SMEs are strongly affected by the incidence of institutional and settlements compulsions, especially if they want to enter the external market;
- SMEs are sensitive to any type of "barriers" (national or international, economic or extra economic), transposed in several high costs of transaction;
- SMEs are characterized by a weak representation of their own interests, including through access to advertising or representation in different organisms, making them vulnerable, especially in competing whit big firms.

In reality, in a modern economy coexist firms of different sizes, but it is noticed that their start-up and their development have the next evolution: usually, it starts from a small firm, and if this one is viable and efficient, than it develops to a middle dimension, big or very big. In modern economies are working networks of enterprises (clusters), in which the competitive position of the firm mostly depends on the suppliers' efficiency. That is why, the competitiveness of SMEs affects the competitiveness level of the overall economy.

## 2.2. Methods and Results

### 2.2.1. Comparative Elements of SME in Romania Against SME in Member and Candidate States of the European Union

An enterprise is registered in the SME category (it can be micro, small or medium sized) if it fulfils all the conditions regarding: employed personnel, turn over and right to vote.

Observing the definition of the SME in Romania and in the European Union, as table no.9 shows, the next comparative elements are distinguished:

- concerning the number of personnel, there are no differences;
- from turnover point of view, the Romanian definition is more restrictive, its maximum level being of 8 mil. Euros compared to the similar condition in the EU, which establishes a maximum level of 7 mil. Euros for small firms and 40 mil. Euros for the medium ones;
- in Romania, there are no restrictions regarding maximum capital of SMES. In EU there are restrictions, but these are progressive: 5 mil. Euros for small firms and 27 mil. for medium size firms.

**Table 9. The definition of the SMEs in Romania and in the European Union**

Conditions for SMEs	Micro	Small	Medium
1 ROMANIA			
2 Number of employees	<10	<50	<250
3 Turnover	<8	<8	<8
4 Other conditions (owners equity/ voting power of other firms)		25%	25%
5 EUROPEAN UNION			
6 Number of employees	<10	<50	<250
7 Turnover (mil. Euros)	n/a	7	40
8 Current Liabilities (mil. Euros)	n/a	5	27
9 Other conditions (owners equity / voting power of other firms)	n/a	25%	25%

*Source: Processed based on data provided by [www.mimmc.ro](http://www.mimmc.ro)*

It is observed that the Romanian definition is in accordance with the one recommended within European Union.

Most of the SME in Romania, as well as in candidate countries, are micro-firms. In Romania, of the total number of SMES, 91,2% have been micro-firms. In Romania, of the total number of SME, 91,2% have been micro-firms at 2001 level.

From the point of view of the *employed working-force weight* in the SME sector in the total working force employed in economy, the situation is the following:

- in EU countries, including EFTA, the weight of the personnel registered in SME is of 66% of the total;
- in candidate states, it weight is of 72%;
- in Romania, 40%.

*The average of employees in small and medium firms* is 5,5 employees in EU, including EFTA, 6,9 in candidate states and 4,8 employees in Romania, a level under the European average. There is a difference between SMES average in candidate states and member states. In Malta, Cyprus and Turkey – 3 candidate states which don't have a command state economy, the no of SMES is situated at the same level as countries within the EU. The South part of the continent represented by Greece, Italy, Spain and Portugal is characterized through a higher weight oh micro-firms.

The situation of *the distribution of SME on areas of activity* is presented in Table no. 10.

**Table 10. The distribution of SME on areas of activity**

Areas of activity	Romania	Candidate States	Europe-19 (EU+EFTA)
1 Industry	11.6%	12%	10%
2 Agriculture	2.0%	-	-
3 Construction	3.3%	16%	13%
4 Trade	63.0%	19%	25%
5 Tourism	0.5%	5%	6%
6 Transport	3.6%	12%	6%
7 Services	16.1%	36%	30%

*Source: Processed based on data provided by [www.mSMEc.ro](http://www.mSMEc.ro)*

The percentage of SMEs in service area within candidate states and those in Europa-19, also includes small and medium firms activating in financial services domain (banking services, insurance and securities).

Comparatively the weight of Romanian SMEs compared to SMEs in candidate states and SMEs in Europe-19, the next particularities of SMEs in Romania appear:

- the percentage of SMEs in industry is 11,6%, compared to the one registered in Europe-19 (10%) and in candidate states (12%);

- tourism is weakly represented, by only 0,5% compared to 5%, respectively 6%, which means 10 times weaker;
- SMEs percentage in constructions is over 4 times lower than the European average registered in candidate states and in the Europe of 19;
- most of SMEs in Romania are involved in commerce activities, the percentage at European level being lower more than 2,5 times.

### 2.2.2. Work Productivity

The work productivity obtained by SME's in Romania compared to countries in the European Union at 2001 level is presented in table 11.

**Table 11. Average Value of Work productivity on types of SME's, in 2001**

	very small	small	medium	TOTAL
<b>1 Europe – 19</b>	<b>40000</b>	<b>75000</b>	<b>105000</b>	<b>65000</b>
<b>2 Romania</b>	<b>2688</b>	<b>3688</b>	<b>3542</b>	<b>3278</b>

*Source: Processed based on data provided by [www.mimmc.ro](http://www.mimmc.ro)*

It is noticed that average value of work productivity registered by small and medium firms in Romania, overall, as well as on size classes, is over 19 times lower the one registered at European level. When evaluating these results it has to be considered the fact that the definition of small and medium firms in Romania is not identical to the one in EU, considering the turnover. From this point of view, the Romanian definition is more restrictive, establishing a maximum level of 8 mil. Euros for turnover, compared to the similar condition in EU, establishing a maximum level of 7 mil. Euros for small firms and of 40 mil. Euros for medium firms.

### 2.3. Constraints on business formation and growth

The SME sector is still small and weak relative to the EU as well as to other transition economies.

This might be explained by a number of constraints:

- The entrepreneurial culture is generally weak;
- The regulatory and tax environment is burdensome. There is a confusing array of taxes and regulations with which SMEs must comply. The enforcement of regulations is often patchy leading to allegations of corruption;
- Banks in general do not address start-up businesses and infant companies, and make demand on collateral to the other businesses which is

often hard to met by undercapitalized SMEs who owners also lack sufficient personal assets to collateralize bank loans. Other forms of financial support (venture capital and leasing) are in their infancy;

- Sources of advice, training and information are inadequate, though there is a real need and demand for support services for SMEs. These are services that would be publicly subsidized in EU countries;

- Long-life learning is not yet a popular concept among Romanian companies and individuals. As a result, there is a growing mismatch between labour skills and market requirements;

- Both ownership and actual availability of premises is a problem. A total of 40 industrial / business parks were identified in early 2003, totaling 1,246 hectares of business infrastructure space equipped for enterprise establishment. The amount of space devoted in Romania to industrial / business park development is very small when compared with Poland, Hungary, or the Czech Republic;

- Little support is available for early stage innovation activities, due to lack of contact with universities, special premises, ability in technology transfer. Most SMEs remain in conventional sectors where competition is more intense;

- Supplier linkages between large enterprises and SMEs remain weak, due to insufficient technological endowment of SMEs as well as high risk for SMEs to deal with large state-owned enterprises affected by financial problems. Largest foreign investment could have a very positive effect on the development of Romanian enterprises.

#### ***2.4. Priorities of the SME Strategy in the context of European Integration***

Romania's long-term plan is to achieve a stable economic growth faster than the EU average, within the context of a balanced development of its territory, and especially the reduction of rural versus urban disparities. Therefore, the long term National Development Strategy was formulated to support investment in sectors with growth potential, thus also supporting employment creation and safeguard.

As this National Development Plan 2004-2006 covers a three-year scale, this period of time shall not be sufficient to implement a comprehensive national development policy. The purpose of this Plan is therefore to target the major issues raised in the socio-economic analysis, in order to progressively reduce the current gaps between Romania and the EU countries.

From SMEs' point of view, the strategy aims to support growth in both qualitative and quantitative terms and to further diversify its productive basis in order to provide further developing opportunities to the productive system. It was composed a loan guarantee scheme to support SMEs' capital investment and of grant programs to promote investment in new technologies and know-how and to assist internationalisation. Preference is given to SMEs entering in activities unexplored before in Romania, with a strong technological component and subject to international competition. *Ad hoc* promotion of FDI-led supply-related clusters will also be possible. These schemes is complemented by an initiative capitalising on existing labour-intensive handicraft traditions with a view to better exploit their potential in the international and local markets. All schemes are directly targeted at entrepreneurs and are managed at the national level, in one case with the assistance and direct involvement of the banking system. The different schemes differently contribute to the different intermediate objectives. While the loan guarantee scheme and support to craftsmanship are mainly a tool to expand the entrepreneurial basis, technological grants are expected to have a more direct impact on the added value and diversification of the productive basis, while internationalisation-related measures are directly linked to SME global competitiveness.

The SME Strategy highlights the priorities:

1. Improvement of the Business Environment for the Stimulation of the SME Sector by:

- Improving the institutional framework and public-private dialogue;

- Simplifying and improving the legislative framework;
- Reducing bureaucratic barriers to SMEs;

2. Development of Economic Activities and Increase in the Competitiveness of SMEs by:

- Improving access to financing for SMEs;
- Creating a friendly tax system, aimed at stimulating investment;
- Developing business infrastructure and a national market for consulting services for entrepreneurs;

- Improving access to business information;

- Facilitating access to public procurement;

3.Improvement of he SME Access to External Markets by:

- Elaborating a strategy to support SMEs with export potential;

- Supporting regional collaboration;

- Supporting SMEs via international fairs and exhibitions;

- Providing training on marketing techniques for external markets;

- Supporting access to information on external markets;
- 4. Promotion of an Entrepreneurial Culture and Stimulation of New SMEs by:
  - Supporting training programs focused on entrepreneurship;
  - Supporting entrepreneurs' access to consulting services;
  - Improving managerial education in secondary schools and universities;
  - Involving mass media in generating a positive image of entrepreneurs.

All these kinds of action will require a combination of improvements in the regulatory and administrative environments and the provision of an adequate mix of “soft” incentives accordingly with the European acquis. The SME sector should be greatly expanded in both size and scope, as well as better integrated into the international economy and technologically enhanced.

The problems SMEs currently face in accessing medium-long term credit for investment must be adequately addressed, and this is even more so in the light of the possible consequences of the Basel banking regulations on the SME sector. Direct support measures will have to be targeted accordingly. Finally while the development levels of the manufacturing and business-service sectors can be broadly assumed to progress in parallel and to be mutually supportive of each other, there are a few areas where a more proactive stance is needed to provide the necessary “size effects” and foster the start of an autonomous growth process. This is especially the case for the opportunities opened by Romania's endowment of potential tourism attraction currently heavily underexploited and by the e-revolution that, if properly supported, could capitalise on the existing flourishing Romanian IT service industry.

SMEs are expected to remain the larger suppliers of jobs in the future. Together with a general purpose SME guarantee scheme aimed at easing the well-known problems SME have in accessing medium-long term credit for investment purposes a number of grant programs will be devised for SMEs specifically investing in hi-tech or entering the international markets. Technological priorities will reflect trends in the world markets and include, among others, biotechnology, new materials, environmentally friendly techniques and products, micro-technologies. In order to diversify the country's productive basis and foster possible imitation phenomena, a preference will be given to enterprises entering into new sectors.

## **Abstract**

*Strong saving tendency, preference to some traditional and financial instruments and distribution flows, mainly in some bank branches – these are the main specific features of a typical Czech customer and also are connected and closed to the small and medium enterprises (SMEs). One of the most important business problem in the Czech Republic is the existence of some „elephant socialist“ enterprises unable to survive without the government help. There are SMEs support programmes in contrast to them. There have been announced many discussions about some help activities before 2000. For example education development and maybe also a sort of financial help from EU. Zlín area is a specific business area with many SMEs. They cope also with financial problems as other SMEs in the Czech Republic. Talking about their support after the year 2000 we have to mention the support of their competitiveness. There was provided the research between them to realize SMEs positives and negatives and their financial problems. The results can recognize SMEs weak and strong sides in financial questions and also can show the direction of their business future.*

**Key words:** *small and medium enterprises (SMEs), financial sources, support, competitiveness, Europe union (EU).*

## 1. Introduction

The liberalization of economic activities is the world trend. The integration of economic and financial activities, too. All these developments indicate freer flows of goods and services. During the past 15 years or so, academics as well policymakers have turned their attention to the internationalization of small firms, especially SMEs (small and medium enterprises). There are changes in the institutional framework governing world trade and production, combined with rapid advances in communication and information processing technologies. The inability to control prices because of lack of market power, a dependency upon a relatively small customer base – there are some typical features for Czech SMEs. The financial resources available to SMEs can act as a considerable constraint in developing an international orientation.

This can take two forms:

- Lack of finance may hinder the firm's ability to identify opportunities arising from the opening up of national markets while.
- Inadequate financial resources may restrict the exploitation of opportunities already identified.

Additional constraints derive from the management time and expertise may be in very short supply. As a consequence, there are significant problems in the acquisition of market information, in the coordination of the actual management effort. The lack of SMEs financial sources was the reason of the SMEs survey. This survey was proceeded in Zlín area to show up the SMEs world common features with an emphasis to financial problems.

SMEs cope with plenty of problems. This article should take out all their most important especially financial problems and go through the part of their financial management also with a note about their personal questions. The aim of the survey is to specify the SMEs financial sources in area Zlín. The article is gradually proceeded in the following steps:

- the recent SMEs situation and their definition
- SMEs financial sources in Zlín area
- strong saving tendency
- personal influence in SMEs management
- competitiveness
- survey results – positives and negatives
- discussion
- conclusion

There was proved by the questionnaire also the hypothesis from financial management area and personal influence. *The first hypothesis* expresses the idea that SMEs do not effectively use external financial sources. *The second hypothesis* is directed to personal influence and expresses the idea that SMEs do not follow carefully all necessary information directed to SMEs and their personal influence could improve SMEs competitiveness. SMEs cope with a lack of financial sources, that's why with a lack of employees and consequently with problems in personal influence.

There has been used some economic and statistics methods – as induction, deduction, analysis, synthesis including the SMEs survey. The survey was provided at VOŠE Zlín in area Zlín [8] and its surrounding. It started in 2001 and finished in 2004.

## 2. SMEs, their definition and specific features

### 2.1 The recent SMEs situation and their definition

In all the short history of modern business there is well known that larger companies have the traditional belief in the rightness and power of size. Rationalisation, standardisation and concentration are the watchwords. In 1969 a Committee of Inquiry on Small Firms was set up (The „Bolton“ Committee). Another „Wilson“ Committee on the Financing of Small Firms, in 1979, updated the Bolton turnover requirements. [1] This brought the definitions temporarily in line. In the EEC small firms [3] are usually categorised by employees, but there is no general agreement on the number that is covered by the term „small“. Businesses were split into medium-sized and small (though) in practical terms both would normally be regarded as small. (see table No.1).

**Table 1: SMEs definition**

Types of enterprise	Number of employees	Turnover	Balance sheet total
micro	Less than 10	to 250 mil. CZK	to 180 mil. CZK
small	10-49	to 7 mil. EURO to 1 450 mil. CZK	to 5 mil. EURO to 980 mil. CZK
medium	50-250	to 40 mil. EURO to 250 mil. CZK	to 27 mil. EURO to 180 mil. CZK

Source: European Commission definition (7.2.1996) [8]

There are given many *SMEs definitions*. The table 1 shows one of them. The economic definitions make a great of sense. It has three parts:

- market share
- independence
- personal management

The characteristic of a small firms *share of the market* is that it is not large enough to enable to influence the prices or national quantities of goods sold to any significant extent.

*Independence* means that the owner has control of the business himself. It therefore rules out those small subsidiaries which, though in many ways fairly autonomous, nevertheless have to refer major decisions (e.g. on capital investment) to a higher level of authority.

*Personalised management* [4] is the most characteristic factor of all. It implies that the owner actively participates in all aspects of the management of the business, and in all major decision-making processes. There is little devolution or delegation of authority. One person is involved when anything material is concerned.

One owner – manager has to manage everything. Unlike the chief executive of a large corporation who can employ a secretary, a financial director, a treasurer, a solicitor and an accountant, all well informed in their own professional fields, and all willing and able to advise him, the small business proprietor has to be himself, a „man for all season“. It is obvious that this has been the case for many years. SMEs cope every day with personal, economic and mainly with financial problems.

## **2.2 *SMEs financial sources in Zlín area***

Trying to sort out a part of SMEs especially financial problems, there has been started the SMEs research at VOŠE Zlín in 2001. This project has taken till 2004. The main achievement was to realize what is the reason of SMEs problems and go through all parts of SMEs financial management to their personal influence. The questionnaire for SMEs was spread in Zlín area. The main aim of the questionnaire were the SMEs financial sources.

Every year was spread 300 questionnaires to SMEs in Zlín area. The best returnability was in 2001 – 54 per cent. The questionnaire has been given to SMEs in region Zlín every year since 2001. In 2002 the returnability was only 32 per cent and in 2003 only 27 per cent. The research finished in 2004 with the returnability 29 per cent.

**Table 2: Financial sources (in per cent)**

<b>Internal sources (the owners)</b>	33

<b>Leasing</b>	19
<b>Loan</b>	17
<b>From friends, family</b>	3
<b>Silent Partner</b>	2
<b>Grants</b>	1

Source: research at VOŠE Zlín [8]

It was proved that SMEs in Zlín area prefer internal financial sources to external by the research at VOŠE Zlín. (see the table No. 2). The respondents used grants only a little (1 per cent). From external sources is the most favourite leasing (19 per cent) and then loans from the bank (17 per cent). At the beginning of this research was said, that *SMEs do not use effectively external sources*, especially bank products and services.

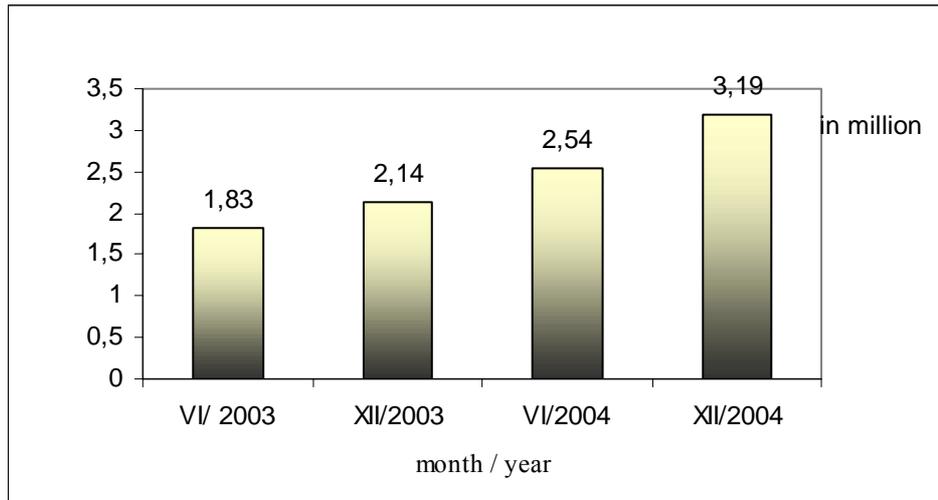

### **2.3 Strong saving tendency and growing number of loans**

But there is the fact – the amount of Czech crowns is growing up in Czech banks. It is in an absolute agreement that SMEs prefer internal financial sources to external ones. As was proved by the research. SMEs prefer internal financial sources – „own“ sources. They like „to keep“ cash. That's why they prefer to operate with their accounts.

The following discussion should help SMEs to believe that bank products and services are for SMEs helpful and useful and effectively used also can improve SMEs effectiveness and competitiveness.

For example the number of loans in the Czech Republic is growing up as seen in graph No.2.

**Graph No.2 The development of bank loans in the Czech Republic**

Source: CCB [12]

Discussing external financial sources Czech SMEs prefer leasing and loans when using bank products and services. As was also proved by the financial sources research. The reason is in a very good rate conditions. The discount rate is falling down. The economists do not expect its rising yet. Banks offer every day loans. They push their clients to use loans for their activities. The economists also refer to very good loan conditions as seen at the graph No.1. [12]

The research proved the hypothesis that SMEs do not effectively use external sources, as bank products and services. They did not understand the necessity of external sources in their cash flow, they did not believe in fact, they could *improve their effectiveness* and put up their competitiveness. Even Czech economists trust all Czech SMEs.

#### **2.4 SMEs and the information**

The most important problem in this research was the *information* spread. The respondents were not interested in further information. It was proved the the lack of information is also the reason of financial problems in SMEs. We can say it is an absence of personal influence. The questioning [8] was provided with 300 respondents every year from 2001 - 2004. The absence of information could be also the reason of SMEs problems. That is the „whole“ in their personal influence, which should be filled up. With all

necessary information for their production and other activities SMEs could rise their effectiveness and competitiveness. Czech SMEs do not survive on the remote island. They work a cope with „everyday“ problems. Good managers should look after a good running. They run their business and try to make their profit by using all necessities as financial, producers' or personal. There are shown some personal advices for SMEs managers bellow.

## **2.5 Personal influence in SMEs management**

The research at VOŠE Zlín [8] proved that SMEs in Zlín area do not effectively work with information. There is a lack of personal influence in SMEs management. This is the space that has to be filled up. SMEs managers should improve their personal attitudes. While improving them that is the way of rising up SMEs competitiveness at the SMEs market.

What kind of attitudes do the managers and employees in SMEs need to have, what kind of management system would encourage such attitudes? Mr. Masaaki Imai in his book, „Kaizen“, very simply but eloquently explains that there are three categories [6] of work. The first is maintenance work, meaning doing the prescribed work very well, following the standards and procedures. The next is improvement based on the past experience. You should not be doing your job the same way year and year out. And the last and final category is „innovation.“ While improvement is based on past work doing it better, innovating is something entirely new. You should be thinking of new ideas and new methods for future growth. And as you go up the managerial ladder, more time and effort should be devoted to the second and the third category of work.

There are five important attitudes by Etsu Inaba [2] that the successful manager in the 21st century should possess:

- Search for problems - „problem should be a key word to describe what you must seek
- „Steal“ knowledge - Do not wait for others to teach you
- Apply ideas - Learn how to use unrelated ideas for your organizational benefits
- Report for credibility - Remember, Report, Inform and Consult, without being asked
- Be at the center of communication - Be close to your subordinates. Let knowledge flow up as well as down.

Some people think that it is not difficult to recognize a good manager. The personal influence [5] seemed to be important even at the first interview

asking for a new job. But there are many modern methods for managers' and successful workmen's choice. They were used since the first world war. At these days were first used the psychological tests for american soldiers. Using of this method was widered also in many american companies as Ford. Also in Czech conditions have been started these choice methods with Tomáš Baťa company in Zlín. It was even established The Masaryk Labour Research Institute. These methods highly improved better probability of good decisions in personnel questions.

A good manager [11] should obtain confidence not only by his hard-working, outlook, calm and peace, firm decisions in difficult situations, his character features but also by his appreciation. There could be answered the question, if there is any difference between a good manager of a large company and of a small or medium enterprise. The theory usually gives many advices and management methods with no differences.

## **2.6 Competitiveness for SMEs**

Competitiveness is the important aspect of all industrial producers and all business companies not only in Zlín but also in all other regions in the Czech Republic. The approaches to competitiveness of industrial producers were not presented in the Czech Republic till 1990. Considering creation and strengthening of stability of regional policy, including other influences, tendencies and typical regional aspects of macro and micro economic tools, competitiveness could stay side by side those factors. [9]

### **Definition of competitiveness**

The economists in the Czech Republic did not find a convenient definition of the expression „competitiveness“ yet.

- producers' competitiveness and its definition does not exist yet
- competitiveness is a part of trade market
- competitiveness is also a possibility of some business undertaking advantage
- as a tool of competitiveness can be used for example low cost, product differentiation and funktion differentiation
- producers shall be able to use their competitiveness in their economic and product growth

Competitiveness is made by using best approaches from all business areas and processes as organization, new product methods, marketing, research, production, service and others.

Considering competitiveness and its sources we can talk about two factors: external and internal.

- External factors:
- sources, price and access
  - trade area
  - law and administrative regulators
- Internal factors:
- production processes
  - production instruments
  - production programme
  - management
  - employees
  - information systems

As the important part of small and middle-sized companies competitiveness is their place and part at the market. Region Zlín has quated a luck of businessmen at recent time. Zlín was a model of business development 10 years ago. Company and business closing can show that region Zlín as former model of Czech business activities rapidly got down. Zlín was considered as the richest business centre in the Czech Republic 10 years ago. This fact was influenced mostly by the agriculture cooperative Slušovice and its position at the trade market in the communist Czechoslovakia. There were many important business experiences which have been probably already all forgotten for ever. Unfortunately.

### **3. Survey results**

By using all methods mentioned above there have been proved by the SMEs survey in Zlín area two hypothesis [8]:

- SMEs do not effectively use external financial sources
- SMEs do not follow carefully all necessary information directed to SMEs and their personal influence could improve SMEs competitiveness.

It was proved that the SMEs financial and personal management is identical for SMEs and also large enterprises with some exceptions. SMEs should work more with all information. They are not interested in new technologies, new equipments because of their financial problems. They prefer in financial management internal sources to external ones (see table No.2). They are not aware of the fact that external sources could improve their effectiveness and competitiveness. SMEs should take care more about personal management which is the space for their improvement. Their personal influence could help them for example to find out white places in the market or to be more flexible.

### 3.1 Discussion

Considering competitiveness and its sources we can talk about two factors: external and internal. *External factors*: sources, price and access (trade area, law and administrative regulators). *Internal factors*: production processes (production instruments, production programme, management, employees, information systems).

As the important part of small and medium enterprises competitiveness is their place and part at the market. Region Zlín has quated a luck of businessmen at recent time. Zlín was a model of business development 10 years ago. Company and business closing can show that region Zlín as former model of Czech business activities rapidly got down. Zlín was considered as the richest business centre in the Czech Republic 10 years ago. This fact was influenced mostly by the agriculture cooperative Slušovice and its position at the trade market in the communist Czechoslovakia. There were many important business experiences which have been probably already all forgotten for ever.

The unemployment in Zlín is growing up. The unemployment extent is about 0,3% higher in Zlín than the republic average with 9,28 per cent. Businessmen in Zlín realized some important approaches [5] which could be useful in looking for the conclusions:

- first they think that the cooperation between them and universities or other school could help for looking for financial sources for small and middle-sized companies
- secondly there should be built „a new transport channel“ to the Slovak Republic because it could help in business cooperation increase
- thirdly there could be wider cooperation in goods and service exchange with our east neighbours.

There could be mentioned also some entrance steps towards these activities for business support, but not only in the area Zlín [7]:

- region economy
- region policy
- region development with all producers' activities with their strategies and aims. They are made by their long period achievements and strategies and by business development purposes and projects.

Also the Czech Republic came with the support for the small and medium enterprises. There was established Českomoravská záruční a

rozvojová banka in 1992 as an institution for financial support for small and medium enterprises. Unfortunately the businessmen say that to get subsidies or grants takes a long time and usually is not very successful. But there is appearing another new possibility for all areas in the Czech Republic – new information centres for small and medium enterprises (RPIC). They are called The regional information centres. They seem to be very useful and fortunate. [10]

Another help came from EU funds. Business could follow web pages with information about EU funds. This financial help is usually specified to direct business positions, to special business activities. While using these funds SMEs can obtain new external financial sources. They could also support their competitiveness. It is necessary to choose a convenient programme for their business activities. Recently the most popular area is the nature, environment support and the education support.

#### **4. Conclusion**

The SMEs survey proved two hypotheses. SMEs prefer internal sources to external ones. That's why they have problems with improving their effectiveness and competitiveness. SMEs do not effectively use all necessary information and the personal influence is not the main part of the SMEs management. There were shown some steps for improving SMEs management, especially in personal influence. Even the size of SMEs could be their advantage. For example because of their elasticity or their quick reaction on market demands.

In order to create a favourable environment for the small and medium enterprises the government could lay down certain policies. In education and training, savings and investment in primary resources, foreign trade, or others, etc. For example investors are missing not only in Zlín. All these factors (including macro and microeconomic influences) have been considered and have been considering since the Czech Republic entrance to the Europe Union.

## **Abstract**

*The article discusses particular forms of reinsurance treaties that are used within activities of insurance companies. Each of the treaties in question offers different possibilities of protecting an insurance company's portfolio by providing different ways of the risk transfer. Reinsurance is necessary to perform correct financial economy of an insurance company. Hence, appropriate selection of a scope and methods of reinsurance in the context of insuring risks of catastrophic nature gains in particular importance. Catastrophical risk are more and more frequently observed and they are more and more expensive. The paper suggests application of a decision tree as a tool that supports an optimal selection of the scope of reinsurance for a given structure of the insurance portfolio.*

**Keywords:** *reinsurance; catastrophic risk ; decisions tree*

## **1. Introduction**

Risk is a phenomenon that is directly connected with carrying out any insurance activities. Moreover, risk is an inherent element that accompanies all insurance and reinsurance decisions. The notion of 'risk' is of cardinal importance for both theory and practice of insurance. The latter classifies insurance risks according to sectors and groups, and divides them while determining premium tariffs and selecting forms and scope of reinsurance. Nowadays risk functions as an ambiguous term in insurance. Such multi-aspectual nature of understanding risk – and at the same time searching for different methods of decreasing its effects and related burdens – results in the increased attention paid to an issue of the insurance risk transfer. It particularly concerns reinsurance of catastrophic risk whose effects and consequences are more and more frequently to be faced by insurance companies these days (the World Trade Center attack in September 2001, earthquake and tsunami in the South-East Asia in December 2004, hurricane Katrina in the USA in September 2005, earthquake in Pakistan in October 2005 or a series of aviation crashes in 2005).

Each insurance company is obliged to run sound financial economy that would make it possible to satisfy all claims resulting from already concluded insurance contracts.

Therefore, a problem of making optimal decisions that are related with carrying out activities of a non-life insurance company may be presented in the following way:

- meeting statutory financial requirements that are connected with covering
  - by own means - a solvency margin, amount of guarantee capital and covering an insurance fund by means of deposits,
- carrying out a deposit policy that complies with statutory constraints,
- creating technical insurance reserves that would be adequate to the size and scope of undertaken insurance activities,
- acquiring right structure of the insurance portfolio,
- reaching a planned level of the loss ratio in the insurance portfolio, and
- carrying out an optimal reinsurance policy.

## **2. Reinsurance**

Reinsurance is a specific form of insurance where an insurer transfers some part of all liabilities that result from already concluded insurance contracts to a reinsurer. Reinsurance companies usually do not cover individual risks. Covers provided are to make sure insurance companies enjoy financial security. Reinsurance is sometimes referred to as insurance of insurance in

order to highlight a fact that reinsurance is supposed to secure or strengthen meeting all insurance companies' liabilities to the benefit of the insured. However, it is necessary to underline the fact that a reinsurer has no obligations or rights that result from insurance contracts that are concluded by an insurance company that is reinsured. Therefore, reinsurance does not affect the insured or insurer directly.

Wishing to demonstrate all formal and legal aspects of reinsurance thoroughly, it is necessary to quote its definition coined by Montalbetti: 'reinsurance is a contract by virtue of which one insurance company that is called a ceding company cedes all or part of the risk insured or a group of risks insured of a particular sort together with an appropriate part of premiums to some other insurance company that is called a reinsurer. The reinsurer then commits itself to pay its ceding company an appropriate part of benefits that are to be paid to the insured'.<sup>1</sup>

Reinsurance is a specific extension of insurance. Insurance companies accepting some risk in their portfolios demand some premiums that together with incomes generated while depositing insurance funds should be sufficient to cover compensations and benefits, and other costs born while carrying out insurance activities. The means in question should also allow for generating some profit. However, it sometimes turns out that insurers' incomes obtained are insufficient.

Such a situation may result from:

- fierce competition on the insurance market that makes insurance companies reduce insurance premiums;
- disadvantageous loss distribution that results in some increase in the loss ratio;
- accumulation of great damages or emergence of catastrophe damages;
- decrease of incomes generated by means of insurance deposits; and
- exceeding of planned volume of insurance activity costs.

Reinsurance is one of the means that provides some cover against events that might prove disadvantageous for any insurance company, and it makes up a major factor that supports insurance companies' activities allowing them, inter alia, for:

- risk distribution together with a possibility to apply a principle of mutuality;
- stabilization of the loss ratio level;
- increase in insurance capacity;
- protection of insurance company' balance surplus; and
- additional financial cover against effects of catastrophe damages.

---

<sup>1</sup> See Montalbetti [1970], PWE Warszawa, p. 13.

Hence, reinsurance fulfils two fundamental functions: a technical function and a financial one.

As quoted from E. Montalbetti: ‘a technical function of reinsurance protects insurance companies from excessive increase in the loss ratio in a given period incurred as a result of occasional great damages or unusual accumulation of normal damages in time resulting in significant deviation from the average loss ratio’<sup>2</sup>.

On the other hand, a financial function is mainly manifested in accepting a large part of compensations paid to the insured by insurance companies. It allows ceding companies to save some means in form of reserves of premiums and reserves for non paid losses.

Reinsurance may be carried out in different forms. A form of reinsurance should be understood as a way of sharing risk between a ceding company and a reinsurer. Reinsurance contracts are most frequently divided into two basic groups:

- Proportional reinsurance contracts that are to be divided into quota share treaty, surplus treaty and quota and surplus treaty share; and
- Non-proportional reinsurance treaty that include excess of loss treaty (with a further division into reinsurance excess of loss treaty for risk and for event ) and stop loss ratio (aggregate excess of loss ratio treaty)

Proportional reinsurance is characterised by the fact that a reinsurer’s share in each market is determined in the agreed relation to a ceding company i.e. the reinsured. The reinsurer takes over a determined part of an insurance premium that is decreased by the reinsurance commission and then participates in covering all damages that are reported in the reinsured portfolio to the same extent. In proportional reinsurance the reinsurer unequivocally shares their lot with the reinsured.<sup>3</sup>

Conversely, unproportional reinsurance is characterised by the fact that while sharing risk between the reinsured and reinsurer there are no pre-arranged proportions.<sup>4</sup> Reinsurer will be obliged to cover damage or equalise value of the loss ratio only in the very case when their pre-set volume is exceeded.

### ***2.1 Quota share reinsurance***

Quota share treaty are the simplest form of reinsurance. They involve providing reinsurers with a given part of the whole risk portfolio included in the contract. The major advantage of the quota share treaty is to be found in its simplicity. In order to administer such a contract neither particular

---

<sup>2</sup> See Montalbetti [1970], PWE Warszawa, pp. 28-29.

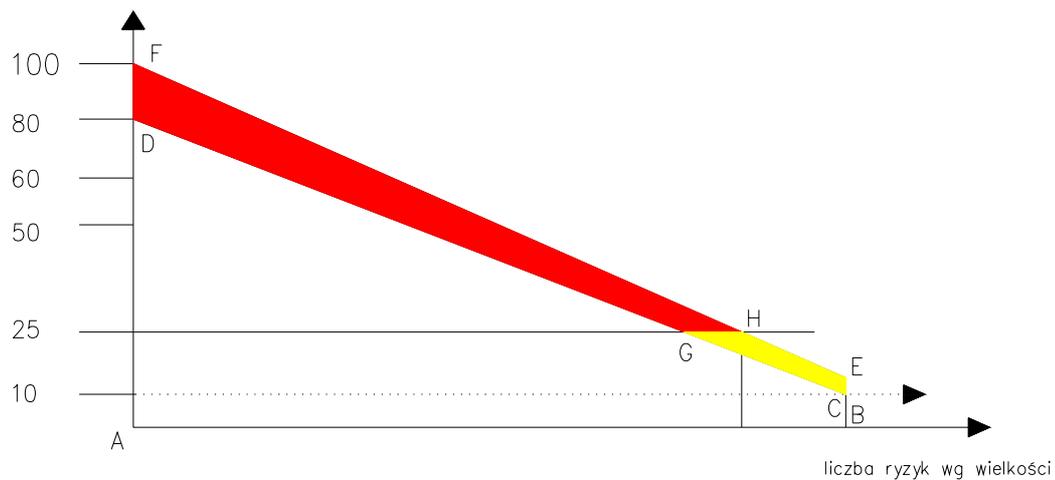

<sup>3</sup> Banasiński: [1993], pp. 68-169.

<sup>4</sup> Montalbetti: [1970], p. 89.

qualifications of the insurer's personnel nor specialist information technology assistance are required because – as a general rule – risks subject to contracts are automatically subject to reinsurance in their determined part.

In the quota share treaty cession refers to a specific amount or share in each ceded risk. The same proportion will be applied with reference to the sum of insurance, premium and possible damage. The Figure 1 presents a mechanism of quota share reinsurance.

**Figure 1 Quota share reinsurance**

Where: liczba ryzyk wg wielkości – a number of risks according to their size  
 Source: Monkiewicz. [2000], p. 142.

In the Figure 1 a vertical axis shows volume of risks measured by sums of insurance. Horizontal axis illustrates a number of risks. Total volume of risks subject to insurance protection is manifested by the ABEF quadrangle field. Applying 20% of quota share reinsurance a ceding company's participation in risks will be decreased, and manifested by the ABCD quadrangle field. Field of a CEFD figure, on the other hand, manifests reinsurer's 20% share in risks.

Quota share reinsurance disadvantage is observed when an insurance company changes its decisions. For instance, the insurer may conclude that they accept higher deductible (PLN 25 million) CEHG field is unnecessarily reinsured. Quota share reinsurance is always on the same level and it covers small and great risks and good and bad risks

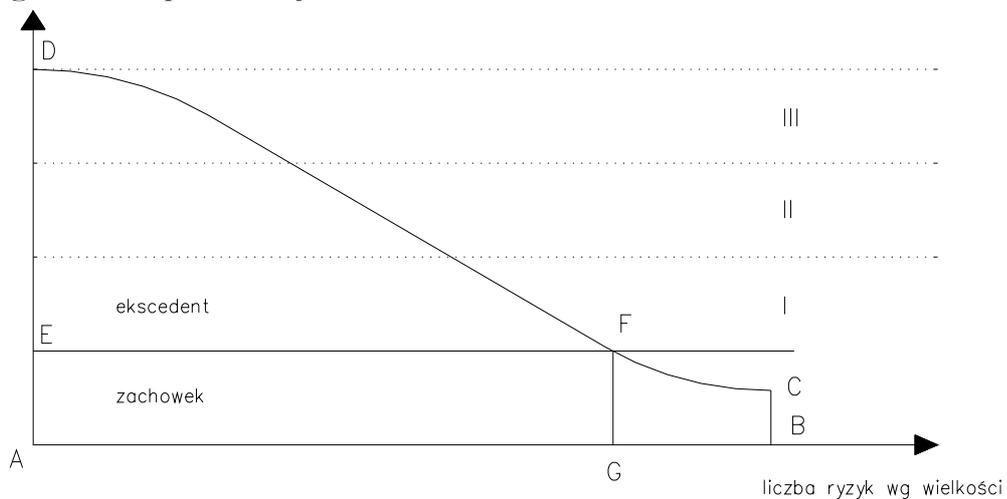

## 2.2 Surplus treaty reinsurance

Quota share treaty disadvantage may be – to some extent – eliminated by surplus treaty reinsurance that allows for complete equalisation of volumes of risks that are observed in the insurance portfolio. In surplus treaty insurers – utilising statistical information and actuarial tools – firstly determine volume of maximal deductibles in particular risk sectors. Such shares are called , line or maximum. Other than these shares of some part of risk (excedents) are ceded to reinsurer by the insurance company.<sup>5</sup>

Mechanism of surplus reinsurance treaty is presented in Figure 2. Risk field is shown by the field of ABCD. Field of risks that are not subject to reinsurance is a field of GFBC. The other part of the ABCD figure i.e. AGFD is a field of risks that are subject to reinsurance. EFD represents an excedent and AEFG shows insuring company's.

In practice excedent is determined to the value of line. In case of greater risks a few excedents may be set. The Figure 2 presents the situation when three excedents are observed.

**Figure 2 Surplus treaty reinsurance**

Where: zachówek – maximum, ekscedent- line  
 liczba ryzyk wg wielkości – a number of risks according to their size

Source: Monkiewicz , [ 2000], p. 142.

<sup>5</sup> Ciuman: [1996], p. 27.

In business practice there are also quota share and surplus treaties.

### ***2.3 Excess of loss treaty***

As a result of such reinsurance contracts the whole portfolio of particular insurance is reinsured quotatively, and selected determined risks that are higher than the insurer's accepted level are reinsured by means of excess of loss treaty insurance.

Essence of the excess of loss treaty lies in reinsurer's commitment to cover this part of a loss that is higher than a ceding company's share in the loss, and lower than the sum that is a limit of reinsurer's liability. The amount of loss that makes a reinsurer take over ceding company's liability is called a priority or excess point.

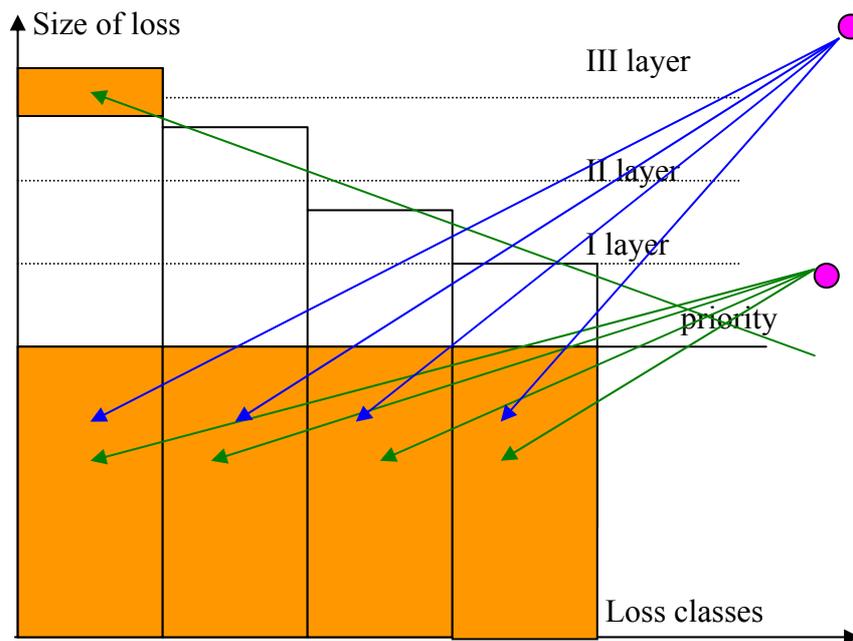

A limit of reinsurer's liability taken as a result of one fortuitous event is called loss ratio working layer.

Excess of loss treaty is applied in order to secure financial equilibrium of insurance transactions that might be disturbed by emergence of particularly high losses in the portfolio. Excess of loss may take two forms:

- a surplus that is calculated in the relation with risk; and
- a surplus that is calculated in the relation with an event.

In case of a surplus that is calculated in the relation with risk, a loss that concerns the whole single risk is involved. In case of a surplus that is calculated in the relation with an event, a sum of losses that result from a single event is involved. Excess of loss treaty is shown by the Figure 3.

**Figure 3 Excess of loss treaty**

Source: Monkiewicz , [ 2000], p. 145.

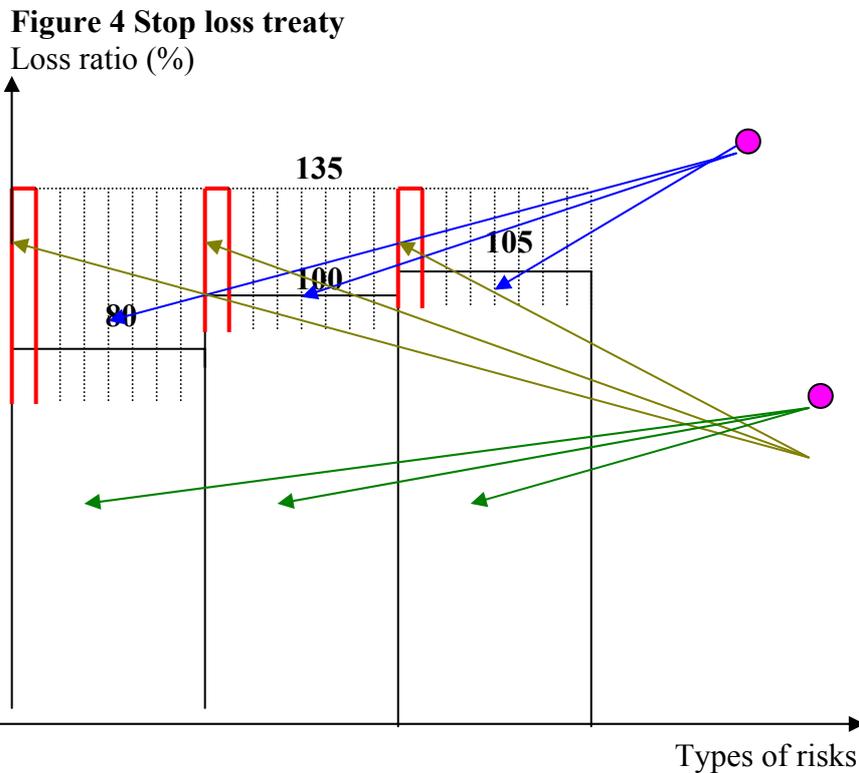

In the Figure 3 particular losses were placed on the horizontal axis. The vertical axis illustrates the amount of losses in question. A ceding company's liability concerns losses up to priority (deductible) and losses that exceed the last loss ratio working layer. Losses below priority and above loss ratio working layer are covered by the reinsurer. Loss layer field is usually divided into some number of limits reinsured by different re-insurers (the Figure 3 presents three of them). Such diversification of liabilities among different reinsurers is particularly important in the situation of a complex cover whose priority is set on a very low level.

Aggregate excess of loss treaty (stop loss) is another form of non-proportional reinsurance. In this type of reinsurance reinsurer's liability concerns a situation when value of reported losses in a given year results in either exceeding of a determined loss ratio or a determined quota level. This type of a reinsurance contract concerns the whole insurance portfolio of a given kind or even the whole portfolio of insurance of an insurance company. In aggregate loss treaties three basic principles are followed:

- generally, reinsurer's liability commences only when an insurer enters the zone of a technical loss or exceeds a calculation level of rates;
- a ceding company participates in re-insurer's losses i.e. reinsurance cannot cover the whole excess of loss; and

- reinsurance cover has upper limits exceeding of which results in the complete liability of the ceding company<sup>6</sup>.

Aggregate excess of loss is shown by the Figure 4.

Source: Monkiewicz , [ 2000], p. 147.

Assuming that a concluded contract stipulates a reinsurance cover of excess of loss in the situation when loss ratio exceeds 80%, 105% and 110% depending on the kind of risk Simultaneously assuming the cover in question finishes at the moment when the loss ratio exceeds a level of 135%. In the 80%-135% loss ratio range depending on the kind of risk a determined reinsurer's liability amounts to 80%. In case of a ceding company it is 20%.

To conclude, it is necessary to state clearly that insurance activities are always accompanied by the reinsurance ones. The only thing that changes is the form and scope of reinsurance since technological development results in emergence of new risks and in the increase of those already existing.

<sup>6</sup> Compare Monkiewicz, [2000], pp. 143- 148.

Reinsurance market development is a natural consequence of the increase observed on the market of insurance services. The problem to be solved by insurers is to select the most beneficial combination of reinsurance forms. In principle, all presented above forms of reinsurance may be applied by insurers to different extent and in various combinations. Each of the variants to be applied will differently influence the kind and amount of loss recovered by insurers. Quote share treaties and surplus treaties together with excess of loss treaty based on single risks will decrease a size of losses incurred as a result of single events. On the other hand, excess of loss treaty as a result of a single event will decrease insurance company's exposure to catastrophe events or accumulation of events in a given year. In contrast, aggregate loss treaty is the most suitable to avoid adverse effects of mass events that are observed in a given year.

Forms and methods of reinsurance that is applied by reinsurers will depend on numerous factors including:

- a level of reinsurance market development;
- a form of risks to be reinsured;
- a size of insurance company's portfolio;
- current insurance company's financial standing;
- their experience in reinsuring insurance; and
- skills of managerial staff<sup>7</sup> and threats posed by catastrophe risks.

An insurance company should carry out an optimal reinsurance policy. In order to do this and to foresee changes in its environment effectively, such a company does need to know the market well and it has to be flexible.

In their portfolios, reinsurers do not always retain all risk ceded by insurance companies. They may carry out secondary distribution of already underwritten risks by means of further reinsurance, i.e. retrocession. A necessity for retrocession arises when reinsurers have already underwritten in their portfolios risks that are excessively high and potential coverage of such risks exceeds reinsurers' financial capacities.

### **3. Optimal reinsurance**

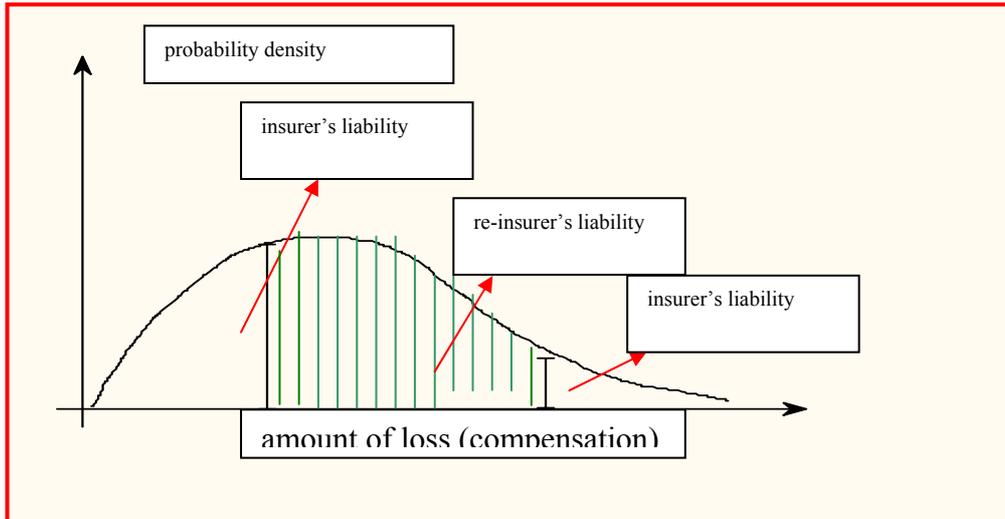

A reinsurance contract is concluded between an insurance company and a reinsurer who makes a charge in form of a part of premiums collected by an insurance company in return for appropriate protection of a part of insurance company's portfolio. However, it is not the last stage of risk distribution. A reinsurer may also transfer some part of its portfolio to a

---

<sup>7</sup> Ciuman: [1996], pp. 35-36.

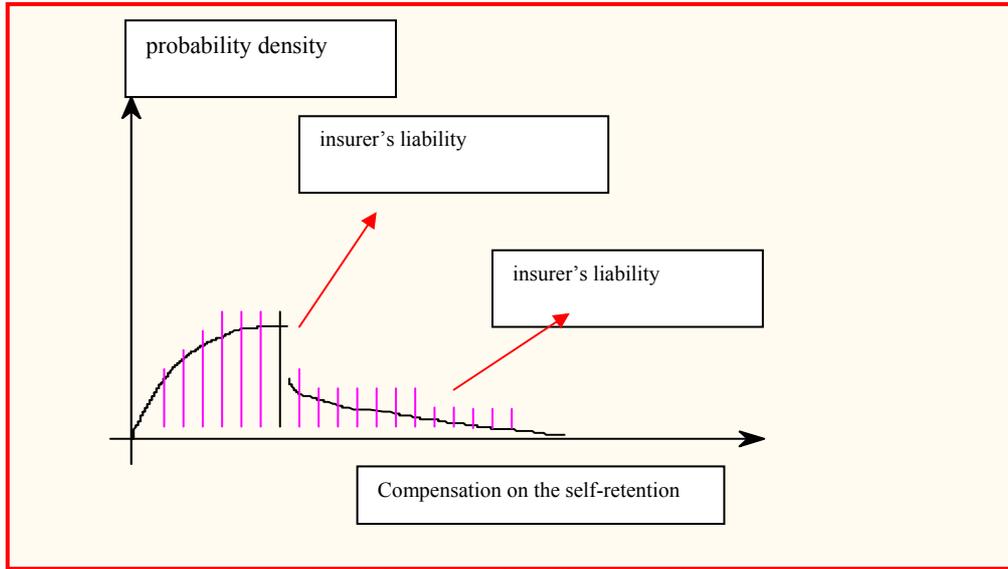

retrocesionaire who will then reinsure it. Such a process may consists of many stages and, as a result, some part of insurance company's own risks together with parts of other insurance companies' portfolios may return to the portfolio of the insurance company in question. Risk sharing by means of self retention, different forms of reinsurance contracts or setting limits of reinsurer's liability leads to some change in the shape of the very distribution. This way two distributions are obtained: a retained part of risk and a transferred part of risk (meant for reinsurance). Figures 5, 6 and 7 present these distributions graphically.

**Figure 7 Scope of insurance company' liability in the distribution of loss**

*Source: own on the basis of: Samson, D., Thomas, H.,*

From the perspective of an insurance company, it is important to find optimal proportions of the very distribution taking insurance company's

portfolio structure into consideration, i.e. to choose a scope and forms of reinsurance that would bring the insurance company in question the highest possible financial benefits. A very good and effective tool that might help while solving this type of problems may be provided by decision trees.

As it has already been mentioned, a method of equality of collected premiums and expected amount of paid compensations is a basic method that is used in insurance to calculate premiums. An insurance company has to match a scope and forms of reinsurance with its insurance portfolio size and structure correctly. A problem of insurance risk transfer that is a prerequisite for a reinsurance contract arises here. Because of their construction, proportional reinsurance contracts naturally ensure risk transfer. There is only one exception when a re-insurer determines an upper limit of its liability. A similar situation takes place in case of a disproportional reinsurance contract of an excess of loss type.

There is a different situation in case of reinsurance of aggregate excess of loss. For this type of reinsurance, it is not possible to point out elements of risk transfer evidently. Since risk transfer is one of the elements of the reinsurance contract, there is a clear necessity to determine constraints that will facilitate transferring some part of ceding company's liabilities adequate to the costs borne to a re-insurer in order to comply with reinsurance contract provisions. The fact that both in Poland and in the world such constraints have not been determined yet is a major problem that generates additional risk for activities of insurance companies.

As Seweryn<sup>8</sup> writes, a standard number 113 ('Accounting and Reporting for Reinsurance of Short – Duration and Long Duration Contracts') was published in 1992. This document determines the following conditions for reinsurance contracts:

- reinsurer underwrites a large part of insurance risk; and
- there is a real probability that a reinsurer will incur major financial loss as a result of a transaction made.

To meet all conditions stipulated in the re-insurance contract it is necessary to meet the above conditions simultaneously. Hence, with reference to the above statements, a contract between a reinsurer and an insurance company may be deemed a reinsurance contract only in the situation when there is a real probability that a reinsurer will incur major financial losses. However, there are some problems to be discussed here:

- firstly, how to understand a notion of 'a major financial loss?';
- secondly, how to assess a level of such probability?; and

---

<sup>8</sup> Compare: Seweryn [2002], pp.3-6.

- thirdly; are there sufficiently exact and historically complete statistical data that will allow for estimation that would be precise enough?

As far as the major loss is concerned, such loss is thought to be incurred when there is at least 10 per cent loss in relation to the price of reinsurance. However, this statement is not explicit. After a one year period such understanding is clear for an insurance company. Before a reinsurance contract is concluded – it is not. Theoretically, a good measure of a loss incurred by a reinsurer may be provided by a traditional loss ratio of a premium written to a contract. Such ratio is defined in the following way:

$$\text{LR} = \frac{\text{total amount of compensation paid}}{\text{premium earned}} \quad (1)$$

However, this ratio does not include costs of loss liquidation borne by insurance companies<sup>9</sup>. As a result, an important question if a value of a loss ratio that will allow for assessing effectiveness of a concluded reinsurance contract is known emerges. To follow FASB 113 standard properly, it is necessary to know exact probability distribution of a loss ratio on the basis of historical data. Nevertheless, even the most accurate statistical data do not guarantee that a forecast to be obtained will come true. Therefore, a decision tree is a tool that may effectively support decision made by an insurance company in the discussed area. A decision tree enables to analyse consequences of all decisions that are made in the conditions of uncertainty and risk. Such a situation is to be dealt with by an insurance company while it decides about a form and scope of reinsurance.

#### 4. Decision tree

An insurance company in its activities aims at reaching certain objectives of a pre-determined hierarchy. The hierarchy in question determines preferences and selection criteria of decisional variants. Decisional variants determine possible actions that meet pre-set constraints and are to help the insurance company in question realise its objectives. Such a mechanism leads to a necessity for making decision in conditions of uncertainty and risk. In conditions of uncertainty and risk typical elements that compose a decisional situation include:

---

<sup>9</sup> See: Seweryn [2002] pp. 3-6.

- a decision maker (an insurance company);
- a set of acceptable decisions (variants of forms and scope of reinsurance);
- a set of the external world states (a set of possible realisations of value of a random variable);
- a utility function that presents profits or losses that result from making certain decision; and
- a level of uncertainty about realisation of states of the external world<sup>10</sup>.

State of the external world – sometimes referred to as the states of Nature – directly influence effectiveness of realisation of objectives set. They are of random nature and are characterised by a possibility to realise only one state in the analysed period. They result from the effect of external factors that are out of a decision maker's (an insurance company's) control.

Making decisions in conditions of risk and uncertainty is always accompanied by the selection of the utility function form. This function determines utility (amount of payment) that accompanies each decision made (each selected strategy) for each of the states of nature.

Realisation of the specific state of nature is characterised by uncertainty that is expressed by the probability that some particular event will take place. If the probability is known, decisions are made in the conditions of risk. However, if it is unknown - decisions are made in the conditions of uncertainty.

While determining a specific set of states of Nature the following conditions have to be met:

- states of nature must be events that are mutually exclusive;
- probabilities of realisation of all states must sum to 1;
- it is necessary to include all possible states of nature;
- probability of realisation of each state must be within an interval (0;1);
- probability of a sum of two states is equal to the sum of probabilities of emergence of each of those states.

A decision tree is a graphic method to present and solve a specific decision problem. Such a tree consists of decision and chance nodes. A decision node signifies an event that is related with a selection of one decisional variant. A chance node means a random event that involves realisation of one of possible states of nature. Arrows that come out of decision nodes indicate possible decisional variants. Arrows that come out of chance node show possible states of nature. Above a chance node an expected amount of payment is given.

---

<sup>10</sup> Compare Nowak [1999] p.10

In order to construct a decision tree for any problem, it is necessary to form a matrix that presents utility of particular decisions for a decision maker. Insurance company's decisions that concern an optimal selection of a sort of methods and scope of reinsurance may be very well modelled by means of a decision tree, as it is illustrated by the following example. To solve a problem of an optimal selection of reinsurance by means of a decision tree an insurance company must have two pieces of information:

- probability of realisation of a particular state; and
- expected utility or benefit that results from realisation of a specific state.

Let us consider the following decisional problem of an insurance company. An insurance company has its insurance portfolio that does not require reinsurance or may be reinsured by a surplus reinsurance treaty with one or two surpluses. Cost of purchase of the first surplus for the loss 25-50 million PLN amounts to 20 million PLN. Cost of purchase of the second surplus for the loss 50-75 million PLN amounts to 15 million PLN.

With the above assumptions, the following matrix of payments for the problem in question is obtained:

**Table 1 . Matrix of payments for reinsurance decisions**

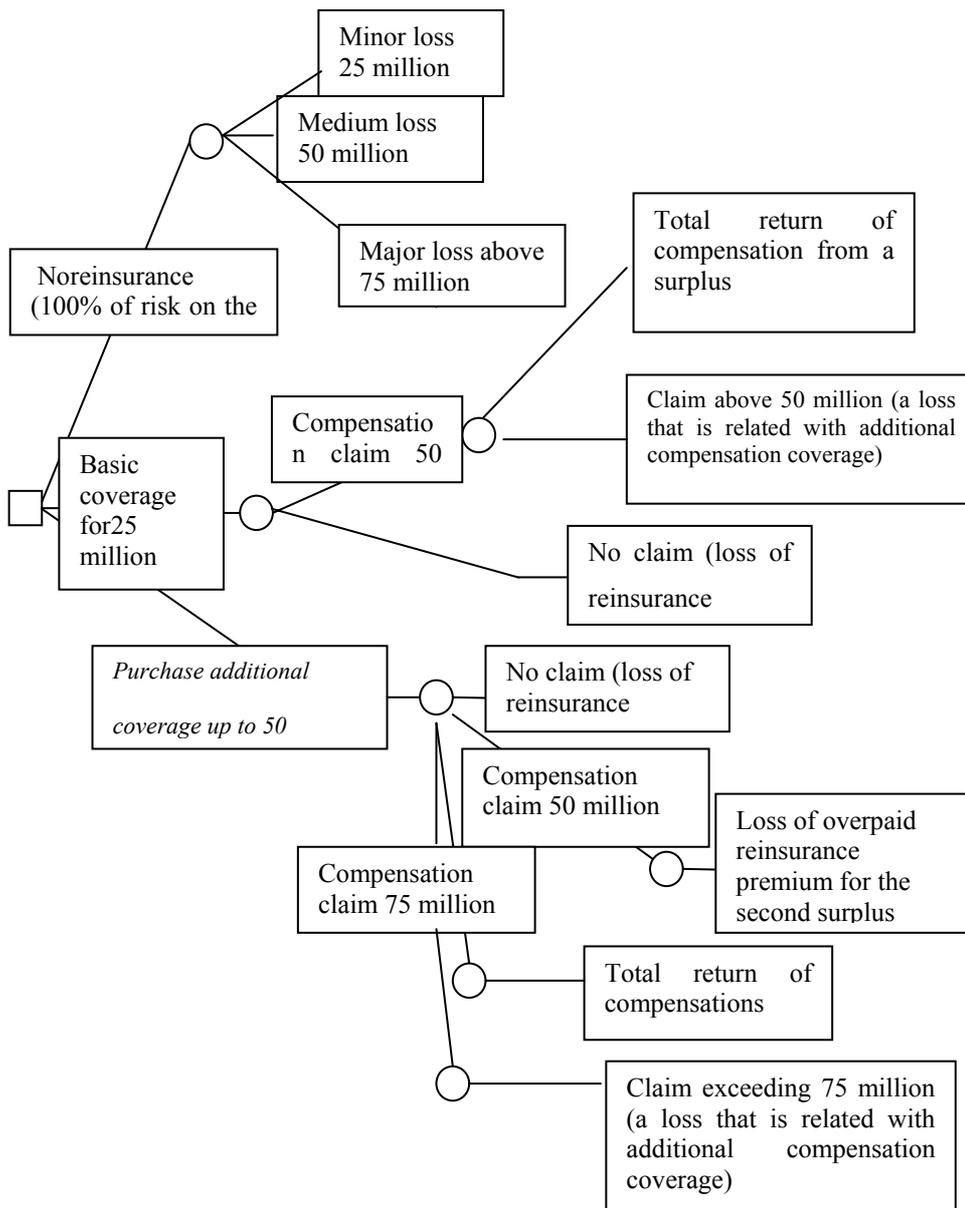

Decision of an insurance company	Cost of compensation		
	loss of 25 million	loss of 50 million	loss of 75 million
No reinsurance	25	50	75
Reinsurance with one surplus	45	20	70
Reinsurance with two surpluses	60	50	60

*Source: own based on pre-arranged data*

On the basis of this information it is possible to construct a decision tree that allows for making the most beneficial reinsurance decision for an insurance company.

Below, The Figure 1 presents a decision tree for the quote reinsurance treaty in a non-life insurance company.

**Figure 1 Decision tree for the optimal selection of the quote reinsurance**

Source: Author's calculation on the basis: Samson, D., Thomas, H.,

## 5. Conclusion

While selecting a decision it is possible to use a principle of benefit maximisation. This principle may be characterised in the following way:

Using a probability distribution of emergence of subsequent states of nature, expected benefits for particular decisions are calculated. A recommended decision is a decision for which an expected benefit is maximal. In case of ambiguity, all decisions for which the above condition is met are recommended.

The approach suggested above allows an insurance company to analyse all decisional situations exactly and select a scope and forms of reinsurance in the optimal way.

## **Abstract**

*The last years events on the international insurance market point out that, the financial market volatility and the dynamics (more and more emphasized) of the business environment influenced in a high measure the financial security of the insurance companies. In this way, International Association of Insurance Supervisors – IAIS – has elaborated some principles, which have to represent the base for the solvability regime. The systems utilized by the surveillance institutions to evaluate the solvability insurance companies differ from one country to another. Regarding the IAIS opinion, the objective of surveillance institution is to maintain an efficient, fair, sure and stabile insurance market in order to protect the interest of the insured persons. As well, the solvability and the adequated capital regime represent one of the most important elements for the surveillance activity of the insurance companies. The solvency causes discussions permanently and, as a recent proof, in the European Union, it has been started the so-called Solvency II project which will run on a few years period and it will have as purpose to determine whether fundamental changes of the solvency system and a risk orientated approach are necessary.*

**Keywords:** *insurance activity, risks, solvency system, surveillance institution, models of solvency*

## 1. The importance of the solvency in the insurance activity

The solvency reflects the capacity of an insurance company to achieve all obligations resulting from the contracts in any moment, even some obligations related to the current activity will be closed after few years.

The international law in the insurance field forecast the existence and the maintenance of a minimum amount of the net asset of a company, that is a solvency margin.

*The International Association of the Insurance Surveillance Institutions – IAIS* – defines the **solvency margin** as been represented by the positive difference between the assets and liabilities of the insurer, in the conditions which are determined in accordance with some standards that refers to their evaluation process. This difference should be higher than the value established by the standards regarding the minimum limit of the solvency margin of the insurers.

The settle up of the solvability supposes *the knowing of the risks* the insurer is confronted with and the *necessity of capital in order to face these risks*. The future activities of the insurer are uncertain, and the role of the solvability margin is *to guarantee the fact that insurer has sufficient assets in order to pay the future damages*, with the purpose of insured person's protection.

In the directives of the European Union is underlined the necessity to settle up a solvency margin which should take into consideration the whole activity of the insurers and which is represented by “ the free obligation assets”.

In the condition of the free circulation of the services, *the protection of the insured person interests supplied by the insurers should be the same*, which means that the solvency requests – as main protection instrument – should be the same for all insurance companies from the European Union.

## 2. Solvency Margin Types

There are several notions regarding the solvency margins, as following:

**1. The commercial solvency margin** reflects the net asset of an organization and is determined on the base of the current reports established by the normative. The drawback consist on the fact that in the determination of the commercial solvency margin are taken in the consideration the assets from the balance sheet, even some of these should not be included because

prudential considerations, as well, all obligations, with no adjustment in function of their underevaluation risk.

**2. The statutory solvency margin** represents the surplus of the assets over the liabilities, both being evaluated on the base of strict relementation. These relementation regards the accounting statements, imposing special prudential principles and rules, as well, the limits of the margin necessary in a context. In the category of the assets which were not taken into account are included the assets with a high risk, eventually the tax exemption offered as a result of a accumulated losses and some investment of the company in the affiliated societies. The level of the statutory solvency margin will be always less than the commercial solvency. The difference between these will be as higher as is the weight of the excluded assets in the total assets.

For the difference between the assets and the liabilities of the insurer determined and evaluated in conformity with the law it is used the name of **disposable solvency margin**.

**3. The minimum required solvency margin** represent the minimum level of the statutory solvency margin, calculated in conformity with a methodology established by law or methodological standards. The surplus over the compulsory minimum solvency margin is named **the surplus of the minimum margin**.

Considering the minimum solvency margin as an expression of the insurer's capacity to accomplish all his liabilities against the insured persons in an extreme situation, it should not be understood that an insurer does not have the paying ability if the margin is under a admitted minimum level.

The role of the minimum solvency margin is to take over the effects of the unquantifiable risks, as well, the impact of underestimation the quantifiable assumed risks or the risk of unusual variation of those, in order to offer to the insurer and to the surveillance authorities enough time to correct the situation generated by the materialization of the respective risks.

### **3. Regulation systems of the solvency used on the international level**

The modalities used by the surveillance institutions for controlling the financial security of the insurance companies are different from a country to another. In many countries, for the insurers are imposed minim values for the solvency margin and in some of them are imposed the constituting of deposits as a form of protection for the insured person interests. We can mention the main regulation system for the solvency used on the international level, as they are defined in note sent to the Subcommittee for Solvency of

the Insurance Commission from the European Commission, document issued in March 2001 and in the OECD Report regarding the supervision of the solvency in the member countries (Insurance Solvency Supervision, OECD Country Profiles, 2002):

***1. Solvency systems which are based on the models adapted to the specific of each company (ruin models, resilience tests).***

This approach comes from The United States and is less familiar to the European supervision institutions, being used just in Canada, Australia and some of the North American states. In conformity with these methods, the insurance companies should pass a test which simulate the possible financial consequences, starting from the hypothesis of some negative changes of the assets or liabilities' values. The difficulty, and in the same time, the major deficiency of this model consist, in principal, on the selection of the test scenario: the risk factors taken into consideration should be chosen and dimensioned with a lot of attention in order to get a correct image on the solvency of the tested company. The subjective nature of these working hypothesis selection, as well the choose of the type of test used determine this model to be less popular.

***2. RBC Systems (Risk - Based Capital)***

The RBC system, used on large scale in US was adopted by NAIC (National Association of Insurance Commissioners), for the life and health insurance industry, with the purpose to answer to the necessity of a standard regarding the capital adjustment which should take into consideration all risks which each insurer is confronted with: technical, investment, commercial, management and so on. The weight amount of the adequate values for each risk represents the minimum capital requested to that insurer. New versions of this model are used in Canada and Japan.

The most objections raised by this model are related to the difficulty and accuracy of the calculation, as well to the lack of transparency for the public.

***3. The three pillars system (solo solvency)***, used mostly exclusively in the European countries, this system is based on three requests imposed to the insurers: adequate reserves, assets and the minimum solvency margin imposed, calculated with the method of fixed ratio. The limits of this approach have the origin in its own quality, simplicity. The most objections mentioned in the specialty literature refers to the narrow profile taken into consideration and to the incapacity of the capital requests formulated in order to reflect the risks specific to every company, as well to the capital or the reserves report to the gross or net premium, gross or net reinsurance, which

do not take into consideration the variation of the premium, which, in the case of a soft market, have no advantages for the insured persons, the level of the guaranteed protection being reduced.

The system has not being contested by the European supervision authorities so far, and need some improvements in the scope of harmonize and reciprocal validation of the supervision activity in the European Union countries.

#### **4. The standardize of the solvency requests for the insurance companies from European Union**

When talking about the free movement of services, the protection by the insurers of the interests of those insured must be the same, this meaning that the solvency requirements – as a major protection instrument – must be the same for all the insurance companies in the European Union.

The establishing of the solvency means to know the risks to which an insurer is exposed and a necessary capital to overcome those risks. The insurer's future activities are uncertain, and the part of the minimum m.s. is to guarantee that the insurer has sufficient assets to pay the future damages, with the purpose of protecting the insured.

The present system of solvency was created in the '70s, being actualized relatively recently throughout two Directives issued in 2002, as part of the *Solvency I project*. The solvency permanently causes discussions and, as a recent proof in the European Union, it has been started the so called *Solvency II project* which will run on a few years period and will have as a purpose to determine whether fundamental changes of the solvency system are necessary, a risk orientated approach.

In the two directives, the following **concepts** are used:

- *compulsory solvency margin*, representing the amount by which the assets value overcome the bonds' value, imposed to an insurance company which is going to practice the authorized activity;

- *the solvency margin available*, representing elements by the nature of capital, which can be taken into account for the estimation of the compulsory solvency margin;

- *the guarantee or safety fund*, representing 1/3 of the compulsory solvency margin, which can't be lower than a minimum level.

One of the **new elements** introduced by the 2 directives from 2002 refer to the existence of the safety fund, its volume being different for the two

types of insurance, respectively: 2 million EUR for non-life insurance and 3 million EUR for life-insurance.

The two directives through which the solvency margin are actualized ensure minimum conditions for the harmonization of the legislation of the member states, and, in turn, the states can impose even more restrictive conditions through their national legislation, thus maintaining their freedom of adapting the compulsory solvency margin to the specific conditions of their markets.

## **5. The solvency regime for the Romanian insurance companies**

### ***5.1 Results obtained on the Romanian insurance market compared to the European Union States***

*The international insurance market* has shown fluctuating evolutions from one period to another. Thus, at the end of 2003, some economically developed countries dominated the insurance market, like USA with a market share of 36% of the world market total, Japan with 16% and Great Britain with around 9%, together having 61% of the total gross premiums received on the whole insurance activity. Referring to the structure of the insurance, in the life insurance domain, on the first three ranks worldwide there are the same countries with a market share of 29%, 22% and 10%, but in the non-life insurance domain, the rank of Great Britain is undertaken by Germany, closely followed by the latter. So, the weight of the gross premium in the non-life insurance domain by the first three countries is of 60.51% as it is shown in Table 1.

These countries together with France, Italy and Canada, meaning the great seven industrialized powers of the world, known as the G7, obtained around 78% of the amount of insurance premiums from total market, life insurance and non-life insurance.

**Table 1 Worldwide market share regarding gross premium level on total insurance activity and on structure in 2003**

<i>Country</i>	<i>% Total insurance</i>	<i>% Life insurance</i>	<i>% Non-life insurance</i>
<i>United States of America</i>	<b>35.90</b>	<b>28.79</b>	<b>45.23</b>
<i>Japan</i>	<b>16.04</b>	<b>22.23</b>	<b>7.92</b>
<i>Great Britain</i>	<b>8.63</b>	<b>9.64</b>	<b>7.31</b>
<i>Germany</i>	<b>5.77</b>	<b>4.56</b>	7.36
<i>France</i>	5.48	6.22	4.51
<i>Italy</i>	3.75	4.29	3.05
<i>Canada</i>	2.03	1.43	2.81
<b>G7</b>	<b>77.60</b>	<b>77.16</b>	<b>78.19</b>
<b>EU 15</b>	<b>31.71</b>	<b>32.70</b>	<b>30.41</b>
<i>EU 25</i>	32.27	33.06	31.23
<i>Total worldwide</i>	100	100	100

*Source: Swiss Re, Sigma, No 3 (2004), update February 2005, processing page 3-9*

*The European insurance market* registers quick and consolidating changes, mainly due to the plans and strategies made by the European Union, which refer to the extending of the insurance transactions. However, the differences between the organizational and the national cultures have hindered the creation of the required financial mechanisms. The best results have been obtained on the life insurance market, which have promoted the efficiency of the activity by cost reduction.

The evolution of the main indicators registered on the **Romanian market compared to the results of the European countries** and to the worldwide results, in 2003, shown in Table 2, emphasizes the development of the insurance activity in these countries and the capacity of absorption of the insurance market.

Despite the fact that the effective gross premium volume is higher in some states than in others, **the indicators of the insurance market**, meaning the insurance density and insurance penetration, do not show the same situation. So, as it concerns the gross premium, on the first three ranks there are situated Great Britain, Germany and France, while from the insurance penetration in GDP, on the first three ranks there are situated Great Britain with 13.37%, Switzerland with 12.74% and both Holland and Belgium with 9.77%. If we consider the insurance density, in the hierarchy are placed

Switzerland, Ireland and Great Britain with 5 010 EUR/capita, 3 932 EUR/capita and 3 689 EUR/capita.

**Table 2 Romanian insurance market compared to the results registered in the European countries in 2003**

Country	GP* (mill EUR)		Insurance density** (EUR/capita)		Insurance penetration*** *

\*Gross premium

\*\*Insurance density shows the level of gross premiums per inhabitant

\*\*\*Insurance penetration shows the weight of gross premiums in GDP

In Europe, **Romania** ranks as the 26<sup>th</sup> regarding the amount of the gross premium, among the 34 countries, as the 33<sup>rd</sup> regarding the insurance

density and the insurance penetration – Ukraine, respective Turkey, being on the last places.

Concerning the **structure of insurance**, the highest premiums volume per capita is bigger for life insurance than for non-life insurance, respective of 60% in the countries of Europe - 15, and of 57% worldwide. In Romania, the structure of life insurance is in favor of general insurance, respective of 76.5%.

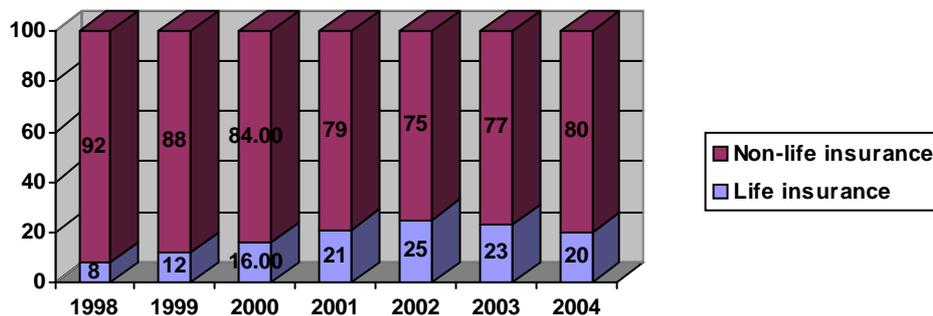

**Table 3 The evolution of gross premium on total insurance activity and on structure, in Romania, in the period 1998-2004**

<i>Year</i>	<i>Life insurance gross premium (%)</i>	<i>Non-life insurance gross premium (%)</i>
1998	8	92
1999	12	88
2000	16	84
2001	21	79
2002	25	75
2003	23	77
<b>2004</b>	<b>20</b>	<b>80</b>

Source: processing from the ISC Annual Report for 2001, 2002, 2003, adding data from a specialized magazine "PROFIL Insurance", March the 30<sup>th</sup>, 2005.

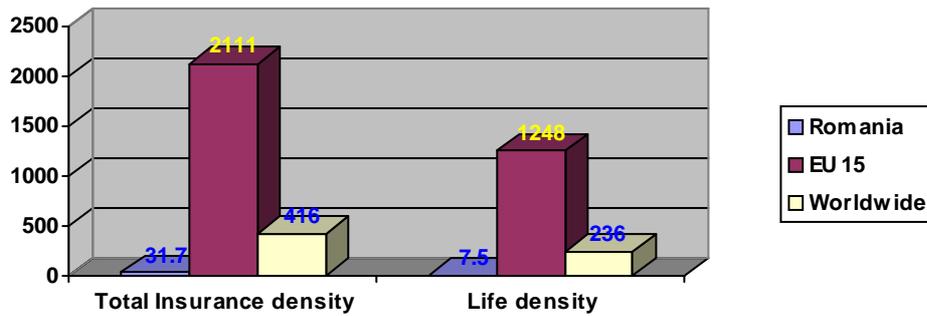

From Table 3 and Figure 1, it can be seen that the highest percentage on total insurance market in Romania, of 80%, still belongs to non-life insurance, increasing from 2003 and with fluctuating evolutions in the analyzed period.

**Figure 1 Structure of gross premium on life insurance and non-life insurance, in Romania, in the period 1998-2004**

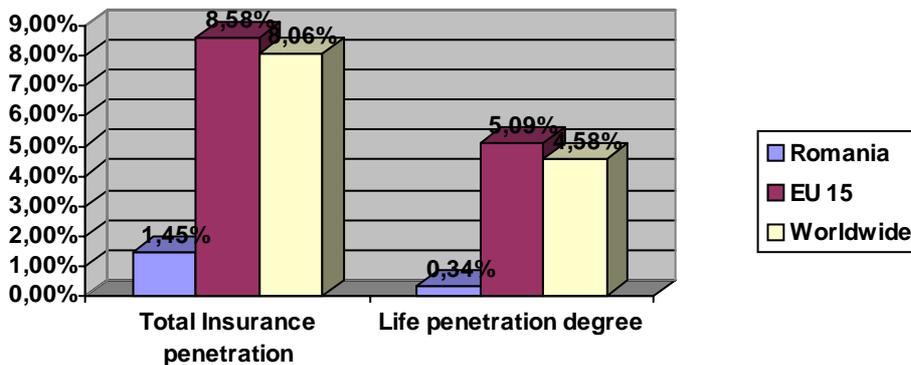

*The insurance density* in Romania has achieved a level of 31.7 EUR/capita, of which gross premium from life insurance – 7.5 EUR/capita, and from non-life insurance – 24.2 EUR/capita, while in the European Union states, the insurance density represents 2 111 EUR/capita, and on worldwide a level 416 EUR/capita, shown in Figure 2.

**Figure 2 Insurance density on the whole insurance market and the life insurance, in Romania, EU 15 and Worldwide in 2003**

For a level of the GDP per capita of 2 193 EUR<sup>1</sup>, in Romania, *the penetration degree* registers a level of 1.45%, shown in Figure 3. Even though increasing from previous years, the insurance penetration in Romania remains low compared with the ones registered in Central and Eastern European countries – which are between 3% and 5%, with the European Union average of 8.6% or with the worldwide average of 8.06%.

**Figure 3 Insurance penetration on the whole insurance market and the life insurance, in Romania, EU 15 and Worldwide in 2003**

<sup>1</sup> Xprimm Magazine, Insurance Profile, year II, no. 4 (2004), page 3: <http://www.lasig.ro>

*The insurance gross premium by the first ten insurance companies from Romania*<sup>2</sup>, at the end of 2004, represent 83% of gross premiums received on the whole market, situation that reveals the insurance market's level of concentration. On the first three ranks are situated the following insurance companies: Allianz-Tiriac, Asirom and Omniasig, with a total market share of 46%.

*The gross premium by the first ten insurance companies providing life insurance* in the same period (from the 23 insurance companies that had activity in life insurance domain) represent 93% of the total insurance gross premium received on this insurance industry. ING Life Insurance remains the leader of life insurance, with a market share of 40,5%. The first three insurance companies (ING Life Insurance, Asirom, AIG Life) hold together a share of 64% of life insurance market.

The number of societies that provided *non-life insurance*<sup>3</sup> has been of 34, and the percentage of gross premium for the first 10 insurance companies has represented 86% of the total gross premium in the non-life insurance domain. Also, more than half (53%) of the gross premium was made by the first three insurance companies, and those are: Allianz-Tiriac, Asirom and Omniasig.

Regarding *the preferences of individuals for financial investments*, in *the European Union*, insurance rank on the 2-nd place, with a percentage of 24.5% in the investment portfolio structure, followed by pension funds with 13% and mutual funds, with 10.6%. *In Romania*, the investment portfolio structure of individuals, according with a study made by an Italian group UniCredit at 22.10.2004, was: banking deposits, 63.3%; cash, 14.9%; listed stocks, 9.6%; other commercial papers, 8.3%; savings insurance, 3.8%; mutual funds, 0.2%.

The explanation given to this evolution is based on the connection between the modest performances registered on a global level by the insurance market and the unfavorable economic conditions, a high inflation rate, the depreciation of the local currency, the excessive taxation and the reduction of purchasing power of population. Along with these general inconveniences, there can be added the specific ones of the insurance domain, like the legislation

---

<sup>2</sup> Insurance market in 2004 – Top 10, 31.03.2005: <http://www.lasig.ro>

<sup>3</sup> Top 10 – non-life insurance, 30.03.2005: <http://www.lasig.ro>

## **5.2. The calculation methodology for the solvency margin in Romania**

Romania has adopted the European Union Directives by submitting the insurance companies to estimate **solvability margin** at the end of every year and to transmitting the report application about the solvency margin to the insurance supervision commission. Solvency margin represents the value by which the assets of an insurer are higher than the value of his bonds and which has to be higher than the value established throughout regulations related to the minimum limit of the solvency margin of the insurers.

The solvency margin settle up by the insurer will be compared with the minimum solvency margin, recommended by the standards issued by the Insurance Supervisory Commission<sup>4</sup>.

For each insurance category, non-life and life insurance, there are established particular methods of calculation the solvency margin, the criteria regarding the assets and liabilities evaluation and the category of the assets and liabilities which can not be taken into consideration for the calculation of the solvency margin for the insurer or which will be taken into consideration just in a certain proportion.

The evaluation of the insurers' assets and liabilities for determining the solvency margin is based on their values and they are underlined in the balance sheet.

The authorized insurers to practice **non-life insurance** has the obligation to have permanently a **available solvency margin**, in concordance with their activity, at least equal with the minimum solvency margin calculated in conformity with the present standards.

To the available solvency margin corresponds the total of **the free obligation assets**, excepting the immaterial assets.

For determination of the available solvency margin, the following elements are taken into consideration:

a) the share capital subscribed and paid or, in some cases, if it is about mutual societies, the free reserve fund at which will be added all members' accounts;

b) all reserves, others than the technical reserves, as followings: the reserves of capital premium, the reevaluation reserves, legal, statutory, conversion or other reserves;

---

<sup>4</sup> The standards from 12. 27 . 2001 regarding the minimum limit of the solvency margin of the insurers which practice non-life insurance and the its calculation methodology, MO no 43 from 01. 22 . 2002

c) the net profit resulted from the deduction of the dividends which should be paid or, in some cases, the loss registered by the insurer.

The available solvency margin is diminished with the value of the shares owned by the insurer.

Besides these, in the calculation of the available solvency margin *can be included* the following components:

a) the cumulative preferential shares and the liabilities subordinated till 50% from the least value resulted from the comparison between the available solvency margin and the minimum solvency margin. From these maximum 25% should be constituted from the debts subordinated with fixed deadline and/or cumulative preferential shares with a determined term of payment.

b) the securities with undetermined term and other securities, including the cumulative preferential shares, till a level which can not overtake 50% from the least value resulted from the comparison between the available solvency margin and the minimum solvency margin.

**The determination of the minimum solvency margin** is different for the general insurance and for the life insurance, following a calculation algorithm presented in the Insurance Supervisory Commission standards in that sense.

The minimum solvency margin for the general insurance can be determined by two methods:

- a) the report to the yearly premium or the contributions;
- b) the report to the average gross damages paid in the last fiscal years.

If an insurance company take in the insurance one or more risks: the credit risks, the storms, the freeze, the reference period for the calculation of the average gross losses paid will correspond to the last 7 fiscal years.

The minimum solvency margin is equal with the highest value between the two results got through the application of the methods presented above.

A third from the minimum solvency margin of the insurer **form the security fund**. The minimum value of the security fund for the general insurance is the lei equivalent for 2 million Euros at the report date, as results from the table 4.

The Euro value of the security fund will be revised yearly in function of the changes of the European consumer price index, published by Eurostat.

*The determination of the minimum solvency margin for the life insurance* will be achieved taking into consideration the specific of the life insurance' products, respectively insurance classes which cover the survival risk, the demise risk, accident risk, which represents an investment component.

The insurer is forced to determine permanently the available solvency margin, the minimum solvency margin, as well, the security fund based on the financial statements and to transmit to the Insurance Supervisory Commission, a report at the end of every fiscal year.

The introduction of the safety fund in the calculation of the solvency margin, at this moment, would have a negative impact for almost 60% of the insurance companies. New regulations regarding the method of establishing the solvency margin for the insurance companies in Romania will be introduced, considering the fact that for 2005 the level of minimum capital will be taken into consideration, this being replaced in 2006 by the safety fund. Under these circumstances, there have been issued regulations regarding the gradual annual increase of the minimum capital of the insurance companies, up to the levels required by the EU, the last increase ending at 30 of June 2006. A process in two steps regarding the establishment of the solvency margin according to the EU regulations offers the time needed by the companies with a lower level of capital in order to act for adapting to these new requirements.

**Table 4 The actualization of the owners equity by the insurance companies in Romania, according to the EU regulations – mill. EUR**

	<i>Until June 30<sup>th</sup>, 2005</i>	<i>Until Dec 31<sup>st</sup>, 2005</i>	<i>Until June 30<sup>th</sup>, 2006</i>
<i>a) Non-life insurance, except for compulsory insurance</i>	0.8	1.3	2
<i>b) Non-life insurance</i>	1.3	2	3
<i>c) Life- insurance</i>	1.2	2	3

The models used for establishing the credit worthiness status are those existing in the present directives. There are some options that say that the model of National Bank of Romania should be used, but insurance companies have not yet fulfilled the process of aligning the capital of credit institutions, because they first have to financially consolidate the insurance capital, i.e.

capital increase, and after this step Solvency II model can be successfully applied.

An extremely interesting source is the Basel Accord on regulations of capital alignment in the banking field. Based on the conclusions of the study, elaborated in May 2002, on European Commission request, a model of credit worthiness surveillance for insurance companies, inspired by the solutions adopted through the Basel Accord, should comprise of the following 3 pillars:

1. Financial resources – minimum requests on capital, elaborated based on a risk profile estimated in direct connection to the subscription data, assets and liabilities gathered in financial reports; companies can be the beneficiaries of elaborating their own model of risk profile;

2. Surveillance – the evaluation of the risk management system through checking on exposures, risk profiles elaborated on internal level, stress tests on technical reserves and assets, managerial performances;

3. Market discipline – the compulsory communication of information, fully transparent, which allows for the other operators to evaluate the financial stability of the company.

*In conclusion, the solvency margin represents the amount with which the assets value overtake the liabilities value, which should be higher than the value settled by the standards regarding the minimum limit for the solvency margin of the insurers. .*

For the insurance companies is compulsory to determine the solvency margin at the end of every year and to transmit to the Insurance Supervisory Commission, together with the balance sheet, a report regarding the solvency margin. The first report regarding the solvency margin will be transmitted to the Insurance Supervisory Commission together with the yearly reports for 2002, and in 2003, Insurance Supervisory Commission will analyze its values and will take the necessary measures in order to prevent the insurers' insolvency.

**The solvency ratio for the insurance companies (S)**, can be determined by the report between the solvency margin of the insurers and the minimum solvency margin, as follows:

$$S = \frac{M_s}{M_{s\min}}$$

In order to prevent the insolvency for the insurer, as well for its recover, the Insurance Supervisory Commission will do, at least once a year, a control regarding the financial situation of the insured persons, in order to

check the observance of the legal rules regarding the solvency margin and the maintenance of the share capital.

In function of the **result got from the determination of the solvency margin of the insurer**, the insurers are appreciated as following<sup>5</sup>:

- a) **the insolvency** insurers, in the case the report's result is less than 1;
- b) the insurers being at the **insolvency limit**, in the case the report's result is equal with 1;
- c) the insurers for which exist a **high insolvency risk** , in the case the report result is between 1 and 5;
- d) the insurers for which exist a **low insolvency risk** , in the case the report result is between 1.5 and 2;
- e) the insurers for which do not exist a **insolvency risk** , in the case the report result is higher than 2.

These evaluations are synthesized in the table 5.

**Table 5 The evaluation of the insurers in function of the results of the insolvency level**

	<b>Results regarding the solvency level</b>				
	<b>&lt;1</b>	<b>=1</b>	<b>1-1.5</b>	<b>1.5-2</b>	<b>&gt;2</b>
<i>The evaluation of the insurers</i>	insolvency	at the insolvency limit	high insolvency risk	low insolvency risk	no insolvency risk

If as a result of the financial report and the controls, the Insurance Supervisory Commission find out that the insurers is at the *limit of the insolvency or has a high insolvency level*, which threaten the payment of the assumed obligations to the insured persons, this will request the elaboration and application of a **financial recovering plan**, which should forecast the following aspects:

- a) the limitation of the gross or net premiums subscribed for a period, thus these should not overtake certain values;

---

<sup>5</sup> The standards from 12. 27. 2001 regarding the insolvency of the insurer and the special administrator, MO no. 43 from 22 January 2002

- b) the interdiction of the selling and renewing the insurance contracts of a certain type;
- c) the interdiction of some investments;
- d) the increasing of the paid share capital or of the paid reserve fund;
- e) any measures which are considered necessary for the recovering.

If the insurer, as a result of the determination of the solvency level, realize that is at the insolvency level or has a high insolvency level has to fill and send to the Insurance Surveillance Commission the financial recovering plan, which being approved by the Insurance Supervisory Commission, will include the deadlines for achieving the objectives.

Till the complete recovering of the insurer, as well in the case in which the Insurance Supervisory Commission consider that the financial situation of the insurer will get worse, this can narrow or forbidden the insurer to use a part or all assets and can take any other measures in order to protect the insured persons.

The Insurance Supervisory Commission can withdraw the authorization for the a part or all insurance classes used by an insurer, if this can not recover till the settled deadline.

In the case that *measures of financial recovering did not get the expected results*, the Insurance Supervisory Commission can ask the Low Court from Bucharest for an appointment of a **special administrator** for that insurer.

The special administrator will administrate the insurer's activity, setting up the optimum conditions for assets' conservation and for the debt payment in the interest of the insured persons and other creditors. He will present monthly or any time it is solicited to the Insurance Supervisory Commission an evaluation of the financial situation of the insurer.

If, based on the received reports, Insurance Supervisory Commission will consider that the insurer is recovered financially and correspond to the prudential parameters, this will ask to The Low Court the revocation of the disposal concerning the financial recovering plan.

The Insurance Supervisory Commission takes into consideration the possibility to simplify the solvency classification, which divide the insurance companies in insolvency ones, low solvency level ones, high solvency level ones and no insolvency risk ones. As well, the Insurance Supervisory Commission intends to not make public the solvency level of each company, just the solvency category: solvency company (with a solvency level higher than 1) and insolvency company (with a solvency level less than 1).

**The liquidity ratio** represents the report between the liquid assets and the certain liabilities on short term of the insurer against the insured persons.

In the category of the *liquid assets* are included : the state certificates; the bank deposits of which placement do not overtake 50% at a bank, but not more than 20% in a bank from the same financial group or which is main shareholder at the insurer ; the cash and current accounts.

In the category of the *certain liabilities on short term* of the insurer against the insured persons are included the damage reserve and the unexpected damage reserve.

The minimum request regarding the liquidity ratio is fulfilled if the liquid assets of the insurer will represent at least 50% from the certain liabilities on short term.

## **6. Conclusion**

For the elaboration of a new solvency system, the first step was represented by the definition of the requests which this should get answers, as followings:

- to protect the beneficiaries, insuring for the supervision institutions a period of time necessary to identify and recover the negative phenomenon registered in a company;

- to offer comparability, transparency and continuity, thus creating an uniform action environment;

- to establish a set of requests regarding the solvency margin in conformity with the real risks. The methodology of calculation of the minimum solvency margin should permit the transmission of a correct signal toward the management, without encouraging the imprudent behavior;

- to avoid the useless complications – a simple system, easy to understand and to be applied, which should not generate supplementary costs. The purpose of monitorizing the solvency is that to notice from the beginning the negative trends, not to supply a guarantee against the bankruptcy;

- to reflect properly the market evolutions;

- to avoid, as it is possible, to generate supplementary financial reports, valorizing thus the information from the financial statements;

- to avoid the excessive capital requests which could lead to the decrease of the competitiveness of the European insurance market.

In general, the using of a sophisticated solvency system on a such wide and diversified industry as the insurance one is suppose to surpass some substantial practical problems, especially because these are going to be taken at the international level.

## **Abstract**

*In this paper we add some remarks on using econometrics theory in ratemaking the automobile insurance. The tariff system studied in the paper has the objective to incorporate a priori and a posteriori information in the premium, mainly according to the bonus-malus system proposed by Dionne & Vanasse (1989). For an important car insurance portfolio, within an empirical study, the explanatory variables related to the number of accidents, respectively the claim size are selected. The econometric count model for the number of accidents, respectively the log-linear econometric model for claim size are estimated. We also point out the necessity of including in the premium the explanatory variables of the claim size and a bonus-malus system that incorporates the individual past experience of claim size.*

**Keywords:** *ratemaking, a priori classification, count models, loss distributions, bonus-malus system.*

## 1. Introduction

Automobile insurance portfolios are heterogeneous because there are a series of characteristics that influence the damage frequency, respectively the severity. The insurers usually combine a priori and a posteriori tariffication systems (Lemaire, 1985). The equity of insurance pricing means that the policyholders pay rates according to their level of risk. In a priori rating, it is used a series of characteristics referring to policyholders, vehicles and territory to estimate a policyholder's risk. Some of the commonly characteristics used by the policyholders are: driving record, territory, vehicle use, the country where the vehicle was made in, the model of vehicle, gender, age and marital status of policyholders, type of coverage etc. Risk classes might prove heterogeneous even after an a priori rating, as there are a series of directly unobservable variables (prudence, personality, the driver's health etc). An a posteriori bonus-malus system is used to revise the a priori rating; the individual premiums are adjusted according to accident record of the policyholder. Generally, the a posteriori rating system suits the non-homogeneous portfolios where the individual characteristics are difficult to be measured a priori.

The objective of this study is to use multivariate regression models in selecting the main explanatory variables for the number of claims respectively the claim size dependent variables. The results are used for a priori rating, but a bonus-malus system is also retained in order to improve the insurance rating.

The univariate Poisson model is a plausible model for the distribution of the number of claims inside a homogeneous portfolio. The negative binomial distribution is more adequate for the distribution of the number of claims in heterogeneous portfolios. When the parameter  $\lambda$ , that represents the mean and the variance of the Poisson variable, varies across the portfolio being a random variable that follows the gamma distribution, the number of claims follows a negative binomial distribution (Petauton, 2000).

The most common distributions used in the study of claim size, called the loss distributions, suit the lognormal distribution, the Pareto distribution, Weibull distribution or a mixture distribution.

The univariate models for the number of claims are often rejected from empirical studies as a consequence of the heterogeneity of risk. The count models are used here in order to estimate the distribution of the number of claims and to select the significant variables that explain the variance of the number of claims; the linear regression models are not adequate for discrete variables (Greene, 1997). The Poisson respectively the negative

binomial models with a regression component are used in rating automobile insurance and a bonus-malus system is proposed in order to integrate a priori and a posteriori information in the tariff by Dionne and Vanasse (1989). Premium tables are obtained for liability automobile insurance.

The linear regression model is proposed to be used for the logarithm of claim size in order to select the significant explanatory variables for claim size.

A private insurance company provided the database for which we intend to analyse the distribution of the number of claims and respectively of the claim size; this insurer holds a significant part of the market. We use a sample of 38770 policies. The policies cover damages of the private automobile, caused by accidents produced by the policyholder. Therefore, the automobile insurance taken in view in this empirical study covers only the costs in case of physical damage to own car caused by accidents.

## 2. Probability distributions and econometric models

The simplest model for the number of claims  $y_i$  made by the policyholder  $i$  during a given period of time (one year) is the univariate Poisson distribution:

$$P(y_i = k) = e^{-\lambda} \frac{\lambda^k}{k!}, \quad k=0, 1, 2, \dots \quad (1)$$

where  $\lambda$  is the Poisson parameter, which equals the mean and the variance of the variable. We assume here that the Poisson parameter is constant across the portfolio. Consequently, this model is suited only for a homogenous portfolio.

If the number of claim  $y_i$  follows a Poisson distribution and the mean  $\lambda_i$  follows a gamma distribution, with parameters  $\alpha$  and  $\beta$ , then the marginal distribution of the number of claims is negative binomial:

$$P(y_i = k) = \frac{\Gamma(\alpha + k)}{\Gamma(\alpha)k!} p^\alpha q^k, \quad k=0, 1, 2, \dots \quad (2)$$

where  $p = \frac{\beta}{\beta+1}$  and  $q = 1 - p$ . The mean and variance of negative binomial distribution are:

$$E(y_i) = \frac{\alpha q}{p} = \bar{\lambda} \quad (3)$$

$$Var(y_i) = \frac{\alpha q}{p^2} = \bar{\lambda} \left[ 1 + \frac{\bar{\lambda}}{\alpha} \right] \quad (4)$$

The parameters of these two distributions can be estimated by the maximum likelihood method or the method of moments.

Let us begin with the count model for the dependent variable the number of claims  $y_i$ . The explanatory variables  $x_1, x_2, \dots, x_k$  represent a priori classification variables, which explain the variance of the number of claims. The vector of explanatory variables specifies a model for the conditional mean of the dependent variable:

$$E(y_i/x_i) = \exp(x_i\beta) \quad (5)$$

where  $\beta$  is a vector of parameters ( $k \times 1$ ) and  $x_i = (x_1, x_2, \dots, x_k)$  the vector of explanatory variables. For the Poisson model, the conditional density of  $y_i$  given  $x_i$  is

$$f(y_i/x_i) = \frac{e^{-\exp(x_i\beta)} [\exp(x_i\beta)]^{y_i}}{y_i!} \quad (6)$$

and

$$E(y_i/x_i) = \lambda_i = \exp(x_i\beta) \quad (7)$$

The probability that the policyholder to be involved in  $k$  accidents is:

$$P(y_i = k/x_i) = \frac{e^{-\exp(x_i\beta)} [\exp(x_i\beta)]^k}{k!} \quad (8)$$

By maximizing the log likelihood function

$$l(\beta) = \sum_{i=1}^n [k(x_i\beta) - \exp(x_i\beta) - \ln(k!)] \quad (9)$$

the maximum likelihood estimator of the parameter  $\beta$  is obtained (Greene, 1997). It has been supposed that the variables  $y_i$  are independent.

An alternative to the Poisson regression model is to estimate the parameters of the negative binomial specification. The negative binomial distribution is more adequate when the variance in the data is bigger than the mean and arises from a natural formulation of cross-section heterogeneity (Greene, 1997).

The lognormal distribution is often used as a model for the claim size distribution. A random variable  $Y$  has a lognormal distribution with parameters  $\mu$  and  $\sigma$  if the variable  $\ln Y$  has a normal distribution with mean  $\mu$  and standard deviation  $\sigma$ . The probability density function is:

$$f(x) = \frac{1}{\sigma x \sqrt{2\pi}} \exp\left[-\frac{1}{2}\left(\frac{\ln x - \mu}{\sigma}\right)^2\right], \quad x > 0 \quad (10)$$

This is positively skewed; there are a lot of small claims.

The linear regression models are based on normal distribution. Therefore, for the dependent variable  $m_i$ , the claim size, we propose a log-linear multivariate regression model

$$\ln m_i = b_1 z_{i1} + b_2 z_{i2} + \dots + b_r z_{ir} + \varepsilon_i, \quad i = 1, 2, \dots, n \quad (11)$$

The  $\beta$  parameters are estimated by ordinary least squares. This model is used to select the significant explanatory variables for the claim size.

Dionne and Vanasse (1989) proposed a bonus-malus system which integrates a priori and a posteriori information. The premium tables take account of time, accidents record and the individual characteristics. The expected number of accidents is estimated from a Poisson and negative binomial model with a regression component. Let us take  $y_i^j$  the number of accidents for the policyholder  $i$  during the period  $j$  and  $x_i^j = (x_{i1}^j, \dots, x_{ik}^j)$  the vector of explanatory variable observed at period  $j$ . The expected number of accidents of policyholder  $i$  during the period  $j$  is a function  $\lambda_i^j(x_i^j, \varepsilon_i)$ , where  $\varepsilon_i$  is a random variable. The best estimator of the expected number of accidents for the next period,  $\hat{\lambda}_i^{t+1}(y_i^1, \dots, y_i^t; x_i^1, \dots, x_i^{t+1})$ , depending on the past experience and on the  $k$  characteristics known a priori should be determined. Applying the negative binomial distribution to the model, Bayes's optimal estimator of the expected number of accidents for policyholder  $i$  is (Dionne and Vanasse, 1989):

$$\hat{\lambda}_i^{t+1}(y_i^1, \dots, y_i^t; x_i^1, \dots, x_i^{t+1}) = \hat{\lambda}_i^{t+1} \left[ \frac{\alpha + \bar{Y}_i}{\alpha + \bar{\lambda}_i} \right] \quad (12)$$

where  $\lambda_i^j = \exp(x_i^j \beta) \varepsilon_i = (\lambda_i^j) \varepsilon_i$ ,  $\bar{\lambda}_i = \sum_{j=1}^t \lambda_i^j$  and  $\bar{y}_i = \sum_{i=1}^t y_i^j$  the total number of accidents over  $t$  periods for the policyholder  $i$ .

For a new policyholder when  $t=0$ ,  $\hat{\lambda}_i^1 = \lambda_i^1 = \exp(x_i^1 \beta)$  the only a priori rating is used. When the regression is reduced to a constant, one obtains:

$$\hat{\lambda}_i^{t+1}(y_i^1, \dots, y_i^t) = \bar{\lambda} \left[ \frac{\alpha + \bar{y}_i}{\alpha + t \bar{\lambda}} \right] \quad (13)$$

which is the Bayes's estimator of an individual's expected number of accident based only on past accidents  $\bar{y}_i = \sum_{j=1}^t y_i^j$ .

In order to calculate the premium for the policyholder  $i$  we propose to take account of the significant characteristics for the number of claims and for the claim size respectively of the accidents record

$$\hat{m}_i^{t+1} \cdot \hat{\lambda}_i^{t+1} \cdot \left[ \frac{\hat{\alpha} + \bar{Y}_i}{\hat{\alpha} + \lambda_i} \right] \quad (14)$$

where

$$\hat{\lambda}_i^{t+1} = \exp(x_i^{t+1} \hat{\beta}) \quad (15)$$

$$\hat{m}_i^{t+1} = \exp(z_i^{t+1} \hat{b}) \quad (16)$$

### 3. An empirical study

An important Romanian insurance company provided the database used in this empirical study and it includes a considerable number of policies (38770 policies). The policies cover damages of the policyholder's car, caused by accidents produced by the policyholder. For each policyholder, we observe the following variables:

- the dependent variable: the number of accidents produced over a period of time of one year and the individual claim size.
- the explanatory variables: the cylindrical capacity of the engine, the age of the car, a variable explaining the country where the car was manufactured, the legal status of the policyholder, the number of seats in the automobile, the gender of the policyholder.

First, we are looking for a probability distribution that describes adequately the number of accidents that actually occurred. Observed and fitted numbers of accidents for the Poisson distribution are presented in table 1 from appendix. The Kolmogorov-Smirnov test enables us to reject the Poisson distribution hypothesis, as the statistics  $Z= 12,9$  is significantly different from zero for a significance level of  $\alpha = 1\%$ . We observe a poor fit of the univariate Poisson model for the distribution of number of accidents. Also in table 2 from appendix we present the observed distributions for claim size.

For the explanatory variables we have introduced indicative variables:

- the age of the car (A)

$A_1 = 1$ , if  $A \leq 1$  (reference class), otherwise it is 0

$A_i = 1$ , if  $A = i$ , otherwise it is 0, for  $i = 2, 3, \dots, 10$

$A_{11} = 1$ , if  $A \geq 11$ , otherwise it is 0;

- the cylindrical capacity of the engine (C)

$C_1 = 1$ , if  $C \leq 1200 \text{ cm}^3$  (reference class), otherwise it is 0

$C_2 = 1$ , if C is between 1201-1400  $\text{cm}^3$ , otherwise it is 0

$C_3 = 1$ , if C is between 1401-1600  $\text{cm}^3$ , otherwise it is 0

$C_4 = 1$ , if C is between 1601-1800  $\text{cm}^3$ , otherwise it is 0

$C_5 = 1$ , if C is between 1801-2000  $\text{cm}^3$ , otherwise it is 0

$C_6 = 1$ , if C is  $\geq 2000 \text{ cm}^3$ , otherwise it is 0;

- made in :

$ROM = 1$ , if the automobile is manufactured in Romania, otherwise it is 0

$STR = 1$ , if the automobile is manufactured abroad, otherwise it is 0

$DW = 1$ , if the trade mark of the automobile is Daewoo (reference class), otherwise it is 0;

- the gender of the policyholder

$M = 1$ , for the male group (reference class), otherwise it is 0

$F = 1$ , for the female group, otherwise it is 0;

- the use of the car

$P = 1$ , if the car is for private use, otherwise it is 0

$B = 1$ , if the car is used for business, otherwise it is 0.

The classes for the explanatory variables have been constructed by taking into consideration the tariff classes used by most of the insurance companies from our country.

The dependent variables are the following:

NRC – the number of accidents per year

LNC – the logarithm of the claim size

In order to estimate the econometric models, we used the statistics packages EViews 4.1.

### ***3.1 The econometric model for the number of accidents***

We estimate the parameters of the Poisson count model and of the negative binomial model. Many variables were found significant. Table 3 from appendix includes the results obtained after the estimation of the Poisson count model (the conclusions regarding the significant variables are identical to those resulting from the negative binomial count model).

The coefficients of the indicative variables  $P$ , respectively of  $A_2$ ,  $A_3$ ,  $A_4$  were found insignificant in both methods of estimation. The variable use of the car does not exert a significant influence on the number of accidents; the number of accidents is similar in the case of private cars as well as in the case of those used for business. In addition, the count model does not show any justification of distinct tariff classes when the age of the automobile is of 0, 1, 2, 3 or 4 years. In the new model for the dependent variable the number of accidents which includes only the significant explanatory variables, presented in table 4 from appendix, the reference class for the age of the car is defined as  $A = 1$ , if the age of the car is of 0, 1, 2, 3 or 4 years, otherwise it is 0. The number of accidents is significantly lower for older cars than for the relatively new ones (less than 5 years of age).

The dummy variable related to the cylindrical capacity of the engine illustrates positive significant coefficients: the bigger the cylindrical capacity of the car, the higher the number of accidents.

For the gender variable, we observe, as expected, that women are involved in a considerably lower number of accidents as compared to men. The empirical result that has been obtained is similar to that contained in other studies (Dionne & Vanasse, 1989; Dionne & Ghali, 2003).

As for the “made in” variable, the cars made in Romania are involved in a considerably lower number of accidents than those manufactured by Daewoo. However, the study does not show any justification for the existence of a distinct class for automobiles manufactured abroad.

### ***3.2 The econometric model for the claim size***

For the dependent variable the claim size we used a log-linear regression model. In a first step we considered all the explanatory variables described above. The sample comprises 7247 individual claims. The model, estimated by techniques specific to linear econometric models, is presented in table 5 from appendix.

The variable related to the use of the car proves to be significant. The claim size is considerably higher if the automobile is used for business purposes. The claim size is also considerably higher for the automobiles that

have a bigger cylindrical capacity of the engine. As for the age of the car, we notice that the claim size does not vary in a significant manner comparing with the reference class. Therefore, the study does not show any justification for differentiating the insurance premium for each of these tariff classes. The cars made in Romania register a significantly lower claim size while those manufactured abroad have a higher one as compared to the reference class. The new model, after the exclusion of the variables of age and gender, is presented in table 5 from appendix.

As for the validity of the model:

- the residuals are not correlated according to the Breusch-Godfrey serial correlation LM test, as the LM statistics equals 0,75. The same result is given by the Durbin-Watson test, as well as by the Ljung-Box one;
- the residuals are not heteroscedastic, according to Lagrange's multipliers test for ARCH heteroscedastity; the LM statistics is LM = 1,466.

The level of significance, which has been considered here, is of 5%.

#### **4. Conclusions**

The tariff system studied here has the objective to incorporate a priori and a posteriori information in the premium, mainly according to the bonus-malus system proposed by Dionne & Vanasse (1989). For an important car insurance portfolio, the empirical study presented here selects the explanatory variables related to the number of accidents, respectively to the claim size. The econometric count model for the number of accidents, respectively the log-linear econometric model for claim size are estimated. We also point out the necessity of including in the premium the explanatory variables of the claim size.

## **Abstract**

*The paper is fission into 4 parts. In the first part are introduced changes, which with teak system of insurance into year 2000. Here go above all about nullification monopoly some insurance company and conformity market environment. Second part a short characterizes the changes from year 2000. News was drawn law about system of insurance conformable with European rightly the lawful insurance of responsibility from operation motor vehicle was abolished. A tax deduction was accepted insurable on life insurance. Third part describe responsible position changes from year 2004, it means after entrance Czech republic into European union and at once A and B validity biennial important law - law about premium agreements and law about insurable mediator. Fourth part collation responsible position indices insurable market from year 1991 till this time. They are target premium and the expenses on the indemnifications. In conclusion is then mentioned growth specified insurable near industrial insurance in proportion to inanimate and general vegetative trend specified insurable compared to fall load on the indemnifications, which is denote as a prosperous development insurable market in Czech republic.*

**Keywords:** *Class of insurance, life assurance, non-life insurance, technical reserves, insurance technical rate of interest*

<sup>1</sup> Preparation of the paper was supported by the Czech Science Foundation within the project GAČR 402/05/2758 "Integration of the financial sector of the new EU member countries into the EMU"

## **1. Introduction**

On the break of the 80s and 90s significant political-economic changes occurred in the Middle and East Europe. At that time one of the main objectives of then Czechoslovakia was to re-build insurance environment, which will function on the base of the market –economic principle. Consistent with this clear requirement on April 26, 1991 the Law on Insurance Industry which corresponded to that by its character and content and published in the Collection of Laws under no. 185/1991 was accepted by the Czech National Council.

The Law adjusted specific conditions of entrepreneurship in the insurance industry, was valid for the territory of the Czech Republic and established above it the government control the execution of which was entrusted to the Ministry of Finance of the Czech Republic. The executor regulation of the Ministry of Finance no. 259/1991 Col., which was issued to the Law, set the way of creating and using special-purpose insurance funds.

The Law no. 185/1991 Col. corresponds in its principle to the transient time and therefore it was based on the rules of the material supervision. The licence system activity was concentrated on setting permitted legal forms of domestic insurance companies and reinsurance companies and on the performance of the government control when approving general policy conditions. That was at the same time in agreement with a very short adjustment of the insurance policy, which is incorporated into the still valid Civil Code. Financial supervision then according to the legal adjustment restricted on the obligatory bailment in the amount of CZK10 million for the benefit of the Ministry of Finance of the Czech Republic on submitting of three-years commercial and provisory plans and on the setting of special-purpose insurance funds.

The licence system and control activity of the state supervision in the spheres associated with entrepreneurship in the insurance industry as e.g. an intermediary activity in the insurance industry had only a common character. According to some provisions it was obvious that that activity constructed the inequality of entrepreneurship conditions among domestic and foreign companies.

## **2. Insurance Industry in the CR in the Year 2000**

Already in the first half of the 90s it was obvious that the legal adjustment would require fundamental changes mainly in the bigger security

of a consumer. It meant readjustment to the law of the European Economic Community both in the financial control of entrepreneurship and in the national legislature in the sphere of private contractual insurance. In its concrete form it meant mainly legalization of the duty for all insurance companies and reinsurance companies registered to transact business in the CR to create to its liabilities which result from contracted policies technical reserves in concurrence with a new account classification of insurance companies, at the same time to cover these reserves by corresponding assets and to show fixed rate of solvency.

This significant change was defined in the amendment of the Law on insurance industry, that is the Law no. 320/1993 Sb. (Coll.) and by the regulation no. 52/1994 Sb. of the Ministry of Finance. By this regulation at the same time the prior regulation no. 259/1991 Sb. was revoked. However, after implementation of stated changes the legal adjustment remained tributary to the time of its origin and it required fundamental revision. The amendment of the Law, which was done by the Law no. 60/1995 Sb., contained in addition a problematic regulation, which make possible for health insurance companies to carry business in private insurance industry.

Despite those mistakes occurring in the Law and its amendment it is necessary to say that the Law no. 185/1991 Sb. fulfilled its role by enabling the origin of insurance industry in the Czech Republic.

### **3. Insurance Industry in the CR after the Year 2000**

Only by the end of the 90s it was managed to enforce the fundamental legislature change, which meant de-monopolization of motor vehicle driving liability that is by accepting the Law no. 168/1999 Sb. Since the beginning of the year 2000 about 12 insurance companies which fulfilled strict conditions for granting authorization to operate this insurance could offer to roughly five million of car vehicle owners a quite new product, that is contractual liability insurance for the damage caused by driving a vehicle. Despite certain restrictions in the creation of insurance rates which were valid till the end of the year 2002 and which incorporated into the law this insurance fulfils all parameters valid no the EU and a consumer has thus the possibility of the choice of the insurance company and the product as well with preserving high security and certainty of the damaged with the compensation of the damage which he was caused by another vehicle.

Adoption of the Law no. 363/1999 Sb. was another significant step and consequently then the executor regulation no. 75/2000 Sb. Both of these

legal norms inured the virtue on April 1, 2000. In a significant way they changed conditions of carrying out insurance and reinsurance activities, mediator activities in the insurance industry and in the way and extent of performance of the government control in the insurance industry. The licence system activity set other conditions of capital facilities of claimers related to performed nurturance industry. From this date life and general insurance and reinsurance were divided. Another significant step was to adopt the law no. 363/1999 Sb. and consequently then the executor regulation no. 75/2000 Sb.

The significant change concerns further the business plan, which is based on the actuarial base with the emphasis on the permanent ability of the society to fulfil its engagements. Simultaneously the control of the criminal-law accountability of the owners of companies and persons with the decisive participation on their management was introduced.

By the example of developed countries the institution of a responsible actuary was introduced, and that is not only in the sphere of life insurance, but also in the general insurance and reinsurance.

Conditions on operating mediator activities in insurance industry were adjusted with distinguishing insurers and reinsuring brokers including the definition of their basic features.

Important changes also concerned the government control in the insurance industry, and that is in the direction of strengthening the financial control emphasizing the protection of a consumer. Thus there were made extensions and specifications of measures, which the Ministry of Finance is not only entitled but as well obligatory to admit provided it finds out deficiencies in the activity of supervised subjects.

The Law further brought changes mainly in creating technical reserves, in the composition of financial setting and solvency of insurance companies and reinsurance companies.

Insurance companies, which operated on the insurance market till the new law on the insurance industry came into force, were obliged to keep a two-years period for adapting their activities to new conditions and a ten-years period for dividing universal insurance companies into insurance companies specialized on insurance activities as for insurance spheres of life insurance or as for insurance spheres of general insurance.

All these changes were set from the reason of even more complete protection of a consumer

Another very significant change for consumers of the offer in the matter of insurance products mainly in the sphere of life insurances is the change of the Law on income taxes no. 586/1992 Sb. as amended, according

to which the amount of CZK12.000 is the deductible for the tax calculation of the income tax which is the sum of the paid insurance on life insurance in case it is this type of insurance:

- An insurance on life,
- With the insurance period for minimal 5 years,
- With the end of insurance at least in sixty years of age,
- When a policy holder and a policy client are identical persons, which means that the insured amount must not be bonded to the credit of another person than the insured

#### **4. Insurance Industry in the CR after Entry the European Union**

The year 2004, which became significant mainly by admitting the Czech Republic as a regular member into the European Union, meant also in the sphere of insurance legislature the release compared to the previous period when it was necessary to coordinate the legislature of the Czech Republic in the sphere of insurance industry with the legislature of the European Community.

The process of common convergence of legal regulations of the CR, repeatedly the CSFR, with the rules of the European Community already began by accepting the CR government decree no. 533/1991 on securing compatibility of the Czechoslovak system of law with the law of the European Community. In the sphere of insurance industry that process was initiated by the CR government decree no. 704/1997 by which the base for the preparation of new legislature was set.

Till the entry of the Czech Republic in the in the sphere of the private insurance it was necessary to prepare many legislature changes directly related to that act. It was mainly introducing the principle of a unified licence, execution of the control over the groups of insurance companies and financial conglomerates with the participation of insurance companies and reinsurance companies, releasing investment possibilities of insurance companies and reinsurance companies, within a free movement of the capital etc.

These changes are the content of the amendment of the Law on insurance industry no. 39/2004 and consequently then the executive regulation no. 303/2004 Sb. Consistent with the law of the European Community this law and the regulation modify conditions of carrying out insurance and covering activities after the entry of the Czech Republic to the

European Union. The above mentioned law came into force on May 1, 2004, that is on the day of the entry of the CR into the EU, the regulation then by the day of its decree, that is on 14.5.2004 and at the same time by this date it annulled the force of the regulation 75/1999.

This was achieved by adopting not only the amendment of the Law on insurance industry, but also the amendment of the law on operating motor vehicle liability insurance and two completely new laws:

- An amendment of the Law no. 363/1999 Sb. on insurance industry, that is Law 39/2004 Sb.,
- An amendment of the Law no. 168/1999 Sb., on operating motor vehicle liability insurance, that is the Law 47/2004,
- Law no. 37/2004 Sb., on insurance policy,
- Law no. 38/2004 Sb., on insurance mediators and independent loss adjusters of insured accident

In the year 2000 the legislature activity of the Institution was concentrated mainly on completing executive regulations:

- to the Law on insurance industry the regulation of Ministry of Finance no. 303/2004 Sb.,
- to the Law on operating motor vehicle liability insurance the regulation of the Ministry of Finance no. 309/2004 Sb.,
- to the Law on insurance mediators and independent loss adjusters of insured accident the regulation of the Ministry of Finance no. 582/2004 Sb.

Now it is necessary to mention a significant change in the regulation 303/2004 Sb., according to which from the date of coming into force insurance companies have the duty and the accountable actuary confirms correctness of rate and reserves calculation for life insurance using at maximum 2,4 % of actuarial rate of interest instead of original 4%. Basically that could mean the rise in price of the insurance; however, from the time being it is not possible to trace whether and how the change has influenced the insurance market of life insurance.

By these laws implemented all valid regulations for the sphere of insurance industry, a full harmonization of legislature of the Czech Republic with the current legislature of the European Community has been reached. The Czech Republic was one of the first countries, which implemented into the national legislature one of the important directive of the European

Community- Directive 2002/92/ES concerning mediator activities in the v insurance industry.

By the end of January 2005 the mentioned directive was implemented only in 13 countries of the European Community, which does not represent even the half.

## **5. Comparing Indexes and their Development from the Year 1991 So Far**

The development of the insurance industry in the Czech Republic had a positive influence on most of the indexes which were from the year 1993 regularly monitored at first by the ministry of Finance of the Czech Republic, then from the year 2000 by the Office of Government Control in the insurance industry and pension scheme supplementary insurance and at the same time from the year 1995 by the Czech Association of Insurance Companies which is a special interest association of commercial insurance companies and from 42 subjects which are licensed for entrepreneurship in the insurance industry on the territory of the Czech Republic, 28 insurance companies are its members.

Technical reserves, which are exactly defined by the Law on insurance industry, are one of the most important indexes of activities of insurance companies. However, in the course of the last 14 years, that means since de monopolization of the insurance industry in the Czech Republic in the year 1991 setting their amount has been subjected to many changes. Simultaneously with the development of the insurance industry in the CR values of these parameters have been changing gradually.

In the tables which are the enclosure of this article there are given mainly the values important for the insurance company functioning, which are fixed capital, specified insurance, indemnification expenses consistent with the development of insurance on the market in the CR in single years gradually from 1991 to 2004. Tables are in two variations, that is to the year 2000 and from the year 2001 as only since the year 2001 mainly the reserves on indemnification, the number of settled and unsettled insurance events were monitored.

Tables are the resource of the Ministry of Finance of the CR, and so they show he development of the insurance market on the base of all insurers operating on the Czech insurance market.

## 6. Conclusion

From the results of the Czech Association of Insurance Companies (ČAP) for the year 2004 it concludes that the insurance market has a constantly growing tendency. Total specified insurance of the ČAP members has increased since the year 2003 by 6,6% and has reached the level CZK111,5 mld.

Even from now on it can be observed the growing trend of the life insurance at which the specified insurance has increased by 7,5 % on CZK44,2 mld. Its ration on the total specified insurance has grown and amounted to 39,6 %.

In the same period general insurance has increased exactly by 6 % and amounted thus CZK67,3 mld.

Growth of specified insurance in total in the year 2004 is again higher than the rate of inflation 2,8 %. Compared to previous years, however, the growth rate slightly slowed down.

Definitely as for the positive phenomenon it can be considered the decrease of total indemnification expenses, that is by 2,5 %.

According to preliminary results of the ČAP, which it received from its members for the period 1-9/2005, it concludes that the insurance market in this period will increase. Total specified insurance of the ČAP members has increased compared to the same period of the year 2004 by 3,4 % and has reached the amount of CZK87,3 mld.

In the life insurance specified insurance has increased for the period 1-9/2005 by 1,1 % to CZK32,7 mld. It is important that currently paid insurance has increased by 9,9 %. Single-payment insurance, which is calculated into specified insurance immediately for the whole period of the validity of the insurance policy, however decreased by 16,4 %.

In the general insurance for the period 1-9/2005 the inter year growth 4,9 %, that is on CZK54,6 mld., has been recorded.

# PERSPECTIVES OF BANCASSURANCE DEVELOPMENT IN POLAND

**Hanna Kociemska Pocięcha**

## **Abstract**

*The beginnings of co-operation between banks and insurance companies reach the 70-ties. Along with changes on the world's financial market a new formula of providing financial services was formed – it was given the name "bancassurance". In its broadest meaning the bancassurance service covers products and activities related to those services that are needed by an individual or institutional customer in order to create, manage and secure one's property.*

**Key words:** *bancassurance services, development, legal rules, economic factors*

## 1. Introduction

To explain the term of bancassurance in a wider sense we can point out to three basic organisational and functional forms in which banks get involved to sell insurance products:

insurance companies owned by banks; in this case the bank has the majority share in the company settled by the bank, or a company it took over, or merged with;

bank - insurance captive: products of such company owned by the bank and offered mainly at bank establishments,

banks acting as insurance agents: the bank enters into distribution alliances with insurance companies at a low capital involvement and operates as an insurance agent selling products of one or more companies<sup>1</sup>.

All of these forms of co-operation between banks and insurance companies warrant a comprehensive financial service desired by customers. This complexity is advantageous for clients and justifies the existence of bancassurance services. Customers of modern financial institutions search for products that would entirely satisfy their financial needs in the quickest and most comfortable way. Thus, merging banking facilities with insurance seems obvious and while offered to a customer along with active finance consulting makes a full financial service.

## 2. Legal frames of bancassurance in Poland.

The basic factor conditioning bancassurance development is the adjustment level of legal regulations referring to distributing insurances through banks. One model of co-operation between a bank and an insurance company assumes informing the bank's customer about an opportunity to enter into an insurance agreement with a specific insurer. In this model a chosen insurance company is advertised on the bank's premises by displaying the company's informational brochures. Bank's activities of this kind can base on a promoting agreement concerning selling insurance policies by the bank. However, this procedure raises some reservations, particularly in reference to the act from the 22 of May 2003<sup>2</sup> concerning insurance intermediation, according to which agency activities include activities

---

<sup>1</sup> M. Śliperski, *Bancassurance w Unii Europejskiej i w Polsce*, Biblioteka Menedżera i Bankowca Warszawa 2001r, s.8.

<sup>2</sup> *Ustawa z dnia 22 maja 2003 r o pośrednictwie ubezpieczeniowym*, Dz. U. Nr 124 poz. 1151

consisting in winning over customers and executing actions preparing to enter into an insurance contract. Thus, in order not to fall within the scope of this broad concept of insurance intermediation the bank has to adopt a policy consisting in simple promotional actions devoid of elements providing information about insurance conditions and not allowing getting the bank's client in touch with a particular insurance company agent. It appears that the concept of insurance intermediation is defined more accurately in the European Parliament's and Commission's directive<sup>3</sup>. As insurance mediation does not mean an activity consisting in casual information supply performed in frames of other basic activities, if the purpose of these activities is not aimed at helping the customer in concluding or executing the insurance contract, professional damage managing of the insurance office or valuation and liquidation of damages.

However, experiences of banks on the Polish financial market show that these casual relations between banks and insurance companies are short-termed and as a result lead to development of more durable relations between both institutions. Under the Polish banking law<sup>4</sup>, banks can perform as an insurance agent by providing consulting services in money matters and other financial issues. So the bank acts here as an agent -entrepreneur. Basic legal aspects of this form of co-operation are regulated by both the Act of Insurance Intermediation<sup>5</sup> and the Civil Code<sup>6</sup>. Agency activities include thus activities consisting in winning over customers and executing actions preparing to conclude an insurance contract. New regulations stemming from the Civil Code protect interests of insurance agents in a clear way. Thus it is highly beneficial to put the bank in the position of an insurance agent; in this was the bank gets a significant advantage over the insurance company and a privileged position in relation to its equivalent so far partner – the insurance company. According to novelized regulations of the Civil Code, not only consumers but also banks are subject to protection concerning relations with the insurance office, under unilateral standards of strictly binding force. As an example an agent has a right to compensatory benefit if within the contractual period of the agency agreement he/she won over new clients, or led to a significant increase in turnover with the present customers, and the person who gave the order still derives considerable benefits from agreements with these customers. The agent-entrepreneur - the bank, has the right to obtain a commission on an agreement signed after the termination of

---

<sup>3</sup> *Dyrektywa Parlamentu Europejskiego i Rady 2002/92/WE z 09.12.2002r o pośrednictwie ubezpieczeniowym*

<sup>4</sup> *Ustawa prawo bankowe z dnia 29.08.1997 r. Dz. U. 2002r, Nr 72, poz. 665, art. 6*

<sup>6</sup> *Ustawa kodeks cywilny z dnia 26.07.2000r, Dz. U. Nr 74 poz. 857*

the agency agreement if except for fulfilling other conditions to get the commission the agent obtained the proposition to conclude the agreement resulting in the order before the end of the contractual period.

Moreover, the agent can demand the commission on an insurance agreement concluded after the termination of the agency agreement in case when this insurance contract was concluded mainly due to the bank's activity within the contractual period or within a reasonable time after its termination. By analysing the above-mentioned examples it seems obvious that a bank acting as an insurance agent in this type of relations between banks and insurance companies is put in a very advantageous position which is secured by law regulations binding in Poland in this field of activity.

The situation is different when the bank concludes an insurance policy with the insurer on behalf of a third party - that is a bank's customer. Then the bank as the insurer is obliged to pay the premium. However, this premium is paid from the bank's client's money accumulated on his account. This scheme often refers to payments due for securing transactions made by the bank's customer with a credit card. This situation conforms to the art. 808 § 1 of Civil Code and the Act on Insurance Activity that assume an opportunity to conclude an insurance contract on behalf of a third party.

Development of bancassurance in Poland is possible also due to favourable legal regulations included into widely understood consumer's rights. It is assumed that in case of a bank credit insurance, withdrawal from the credit contract evokes the same consequences to the insurance of the contract<sup>7</sup>.

Bank agreements granting credits, the repayment of which is secured by the creditor's life insurance agreement concluded for the period equal to the crediting period, should thus contain a provision making possible termination of the insurance contract in the situation when the credit agreement is resolved, for example in case of an earlier credit repayment.

Bancassurance is also legally acceptable according to regulations of the Act on Fighting Against Dishonest Competition and the Act on Protection of Competitors and Consumers<sup>8</sup>. In accordance to the first one activities consisting in hindering access to the market to other firms are prohibited. Very often banks condition the decision about concluding a crediting contract

---

<sup>7</sup>Ustawa z dnia 20.07.2001r o kredycie konsumenckim , Dz. U. Nr 100 poz. 1081, art. 11.

<sup>8</sup> Ustawa z dnia 15.12.2000r o ochronie konkurencji i konsumentów, Dz. U. Nr 122 poz. 1319, art.5 pkt.6.

E. Nowińska ,M.Du Vall: „Komentarz do ustawy o zwalczaniu nieuczciwej konkurencji”, Warszawa 2001r,s.131.

on buying the life insurance for crediting purposes in a selected insurance company. However, banks argue that in this case they do not infringe regulations of the above mentioned act as they appoint a company of a good financial position, so that the policy should primarily guarantee an effective security for the interests of the bank. This action also conforms to the Act on Protection of Competitors and Customers which bans agreements that aim at or result in elimination, limitation or infringement of fair competition on the proper market, consisting in particular in restricting the access to the market for other companies not covered by agreements. However, this ban doesn't refer to companies that operate on various levels of circulation and their total share in the market in the calendar year preceding the conclusion of a contract does not exceed 10%. Summing up, one of the main premises of bancassurance development in Poland is the state of various regulations that in this field are convenient for banks. There are no regulations referring directly to the institution of bancassurance and the indicated various forms of co-operation between banks and insurers are acceptable.

### **3. Economics factors**

The other group of factors that influence the development of bancassurance in Poland are market and economic factors such as:

possibility to increase profits of the banks and insurance companies through offering a complex financial service to the banks' clients, and lowering of the joint operational costs without using other financial agents,

possibility to lower the price of banking services and so to better compete in the financial market,

lowering of operational risk of the bank through its partial transfer onto an insurance company,

diversification of sources of the bank earnings allowing greater freedom in deposit policy handling of the bank and ensuring greater financial safety,

winning over a larger group of clients through the effective application of loyalty in relation to clients by, e.g. offering them complex financing services.

The first of the above-mentioned factors confirms the tendency across the globe to offer complex services by the banks, comprising financial advice services, typical bank products, bank innovations and insurance products<sup>9</sup>.

---

<sup>9</sup> „European bancassurance market to 2002” Datamonitor research and analysis 2003,s.43.

Offering of the above-mentioned services “under one ceiling” (meaning under the same roof) guarantees the associations of banks and insurance an increase of their profits. For example, in France, considered to be the leader of the bancassurance market in EU10, insurance is also sold with the use of networks of cash dispensers. In 2000 within bancassurance, 35% of life insurance policies, 60% of deposit type insurance policies and 7% of real estate insurance policies<sup>11</sup> were sold. The gross premium income of the five biggest banks amounted to 27600 million USD<sup>12</sup>. Additionally, the fact of lowering of the operational costs determines attractiveness of the connections between the banks and insurance companies. The market research shows that a cost of distribution of insurance policies in the bank amounts to 8% of a collected premium, which constitutes an amount three times lower compared to an amount of costs designated for remuneration of insurance agents<sup>13</sup>. As much as 80% of the main European banks which started to deal with the sales of insurance services show their operational costs at a lower level than traditional insurers<sup>14</sup>.

The risk transfer constitutes another important factor for the banks to establish the formal links with insurance companies. Thanks to this cooperation, the banks gain access to an enormous amount of capital for many years. Additionally, as a rule they try to transfer the weight of risk onto other entities. The insurance companies, however, deal with ‘taking’ of this risk, therefore the bank becomes for them a perfect partner. The insurers learn the principles and objectives of the investment policy of the bank. They use access to the network of bank branches, their website, and, first of all, to their wide client database. It can also be noted that, in the Polish market, the clients have much greater confidence in the banks than in the insurance companies. Therefore, an insurance company that has started a regular cooperation with the bank counts on loyalty of its clients, their trust and their attachment to ordering management of their finance with bank advisors.

The diversification of services is another equally obvious factor of success. On the current financial market, the trend to complete the traditional bank offer with other products may be observed, mainly advisory services, and insurance products. The modern financial institutions offer their clients a

<sup>11</sup> www.scor.com dated 18.03.2004., „Bancassurance across the globe”.

<sup>12</sup> www.datamonitor dated 07.2003.

<sup>13</sup> M.Śliperski „Zalecenia w strategii bancassurance”, Wiadomości ubezpieczeniowe No. 7-8 1998r,s.10.

<sup>14</sup> R.N.Hanisz „Strategia polskich banków wobec wyzwań rozwojowych”, Katowice 2002r, s.110

package offer which is well adjusted to the needs of individual clients, enterprises or local government units as these clients expect, first of all, to be offered a complex service that saves their time and money.

There are also some barriers that may limit the bancassurance development in Poland in a considerable way. Decrease of the pace of economic growth may result in lower demand for financial products among people. Moreover, the issue of the bank and insurance relations is relatively little known to financiers. The missing experience within that scope and ignorance of the issue may effectively limit development of these services. According to Datamonitor, a research and analysis agency, a negative attitude of the banks may prove to be the next barrier for bancassurance development. It turns out that most of the banks show their “superiority” over the insurance companies and they reluctantly decide to take up new enterprises for fear of typical bank offer sales drop and of putting their make and reputation to the test.

Summing up, it can be stated that creation of the connections between the banks and insurance companies results from the globalization and liberalization of the financial market across the world. This transformation is accompanied by aspiration of the banks to continuously modernize, to search for new income sources and to diversify risks of their operations. If the indicated success factors are met and certain barriers overcome, it will be possible to speak about development and success of the bancassurance market in Poland.

#### **4. The idea of bancassurance service**

There are two more factors also supporting attractiveness of the bancassurance service: it's simplicity and low price - as an English statement puts it: keep it simple keep it cheap. The proposition of linking banking facilities with insurance products completing them brings benefits to both the bank and its customer. The customer saves time on searching and purchasing an insurance product from an external insurance firm. Thus the customer is encouraged by an opportunity to fulfill all his financial needs “under one ceiling”.

The insurance product proposed at the bank establishments can also turn out to be cheaper for the customer than a matching product offered to him by other financial insurances agents that usually take higher commissions for their services. The customer's trust is an extremely important factor to the bank. Apparently, banks enjoy much higher trust than insurance companies, agents or insurance brokers. Yet, so far bank customers

usually lose their chance to choose an insurance offer from the whole palette of all insurance products from financial market offerings. Banks propose their own specific offer or a specific insurer. Obviously, the customer is free to choose: either use the bancassurance offer or to search on his own one and negotiate insurance conditions with an external insurance firm. Yet, there is some risk that the bank will reject an insurance policy other than their own that would contain conditions insufficiently protecting the interests of the bank in securing the credit repayments. For the customer that situation would mean that he would have to accept worse credit conditions or that he would be refused a credit from the bank. Another issue is an option to make an easy resignation from the insurance product offered him along with the bank product as the so called financial services package. It could turn out that an earlier resignation from the insurance bought out in the bank is impossible, ineffective and very costly. On the other hand using by the customer external insurance products that would make an integral part of banking services involves the need to update these agreements and submit them to be accepted by bank. Advantages and inconveniences of using the bancassurance services presented here are similar for the customer in our country and abroad. However, differences may concern the scope, the method and the quality of these services. In Poland this area of banking business is still relatively poorly managed.

It is also necessary to point out to factors influencing the bank's decision to start selling insurances at its enterprises. In conditions of constant changes on the financial market that manifest in a constant drop in the interest profit margin and income of the bank, to be able to ensure a competitive position the bank is obliged to take up actions in the field of expenses control, diversification of revenue sources, implementing modern risk management tools. Bancassurance is a perfect tool to diversify revenue sources and a modern tool which transfers the risk to the insurer. Following the globalisation of financial markets the banks' position dominating in respect to other financial institutions has been reduced. In the face of the strong competition between banks and non-bank institutions operating in the banking sector, consolidation of banks and insurance companies guarantees a definite competitive advantage and it changes the present image. A bank co-operating with an insurance company in one of the mentioned forms:

- increases his capital potential,
- implements modern technologies,
- increases its personnel's qualifications,
- introduces innovative bancassurance services

- obtains additional sources of income,

what proves its high ability to compete on the market. Moreover, an optimal risk level is ensured thanks to the possibility to transfer a part of this risk to the insurer, or due to accepting the same range of risk but by a stronger capital of a bancassurance group. Bancassurance institution is a banking and insurance group created for the purposes of offering comprehensive financial services, called bancassurance services, including fragmentary services typical for a bank, of insurance and consulting character performing as the product's amalgam<sup>15</sup>.

The risk incurred by bank does not increase proportionally to its size and annual turnover obtained by it. A large bancassurance institution characterizes with a lower risk of bankruptcy, and possesses increased bargaining power on the financial market. This enables reducing expenses related to capital acquisition by giving it a form of a credit and loans interest rate in case of individual customers or deposits for banks. A large financial institution, possessing a bigger credit wallet, spreads losses to a significantly higher number of transactions and moreover is capable of limiting them by applying insurance products or covering them with profits from an extra insurance activity. Co-operation between banks and insurance companies makes society perceive banks as developing financial institutions aimed at comprehensive customer service. Complex financial services comprising finance consulting and modern bancassurance products, has significant importance not only from the customers' points of view, but also for strengthening their loyalty to the very institution.

## **Abstract**

*The Romanian life insurance market is in full expansion. There exists competition between insurance companies as well as between different products of the same company. In this article we describe a study using data that we collected from clients of a Romanian insurance company. We have observed two types of variables: characteristics of insurance products (e.g. profitability, risk), as well as characteristics of individuals (e.g. sex, age, income). We use a Discrete Choice Model – The Multinomial Logit Model. We estimate the variations in the market shares of life insurance products using marginal effects. The variations are due to possible changes in the values of some characteristics such as age or income.*

**Keywords:** *life insurance; demand; multinomial logit; market shares.*

## 1. Introduction

In the past years, Romanian insurance industry has gradually emerged to become an important part of the financial services sector. While in the Western Europe countries the life insurance sector dropped with more than 3% in 2003, the average of the Central and Eastern Europe (CEE) growth rate in this field was of 15,22%, exceeding the last ten years average growth rate with almost 80%.<sup>1</sup> It is expected that, while the welfare of the CEE inhabitants will grow, the density and the penetration degree will show a sustained evolution. According to the results provided by the insurance companies for the year 2004, there is a certain fact: the Romanian Insurance Market is rising and the life insurance sector has increased of about 10% from 2003. The life insurance line of business remains polarized, the market share held by the top ten companies ranked by gross written premiums is of 92% and the market share of the leader company exceeds 40%.

The study of life insurance demand has attracted the interest of a number of researchers in the past. Theoretical models on life insurance demand have been developed and empirical studies also have been conducted extensively to examine the influence of specific factors on the demand for life insurance.

This paper proceeds to review the literature related to life insurance demand, to present the Romanian life insurance market, to describe the data and estimation model, to present and discuss the empirical results, and to conclude with the findings of this study.

## 2. Literature Review

Economic theory predicts that households will save and insure in order to enjoy the same living standard over time and in the event of the death of a household head or spouse. Economic theory in this case accords with common sense and every day observation. “We save to be able to maintain our life styles in retirement. And we buy life insurance to make sure our survivors can continue to live at the same standard to which they have become accustomed” -Kotlikoff, Gokhale (2002).

There is no unique theory for life insurance demand. Yaari (1965) was the first to develop a theoretical framework to study the uncertainty of lifetime and the demand for life insurance. He predicted that investors make asset allocations decisions and life insurance purchase to maximize their

---

<sup>1</sup> “*Insurance Profile – Romanian Insurance Market*” - Quarterly Insurance Review, issue 4, 2004.

lifetime utilities of wealth and consumption. Almost all of the theoretical works which study the impact of wealth and bequest motives on life insurance demand developed later have expanded their models based on the study of Yaari (1965).

There are a number of empirical studies of life insurance demand that have been developed in the past. Bernheim (1991) uses estimates of the demand for life insurance to assess the strength of bequest motives. He finds that a significant fraction of total saving is motivated by the desire to leave bequests. Browne and Kim (1993) present evidence on life insurance demand across 45 countries. They find that the main determinants of country variations in the demand for life insurance are the dependency ratio (the number of dependents per potential life insurance consumer), income, inflation and price of insurance.

The findings of Browne and Kim (1993) and Outreville (1996) confirm that the income level affects significantly the life insurance demand. Life insurance becomes more affordable when income increases.

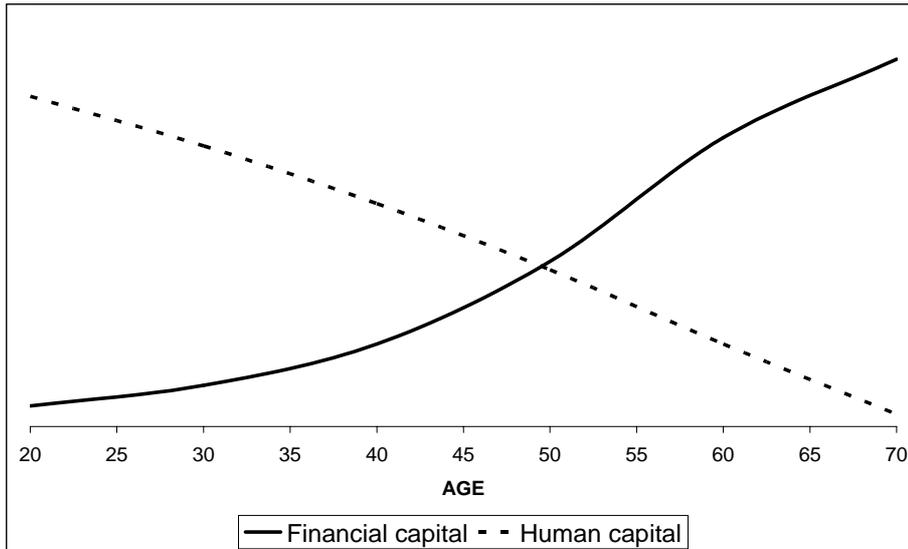

Over time, the life insurance decisions and the asset allocation have been analyzed separately, both in theory and practice. The human capital is the factor that makes the linking between these two, because it affects both the optimal asset allocation and the demand for life insurance – Chen, Ibbotson, Milevsky, Zhu (2005). They defined the human capital as the present value of an investor's future labor income.

An investor's human capital contains a unique mortality risk, which is the loss of all future income and wages in the unfortunate event of premature death. Life insurance has been used for long time to hedge against mortality risk. The greater the value of human capital is, the more life insurance the family demands.

Younger investors have far more human capital than financial capital. This is because younger investors have more years to work and they have had few years to save and accumulate financial wealth. On the other hand, young investors tend to have more financial capital than human capital, since they have fewer years ahead to work but have accumulated financial capital over a long career.

Figure 1 illustrates the amounts of financial capital and human capital over an investor's working years from age 20 to age 60. When the investor is young, his human capital far outweighs his financial capital. As the investor gets older, he will continue to make savings and with the return from the existing financial portfolio, the amount of financial capital will increase.

**Figure 1. Financial Capital and Human Capital over the Life Cycle**

Source: Chen, Ibbotson, Milevsky, Zhu (2005) - “Human Capital, Asset Allocation and Life Insurance”, Working Paper

The human capital gradually decreases as the investor gets older and the remaining number of working years gets smaller. The amount of financial capital increases as the investor ages. This is the result of the growth of the existing financial wealth and additional savings that the investor makes each year.

The allocation of capital in risky asset decreases as the investor ages. This result is due to the dynamic between human capital and financial wealth over time. When an investor is young, the investor’s total wealth is dominated by the human capital. Since human capital in this case is less risky than the financial risky asset, young investors will invest more financial wealth into risky assets to offset the impact of human capital on the overall asset allocation. As the investor gets older, the allocation to risky assets is reduced, as human capital gets smaller.

### **3. Data Issues About Life Insurance**

There are two issues about life insurance that we have to emphasize: first we provide descriptive statistics on the structure of life insurance policies in Romania and secondly, we briefly present the types of life insurance products that we are referring to.

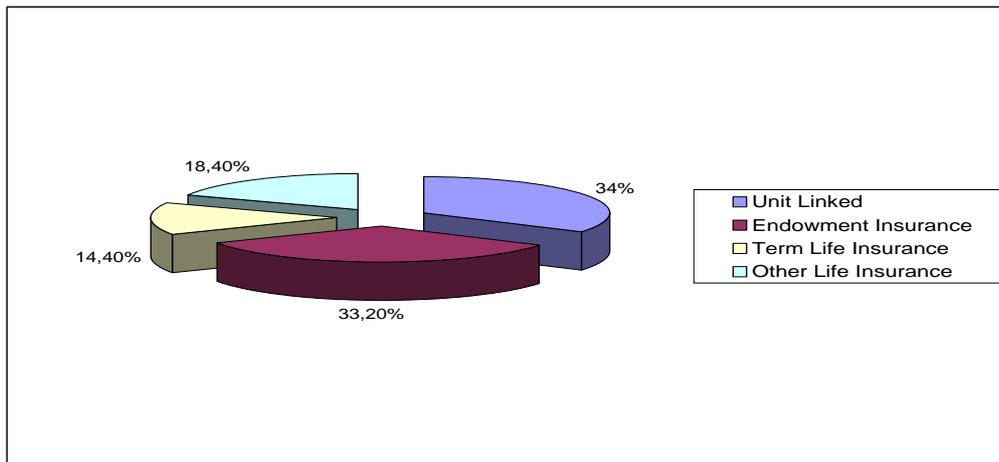

### 3.1 The Classification of the Life Insurance Products in Romania

The main types of life insurance products offered by the insurance companies in Romania are the *Term Life Insurance*, the *Whole Life Insurance*, the *Endowment Insurance*, the *Life Insurance Annuities* and the *Unit Linked Life Insurance*.

In the year 2004, three types of life insurance products held 81,6% from the total of gross written premiums, as follows<sup>2</sup>:

- *Unit Linked Life Insurance* with a market share of 34% from the total of gross written premiums;
- *Endowment Insurance* with a market share of 33,2% from the total of gross written premiums;
- *Term Life Insurance* with a market share of 14,4% from the total of gross written premiums.

**Figure 2. The Market Share of the Main Types of Life Insurance Products considering the Volume of the Gross Written Premiums, in 2004**

Source: *The Insurance Supervision Commission, Annual Report for the Romanian Insurance Market, 2004.*

Taking into consideration this ranking of the insurance products, we have analyzed for a certain insurance company the factors that influence an individual to choose one these three top products. From here on, we will briefly present the three types of life insurance products mentioned previously.

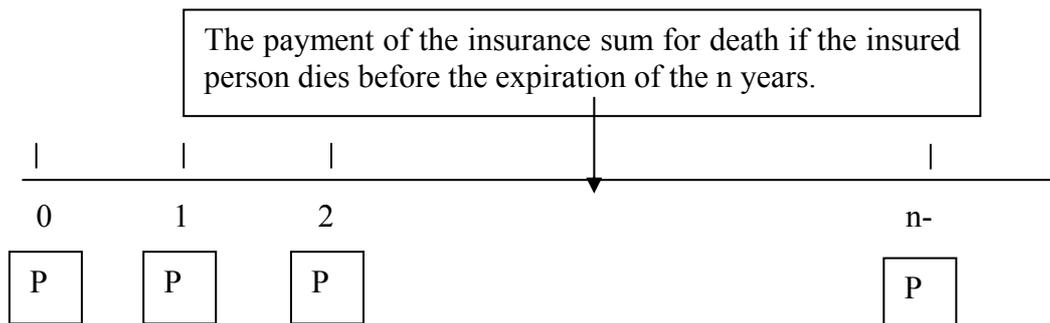

<sup>2</sup> The Insurance Supervision Commission, Annual Report for the Romanian Insurance Market, 2004.

## 3.2 A Brief Presentation of the Analyzed Insurance Products

### 3.2.1 The Term Life Insurance

This insurance provides protection for the risk of death only, it doesn't imply saving or capitalization. The insured person pays periodically the prime, for which a third person – the beneficiary - will collect the insured sum at his death. If when the term is reached the insured person is alive, he or the beneficiary doesn't receive anything. This is the reason for the prime to be quite small in relation with other types of insurance.

**Figure 3. The scheme of the Term Life Insurance**

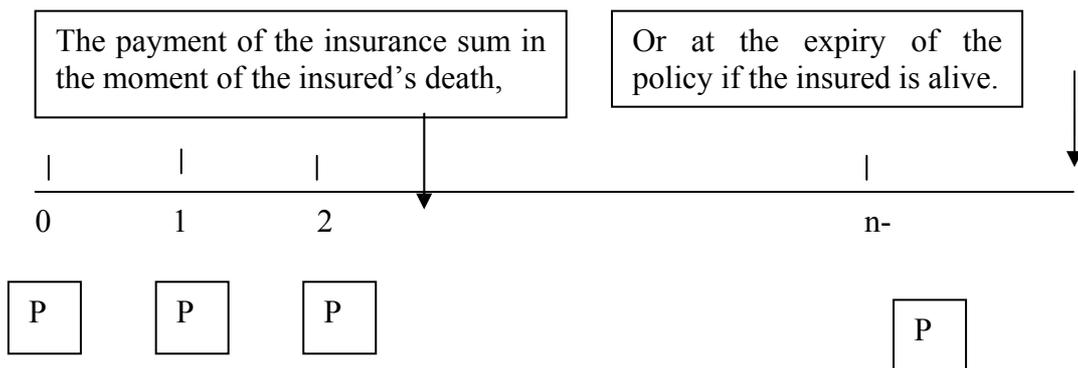

*Source: Corfias, Th, (2003), Assurance-vie: techniques et produits, L'Argus de L'assurance, Paris.*

### 3.2.2 Endowment Life Insurance

The Endowment Life Insurance is a capitalization insurance, which covers both the risk of death and the risk of "surviving". If the insured person is alive at the end of the contract he personally gets the insured sum, and if he dies before the end of the contract the insured sum would be collected by the beneficiary. The advantage of this insurance type is the fact that the sums paid as insurance premiums are capitalized and can be used when the policy expires. Obviously, the insurance premium in this case is greater than in the case of the term life insurance.

**Figure 4. The scheme of the Endowment Life Insurance**

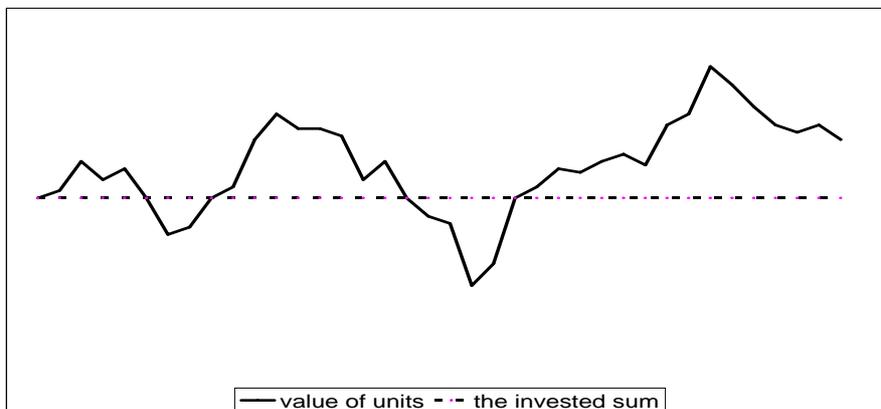

Source: Corfias, Th, (2003), *Assurance-vie: techniques et produits*, L'Argus de L'assurance, Paris.

### 3.2.3 Unit Linked Life Insurance

The Unit Linked Life Insurance has an investment component and a protection component. The *protection component* is represented by a whole life insurance. In case of death, the beneficiary will get the maximum between the invested sum and the value of the count. The value of the count represents the value of the units held in the funds of the insurer.

The *investment component* consists of buying units in the financial funds constituted for this type of insurance. The value of the count is obtained by multiplying the number of units with the value of the unit fund for that day. The profits obtained by investment are connected to the performance of the funds, which may imply a lower or a higher risk.

**Figure 5. The scheme of the Unit Linked Life Insurance**

Source: Corfias, Th, (2003), *Assurance-vie: techniques et produits*, L'Argus de L'assurance, Paris.

For the traditional insurance products, the insured person has considerable guarantees which consist of a fixed insured sum at death or when the policy expires.

The risk of the investment belongs to the insurance company:

- The company must adopt a prudential attitude towards the future profits obtained from investments;
- The company has to invest their clients' money in safe financial instruments like governmental bonds, treasury bonds or bank deposits at safe banks.

In the case of Unit Linked Life Insurances, when it comes to investing his savings, the insured person is given the possibility to choose between different funds (having different composition in bonds and shares). The policy profitability depends on the risk exposure of the chosen funds and on the proportion invested in them. The risk of the investment belongs to the insured. If the insured is willing to take greater risks he will select the funds with a greater proportion of shares, which offer the opportunity of a higher profitability.

We will estimate the variations of the market shares of these three life insurance products using marginal effects, in the case when the values of the two variables, age and income, are modified.

#### **4. Data and Estimation Model**

Our application involves clients of a Romanian insurance company, whose name will remain unrevealed, out of competition reasons. In July, we have made a poll consisting of 78 subjects who possess insurance policies at that company. Three insurance products have been taken into consideration: term life insurance, endowment life insurance and unit linked insurance, which altogether represent 80% of the turnover of the company.

##### ***4.1 The Sample***

The individuals from the sample have been questioned about two kinds of variables: variables that characterise the insurance products and variables that characterise the insured person.

1. Defining the profitability of an insurance as being the income produced for a given value of the insurance premium, mark on a scale from 1 (lowest profitability) to 10 (highest profitability) the following products:
  - a) term life insurance : .....
  - b) endowment life insurance : .....
  - c) unit linked insurance : .....
  
2. Defining the risk as being the certainty of achieving the estimated income, mark on a scale from 1 (lowest risk) to 10 (highest risk) the following products:
  - a) term life insurance : .....
  - b) endowment life insurance : .....
  - c) unit linked insurance : .....
  
3. You have a:
  - a) term life insurance : .....
  - b) endowment life insurance : .....
  - c) unit linked insurance : .....
  
4. You are: ..... years old.
  
5. You are a:
  - a) Male
  - b) Female
  
6. Your monthly income is: ..... RON/month .

#### ***4.2 The Model***

Supposing that each one of the individuals of the sample chooses only one type of life insurance, the decision of choosing the product is discreet. Consequently, the model chosen for explaining the choice of an insurance product is a discreet one, so the estimation will be made using the econometrics of qualitative variables. The model will be a multinomial one because the qualitative dependent variable  $y$  has more than two states,  $y_i = j$ ,  $j = 0, 1, \dots, m$ , respectively. In our application, the states of  $y$  are the insurance products.

**The Multinomial Logit Model.** The multinomial Logit is actually an extension of the binary Logit model, having more modalities of choice. Let  $(p_0, p_1, \dots, p_m)$  be the probabilities of  $m+1$  modalities of choice. The probability of an individual  $i$  to choose the modality  $j$  is given by:

$$p_{ji} = P(y_i = j) = \frac{\exp(x_i b_j)}{1 + \sum_{j=1}^m \exp(x_i b_j)} \quad j = 1, 2, \dots, m \quad (1)$$

where  $x_i$  is the vector of the explicative variables associated to the individual  $i$ , and  $b_j$  is the vector of parameters associated to the modality  $j$ .

**The Conditional Multinomial Logit Model.** The generalization of the Logit model for the multinomial case is made taking different parameters  $b_j$  depending on the variants of choice (products), such that the explicative variables  $x_i$  remain constants depending on the products. Still, there is another possibility: the McFadden conditional Logit model which considers a constant vector of parameters  $b$  and allows the explicative variables  $x_{ij}$  to depend on the variants (McFadden 1973, 1980). The probability of an individual  $i$  to choose the modality  $j$  is given by:

$$p_{ji} = P(y_i = j) = \frac{\exp(x_{ij} b)}{\sum_{k=1}^m \exp(x_{ik} b)} = \frac{\exp(x_{ij}^* b)}{1 + \sum_{k=1}^m \exp(x_{ik}^* b)} \quad j = 1, 2, \dots, m \quad (2)$$

where  $x_{ij}^* = x_{ij} - x_{i0}$ , and the proportion of the probabilities is:

$$\frac{P(y_i = j)}{P(y_i = l)} = \frac{\exp(x_{ij}^* b)}{\exp(x_{il}^* b)} = \frac{\exp(x_{ij} b)}{\exp(x_{il} b)} = \exp[(x_{ij} - x_{il})b] \quad \forall j, l = 1, 2, \dots, m \quad (3)$$

which, as in the case of the multinomial Logit is independent of the other variants of choice.

When computing the marginal effects, we are interested in the estimated variation of the probability of an individual  $i$  to choose modality  $j$ , when the explicative variable  $k$  associated to a product varies. We have:

$$p_{ij} = \frac{\exp\left(\sum_{k=1}^K x_{ijk} b_k\right)}{1 + \sum_{h=1}^m \exp\left(\sum_{k=1}^K x_{ihk} b_k\right)} \quad (4)$$

the marginal effect  $\frac{\partial p_{ij}}{\partial x_{ilk}}$  being:

$$\begin{cases} b_k p_{ij}(1-p_{ij}) & \text{daca } j=l \\ -b_k p_{ij}(1-p_{il}) & \text{daca } j \neq l \end{cases} \quad (5)$$

**The General Multinomial Logit Model.** Due to the fact that our application involves both explicative variables that characterise the products and variables characterising the individual, a more general model will be used, which contains both the multinomial and the conditional Logit models. The probability of an individual  $i$  to choose the modality  $j$  is given by:

$$p_{ji} = P(y_i = j) = \frac{\exp(x_{ij}b + x_i b_j)}{\sum_{k=1}^m \exp(x_{ik}b + x_i b_k)} \quad j, k = 1, 2, \dots, m \quad (6)$$

Once the parameters have been estimated, by replacing the values of the explicative variables with the mean values from the sample, we can obtain an estimation of the probability  $\tilde{p}_j$  that a randomly chosen individual (average individual) will choose the product  $j$ . By multiplying this number by the total number of consumers  $N$ , an estimation of the demand (or of the market share) for the product  $j$  will be obtained:

$$\tilde{D}_j = \tilde{p}_j \times N \quad (7)$$

We can also obtain simulated market shares for products, computed for other values of the explicative variables, thus facilitating the foundation of some product policies.

### The Variables

Profitability – values from 1 to 10

Risk – values from 1 to 10

Age – years

Sex – 0 if the individual is a woman, 1 if it is a man

Income – RON/month

Term – dummy variable. Equal to 1 if the term life insurance product is chosen, 0 otherwise

Endowment – dummy variable. Equal to 1 if the endowment insurance product is chosen, 0 otherwise

Unit linked – dummy variable. Equal to 1 if the unit linked insurance product is chosen, 0 otherwise

Age\_term = Age × Term

Age\_endowment = Age × Endowment

Age\_unit linked = Age × Unit linked

Sex\_term = Sex × Term

Sex\_endowment = Sex × Endowment

Sex\_unit linked = Sex × Unit linked

Income\_unit linked = Income × Unit linked

Income\_endowment = Income × Endowment

Income\_unit linked = Income × Unit linked.

## 5. Results Presentation

**Table 1 The average values of variables in the sample**

	Variables				
	Profitability	Risk	Age	Sex (% of males)	Monthly income (RON)
<i>Term Insurance</i>	4.44	6.05	59.3	33.3	819
<i>Endowment</i>	2.78	2.01	50.4	48.1	928
<i>Unit Linked</i>	8.17	6.90	40.6	66.8	1118

### 5.1 The Estimation of the Model

For estimating the parameters, the LIMDEP 7.0 program will be used and as an estimation algorithm, the Newton-Raphson method.

**Table 2 Parameters estimates – all variables**

Discrete choice (multinomial Logit) model

<i>Income_endowment</i>	0.0021	0.0034	0.845
<i>Income_unit linked**</i>	0.0082	0.0041	2.004

\*\*\*p<0.01 \*\*p<0.05 \*p<0.10

The values of the parameters are according to prediction. The plus for *profitability* shows an increased probability of choosing the product when the value of the variable increases. The minus for *risk* shows a decrease of probability. The minuses for *age\_endowment* and *age\_unit*

linked show the fact that when age increases, it decreases the probability of choosing the endowment insurance and unit linked insurance products, with respect to the reference product, the term insurance. The minuses for `inc_endowment` and `inc_unit_linked` show the fact that when income increases, it increases the probability of choosing the endowment insurance and unit linked insurance products, with respect to the reference product, the term insurance.

For each individual, we can compute according to the formula (6) the probability of choosing each of the three insurance products:

**Table 4 Predicted Probabilities (\* marks chosen, + marks prediction.)**

Indiv.	term insur	endow.insur	unit_linked.insur
1	.7456*+	.2515	.0029
2	.9690*+	.0246	.0064
...	...	...	...
17	.9684*+	.0276	.0039
18	.9987*+	.0007	.0006
19	.6737 +	.2945*	.0318
20	.3366	.6566*+	.0068
...	...	...	...
44	.0036	.7231*+	.2733
45	.0355	.9518*+	.0127
46	.0000	.0001	.9999*+
47	.0021	.0088	.9891*+
...	...	...	...
77	.0001	.0107	.9893*+
78	.0064	.0063	.9873*+

A study of the estimated probabilities show that the model is an evolved one from the point of view of predictions, the percentage of correct prediction being 84.6%.

### ***5.2 The Applicability of the Model***

We may consider the case when the values of the explicative variables change. We compute the marginal effects, the percentage variations of the share markets of the products respectively, when the *profitability* and *risk* variables are increased by 1.

**Table 5 The marginal effects (%) for the variable *profitability***

		<i>The marginal effect over the product</i>		
		<i>Term insurance</i>	<i>Endowment</i>	<i>Unit Linked</i>
<i>The product for which “profitability” varies</i>	<i>Term</i>	6.45	-4.62	-1.82
	<i>Endowment</i>	-4.62	10.93	-6.31
	<i>Unit Linked</i>	-1,82	-6,31	8,12

*Source: Author’s calculation*

The results obtained are according to prediction: the increase of the profitability of a product determines the increase of its market share and the decrease of the market shares of the other products, but of different values. For instance, the increase of profitability for the term insurances will have a greater impact on the endowment insurances than on the unit linked ones.

**Table 6 The marginal effects (%) for the variable *risk***

		<i>The marginal effect over the product</i>		
		<i>Term insurance</i>	<i>Endowment</i>	<i>Unit Linked</i>
<i>The product for which “risk” varies</i>	<i>Term</i>	-8.02	5.76	2.26
	<i>Endowment</i>	5.76	-13.61	7.85
	<i>Unit Linked</i>	2.26	7.85	-10.12

*Source: Author’s calculation*

For the *risk* variable, the results are very similar, but of opposite sign: when the risk of a product increases its market share decreases and the market share for the other products increase.

The model can be also used for founding some product strategies (advertising, promotion). Considering this, we estimate the markets shares of the three insurance products, for different values of the variables *income* and *age*. The variables *profitability* and *risk* keep their medium values from the sample.

**Table 7 The market shares for the three insurance products in the group age 30-40 years**

	<i>Medium income (RON/month)</i>							
	700	800	900	1000	1100	1200	1300	1400
<i>Term</i>	2.1	1.2	0.7	0.3	0.2	0.1	0.0	0.0
<i>Endowment</i>	56.4	43.9	31.8	21.7	14.0	87.8	5.4	3.2
<i>Unit Linked</i>	41.5	54.9	67.5	78.0	85.8	91.1	94.6	96.8

## 6. Conclusion

All in all, we have succeeded to explain through The Multinomial Logit Model different aspects of the demand for life insurance products in a company from the Romanian insurance market. The results obtained in the application match perfectly to the theory presented previously. The demand for products with lower risk level increases, as a person is getting older, to the detriment of the products of higher risk level. Moreover, the income is a major factor that influences the choice of a specific insurance product: as income increases, there exists an increased affordability for the higher risk products.

The demand for each product is well forecasted, as well as the attributes of the products (and individuals) that determine the choice. The model can be used for modifying the characteristics of the life insurance products, in order to obtain among these a relation that would maximize the profit of the company. One insurance product may be more profitable than another, while the achievement of a demand structure, as profitable as possible for the company, can be determined based on the estimations of the marginal effects of the risk and on the profitability of insurance products.

## **Abstract**

*Recently, Romania has been confronted with severe floods. Thousands of people found themselves homeless in couple of hours. Lives were lost and people injured. And it seems that the vagaries of weather and its risks will not stop here. On the same token, given its geomorphological and geographical location Romania is permanently exposed to the imminence of a severe earthquake. This paper intends to examine the problems with the introduction of compulsory buildings' insurance in Romania as a solution for managing the consequences of natural catastrophes. Three important viewpoints will be considered: 4the insured, the insurance companies and the recommendations of the World Bank.*

**Keywords:** *compulsory insurance, natural catastrophes, consequences, solutions, World Bank's recommendations.*

## 1. Introduction

According to a recent study conducted by the World Bank in april 2002, Romania is strongly exposed to natural catastrophes risks, especially earthquakes, floods and landslides which could severely lead to a loss of human lifes and important damages. Bucharest, is the European capital most exposed to earthquakes, and one of the first 10 capitals in the world that could face such a risk<sup>1</sup>.

Regarding properties, the above mentioned study estimates that annual damages following possible earthquakes and floods would reach 400 millions USD.

Since 1908, in Romania there have been recorded :

- a) 14 strong earthquakes out of which 3 with a magnitude above 7 degrees on a Richter scale (in 1940,1977,1986) that have affected 60% of Romania's territory.
- b) 8 major floods that affected more than 2 million people and caused important economic damages.

Moreover, 20% of Romania's territory may be exposed to landslides.

**Tabel 1. Top Natural Catastrophes in Romania**

<i>Earthquakes</i>	<i>Floods</i>
<b>1977</b> ; 7,2 degrees Richter scale, 2 bilion USD damages; 1.641 deaths.	<b>1991</b> ; 500 million USD damages, 15.000 people distressed;
<b>2005</b> , 7 earthquakes, above 4 degrees Richter are being produced each 15 through 45 days; specialists estimate a major earthquake (2006).	<b>1997</b> ; 310 million USD damages, 222.320 people distressed;
	<b>2005</b> ; the damages following the April, July, August and September floods reached 1,4 billion EUROS, approximately 2% of the 2005 estimated GDP; 31 deaths.

*Source: Author's compilation*

---

<sup>1</sup> Munich RE's specialists have characterized Bucharest as a " *a large city with a Mexico City effect*". There are only 6 location in the world with such a possible effect, out of which 2 are in Europe: Bucharest and Lisbon.

How will this damages be covered (2005)? How will the reconstruction houses works, socio-cultural objectives' works, the reconstruction of the infrastructure such as piers, bridges be financed?

## 2. Overview of the Romanian insurance market.

### 2.1. Comparisons with the insurance markets in Central and East European countries, European Union 15, European Union 27 and with the global markets.

We will consider useful this comparison, given certain macroeconomic ratios and indicators such as *density of insurance and the degree of insurance penetration*. Below, we will provide a table with data supporting our comparison:

**Table 2 Major macroeconomic indicators concerning the comparison between Romania's insurance market and the insurance market in CEE, EU 15, EU 27 and the global markets.**

Country	Insurance premiums 2004		Population	GDP	GDP/inhabitant	Density of insurance		Insurance penetration	
	total	non-life				total	non-life	total	non-life
	Mil. euro	Mil. euro				Mil. inhabitants	Mil. euro	euro/person	euro/person
Poland	5,538	3,492	38.6	183.2	4,746.0	<b>143.5</b>	90.5	<b>3.02</b>	1.91

Source: *Piata Financiara – Supliment Asigurari, february 2005; CSA, Report CSA 2004*

Considering the 2004 financial year, Romania has a low density of insurance<sup>2</sup>, compared with the Czech Republic. Romanians are almost 8 times more “uninsured” and 8 times more exposed to natural catastrophes risks than the Czechs. If we are to compare Romanian indicators with the global and European ones, we are 10 times more “uninsured” than the global inhabitant and 44 times more insurance deficient than EU 27.

Moreover, Romania has the lowest insurance penetration ratio<sup>3</sup>.

*How can this be explained?*

## **2.2. The Romanian insurance demand.**

At the initiative of the Romanian publication “Piata Financiara” and under the auspices of the Media Controller Research Company, a program is being run named TEBA – “Trends in Economics, Banking and Insurance”. The program aims at periodically evaluating couple of indicators pertaining to the attitudes of the Romanian population towards the financial institutions active on the Romanian market and the financial institutions’ offers<sup>4</sup>.

Three polls have been conducted in Bucharest in September 2001, February 2002 and November 2002.

The results led us to couple of conclusions presented below:

<sup>2</sup> The insurance density is computed as a ratio between gross insurance premiums and the volume of the population.

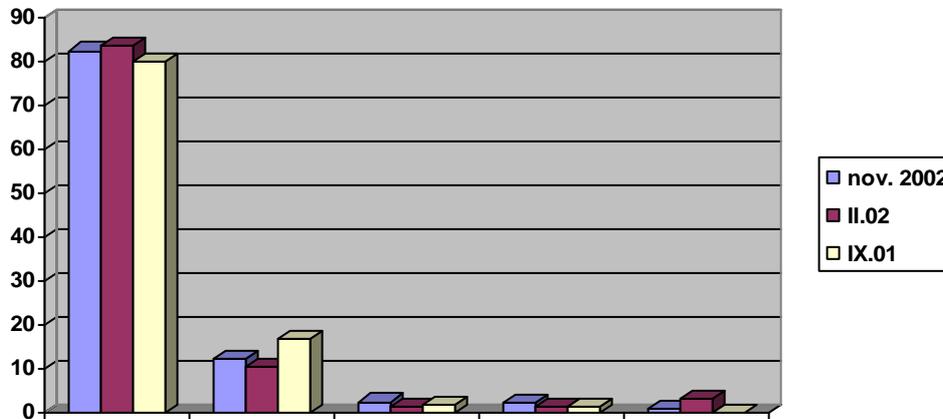

<sup>3</sup> The degree of insurance penetration is computed as a ratio between gross insurance premiums and the gross domestic product (GDP)

<sup>4</sup> Piata Financiara, *Asigurari*, february 2003, pag. 23 – 24.

**Table 3. Do you have an insurance contract (other than RCA – mandatory car insurance)?**

	<i>NO</i> %	<i>Yes, I have a single insurance contract with a single insurance company.</i> %	<i>Yes, I have multiple insurance contracts with a single insurance company.</i> %	<i>Yes, I have multiple insurance contracts with multiple insurance companies.</i> %	<i>NS/NR</i> %
<i>nov. 2002</i>	82,5	12,1	2,5	2,2	0,7
<i>feb. 2002</i>	83,7	10,4	1,5	1,3	3,1
<i>sep. 2001</i>	79,9	16,9	1,7	1,4	0,1

**Figure 1. Do you have an insurance contract (other than RCA – mandatory car insurance)**

Source: Piata Financiara, Supliment - Asigurari, February 2003, page. 24;

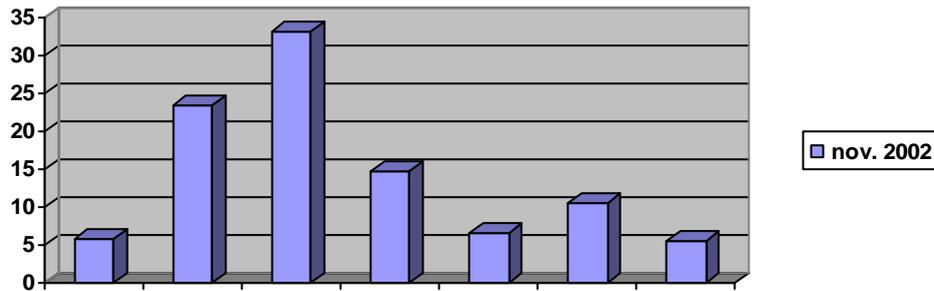

NS/NR: don't know / no answer.

( 1 ) In November 2002, out of the 1330 subjects questioned, only 17% had optional insurance contracts (i.e. less than 1/5)

**Table 4. How much trust do you have in the insurance companies?**

	<i>Very much</i> %	<i>Much</i> %	<i>Not much, not less</i> %	<i>A little</i> %	<i>Very little</i> %	<i>None</i> %	<i>NS/NR</i> %
<i>nov. 2002</i>	5,9	23,5	33	14,7	6,7	10,5	5,7

**Figure 2. How much trust do you have in the insurance companies?**

Source: *Piata Financiara, Supliment - Asigurari, February 2003, page 23;*  
*NS/NR: don't know / no answer.*

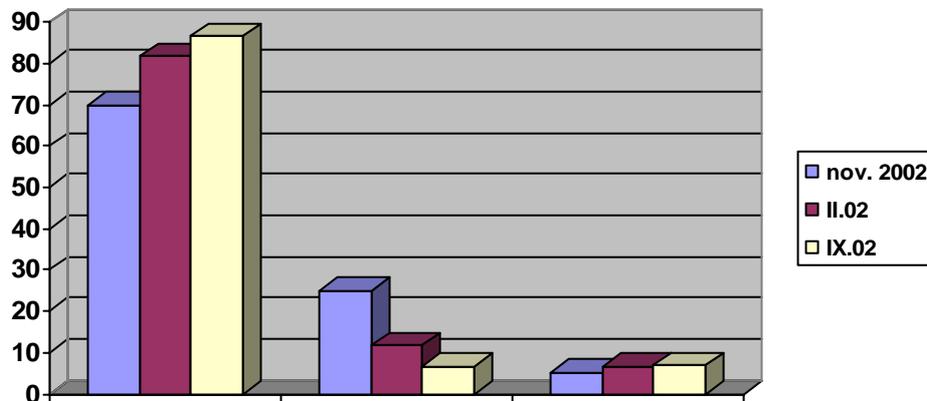

( 2 )30% of the people subject to the poll trust the local insurance companies, 1/3 are skeptical when it comes to the seriousness of the insurance firms and 33% are indifferent. The answers' structure is in equilibrium, indicating that "the trust" is not the critical problem blocking the insurance market development in Romania.

**Table 5. Do you intend to buy an insurance contract in the next 6 months?**

	<i>No</i>	<i>Yes</i>	<i>NS/NR</i>
<i>nov. 2002</i>	69,9 %	24,9 %	5,2 %
<i>feb.2002</i>	81,7 %	11,7 %	6,6 %
<i>sep.2002</i>	86,5 %	6,7 %	6,9 %

Source: *Piata Financiara, Supliment - Asigurari, February 2003, page 24;*  
*NS/NR: don't know / no answer.*

**Figure 3. Do you intend to buy an insurance contract in the next 6 months?**

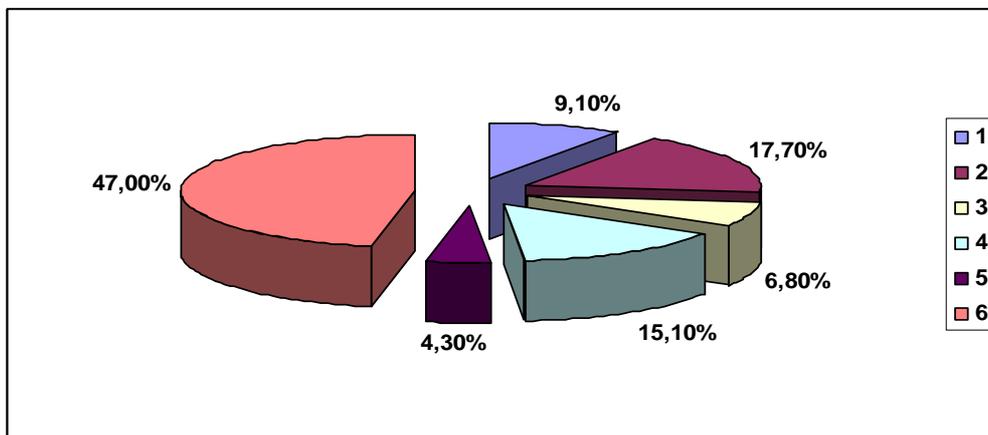

*Source: Piata Financiara, Supliment - Asigurari, February 2003, page 24; NS/NR: don't know / no answer*

( 3 ) In November 2002, the polls indicated that a 25% increase in demand was possible. This percent is higher than 9 months or 13 months ago.

*What is the reason behind this low interest of the Romanians in buying an insurance contract?*

**Figure 4. The reasons why they are not interested in buying an insurance contract.**

*Source: Piata Financiara – Supliment Asigurari, march 2002, page 24.*

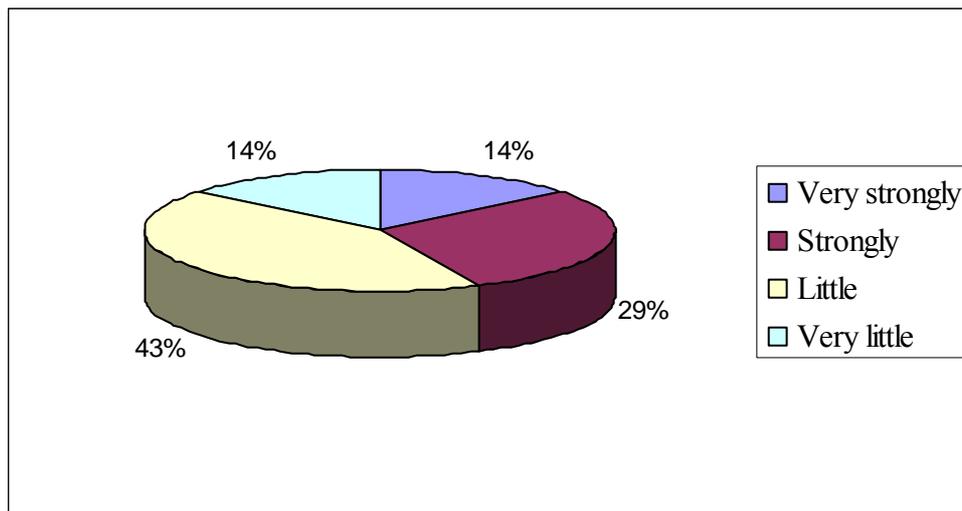

1. 9,1% (935 persons) do not trust the insurance market and system;
2. 17,70% don't think they need one;
3. 6,80% have no information regarding the advantages of buying an insurance coverage;
4. 15,10% are indifferent regarding the subject;
5. 4,30% other reasons, and
6. 47% can't afford one.

*Note:* The subjects of the poll were inhabitants of Bucharest ; the degree of insurance penetration in Bucharest is higher than in the rest of the country.

*How are the perspectives after the major 2005 floods?*

The results of a poll conducted on the portal [iasig.ro](http://iasig.ro) regarding “the measure in which this year floods will influence the population’s proneness towards buying an insurance contract” reflected the following characteristics:

**Figure 5. The population’s proneness towards buying an insurance contract after the 2005 floods:**

*Source: iasig.ro / Archives.*

According to the above figure, 57% of the people participating in the poll believe that the 2005 floods have influence in the population’s proneness towards buying an insurance coverage.

The motives often invoked are:

- lack of population’s education regarding insurance coverages;
- the cost of such insurance coverages.

**The lack of population's education regarding insurance coverages**, is a characteristic of the population living in the rural areas. The rural population is old and has a low purchasing power of insurance coverages. Moreover, as the data presented in Table 4, Figure 2 suggests, the Romanian population does not have sufficient trust in the Romanian insurance system, although the insurance companies have consistently strived through advertising and promotions to overcome this obstacle. The governmental policies regarding the matter are not helping the insurance companies' cause, especially if we think at the fiscal policies enacted.

Often, remarks like «people living in the rural area don't have money ; they live from the crops they harvest in the fields, they don't have cash, they prefer the barter when they need something. This is the reason why they can not insure their house» are made.

There are 2 opinions related to the above mentioned statement: on one hand there are those who represent the insurance companies and who consider that the lack of cash is a false problem as the annual premiums for 10.000 EURO are between 1,5 – 3,5 EURO and that from the increase in the insured properties the state, the insurance company and the insured win ; on the other hand, the insurance premiums used in the Western Europe can not be afforded by a middle romanian employee and the cheap premiums are not worth their money.

*What is the genuine view of the romanian insurance market reflected in numbers ?*

### **2.3. The insurance offer in Romania**

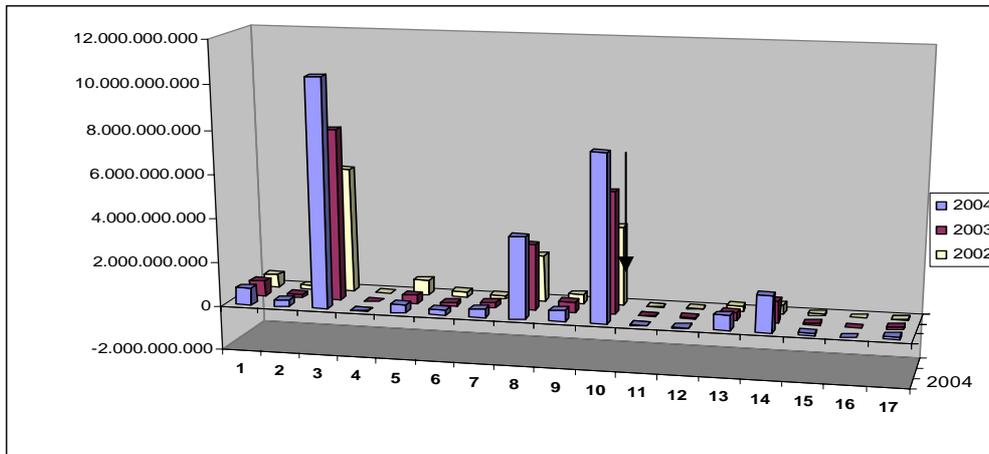

We would like to assert that our perspective, presented below, is synthetic. We will tackle the issue of general insurance coverages and out of those 17 legal insurance categories we will develop the eight one : « The insurance against fire and the insurance against natural catastrophes ». The period considered is that between 2001-2004, according with the official data published by the Insurance Supervisory Commission in their annual reports.

Why 2001 ? Because according with CSA's norm no. 3/2001 regarding the insurance coverages categories that can be used by the insurance companies<sup>5</sup>, for the harmonization of the romanian legislation with the comunitarian one, the legal tipology of the insurance coverages has been modified.

---

<sup>5</sup> Published in Monitorul Oficial al Romaniei, Partea I, nr. 501 in 24 august 2001.

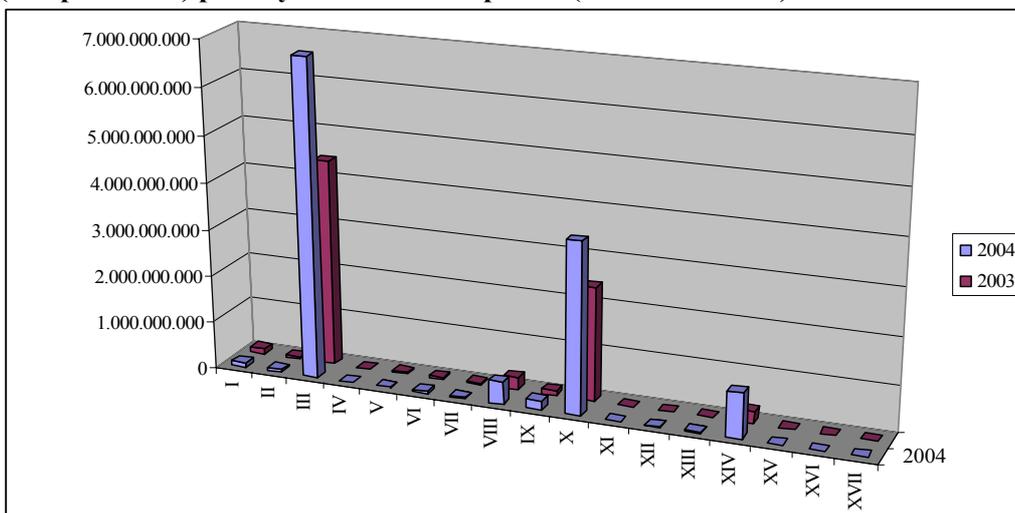

**Figure 6. The insurance against fire and the insurance against natural catastrophes' position in the general insurance coverages – the evolution between 2002-2004 – taking into consideration the volume of subscribed insurance premiums (thousands ROL)**

Source: CSA, Reports 2002, 2003, 2004, [www.csa-isc.ro/Rapoarte](http://www.csa-isc.ro/Rapoarte).

As the above figure suggests, the insurance against fire and the insurance against natural catastrophes was ranked third during 2002, 2003, 2004, after the insurance against car damages (IIIrd category) and the mandatory auto insurance (malpractice) (Xth category).

**Figure 7. The insurance against fire and the insurance against natural catastrophes' position in the general insurance coverages – the evolution between 2003-2004 – taking into consideration the volume of the indemnity (compensation) paid by insurance companies (thousands ROL)**

Source: CSA, Reports 2003, 2004, [www.csa-isc.ro/Rapoarte](http://www.csa-isc.ro/Rapoarte).

Data for 2002 was not available.

During 2004, the insurance against fire and the insurance against natural catastrophes was ranked 4th after the insurance for credit and warranties.

**Table 6. The dynamic of the insurance against fire and the insurance against natural catastrophes market during 2001-2004**

<i>Year</i>	<i>Gross premiums subscribed</i> <i>Thousands ROL</i>	<i>Nominal annual increase</i> <i>%</i>	<i>Inflation rate</i> <i>%</i>	<i>Real annual increase</i> <i>%</i>
2001	1.106.517.000	-	-	-
2002	2.112.478.710	90,91	17,8	62,06
2003	3.011.215.343	42,54	14,1	24,93
2004	3.716.950.266	23,44	9,3	12,94

Source: 1. CSA, Reports 2001, 2002, 2003, 2004, [www.csa-isc.ro](http://www.csa-isc.ro) / Rapoarte; 2. Author's compilation.

**Table 7. The insurance against fire and the insurance against natural catastrophes – macroeconomic indicators**

<i>YEAR</i>	<i>Percent in the total volume of the subscribed premiums – general insurance coverages</i> <i>%</i>	<i>Percent in the total volume of the paid compensation – general insurance</i> <i>%</i>	<i>The rate of indemnity</i> <i>%</i>
2001	14,01	4,45	14,01
2002	14,56	ND	ND
2003	14,89	3,49	8,98
2004	13,78	3,90	12,92

Source: 1. CSA, Reports 2001, 2002, 2003, 2004, [www.csa-isc.ro](http://www.csa-isc.ro) / Rapoarte; 2. Author's compilation. ND: not available

Conclusions:

1. The percent in the total volume of the subscribed premiums of the general insurance coverages during 2001-2004 was approximately 14%, less than 1/5.
2. The positive aspects are:

- a) the real annual increase for this insurance type is above the annual real increase for general insurance coverages.
  - b) the 4% of the compensations paid for this type of insurance in the total volume of compensation paid.
3. The increase in the trend of the indemnity rate, rate that is expected to grow further given the natural catastrophes that are expected in the years to come.

Given this background and adding the issues of the damages produced by the 2005 floods evaluated at 1,4 billion Euros, the indemnities paid by the insurance companies which amounted to 5,5 million Euros, the insurance rate of 0,4% or 4‰ raised the issue of mandatory house insurance.

*What are the opinions of the insured, the insurance companies and the representatives of the supervisory commission? What are the recommendations of the World Bank?*

### **3. The issue of reinstating compulsory insurance on population's houses and apartments.**

#### ***3.1 An Analysis of the main elements and topics involved in compulsory building insurance.***

We consider it is much more compelling to present in a tabular illustration the comparison between the characteristics of the insurance form mentioned in the title of this study and of this chapter for the period 1971 – 1995 (with some necessary observations for 1990 -1995) and the project introduced for debate in 2001, forgotten for a while and then recently awakened– October 2005.

**Table 8 Comparative study regarding the insurance's product characteristics**

<b>Elements</b>	<b><i>During 1971<sup>6</sup> - 1995<sup>7</sup></i></b>	<b><i>Project 2002</i></b>
<b>Insured (Policyholders)</b>	- individuals; - agricultural cooperatives <sup>8</sup> ; - intercooperative economical associations <sup>9</sup> ; - firms.	- individuals

<sup>6</sup> Type of mandatory insurance through the state regllementations (decret) no. 471/197

<sup>7</sup> The insurance was not considered mandatory as enacted in the Law no. 136/1995, the Law regarding insurance and reinsurance in Romania, published in « Monitorul Oficial al Romaniei », Part I, no. 303 from 30 december 1995.

<sup>8</sup> Discontinue after 1990;

<b>Insurer</b>	ADAS (State Insurance Administration (in Romanian: Administratia Asigurarilor de Stat) – state monopoly until 1990.	<i>Type 1)</i> Specialized insurer <sup>10</sup> whose sole shareholder is the state;
		<i>Type 2)</i> Private insurance companies.
<b>Insured risks</b>	1) fire, lightning, explosion, even if the lightning or explosion were not followed by fire, torrential rain and the indirect effects it has ; flooding, storm, hurricane, earthquake minimum 6 on Richter scale, land fall or land slide, snow or ice weight, snow avalanches, fall on buildings or other annexes; 2) destruction or damage provoked by the salvage measures taken during the insured event ; 3) demolishing, dismounting or moving expenses.	<i>Type 1)</i> Earthquake plus fire or explosion produced by the earthquake.
		<i>Type 2)</i> 1) storm; 2) earthquake; 3) floods; 4) land fall and land slides.
		<b>Exemptions :</b> Financial loss following the insured risk appearance (loss of income from rent, costs associated with finding an alternative accomodation)
<b>Insured object</b>	1. Buildings and other constructions ; 2. Including: a) engines, machines, installations, means of transport and tools owned by the firm; b) raw materials, fuel, semifinished and finished products; c) animal products, agricultural	The insurance is only for <i>individuals' buildings</i> (private) and will provide cover only for buildings not for the objects inside them.

<sup>9</sup> Idem.

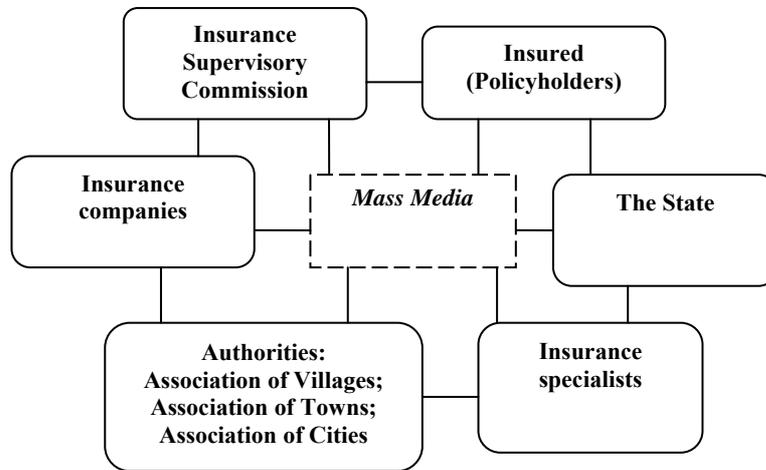

<sup>10</sup> Whose sole purpose would be mandatory building insurance.

	products, fodders and the deposited crop of orchards.	<b>Exemptions :</b> -buildings constructed after 1989 without proper authorizations or that do not fulfil the resistance standards; -buildings deemed as major risk for earthquakes (larger than 7 degrees on the Richter scale)
<b>Insured Amount (Sa)</b>	a) <i>individuals</i> : $Sa = Sc \cdot Na/m^2$ ; unde: Sc –built surface; Na/m <sup>2</sup> - insurance norm / square meter built, differentiated between urban and or rural whereabouts and type of building.	Maximum amount insured = 15.000 euro; “extra value” of buildings can be insured (optional).
	b) <i>firms</i> : value of the buildings as stated in the balance sheet (accounting value).	
<b>Insurance Premium (Pa)</b>	$Pa = ct \cdot Sa$ Tarrifs quota (ct): -urban: 0,3%; - rural: 0,4%.	$Pa = ct \cdot Sa$ Tarrifs quota (ct): - urban: 0,2%; - rural: 0,3%.
<b>Insurers responsibility begins</b>	Automatically: a) immediately after contract is signed; b) if the object is under construction, from the moment the building has walls and roof ; c) when construction begins for buildings belonging to agricultural cooperatives.	24 hours after the day when the contract is signed ends.
<b>Insurers responsibility ends</b>	When the building no longer belongs to the insured or can no longer be used for living or for any economical destination due to degradation or ruin.	At midnight of the last day of validity of the contract,.

### 3.2 Opinions regarding the reintroduction of compulsory insurance of buildings

The dialogue partners will be schematically drawn below:

**The State** is present at discussions through the voice of governmental representatives : R. M. Popescu – state secretary for local communities at the Interior Ministry – coordonating ministry of the relaunched project of 2005; L. Borbely – Ministry of Public Works and Territory Fitting. Both support the idea of reintroducing compulsory insurance of individuals’ houses starting January 1, 2006:

- a) against floods, earthquakes, landslides and storms;
- b) insured value: maximum 15.000 euro;
- c) insurance premiums differntiated by area (rural/urban), not more than 30 euros anually.

**Reprezentatives of Association of Villages, Association of Towns, Association of Cities** have announced their support in promoting the project, their role being that of intermediaries in the process of signing the contracts..

**The Insurance Supervision Agency** through its president, Mr. N. Crisan supports the idea of coercitive measures such as : those individuals that have not signed insurance contracts will not be able to sell their houses or fill inheritance papers.

The representatives of the insurance companies and insurance intermediaries do not disapprove the introduction of compulsory building insurance, but they make couple of remarks related to the subject:

- a) in order for the population not to think of this compulsory insurance as a sort of fiscal burden, a financial and fiscal motivation must be found, such as: the deduction of the insurance premium from the annual building tax paid by the owners.
- b) the insurance companies can not take the state's place and they can not solve the social problems in Romania – such as those concerning the capability of the population to pay the premiums.

**The policyholders** (insured) are very reluctant to the subject. They believe that this sort of mandatory insurance coverages are a sort of “forced consumer protection”. Their opinions regarding the subject are summarized below:

- a) the insurance coverage must be the individual's own option given that the premium is “cheap” and that the compensation is high.
- b) those affected by natural catastrophes must receive aid from the government and not compensations from the insurance companies.
- c) for the insurance companies this mandatory insurance system is their “cup of tea”; besides the insurance companies obvious advantages, the local authorities will certainly act as intermediaries, bringing more clients for the insurance companies.
- d) the biggest complaint is that the authorities and the politicians do not debate or make public the causes that led to such high damages from this year' floods: possible undone protection works of the piers and the bridges, improper construction works etc.

**The insurance specialists**, mainly Prof univ. Gh Badea, PhD, the president of the Insurance Institute thinks that such a mandatory introduction of insurance coverage is wrong on one hand because the state should not intervene in such a problem as the state has proven to be a poor manager when it comes to money management and on the other hand because obliging the population to such a thing would impair the right to property. He sustains the introduction of prevention programs and plans to reduce such damages

and an educational plan that would help people comprehend the risks involved. We totally agree with this opinion.

### ***3.3 The World's Bank Recommendations***

The World's Bank specialists think that an insurance pool is needed because:

1. a dispersion of the risks from natural catastrophes is made at the national level; different regions in the country have different exposure to natural catastrophes so the concept of national solidarity would be brought forward.
2. the "pool" would be an important partner in the dialogues with the government, the capital markets, the reinsurance companies, the hedge funds and the investment bankers.
3. through this pool, optimal levels for insurance retaining would be chosen and there would be an obvious advantage in the international negotiations in the insurance companies.
4. managing the consequences of the natural catastrophes through a pool by exporting an optimal level of risk would reduce the country's risk on the global market with net benefits for public policy and capital markets.

Al the above mentioned advantages would not reduce the difficulties with implementing such a system, difficulties generated mainly due to the low level of insurance penetration (below 1% in GDP – Table 2), low level of optional building insurance coverage and the low level of insurance companies capitalization:

- 1) strict and transparent pool's organization's structure and coordination; transparent management of the compensations procedures and schemes; transparent investment methodologies and techniques.
- 2) types of buildings and houses subject to such an insurance pool: private buildings, companies buildings', public buildings.
- 3) the methods and techniques involved in the monitorization and the supervision of the compulsory insurance coverage must be made public.

## 4. Conclusions

The Government's representative, R. Popescu -state secretary in the Internal Affairs Minister – said on 11.10.2005 that although the government is tempted to adopt the World's bank recommendations regarding an insurance pool according with Turkey's model, the fact that in Turkey only 16% of the population subscribed to such a pool would make the Romanian government willing to adopt another solution or model.

Eugen Gurenko, the World's Bank insurance specialist estimated that there are 3 kinds of dilemmas regarding the management of CAT events.

### I. Government's Dilemmas.

- a. A national program for managing the consequences of natural catastrophes, program that includes mandatory insurance coverages, should surpass the political alternance. On the other hand, the lack of natural catastrophes would make this national program unpopular.
- b. Financing these techniques towards managing CAT events would reduce the financing capabilities for other investment projects.
- c. International aid is diminished whether such an insurance system is used.

**II. Insurance market's dilemmas** concern the low level of insurance premiums used by local insurance companies which provide fronting operations for the international insurance firms. Acting as intermediaries, the local insurance companies receive huge reinsurance fees which are disproportionate with the size of the potential damages from cat events.

**III. The policyholder's dilemma.** The potential policyholder's balance between two way of reasoning: on one hand they believe that nothing bad would happen to them and on the other hand they regard the issue of buying an insurance coverage as futile as long as the government should intervene and help them out. By subscribing to an insurance coverage they will diminish any chance they would have to receive governmental aid. Looking from another perspective, they are at the state's mercy, which can decide to help them or not.

Our own opinions regarding the matter are as follows:

The policyholders: As the analysis provided in subchapter 2.2 shows, 44.2% of the Romanians tend to underestimate the importance of buying an insurance coverage; to this 44,2% we should add the other 49% that can not

afford to buy an insurance coverage due to financial restraints. This proves the low level of insurance penetration (5%) and the indemnity rate of only 0.4% for the year 2005.

Romanians above the age of 60 strongly believe in “charity hazard” which means that they do not consider approaching other means of insurance as they believe they will receive help from the government through some governmental emergency programs. They must learn how to be responsible and how to act proactively when it comes to possible risks and dangers. For this to happen they must be educated.

Our opinion is that they must learn how to be responsible and imposing a compulsory insurance coverage system through the legal governmental constraints will not do them much good; besides, this system greatly impairs the right to property. More “actors” involved there are, more difficult it is to control and manage the whole system.

The state must help educating the population and the potential policyholders and it has certain tools that can help him in fulfilling this goal:

- a. the deductability of insurance premiums in the context of the tax on global income;
- b. offering reductions for the tax on buildings paid for those who have subscribed to an insurance coverage;
- c. different quotas for the insurance companies that provide insurance products against the risks from natural catastrophes.

The public intervention and opinion moulding is being made through the activity of the Supervisory Insurance Commission through:

- access on the insurance market;
- close and permanent supervision of the insurance market operators and “actors”;
- enacting reglementations regarding the insurance conditions.

The insurance companies that offer insurance products that cover CAT risks must have the authorization of the Supervisory Insurance Commission, must make available the data and calculus regarding the maxim level of exposure on each insurance type, the method for estimating the maxim damage possible, must provide the Supervisory Insurance Commission with the reinsurance program for this kind of risks, with copies of the reinsurance contracts, broker’s contracts or the list with the reinsurers mentioning the participation quota.

The insurance companies' services must be organized on modules with coverage types for the risks insured, offering the option for the potential policyholder to choose the level of the amount insured and the availability to index the amount to the inflation rate or to the indices regarding currency devaluation. The insurance companies will decide the tariffs systems, tariffs criteria, but these tariffs should not be below a certain threshold. The Supervisory Insurance Commission may intervene for imposing minimal tariffs. They may fix mandatory insurance tariffs criteria for differentiating the insurance types such as: the type of the building, type of the region where the building is, the age of the building etc.

The category of the compensation, favorable to the insured is that of "the first risk", but the policyholder should have the option of buying an insurance contract with franchise.

But before everything else, the insured must have the option of choosing the insurer.

Certain problems still remain:

- a. The age of many buildings, buildings that do not have a construction authorization and which structure do not follow all the technical procedures imposed in the construction business; these kind of buildings can not be insured.
- b. The impossibility of many people living in the rural area to pay the insurance premiums, not even if the premiums are amounting to 30 euros.

On 11.10.2005, Mr. L. Borbely, the minister of the Public Works and Territory Fitting Ministry said that all the expenses related to the rehabilitation of the buildings exposed to an earthquake would be supported from the state budget and that in 2006 the budget will be supplemented with 67 billion lei. These are signs that those in power acknowledge the risks population is confronted with, but we believe that the government major goal should be not the introduction of mandatory building insurance, but the standard of living of the Romanians.

The insurance industry in Romania, as the analysis provided in subchapter 2.3. (table 6 and 7) suggests, there are positive and encouraging signs that things are evolving in the right direction. Those with the power of decision should keep their promises so that Romania becomes an European country for the insurance industry as well.

## **1. Introduction**

It becomes a serious global problem to everybody that the burden of the modern industrialization on the environment is approaching the limit of nature's capacity. If humans continue to depend on the present social systems and lifestyles, the world of future will face an environmental catastrophe. It is also of big concern that wars and conflicts could break out over the limited energy resources, food and other resources.

In order to use energy effectively, it must be used efficiently. It is also important not simply to minimize energy consumption, but to consider the effects of energy use on the natural environment, taking into consideration of the global environment as well as the environmental costs.

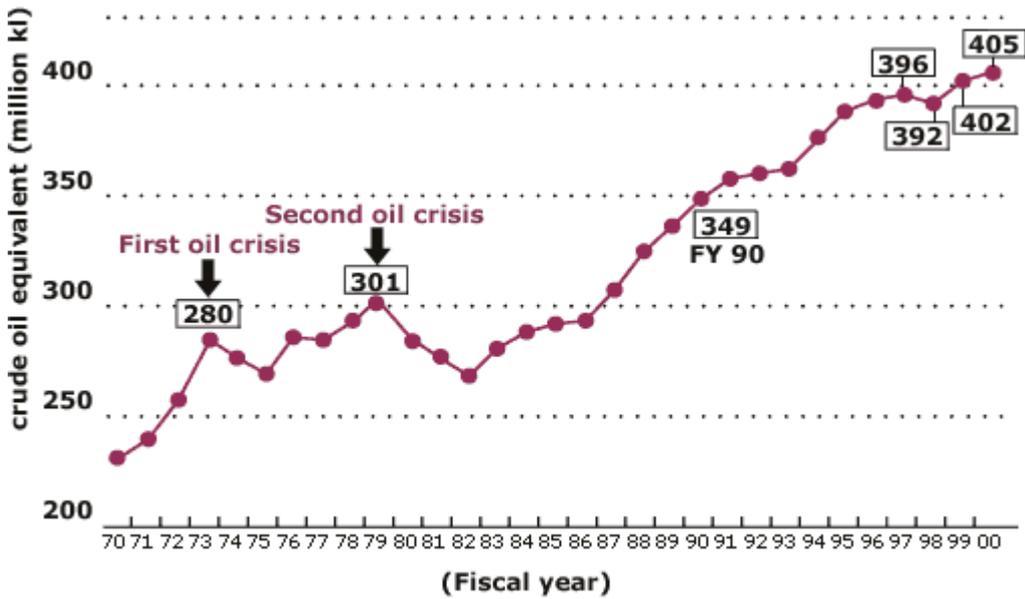

Japan's energy demand-supply structure changed much with the promotion of strenuous efforts for energy conservation in the aftermath of past two oil crises, by 1991. Japan had achieved an approximately 35% improvement in energy efficiency compared with the level in 1973 and now ranks at the top level among the countries of the world in terms of energy conservation. This promotion has been made by close tie up between environmental financing and technical development. In this paper major progress of this two factors have been described.

## **2. Energy situation of Japan**

Japan focused its priority energy conservation measures specifically on the industrial sector, which then account for more than half of Japan's total

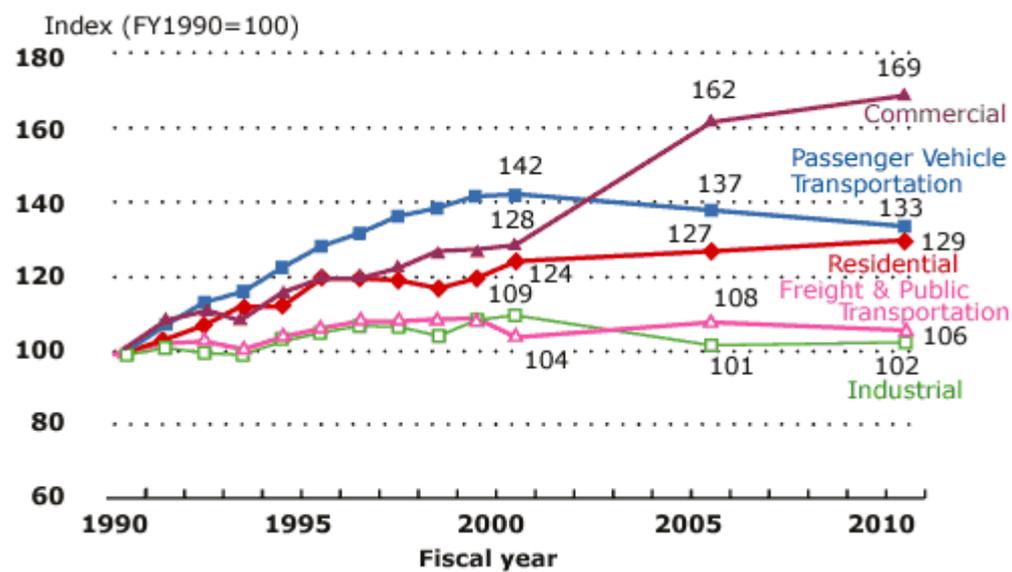

energy consumption, and this led to remarkable improvements in energy intensity and gave international trade competency.

**Figure 1: Changes in Final Energy Consumption from 1970**

(Source: Comprehensive Energy Statistics (preliminary figure for FY2000))

**Figure 2 Changes in Final Energy Consumption by Sector from 1990**

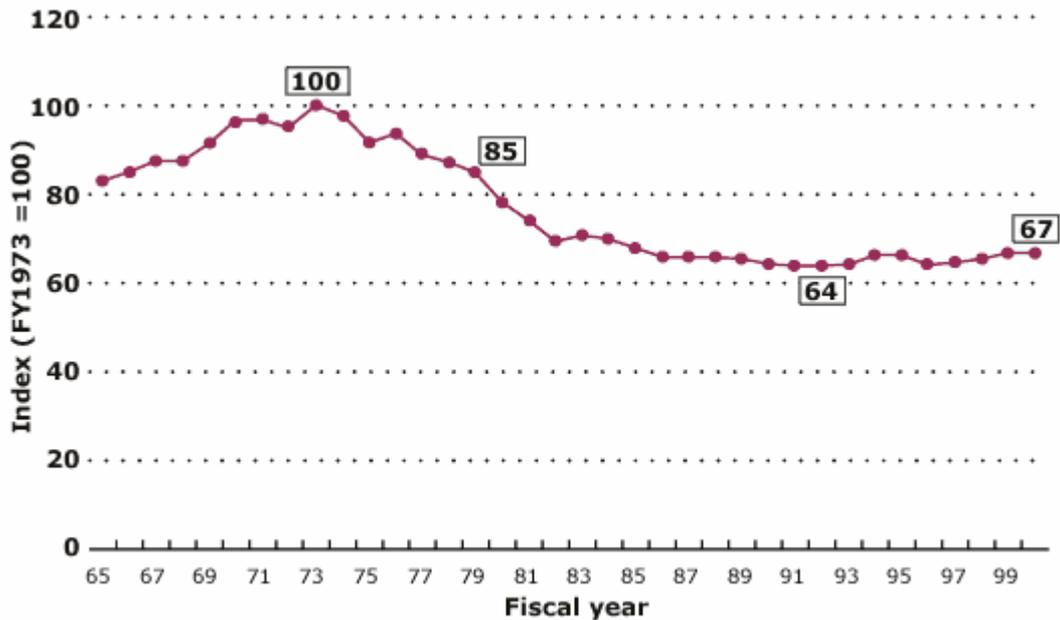

(Source: Comprehensive Energy Statistics (preliminary figure for FY2000))

Since 1991, however, energy intensity has been showing a tendency to increase, mainly due to increased energy consumption by the residential, commercial and transportation sectors as a result of the public's pursuit of convenience and comfort in daily life. In the industrial sector as well, the energy consumption trend is somewhat on the rise as a result of the diversification of products and the increased value added factor.

Japan's level of dependence on oil has decreased drastically since the two oil crises. On the other hand, nuclear energy and natural gas have grown in importance in their supply share of energy. Consumption of nuclear energy has increased from 1% in 1973 to 12% in 2000, while natural gas has increased from 2% in 1973 to 13% in 2000.

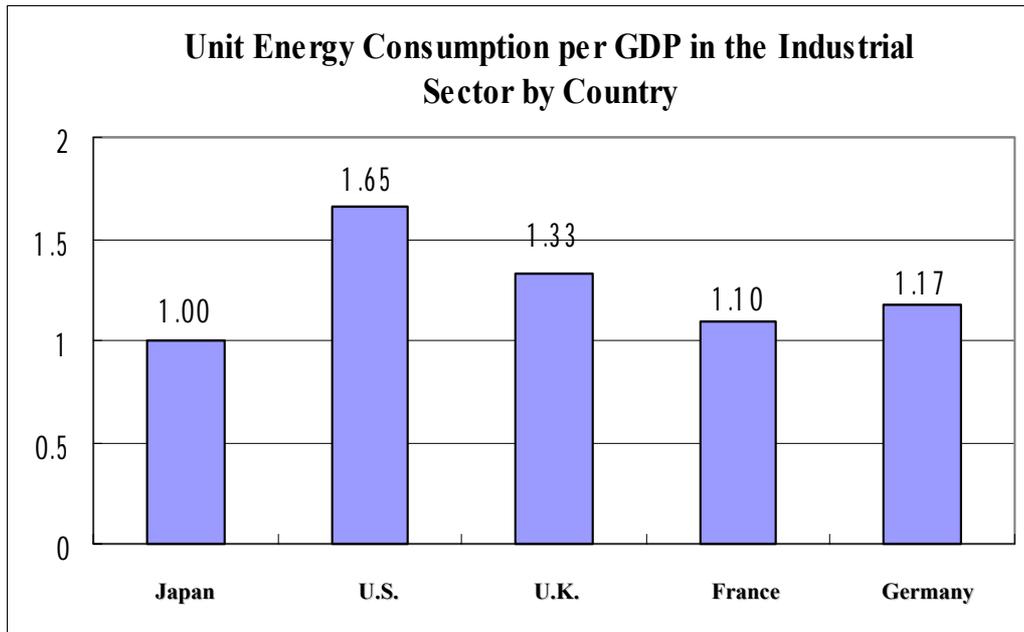

**Figure 3: Energy Intensity per industrial production index in Japan**

Energy consumption in the industrial sector has been generally steady since oil crisis. Energy consumption unit per industrial production index for the manufacturing industry experienced sharp fall through to the 1980S, but has been on a trend of slight increase since the 1990s.

However Japan's energy consumption unit against GDP in the industrial sector is lower than those of other major countries.

**Figure 4: Unit Energy Consumption per GDP**

At the COP3 held in December 1997 at Kyoto Japan, Japan set a goal of reducing its green gas emissions for the 2008-2012 period by 6 % from the level in 1990, and thus it needs to make further efforts to improve energy efficiency.

Under these circumstances, energy conservation measures currently being taken in Japan include both reinforcing regulations, such as the amendment of the“Conservation Law” and providing incentives for investment in energy conservation through financial support.

**Table 1 Japan has made a CO<sub>2</sub> reduction plan by several measures.**

Breakdown of the -5% Reduction in Greenhouse Gases	
-2.50%	Emission control of CO <sub>2</sub> , methane, and nitrous oxide
-3.70%	Carbon dioxide sinks due to changes in land use and forest management
2.00%	Control of emissions of CFC alternatives, etc. (HFC, PFC, SF6)
Remaining(-1.8%)	Use of Joint Implementation and emission trading, etc.

*Reference: The previous "Long-Term Supply and Demand Outlook" In June 1998, the previous "Long-Term Supply and Demand Outlook" was put together following COP3.*

### **3. Energy Conservation Law and Financing**

The "Energy Conservation Law", which has been enacted in 1979 as a fundamental law to promote energy conservation in Japan, stipulates the measures to be taken regarding facilities and equipment that use large amount of energy, such as factories, buildings, household electrical appliances and automobiles.

The Energy Conservation law was amended in June 1998, and came into effect as of April 1999.

**Table 2: Fundamental issues for promoting rational use of energy**

1. Measures to be taken by the central and local governments themselves as energy users, etc.
2. Support to capital investment, etc.
3. Support to energy management
4. Support to technical development
5. Support to the introduction and diffusion of optimum energy supply-demand systems in areas
6. Promotion of research and development, etc.
7. Education, public relations, etc. to people

#### **3.1 Tax incentives**

The "Tax System for Investment in Reformation of Energy Supply and Demand Structure" was established in 1978 with a view to facilitating the equipment investment involved in energy conservation. In reforming the tax

system several times, it was reviewed in line with the technical development, etc, of the subject equipment.

**Table 3 Tax Incentives**

Intended for	Tax incentives
<input type="checkbox"/> 124 facilities <input type="checkbox"/> 64 facilities for small and medium companies <input type="checkbox"/> others	1 Tax exemption equivalent to 7% of the equipment acquisition cost from the income tax or corporate tax payable (applicable only to small and medium companies from fiscal year 1999) or 2 Special depreciation of up to 30% of the equipment acquisition cost.
System approved on the basis of the "Assistance Law" (Improvement of 5% energy intensity or 1,500kl energy saving)	

*Basic acquisition cost = [Acquisition cost] × [Multiplier rate (25 to 100%) Special depreciation; The depreciation is classified as "loss" as defined in the Tax Law, and is included in the calculation of profit in the settlement of accounts.*

### 3.2 Low-interest loans

A system of low-interest financing by governmental financial institutions is available for installation of specific energy-efficient equipment.

**Table 4 Low-Interest Loans**

Intended for	Applicable for	Loan limit	Period of loan (deferment)
Energy facilities and production facilities (An improvement of 20% or more in energy efficiency, and energy saving of 100 kl/y)	Preferential rate	50% of the construction cost.	Up to 15 years
96 facilities and 14 systems approved under the <input type="checkbox"/> Assistance Law <input type="checkbox"/> (Energy saving of 100kl/y)	Preferential rate		
Co-generation facilities (60% or more primary energy efficiency and 50kw or more output)	Preferential rate		
76 facilities approved under the <input type="checkbox"/> Assistance Law <input type="checkbox"/>	Special energy conservation A		
Replacing outdated boilers	Special energy conservation B		

*Interest subsidies are granted to financial institutions from the Oil Special Account.*

### 3.3 Subsidy

The New Energy and Industrial technology Development organization(hereafter referred to as NEDO) grants subsidies for the financing required for the energy conserving technologies that specially need to be disseminated, as stipulated in the“ Energy Conservation Law”

**Table 5: Strategy for subsidy**

1	□□□□□□□□□□ □□ introduction of high-performance industrial furnaces
2	Model projects for installation of advanced energy efficiency facilities
3	Projects for promotion of introduction of cogeneration systems
4	Supporting ESCO enterprises

#### **4. Measures for energy conservation measures**

Outline of efficiency measures is

(1) To further promote the improvement of energy consumption efficiency in automobiles and electrical equipment. (Strengthening measures for electrical equipment and appliances)

Introduction of a Top-runner program, which seeks to advance currently available products to a level above the level of the most currently, advanced products with regard to automobile fuel efficiency standards or energy efficiency standards for electrical appliances (household appliances and Office Equipment, etc). Security measures have also been strengthened (Public announcements, issuing orders, and penalties (fines) for those that do not follow the recommendations)

(2) Complete rationalization of energy use in factories and businesses (Strengthening measures for factories)

The creation of measures obliging the submission of plans for rationalization from specified factories that have up until now had a multi faceted energy consumption approach, in order to bring about structured rationalization of energy use.

For medium-scale energy consumption factories and businesses, the creation of thorough measures for energy efficiency (appointment of energy management, compulsory attendance of energy efficiency course, compulsory recording of the state of energy use).

### (3) Promotion of energy efficiency education

With regard to the sense of values that people have towards different problems, much of that comes from the education we receive in our youth, so priority will be given to providing enlightening activities at schools and educating people from a young age about energy efficiency.

### (4) Promotion of highly efficiency cogeneration

Aiming to popularize Cogeneration, which has a high total efficiency, strengthening of operational measures for regulation (criteria of the Law Concerning the Rational Use of Energy) and implementation support was carried out. Moreover, environmental considerations were made for the technological development and introduction for the power generation efficiency improvement of a decentralized power supply.

### (5) Unutilized energy

Unutilized energy refers to energy we did not give consideration to before, such as temperature difference energy in rivers and sewer, etc. (water that is colder than air in summer, and warmer than air in winter), and waste heat from factories, etc. In recent years, it is becoming possible to meet the heat demand of daily living by utilizing heat pump technology, etc., and introducing the system that properly combines each step of heat utilization from high temperature range to low temperature suitable for local situation, including for power generating purpose.

## **5. Conclusion**

1) Through the energy efficiency efforts of the public and the government, Japan has achieved the highest level of energy efficiency anywhere in the world since the oil crises. With an increasing tendency of energy consumption in commercial/residential and transportation sectors in recent years, the promotion of steady energy efficiency measures in the future is essential.

2) Energy conservation is a key for enhancement of industrial capacity  
Energy conservation has been put into practice sequentially by checking industrial statistics, such as heat balance, material balance, process flow, by grasping the problems of instrumental/control, machinery/process characteristics, condition and quality of utilities such as water, gas, energy, time adjustment between the front and rear lines, impact on quantity and quality of products.

Therefore energy conservation activities should be started based on the knowledge of self-capacity and capability. Without this, we will often meet catastrophic conditions.

3)The fundamental goal of the energy conservation policy for each country is to achieve a stable supply of energy in accordance with demands for environmental preservation and efficiency improvement. It is indispensable activity in the 21<sup>st</sup> century. For this purpose, energy conservation expert development, renewal of old equipments, layout change, improvement of quality of raw materials, energy conservation technology development are needed as prior investment. Environmental financing by the government and banks for monetary support ,tax exemption as an incentive measures for the society.

## **Abstract**

*After December 1989 the Romanian economy had to deal with a new economic environment, due to the transition to a free market. Therefore, the industrial firms had to make changes in order to be competitive on the new market. The production system has to adapt to the new conditions. One of the most important mean to realize this goal is a new approach to flexibility. Flexibility is a very large concept, not a very simple one, including only production aspects. This paper presents the theoretical aspects of the flexibility – organizational, machines and equipment, human resources and how they are implemented in a Romanian firm acting on the cosmetic market. The case study presents the last 15 years of the activity of the firm and the main steps that it followed in order to achieve a sustainable advantage, and also the goals for the future. The final part of the paper tries to present some economic results to emphasize that an industrial firm whose priority is flexibility on a long term is a competitive one.*

**Keywords:** *competitiveness, flexibility, adaptability, continuous improvement*

## 1. The need for flexibility in an industrial firm

In our days, in order to survive on a certain market, a firm has to pay more and more attention to the market and its dynamic needs. This goal seems to be very simple to be accomplished, but the economic reality proves the opposite. The firm has a lot of means that help achieving the previous objective, but it has to know how these means can be used with high efficiency.

Another aspect is the fact that these means have to be used according to the particularities of the industries, revealed by some features like the level of scientific research development, the quality of competitors playing on the market, the implemented production system or the quality of human resources.

In order to be competitive a firm has to know how to gain and sustain a competitive advantage on the specific circumstances that came out from the market. One general solution is *flexibility*, but not only at the production level, like the traditional concept. The roots of flexibility came from production but the concept means much more than being flexible within the production area.

### 1.1 Historical approach to flexibility

- a. *the simple approach* is to see flexibility like “ the ability to adjust your production goals according to the market, not only in quantity, but also in the structure of the production schedules “. Even this simple approach evolved in the last decades and today we can enlarge it with some aspects regarding the market as the main priority. Therefore flexibility means that the firm has to change the parameters of the production system in an on-going process, not only from time to time. The advanced production systems can be implemented in any type of production, not only in mass production because their features afford that. Additionally, we can say today that there is a trend for any firm to reduce as much as possible the economic order quantity, in order to be able to adapt themselves as good as possible to the market demands. There is not any firm today managing with a high level of inventory because the firm has to reduce the costs instead of increasing them using a high level for inventory. Therefore we can say that a firm that wants to be a strong competitor on the market has to have flexible production schedules, established on a short period of time, in order to be able to change the products and to be responsive to the market.

- b. *A complex approach to flexibility is to enlarge its content to the entire firm, not only at the production level. To be competitive on the market you need to be flexible in every aspects of the production system, not only in production. When the firm is able to offer to the market “always a different product compared to the previous one“ we can say that it is flexible. In order to achieve that goal a firm has to:*
- Be able to produce different quantities of a certain group of product
  - Be able to produce different types of products in a certain period of time
  - Use a flexible supplier base in order to be itself flexible
  - Have good and adjustable human resource policies
  - Implement a modern production system
  - Adapt a product at the most recent demands on the market
  - Be innovative, in order to remain a real competitor on the market

Another approach to flexibility is from internal and external point of view. For the last approach flexibility means to respond at the dynamic demands of the market in the shortest time; this goal leads to a sustaining competitive advantage. From internal point of view, the firm has to have the internal capacities and abilities – machines and equipments, human resources, information systems; finally they determine a better external flexibility.

### ***1.2 The Flexible Manufacturing System - an instrument for increasing flexibility in a firm***

A Flexible Manufacturing System (FMS) is an advanced system for organizing, coordinating and assessing the production. At a basis level it implies only the production activity but the results determine better performances for the entire production system. The main features of a FMS are the following:

- A central computer that coordinates the overall production activity and establishes all the production parameters like schedules, priorities for different activities, the utilization of capacities - equipment or human resource
- A computer integrated in the network at every workplace that transmits every change occurred at the work place. The influences over the entire process are processed in an ongoing activity. The 100 % of a FMS is when robots realize all the workplace activity. The

worker has responsibilities regarding the coordination and surveillance of the machine. This is a reason that determines fewer workers compared with a traditional production process.

- A small batch production becomes desirable from cost prospective, very close to the optimum production batch determined by mathematical procedures. This is possible because the set up cost due to changes that occurred because of the changes in structure of production are less time consuming and therefore they do not really influence the final cost.
- A computerized system for transportation and handling that leads to a better coordination between these sectors and production

The advantages of a FMS are:

- Reducing the direct costs of the final product
- Reducing investments because of a better productivity for the new ones compared with the older ones
- A better reaction speed to the market needs
- A better and constant quality level for the whole production
- Better opportunities for coordination and evaluation of the production results because of the computerized system
- Reducing bureaucracy of the firm also due to the computerized system

The main disadvantages of a FMS are:

- The initial investment is big
- The implementation decision is a difficult one because it needs the approval of every level in the firm
- The implementation determines a smaller need for workers compared with the traditional organization
- The creativity and intelligence of the human resource is ignored; the robots and machines have the central role
- The system requires more qualified – with interdisciplinary abilities - employees that determine higher costs for wages
- Better results can be obtained only after a significant period so the benefits are not as immediate as they are expected to be.

In conclusion, we can say that FMS is a solution for an increased flexibility at the production level in the first place and it is an expensive solution related to money and time. For the Romanian industry it is an alternative but, because of the financial aspect, not very desirable for the firms. Therefore we should look to other production systems, less expensive but also more flexible.

### ***1.3 Other production systems that determine flexibility***

There are other production systems that offer a bigger flexibility to the firms. We consider that the most important one is Just In Time system ( JIT ). With its roots in Japan, JIT is in our days implemented all over the world, not always at the firm level but certainly in the most important areas.

A JIT has four main features and one of them is flexibility. Some aspects regarding flexibility in a JIT are:

- *Flexibility in the supply process.*

The philosophy in supply policies is to have a long term orientation, with few suppliers. Also it is recommended to supply as often as possible in order to work with minimum inventory levels. JIT introduces for the first time the concept of “supply on line”.

- *Flexibility in the production process*

It is given by work cells organization that permits to do different jobs by the same worker if he has the required skill.

- *Flexibility of human resources*

Human resources are one of the most critical resources in a firm and that determine a special attention. JIT offers it a central place and pay attention to any problem that may occur. A good level of flexibility is realized by team work whenever is possible and to give the responsibility both to the individual and to the group, also.

- *Flexibility in satisfying the market*

The market determines always what to produce, in what quantity and at a certain level of quality. As much the firm accomplish that, as more flexible will be.

There are other advanced systems that accomplish good level of flexibility through their specific features. All of them regard not only the production, but also other parts in the firm. Most of them include all the firm’s functions and have good performances if they are well implemented.

## **2. Case study: how a Romanian firm is able to compete in the cosmetics market**

The firm F is one of the most famous in the cosmetic product industry in Romania. It was established more than fifty years ago in a period of developing for our area, after the second world war. At the very beginning the firm F had 6 workers and had a diversification range of 5 products.

The firm was privatized in 1995, after a long period of state ownership. In the year 2005 it represents about 45 % of the national cosmetic production and it has more than 700 employees.

Some important elements about the firm F until the year 2000

- During the decade 1950- 1960 the structure of the product increased at 50 types of products, all in the cosmetics industry. Most of them were creams and lotions.
- Beginning with the year 1972 F decided to produce within the factory the packages for the main products
- Beginning with 1973-1974 the creams and lotions lose the leading position for another type of product sprays.
- Until the December 1989 F was the leader of the cosmetic products on the Romanian market
- The financial results after 5 years reveals an average increase by year with 25 % of the revenues
- At the beginning of the year 2000 the number of products was about 320, grouped in four main areas: *deodorants spray and roll-on, creams and lotions*, other cosmetic products like *lipstick-nail care -make up products* and the *chemical home cleaning products*. The first two groups represent more than 70 % from the point of view of both revenues and number of the products.

### ***2.1 What did make F in the last 5 years in order to be flexible?***

The competition on the cosmetic market is very strong beginning with 1990. In the first years F had to deal with competitors that offer a lot of products, not always good quality, but low prices. After 1995 a lot of multinational companies came in and the competition became stronger but with other dimensions: a diversified range of products, a better quality and well developed marketing policies.

On these circumstances, F has to pay attention to *flexibility*, in order to be able to maintain its leading position gained in the previous years, in a more competitive environment.

### ***2.2 Investments in the production area***

F has had a strategic approach of its objective earlier than other Romanian competitors. In this sense, F realized that the old machines and equipment are obsolete and they are not any more able to compete efficiently. The managers in the firm decided in the year 1999 that a big investment has to be made in order to improve the productivity and to ensure a better and constant quality of the production. First, they decided to move some activities outside the city before that these movements has to be make due to the legislation because of ecological reasons. After that, they purchased a new

automatic line for filling the sprays and they decided to move it on the new location. The investment was 3.2 million \$ but the line was delivered from the best European line producer. It was the first investment in Central and Eastern Europe in the cosmetic industries.

The results in the filling line activity were impressive:

- with only 4 workers instead of 40 they increased the daily production with 100%
- increasing the ability to change the product on the line. Initially, it was changed two times a day because the workers had to pay attention to some previous phases of the production, like preparing the solution for filling. With the principal line they purchased some special containers of different capacities; therefore, they were able to prepare different solutions for filling in different quantities, adapting rapidly to the market needs
- on the line they were able to fill not only the deodorants, but also other spray products; after 4 months they moved the entire spray activity in the new location and optimize the capacity utilization.

As we can see, the basic results within the production activity were very good but with them a lot of questions appear, like:

What did happen with the extra-workers, no more needed in the production process? The simple answer is that some of them were retired, other used in other production process and about 20 were fired.

What about the capacity of the market to need a double level of the products? It was a problem for more than 3 months, the level of inventory increased with more than 80 % at the very beginning, but decreased later. Still, the inventory problems remained in the first 2 years of the activity for the new filling line.

What did they do about the connection between the new production rate and the marketing activity? This is still a weakness and the results could be improved by solving it.

### ***2.3 Research and development***

The RD department is organized near the marketing department. The employees have different specialties like chemical engineer or pharmaceuticals, biologists. They are selected very carefully and they are working in a good climate. The main problem is the small budget for RD department that determine results not very good related to the potential of human resources. Another problem is coming from the previous one. Even the RD employees were selected carefully, because of the small budget they

have to work on a poor basis, like very few means for update them according to some research made outside the country, no opportunities to go and do some specialization courses abroad or a salary that do not always motivate them because it is not in correlation with their work.

Still, we consider that their performances are very good under the given circumstances and we consider them a real strength of the firm.

In the RD department flexibility comes out from the specialties diversification and also from the large range of researched products. Also, the activity is very dynamic if we consider that about 50 new products come out from the RD department every year. From these more than 60 % are successfully introduced on the cosmetics market

#### ***2.4 Product and price policy***

The flexibility in the product area comes out from the rate of the new product. If we want to go further in the main groups of product we can say that the first two are the priorities because they represent more than 70 % of the activity.

- *The creams and lotions group.* F pays attention to the over world trend regarding the infusion of natural and medicine products within the cosmetic industry. Only in the last two years they developed 4 new brands for face and foot care. Within every brand we can find between 4-10 different products for different clients or problems therefore every client could be satisfied using the different products of the same brand and having a complete care system
  - These brands are based on using Romanian natural plants with curative properties. The main strength is the relation between price and quality because the competition is a very hard one due to the multinational companies that have similar products at higher prices. We have to say that it is the main group to go for the international market, all over the world.
  - The results in the last years prove that the group is the most powerful one in the firm and also with the biggest development potential.
- *The sprays group.* It is the group that benefited of the 3.2 million \$ investment and the results came out. After a first period not very efficient this sector begins to get better results. The main strengths are namely *product diversification* and *small batches in*

*production* in order to be able to adapt to the market needs in the shortest time. Despite the fact that this group lost some percentages in the overall activity of the firm, we can say that the efficiency increased and the sector is still a competitive one on the market. The new product policy determined 2 new brands in the last 2 years, one for women and the other one for men.

### **3. Conclusion**

1. In order to be competitive a firm has to be able to adapt to the market at the best it can; it has to be able to offer the right product in the right place. This means that flexibility is one of the most important priorities
2. Flexibility has to be seen on a large basis because it is not only about being flexible in production, but in any function for the firm. The start is the production area but the ultimate goal is the market. To be able to achieve this goal it is necessary to adapt your policies in every area of the activity
3. It is obvious that firm F has a lot of development potential but it will have more and more difficult periods of time in the future.
4. Until now the results are good because F paid attention to the market and tried to anticipate the customer needs. F made the investment for the filling line despite the fact it was a big one and it was a risk that the product will not be sold on the market. Also, a flexible product policy determined a good rate for new product development and many new such products were successfully launched.
5. For the future F has to establish goals that have among them a good flexibility in every part of the firm. On a hard competition flexibility is not a desirable goal but a compulsory one. Because it has to be realized everywhere in the organization the main instrument to do that is an efficient production system that leads to achieve the goal.

## **Abstract**

*In today's dynamic business environment sustaining competitive advantage is vital for survival and success of business organizations. In that sense, performance of the organization and its measurement as a mean of strategic control becomes very important for sustaining this competitive advantage. We can say that what organizations need is a real strategic performance measurement system that is balanced, integrated, and designed to highlight the firm's critical input, output, and process variables. The Balanced Scorecard (BSC) is a widely used management tool for optimal measurement of organizational performance. It is a strategic control methodology, which uses a multi-dimensional framework for describing, implementing and managing strategy throughout an organization. An extensive review of the literature made us clear that the effectiveness and successful implementation of the BSC -as a strategic performance management tool- in business organizations depends on some factors. Therefore, these findings in the literature review made up the basis of the research to analyze the degree of importance and the degree of implementation of success factors of BSC in Turkish industrial organizations. Subjects of the study are the managers who are responsible from Balanced Scorecard Applications in business organizations in Turkey. Data were collected from the managers via questionnaire technique.*

**Keywords:** *Strategic control, performance measurement, balanced scorecard*

## 1. Introduction

In today's dynamic business environment sustaining competitive advantage is vital for survival and success of business organizations. In that sense, performance of the organization and its measurement as a mean of strategic control becomes very important for sustaining this competitive advantage. We can say that what organizations need is a real strategic performance measurement system that is balanced, integrated, and designed to highlight the firm's critical input, output, and process variables. Strategic measurement systems do not try to measure everything; only the elements crucial for managerial decision-making. Given the findings of these systems, management should be able to see where value is being created, where investment and improvement are required, and where the firm's strategies are being successfully implemented<sup>1</sup>.

## 2. Literature Review

Balanced Scorecard (BSC) is a widely used management tool for optimal measurement of organizational performance. It is a strategic control methodology, which uses a multi-dimensional framework for describing, implementing and managing strategy throughout the organization<sup>2</sup>. The heart of the BSC system lies in organization's vision and strategy. Vision is where the organization wants to be. Strategy is how the organization is going to get its vision<sup>3</sup>. Balanced Scorecard is a way of implementing strategy, linking strategy to action, and making strategy understandable to those on the front line as well as to senior managers<sup>4</sup>. BSC is a useful tool for translating vision and strategy into a comprehensive set of performance measures to which all levels of the organization can relate<sup>5</sup>.

Traditional performance measurement systems rely only on financial measures. These systems do not provide managers the information they need

to manage all the important capabilities and processes that drive competitive advantage for their organizations<sup>6</sup>. By the early 1980s, there was a growing concern that with the global competition followed by increased customer orientation and technological change, it was no longer appropriate to use financial measures as the only criterion for assessing success<sup>7</sup>.

The Balanced Scorecard supplements the traditional financial measures with three additional perspectives: customers, internal business processes and learning and growth<sup>8</sup>.

### ***2.1 Perspectives of Balanced Scorecard***

Balanced Scorecard methodology requires that companies set goals and specific measures related with customer expectations such as customer satisfaction, quality and service<sup>9</sup>. Customer perspective includes measures such as market share, customer acquisition and retention and customer satisfaction<sup>10</sup>. Measures related with customer needs and satisfaction should be translated into measures of what the company must do internally to meet its customers' expectations. In the internal business processes, the company should focus on core competencies, processes, decisions and actions that have the greatest impact on customer satisfaction. The general measures should then be decomposed to department and workstation levels, where the action takes place<sup>11</sup>. The learning and growth perspective identifies the intangible assets that are most important to the strategy. The objectives of this perspective are to identify which jobs (the human capital), which systems (the information capital), and what kind of climate (the organization capital) required to support the value-creating internal business processes. These assets must be bundled together and aligned to the critical internal processes<sup>12</sup>. As a result of increasing competition, companies should make continual improvements to their existing products and processes and should have the ability to introduce new products with expanded capabilities in order

to survive<sup>13</sup>. The learning and growth perspective could be used to monitor this long-term value creation process<sup>14</sup>.

Financial measures are essential to determine if the company executives correctly identified and constructed their measures for customer, internal business processes and learning and growth perspectives. The financial perspective describes the tangible outcomes of the strategy in traditional financial terms<sup>15</sup>. The financial perspective concentrates on whether the corporate strategy is resulting in bottom line improvement and covers measures such as profitability, growth and shareholder value<sup>16</sup>.

On conceptual basis BSC and its perspectives can easily be understood but its success in business organizations depends on how it is implemented<sup>17</sup>. Successful implementation of BSC provides various benefits to the organizations such as improvements in competitive position of the company in the market<sup>18</sup>, improvements in financial performance and profitability<sup>19</sup> improvements in decision making and problem solving ability<sup>20</sup>. In organizations where BSC is successfully implemented morale and motivation of the employees increase through conceiving how their efforts

contribute to the achievement of strategic goals and objectives of the organization<sup>21</sup>.

But in order to obtain benefits from BSC organizations have to consider some factors at the design and implementation stages of their balanced scorecards:

- The key to success with the BSC concept depends on the appropriateness and quality of the measures chosen<sup>22</sup>. Measures derived from organization's vision, mission and strategy is at the heart of the Balanced Scorecard<sup>23</sup>. The selected measures should represent the strategic objectives<sup>24</sup> otherwise managers will not be able to properly execute the strategy<sup>25</sup>. It is important to have a well-balanced set of measures, from each of the perspectives<sup>26</sup>. BSC measures should be easy to interpret so that scorecard readers should understand both the operational and strategic significance of every measure<sup>27</sup>. When designing a scorecard, it is important to focus on the vital performance measures<sup>28</sup> which are limited in number<sup>29</sup> accurate, objective and reliable<sup>30</sup>, and dynamic since environment, strategy or structure of the organization changes.

-IBID, Sim and Koh

<sup>30</sup> -Parker, C. (2000), Performance Measurement, *Work Study*, 49(2): 63-66.

- Successful implementation of the Balanced Scorecard also depends on the commitment of top management<sup>31</sup>. Clear signals from the top of the organization about the importance of the Balanced Scorecard will help the organization to accept and use it<sup>32</sup>. Besides executives, employees at all levels have to be aligned and committed to it. In the absence of commitment, Balanced Scorecard system is likely to be ignored or abandoned<sup>33</sup>.

- The Balanced Scorecard supports the idea that employees should be observed on how they are performing with respect to the company strategy<sup>34</sup>. The best way to get a work force's attention about corporate focus is to link achievement of desired results directly to rewards<sup>35</sup>. BSC should be linked with well-understood rewards. Rewards that are delayed, uncertain, or ambiguous may be ineffective motivational devices<sup>36</sup>.

- Successful implementation of Balanced Scorecard depends on integrating the information stored in the computer systems of the organization and providing immediate organization-wide access to the status of key performance indicators<sup>37</sup>. When an unexpected signal appears on the Balanced Scorecard, managers need access to the underlying data to investigate the cause of the problem or to analyze trends and correlation. In

that sense automation of BSC and choosing the appropriate software can significantly effect the success of Balanced Scorecard<sup>38</sup>.

- As a performance measurement system, BSC is a dynamic model that needs to be modified, adapted and improved on a regular basis<sup>39</sup>. Because the competitive environment surrounding an organization is changing rapidly, performance measurement systems require continuous improvements and revisions to maintain their relevance.

- As other measurement tools, successful implementation of BSC also requires effective communication of the performance measures to all levels of management and staff within the organization<sup>40</sup>. This enables them to understand how their own efforts can have an effect on the targets set in respect of each perspective<sup>41</sup>.

- Activity Based Costing should be considered as a supportive measurement tool for Balanced Scorecard<sup>42</sup>. Activity Based Costing (ABC) is a method that aims to increase the accuracy of cost measures. ABC ties costs to activities and products much more accurately than traditional accounting

methods<sup>43</sup>. Inaccurate cost data can have a negative effect on the BSC system<sup>44</sup>.

- Organizations that are implementing BSC, can increase their chances of success by starting with a pilot project<sup>45</sup>. A pilot study of BSC allows the determination of best measures that are useful. The development and the introduction of the BSC should not take too much time<sup>46</sup>.

Our findings in the literature review made up the basis of our research to analyze the factors, which are important for the success of BSC implementation in Turkish firms.

### **3.Methodology**

#### ***3.1Population and Data collection***

In Turkey there are 70 companies implementing Balanced Scorecard [As a result of contacting with 500 major industrial enterprises of Turkey listed in Istanbul Chamber of Industry<sup>47</sup> It was found that only 70 of them were implementing Balanced Scorecard ].Our subjects of the study are the managers who are responsible from Balanced Scorecard Applications in these firms. Data were collected from the managers via questionnaire technique. As a survey instrument, questionnaire consisting of sixty items was used. All the items in the questionnaire was developed by the researcher benefiting from the literature. Respondents were asked to indicate the degree of importance of the given statements on a five-points scale. The scale ranged from 1, “not important at all” to 5, “very important”. Besides sixty items questionnaire some demographic questions were also asked. We sent our questionnaire to the managers who are responsible from Balanced Scorecard Applications in these 70 companies and 62 of the questionnaires were returned to us, so the degree of response rate is about 90 %. At the end of the research item analysis were done for the items measuring the degree of importance of success factors of BSC. None of the items on the degree of importance of success factors of BSC scale had an alpha value lower than

0.93 and Cronbach's alpha for full degree of importance of success factors of BSC scale was 0.94.

### 3.2 Findings

According to the data collected from managers responding to our questionnaire 97% of the firms were using all four perspectives of BSC, 65% of the firms tied compensation incentives and rewards to BSC results, 55% of the firms have automated their BSC system, 16.1 % of the firms were reviewing their BSC system once a year whereas 22.6 % of the firms twice a year, 25.8 % of the firms quarterly and 35.5 % of the firms were reviewing their BSC system monthly. 77.4% of the firms had information about Activity Based Costing but only 38.7% of the firms were using ABC and only 29% of the firms were using ABC in the manner to support their BSC system.

*H1: Appropriateness of the measures are important for successful implementation of BSC.*

### 3.3 Discussion and Concluding Remarks

Performance measurement is an issue of growing importance for business organizations, because success of business organizations, achieving competitive advantage and sustaining it depends on how good they are performing. Balanced Scorecard defines what management means by "performance" and measures whether management is achieving desired results<sup>48</sup>. BSC is a powerful concept based on a simple principle; managers need a balanced set of performance indicators to run an organization successfully. The indicators should measure performance against the critical success factors of the business, and the "balance" is the balancing tension between the traditional financial and non-financial, operational, leading and lagging, and action-oriented and monitoring measures<sup>49</sup>. The term "balanced approach" also means that these four measurement categories are given roughly equal weight in supporting management decisions. While this model can be effective, its biggest contribution is that it emphasizes, particularly to traditional managers, that financial measures (the bottom line) are not the only measurements needed to manage companies effectively, there are also other measures of equal importance<sup>50</sup>.

In this study we tried to shed light on the factors which are important for successful implementation of Balanced Scorecard in Turkish business organizations. We have seen that in Turkish firms that implement BSC using appropriate measures, top management support and commitment, linking compensation, incentives and rewards to BSC results, employees' participation and commitment, selecting the appropriate BSC automation and software system, communicating the BSC throughout the organization, reviewing and updating BSC are important factors for the success of BSC implementation. Since managers give importance to the participation, commitment and support of both employees and managerial levels to the BSC and see communication as an essential tool for the success of BSC implementation, we can say that culture of the organization can also be a factor for successful implementation of BSC in Turkish Firms. This is also in accordance with the literature. Franco and Bourne, 2003 in a survey found out that for the success of BSC there is a need for an organizational culture that encourages discussion and analysis. Correlations among the factors that effect successful implementation of BSC (table 1), had also some implications for us: Communicating BSC throughout the organization is significantly correlated to all other success factors. Similarly top management's support and commitment and employees participation and commitment are significantly correlated to all success factors except using a pilot study before implementing BSC. This finding also support our idea that organizational culture can be important for the success of BSC implementation in Turkish business firms. For further research implications a study can be conducted to analyze the type of organizational cultures and components of organizational culture that effects successful implementation of BSC in Turkish firms

There are also limitations to this study, in Turkey the number of firms implementing BSC are very few in size, because it is a new concept for the Turkish firms. For that reason this study can be repeated in future with a larger population when number of companies using BSC increase in size.

## **Abstract**

*The business model at the end of the 19<sup>th</sup> century was , in many industries the vertical integration of the value chain. Towards the end of 20<sup>th</sup> century we began to witness the deconstruction of these integrated models. New business models are introduced transforming thus the boundaries and the competitive skills that define firms and industries and the nature of competition. In this new competitive environment is not unusual that firms that compete on a single layer of the value chain to extend their activity in more industries. Companies use, more and more, the different layers of the value chain to migrate to other markets. This migration not only causes new profitable markets and businesses but also causing the merger of previous separate industries. Thus it becomes difficult to define the industries using the traditional methods. It is very probable that in the future the competition will take place at the value chain layers and not at industry level. The paper concentrates also on the new business models in this new competitive environment: the layer players, the orchestrators, the market makers, the integrators and the navigators.*

**Keywords:** *deconstruction; value chain; business models.*

## 1. Introduction

In many industries the business model at the end of 19<sup>th</sup> century was the vertical integration of the value chain. Towards the end of 20<sup>th</sup> century we began to witness the deconstruction of these integrated models. Competitors with new business models change or sometimes even destroy the competitive advantage of integrated firms. As these new firms introduce new business models, the boundaries and the competitive skills that define firms and industries are also changing, transforming the nature of competition.

Although vertical disintegration may be a relatively invisible part of industry evolution, it can radically transform the sectors in which it occurs. In this new competitive environment it is not unusual that firms that compete on a single layer of the value chain to extend their activity in more industries. Companies use, more and more, the different layers of the value chain to migrate to other markets. This migration not only causes new profitable markets and businesses but also causing the merger of previous separate industries. Thus it becomes difficult to define the industries using the traditional methods. It is very probable that in the future the competition will take place at the value chain layers and not at industry level.

Practical experience and empirical research on vertical integration has stressed that internal transaction costs that make the vertically integrated firm inert and inflexible can be extremely high. As a result many integrated firms began disintegration or outsourcing processes in the 1980's to save on overhead costs or to regain some sourcing flexibility. This was the beginning of the deconstruction of the integrated value chains. Over time factors such as: globalization, deregulation, privatization, increasing sophistication of capital markets and most important – the revolution in the economics of information contributed to the process of deconstruction. The consequence was an increasing number of specialized businesses (focusing on a single or few layers of the value chain), an augmentation of layer specialization and business migration across the traditional industries.

Vertical integration decisions were based on information anomalies. The high cost of getting enough information to suppliers, distribution channels and customers has been the factor that influenced most vertical integration. Today there is the possibility of an open exchange of information at a very low cost and those aspects have two immediate consequences: it allows firm to outsource more activities that was previously possible and encourage the firms that act on a single layer to attack the integrated firms by means of advanced information technology such as the Internet. As a result, the integrated value chains are fragmenting into multiple businesses.

## 2. Causes of value chains deconstruction

It is very important to understand the reasons for deconstruction, which parts of the chain are most likely to be affected and how it can be used by the company to its advantage. There are three main theories that deal with the main reasons for value chain deconstruction : 'rich versus reach', 'interaction versus transformation' and 'three businesses in one'.

### 2.1. *Rich versus reach*

Evans and Wurster<sup>1</sup> hold that the value chain has traditionally been defined in terms of the trade off between 'richness' and 'reach' of information. Companies, for example, set up branch networks to communicate 'rich' (read detailed or complex) information to customers, whilst advertising could 'reach' a broader population, but not deliver rich information effectively.

The authors hold that a company can increase its competitiveness in this situation by moving along the tradeoff line, e.g. offering higher reach but with less richness than a competitor. A second, but more difficult, strategy would be to move the line outward by offering both increased richness and reach.

Evans and Wurster<sup>2</sup> predict that the trade-offline is not only shifted by innovative competitors. Two inventions are causing the line to move. The first is the advent of open, universal communication standards, such as found in Internet communication. The second is the introduction of content standards for the definition, storage and presentation of information. The effect of these changes is that rich information will increasingly reach a much larger audience at a greatly reduced cost. In addition, the market starts performing activities previously requiring managerial co-ordination. Due to this some parts of the value chain might become obsolete and others can be performed in new ways. The outcome is often that the traditional integrated value chain starts deconstructing.

### 2.2. *Interaction versus transformation*

Butler and Hall sustain that organizations frequently compare interaction cost with transformation cost. Interaction refers to 'the searching, coordinating and monitoring that firms do when they exchange goods, services or ideas'. Transformation relates to the economic activities of

---

<sup>1</sup> EVANS, P. WURSTER, Strategy and the new economics of information, *Harvard Business Review*, pg.72, 1997

<sup>2</sup> EVANS, P. WURSTER, '*CLICK.BOOM*', Ivey Business Journal, pg.35 , 2000

production and delivery<sup>3</sup>. The theory of comparative advantage holds that the parties should trade and increase individual and total wealth when one party has a comparative advantage in an activity. Butler and Hall hold that even if one party has a comparative advantage, but the cost of finding, negotiating and exchanging goods is more than can be gained through trading, the parties would not trade. Interaction is estimated to represent as much as 51 percent of labour activity in the United States of America (USA) with an equivalent cost of one third of the gross domestic product<sup>4</sup>. The authors postulate that due to this huge cost, traditional organisations were constructed to decrease the impact of interaction.

If, for any reason, the cost of interaction decrease, the dynamics of industry could change. A decrease in interaction cost could, for example, lead to a component being sourced from a third party rather than manufactured in-house.

### **2.3. Three different businesses**

The 'three firms in one' theory presents one of the most attractive models. This probably results from the instinctive recognition of the different dimensions of an organization that managers have noticed through experience but were unable to describe in terms of a theoretical framework. Hagel and Singer suggest that most organisations engage in three kinds of businesses. The first attracts customers; the second develops products, whilst the third oversees operations. Each unit employs different types of people, has different cultures and even has different economic and competitive imperatives.

The main driver for the customer business is scope (gaining the largest share of market), whilst operations focus on scale. The product unit focuses on speed to market and innovation. Evans and Wurster hold that the integrated value chains often found in industries are sub-optimal because they integrate businesses with different drivers into one. Hagel and Singer agree that the trade-offs resulting from running the businesses as one adds inefficiency to the system. As soon as the cost of these inefficiencies is more than the interaction cost holding the business together, organisations will unbundle into three.

---

<sup>3</sup> BUTLER, P., HALL, T.W. *The revolution in interaction*, McKinsey Quarterly, Issue 1, pg.2, 1997.

<sup>4</sup> BUTLER, P., HALL, T.W. *The revolution in interaction*, McKinsey Quarterly, Issue 1, pg.4, 1997.

The unbundled businesses are not predicted to necessarily remain loose standing entities. Some parts are expected to consolidate with similar sections of other organisations that have also unbundled. Consolidation in the customer and operations businesses is likely as the business drivers are scope and scale. Product companies are foreseen to remain small with fragmented players characterising the new industry. Evans and Wurster argue that in the traditional value chain trade-offs were inevitable. One activity was done at a sub-optimal level to accommodate another. The player with the lowest average cost for all activities held a competitive advantage. With deconstruction, 'de-averaging'<sup>5</sup> occurs. Each part of the value chain must now be competitive. 'Deconstructors' seek out the most profitable part of the chain and focus only on this element, thus gaining a competitive advantage. Traditional players are potentially left with the less profitable activities.

### **3. The Implications of Deconstruction**

The competitive implications of deconstruction are profound and wide ranging:

- The traditional definition of businesses and industries and, therefore, the reference set of competitors, suppliers, and customers becomes obsolete. The development of new technologies, deregulation, privatization, the liberalization of trade, the expansion of Internet have helped to blur the lines between industries and give rise to new businesses that do not readily fit the traditional industry definitions.
- Competitive advantage is de-averaged. Businesses in which the economics of one activity are compromised for the sake of the whole will be especially vulnerable. In an economy of integrated value chains, competitive advantage is a game of averages. Take the simple example of costs. If a company's aggregate costs are competitive, then having a cost advantage at every step of the value chain isn't necessary: the steps are bundled together. But as value chains deconstruct into distinct segments, layers, and markets, average advantage loses its importance. What counts is advantage in each individual piece of the value chain. Deconstruction leads to de-averaging.
- Advantage across the entire value chain no longer matters; it's advantage in each layer that counts. As a result, the new unit of strategic analysis is the layer.

---

<sup>5</sup> EVANS, P., *How deconstruction drives de-averaging*, pg.1, 1998

- Horizontal strategies those that leverage layer capabilities across previously distinct businesses become serious alternatives to traditional strategies of vertical integration and customer franchise in a single industry.
- Managing resource allocation at the layer level requires new ways to evaluate investments and gives birth to a whole new concept of the portfolio.
- The boundaries of the corporation become fluid and permeable. Ownership is no longer a condition for effective co-ordination or control. Companies can now make use of key activities in the value chain without owning them.
- Customers are empowered; brands become vulnerable. Traditional asymmetries of information are challenged by the rise of navigators that search and switch on the customer's behalf.

#### **4. New business models**

The deconstruction of the integrated value chains provides more freedom to search for or create new business opportunities as each layer of the value chain can be the focus of value creation. We can distinguish five new business models: the layer players, the market makers, the orchestrators, the integrators and the navigators.

##### ***4.1 The layer players***

As deconstruction spreads, integrated value chains break apart into independent businesses, or layers. Some of these layers have the potential to become the places where the most value is concentrated and where the highest profits and returns can be found.

The layer players usually try to exploit economies of scale and superior know-how to build a new market by dominating an existent layer of the value chain and maybe they try to expand the layer horizontally across several industries. In order to exist as a layer, a product or activity supplied by a single company must be a key input to one or many value chains, while also being modular enough to stand on its own as an independent business. The most common way to create increasing returns of this sort is to establish an industry wide standard. The existence of a common operating-system standard in personal computing creates enormous value for consumers as more and more software applications are written to the common standard. Microsoft's scale advantage has allowed it to shape the evolution of the personal computer industry. Companies have achieved layer mastery also by

creating markets where none have existed before in the process, triggering further deconstruction and changing the way an entire industry does business.

Any aspiring layer master must carefully anticipate the likely moves and countermoves of other industry players partners, competitors, customers. They have to decide how much of the potential future value they can afford to give away in order to establish a standard. This companies have to be prepared to execute radical changes in strategy as the balance of competitive forces shifts.

Even when layer mastery is finally established, a company must remain vigilant. Mastery is rarely permanent. New technologies can render previously essential information or standards obsolete. Customers can conspire to work around established layers by finding new partners or even by going into business themselves. Although layer mastery often means that the winner takes all, that winner must be prepared to do so over and over again. In a deconstructed environment, defensibility is by definition dynamic. If you stand still, your control is likely to erode.

The best way to defend a layer is to extend it. The most successful layer masters search for opportunities to project their mastery across multiple industry boundaries to amass still more scale, to keep control of the customer, or to defend themselves against competitive threats from other industries. In this way, Microsoft has tried (with uneven success) to spread the Windows standard from personal computers to consumer-electronics devices to cable-television set-top boxes.

An example of layer player is EDS (Electronic Data Systems), a computer company that has specialized by providing services to control and govern comprehensive IT systems. Initially it has operated in the automotive industry- as a part of GM but today it provides IT services ( IT development, online marketing) to firms operating in different industries.

#### ***4.2. The Market Makers***

Another business model is the market maker. The firm's success is based on a pioneering development that has become an industry standard. In contrast to layer player that concentrate on an existing value chain layer, market makers create an entirely new value adding layer. But, like the layer players they develop new markets first by using informational advantages and capabilities in one industry. If the market maker succeeds in creating a new layer, the firm then tries to extend this layer across additional industries.

Sabre, with it's IT- based airline reservation system is a good example of market maker. This system was a marketing invention by American

Airlines and today Sabre is an independent company and it's basic product is now a standard in the entire travel and tourist segment. This system connect thousands of tourism agents, airlines, car rental companies and hotels.

Another successful invention that resulted in a new market is Internet bookselling. Firms like Amazon.com achieved a high volume of business and gained a positive reputation that now develop related Internet markets.

Enron, that constitutes another example of market maker, revolutionized the business by creating a market for energy trading and making that market a key part of the industry's value chain. Today everyone in the business trades energy, but Enron retains a powerful advantage. Because the company has more than twice the trade volume of its next largest competitor, it has a wealth of experience that few rivals can match. The more trades Enron executes, the more information it acquires about how to identify the best deals and develop innovative techniques for structuring financing and for managing risk. That trading information has even given Enron a proprietary advantage in discovering the most profitable asset plays.

### ***4.3. The orchestrators***

As the forces of deconstruction break industries apart into an array of discrete businesses, one compelling strategic idea is to orchestrate the pieces of the value chain rather than own them. The logic is appealing. Instead of holding every link in the chain, orchestrators choose the pieces they want to own and direct the activities of the others by means of a powerful brand, control over critical information, or some other hard-to-create proprietary resource.

Orchestrators create competitive advantage by never acquiring nonstrategic or capital-intensive assets in order to focus on assets that add the most value. Their strategic focus allows them to concentrate capital, time, knowledge, and managerial expertise where they will have the greatest impact. Their unusually high asset efficiency leverages their economics and contributes to extraordinary returns. And their control of key resources gives them an opportunity to dominate the value-added architecture of an industry and even to shape its evolution.

There's no wonder, then, that some of the most successful companies of recent years have been orchestrators. Nike has dominated the athletic footwear business by concentrating on design and marketing while outsourcing and closely coordinating production through an offshore network of low-cost suppliers. Dell Computer has become the leading supplier of

personal computers to businesses by orchestrating a highly disaggregated supply chain to provide fast delivery of made-to-order PCs.

But orchestration can be hard to execute and even harder to sustain. The very changes in industry structure that make it possible also make it vulnerable to miscalculation, imitation, and competitive subversion. Unless orchestrators master new strategies and skills, they can find themselves defeated by the competitive dynamics that deconstruction unleashes.

The very factors that make orchestration possible also make it easy to copy. The process is straightforward: Orchestrators depend on a network of suppliers. If a supplier base does not exist, the orchestrator must create one. The orchestrator defines precise specifications for product design and delivery, then works with suppliers so they can meet them. As suppliers develop specialized expertise, an entire industrial infrastructure takes shape. Eventually, the system becomes so standardized and transparent that the suppliers are able to offer their services and products to anyone not only to the original orchestrator but to competing orchestrators as well.

That is what happened to Nike. Once the company established an efficient network of low-cost suppliers to produce its shoes, it found the network hard to hold on to. There was nothing to stop Nike's competitors from sourcing from the same suppliers on roughly the same terms. Today the athletic shoe market is awash in new labels and excess product, and Nike's growth has stalled despite the company's powerful brand. Orchestrators must learn to anticipate attacks by imitation and figure out how to head them off.

But imitation is not even the most serious competitive challenge that orchestrators face. Far more dangerous and disruptive is the situation where an orchestrator's suppliers themselves become so strong that the balance of power in the industry tilts decisively in their favor. The classic example is IBM's famous decision to outsource the operating system of its PC to Microsoft.

Orchestration is no mere outsourcing decision. It is a strategic choice that can be extraordinarily profitable but also extremely difficult to defend. Successful orchestrators understand thoroughly the economic attractions of their strategy. But they also anticipate the myriad ways competitors can take it apart. They think hard about whether their strategy can be defended and how.

#### ***4.4. The Integrators***

A viable strategic option is still the integrated business model. For some firms, the control of all value chain layers allows for cost or

differentiation advantages. The conditions for the success of value chain integration changed under the deconstruction. As compared with layer players, the integrator must be superior at every layer of the value chain, and in comparison with the orchestrators, the coordination capabilities must be at least as good if not superior. We can find successful integrators in many industries: ExxonMobil in oil industry, Nestle in food and Procter & Gamble in consumer products. As the factors that drive value chain disintegration proliferate, the integrator business model will be increasingly under attack.

#### ***4.5. The Navigators***

Power in a value chain often flows to the company that controls navigation the activities shaping how customers search, compare, and decide what to buy. As value chains deconstruct, a new class of independent navigators is gaining power. These companies threaten to wrest control of navigation from traditional product suppliers, undermining long-standing brands and customer relationships. Fortunately, there are ways to fight back.

Independent navigation isn't a new idea. Retailers have been around for more than a century. More recently, new retail formats such as mail-order houses and big-box retailers have greatly expanded the power of navigators. Now electronic commerce is rapidly accelerating the trend, spreading independent navigation to new industries and to unprecedented levels of efficiency and reach.

The new navigators bring wider choice to more customers, give them more information, and cater more successfully to their individual preferences than ever before. Schwab OneSource, for example, helps investors pick and choose from more than 3,000 mutual funds; Chemdex helps industrial customers select from specialty chemicals offered by more than 100 suppliers. Unencumbered by constraints of geography, inventory, or existing distribution channels, the new navigators aim to control the customer relationship by providing a one-stop solution based on breadth of choice and rich information.

For established product brands, independent navigation is a serious competitive threat. By focusing on easily compared attributes like price, navigators shrink margins and threaten to commoditize every product in a category except the quality leader. By inserting themselves between companies and their customers, they erode the brand experience and hijack valuable customer information and relationships. By deconstructing traditional sales and distribution channels, they strip control from suppliers and profits from the value chain.

Faced with such threats, many companies are tempted simply to give in for example, by adopting the navigator's product standard, buying "shelf space," or even manufacturing a navigator's private-label products. But surrender is a mistake. Incumbents can retake the initiative, but only if they start using the dynamics of the deconstructing value chain to their advantage.

## **5. Conclusion**

Information has always been the glue that has held value chains together. The cost of getting sufficiently rich information to suppliers, distribution channels, and customers has given vertical integration its leverage. As transaction costs plummet, that glue is dissolving. Increasingly, universal access to rich information and common communications standards are enabling the open and virtually free exchange of all kinds of information.

Before deconstruction, a company could maintain an advantage if the average productivity of all the activities it performed was higher than that of its competitors. Today a company must excel in every activity because every link of its value chain is being challenged. That doesn't mean that integrated manufacturers will disappear altogether, but they must be highly productive in everything they do. Otherwise, they should be ready to deconstruct.

As new markets appear at every link in the value chain, the logic of a vertically integrated company must be continually proved rather than taken for granted. Deconstruction is having a considerable impact. But taking apart a value chain is a radical decision. It could mean transforming a company into a collection of independent businesses that buy and sell on the open market.

The key is knowing what you do best. If you are the low-cost manufacturer, could you gain leverage by producing for all players? If your brand can extend into new areas, could you create a licensing and management infrastructure? If you have technology that is applicable across disparate businesses, could you create a strategy to capture that value?

Deconstruction means separating a product or service chain into its component parts and realigning those components to maximize overall value or flexibility. . The goal isn't necessarily to break a company apart; it is to make each layer of the value chain as productive as it can be.

## **Abstract**

*Productivity gap between new EU members and developed western countries has been a topic of recent debates both at macro- and microeconomic level. At micro level, a fundamental role is carried out by management. In this paper we focus on human resources factor as it is believed to be one of the most important determinant of companies growth. We refer to a concept of HR controlling, which stresses the need for complexity in human resources management. For the cross-country comparison of HR management we use the results from research conducted by Deloitte and the University of Economics of Prague.*

**Keywords:** *controlling; human; resources; HR; management*

## **1. Introduction**

Controlling as a management practice is understood as a group function which is carried out equally by the controller and the manager at various company organisational levels. The basis of this function is to determine the strategic and operational company aims, the collection and processing of information in decision making, preparation of material which will assist in the companies direction and also the ongoing control of gathering results.

Development of controlling also supports enterprise growth on a workforce level which up to this point has not demanded individual initiative. Thanks to this, employee activity has grown because of on the one hand delegation entitlement and on the other, the ability to have responsibility in the decision making process. This, however, requires much time and can't be decided upon without direct participation in this process. This conversion requires gradual and controlled introduction, at the same time with commitment from staff and management where the situation for both is completely new.

Employees are, more than often, recognised as the most treasured element in company growth and expansion, they are recognised by modern managers as capital worth investing in. However, in order to create such a friendly environment, it is vital to work through or introduce a successful system in human resource management in a company which will give noticeable effects.

This task is undertaken by human resource controlling, which allows for avoiding the effects of improper decisions in the area of human resource management, which could contribute to unfounded growth in company operational costs.

The purpose of this paper is to present human resource controlling as an advanced management tool to improve companies productivity and effectiveness as well as employees' satisfaction.

## **2. The problem of productivity**

Most of new EU members face the problem of low labour productivity (Table 1). This phenomenon is easily explained on a macro level. Most of these countries were centrally planned economies, which didn't go in the line with the free market mechanism. Therefore, over decades private sector didn't develop at the same pace as in western economies. In

other words, when post communist workforce fulfilled the centrally planed tasks, whereas western economies developed organisations, which were market and profit oriented. Through capital accumulation and continuous quality increase they developed goods and services which are now exported worldwide. Therefore, disproportions in aggregates presented below primarily arise from the fact, that advanced economies are using value added over long period.

Another reason behind low productivity may be poor organisational system and management dysfunctions. Again, it should be mentioned, that advanced economies have at disposal far more experienced managers than developing countries.

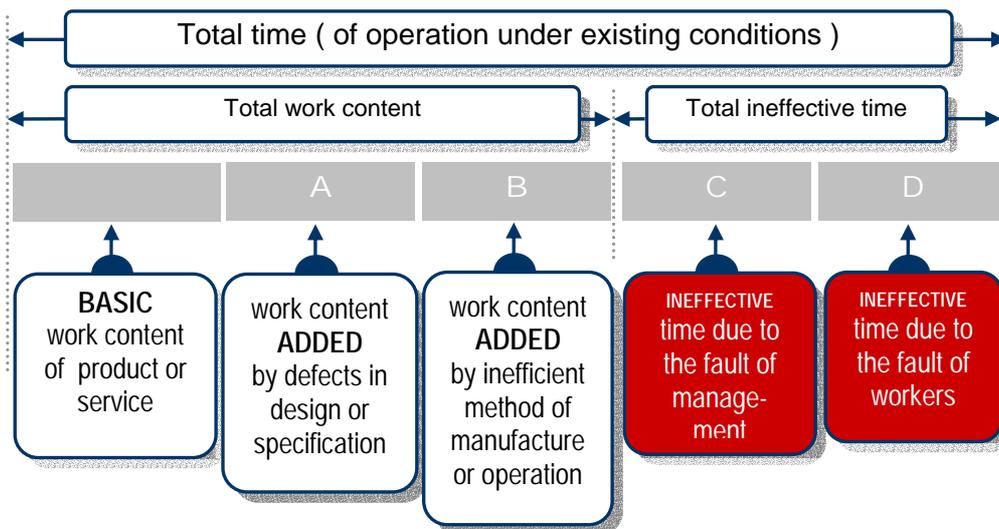

Human resources is recognised as one of the most important factor of company's growth in the neoclassical models. Diagram 1 presents a typical work time structure. Area C and D stand for human resources failures. Both of them may be reduced or even eliminated through a proper design of HR system.

**Table 1. Labour productivity index**

	2001	2002	2003	2004	2005	2006
EU (25 countries)	100.0	100.0	100.0 (f)	100.0 (f)	100.0 (f)	100.0 (f)
EU (15 countries)	107.8	107.4	107.1 (f)	106.8 (f)	106.6 (f)	106.4 (f)
Austria	104.4	103.3	103.5	104.9	105.4 (f)	105.2 (f)
Czech Republic	60.4	60.9	62.7	63.9	65.5 (f)	67.2 (f)
Hungary	64.5	66.9	67.2	69.2	70.5 (f)	71.4 (f)
Poland	49.8	50.5	58.0	59.6	60.7 (f)	61.8 (f)
Slovakia	56.1	59.1	59.0	59.4	61.1 (f)	62.7 (f)
Slovenia	71.6	72.7	74.2	75.9	77.5 (f)	79.3 (f)

Microsoft Office Personal Productivity Challenge discloses HR management dysfunctions. According to the research, unclear objectives and ineffective meetings are representatives of the top three time wasters. This suggest how much there is to be done in the field of human resources.

### 3. The essence, aims and tasks of human resource controlling in companies

Human resource controlling is defined in literature as „...an internal system controlling the achievement of aims in individual areas of human resource management in a company involving planning, control effects and work costs and also factors which influence this...”<sup>1</sup>. Controlling fulfils an extremely important role in the area of human resource management. It permits a better use of the opportunities which resides in the human resource potential the company has. Employees often constitute the companies largest growth and development factors, and proper management of them allows the attainment of high market placement, increasing its value and contributes to effectively making use of the abilities and qualifications of the staff. Via the integration of planning and forecasting, consultancy and also via the informing and controlling in human resource, the possibility of rational administration becomes accessible for all available company resources. This consequently influences a bettering of the competitive position in the market and contributes to achieving company success. The concept of such understood human resource controlling is represented in diagram 3.

**Diagram 3. Concept of controlling in relation to human resource management**

*Source: I.Chomiak, Problemy kadrowe rozwiązywane poprzez wdrażanie systemu informacyjnego controllingu personalnego, Prace Naukowe Akademii Ekonomicznej, Wrocław, 2002, nr 953, s.229.*

<sup>1</sup> J. Lipiecki, Controlling personalny, „Ekonomika i Organizacja Przedsiębiorstwa”, 1998, nr 12, p.28.

In literature there are distinguished the following types of human resource controlling<sup>2</sup>:

- **Strategic**, whose task is one of observation and then analysis and forecasting qualitative factors and effects connected to the process of human resource management. It can be said that this is set on the maximum importance of human capital as well as the amount and quality, with the aim of achieving a greater stable market position and being more competitive.
- **Operational** whose short term activity direction within human resource management is aimed at a definite purpose for the company. The characteristic feature of human resource controlling is above all: much more detailed activities, short term planning, determining the direction of on going aims within the area of human resource management and the company itself.

In regard to the operational tasks of human resource controlling, it is important to<sup>3</sup>:

- combine both the strategy of the workforce with the strategy of management,
- verify the correct strategy to move human resources in the direction of a precise aim,
- control in the gradual carrying out of this strategy and achieving results,
- treating the human resource department as the core for profit and centre for shaping employee value.

It can be said, that the aim of human resource controlling is firstly based on a „bottle neck” principle, which means changes to employees production according to the scope and structure of work costs, recruitment and the qualifications of staff. Other factors such us changes in work related accidents which may effect loss of work time, internal work relationships and work related illness may in the end, effect how the reward system via the company is carried out<sup>4</sup>. The second aim may be determined by how to make the most of and shape the abilities of the staff, so that management may increase their value and to gain a competitive edge.

## 4. Cross-country analysis of the HR function<sup>5</sup>

The HR survey was divided into 5 sections and the questions (multiple choice and open questions) focused on providing us with specific details and insights on:

- HR leadership and staffing;
- HR roles and responsibilities;
- The current state of selected HR processes and activities;
- HR performance metrics;
- The envisaged challenges of the HR function in the forthcoming years.

### *4.1 HR Strategy and Service Delivery*

The HR function in general develops an HR strategy and then links it with the organisation strategy. The responses in the Czech Republic, Slovakia and Slovenia show particularly high percentages. However 25% of the organisations in Poland and Hungary do not link the HR strategies with the organisation strategy. In Austria this is the case in 20% of the population. However in most countries the linkage seems to be only one-way: top-down. The organisations that develop an HR strategy take into account the organisation's situational and environmental changes as well as culture, strengths and weaknesses of the organisation, and social and political changes.

However, only about 50% of the organisations measure the impact of the realisation of the HR strategy. About 75% of organizations in Austria and Slovenia, though, measure the impact human resources have on the organisation while in the Czech Republic just about a third do so.

The most mentioned reasons for not using HR performance metrics are:

- no knowledge about how to measure HR;
- no standard for generally accepted metrics;
- HRIS does not provide required data.

---

<sup>5</sup> Deloitte and the University of Economics of Prague; "The State of HR in Central Europe"; 2004/2005;  
<http://www.deloitte.com/dtt/cda/doc/content/HRSurvey2EN.pdf>

All organisations in Slovenia indicated that they link the organisation with the HR strategy and use HR performance metrics.

When asked, which HR performance metrics are the top 3 HR performance indicators it appears that organisations mostly mention metrics like:

- employee satisfaction,
- employee turnover,
- absenteeism,
- training (hours) per employee.

Most organisations use both qualitative and quantitative indicators. This leads to the assumption that it looks like the HR function is focused primarily internally and not externally. An external focused HR function would stress HR key performance indicators that measure for example the:

- Human Capital return on investment,
- sales revenue per employee,
- productivity indicator,
- error-free service,
- the effect of salary costs on the value-added.

There were only about 5 organisations that mentioned these kind of HR metrics and all are from Hungary. Hungary and Austria are the countries that have the highest percentage of organisations which use HR performance metrics. The involvement of HR priorities in the short- and long-term strategic planning process of organisations differs from country to country. In Hungary in particular the HR function is much involved in the strategic planning process. HR strategies and priorities are involved in this process. This level of involvement might be linked to the HR performance metrics that are used in organisations in Hungary. Also in Slovakia the HR function has established not only top-down links but also bottom-up links with the top organisational level and planning. In Slovenia there is a mixture of answers which vary from “to a significant extent” to a “minimal extent“.

Many of the participants indicated that they are a local subsidiary that is part of a global organisation with a global HR function or they represent the HR function at the global level. Participants have been asked about the implementation and use at the local level of HR processes and services developed at the global level. It appears that in Austria, the Czech Republic and Poland most local subsidiaries develop and/or modify the global HR

processes. Also most local subsidiaries are served with one or more HR processes/services from the global HR function. In Slovakia and Hungary a small percentage of organisations take HR services from a global level.

#### **4.2 HR Structure and Roles**

The main role of the HR function in Austria and Poland is as a strategic partner. The HR function focuses on aligning HRM strategies and practices with business strategy, internal and external resources and competences. The HR function executes the HR strategy and HRM practices support in accomplishing business objectives.

In the Czech Republic and Slovakia the main role of the HR function is as Change Enabler. The HR function focuses on managing transformation and change processes and creates relationships with its stakeholders (e.g. employees, management and unions).

**Table 2. Human Resources Roles**

<b>Country</b>	<b>Administrative</b>	<b>Employee Champion</b>	<b>Change Enabler</b>	<b>Strategic Partner</b>
Austria	0 %	33 %	27 %	40 %
Czech Republic	19 %	21 %	37 %	23 %
Hungary	11 %	39 %	22 %	28 %
Poland	20 %	4 %	31 %	45 %
Slovakia	0 %	6 %	50 %	44 %

*Source: Deloitte and the University of Economics of Prague...*

The main role of the HR function in Hungary is Employee Champion. The HR function is oriented on increasing employee commitment, capability and establishes relations with employees to solve day-to-day problems, concerns and needs.

In Poland and the Czech Republic about 20% of the respondents still indicate that the main role of the HR function is to design and deliver efficient HRM processes; HR builds efficient infrastructures. In Slovenia a mixture of roles is indicated.

Total HR staff : employee ratio and the span-of-control of HR executives/management were calculated. No correlation was found between the HR staff : employee ratio and:

- the main role of the HR function; or
- the use of Human Resource Information Systems; or
- outsourcing of HR processes/activities.

**Table 3. Human resources staff on employee ratio**

<b>Country</b>	<b>HR staff : employee ratio</b>	<b>Span-of-control</b>
Austria	1:108	1:4,8
Czech Republic	1:73	1:3
Hungary	1:51	1:15
Poland	1:59	1:5
Slovakia	1:84	1:4
Slovenia	1:98	1:2

*Source: Deloitte and the University of Economics of Prague...*

HR staff are, in general, qualified at the appropriate level from an educational point of view. Although in Austria, the Czech Republic and Poland for the positions of HR executive post-graduate level is preferred while university level is actual. While for HR manager, technical/professional HR staff university level is ideal and typical. However in Slovenia the expected education level for professional/technical staff is college level.

In Slovakia for the positions of HR executive, HR manager and technical/professional HR staff university level is asked. For all above named countries college level is sufficient for administrative HR staff. In Austria, the Czech Republic and Slovakia previous working experience outside the organisation is perceived as positive but this does not have to be experience in the HR area. However, only in Poland is it preferred to have previous working experience in the HR area.

#### **4.3 HR Processes**

There have been selected following HR processes for more detailed inquiry:

- recruitment & selection,
- performance management,
- compensation & benefits,
- training & development,
- Human Resources Information System (HRIS),
- occupational health & safety.

#### **Recruitment**

In Austria, Poland, Slovakia and Slovenia 80 – 100% of the organisations tend to have specialised recruitment teams in the organisation, where as in the Czech Republic and Hungary this is true for only about 60%

of the organisations. The recruitment process incorporates in all countries most of the activities that are considered as ‘best practice’ approaches: job profiles and competencies are used in the selection process, recruitment policy is linked with the HR strategy and in most cases (65% of participants) organisations have prepared employee value propositions (compensation & benefits, career and development, training possibilities are offered). One of the practices that is less used is the monitoring of the costs, quality and effectiveness of recruitment channels (between 50% and 65% of participants).

### ***Performance management***

In Austria, Slovakia and Slovenia about 90% of the organisations have a performance management process in place. In the Czech Republic, Hungary and Poland this percentage is about 60%. For the organisations that have a performance management process implemented the use of all recognised ‘best practices’ is not that common. Almost all organisations however have regular performance appraisals with employees but on the other hand most organisations do not have a linkage between performance management and resourcing (internal and external recruitment).

Another weak linkage in most countries except Austria, Poland and Czech Republic is how performance management practices are connected to the development and deployment of employees. Examples of these practices are linkages between performance management and training & development, career & succession planning and personal growth plans.

Only in Austria and Slovenia is the use of performance management measurements broadly used (85% of participants). In the other countries this percentage is between 60% and 70% while for Hungary it is just 50%.

All countries, except Slovakia, have a propensity to link their compensation & benefits process well with other HR practices. And in all countries, except Slovakia, the compensation & benefits policy takes into account topics like motivation, employees’ needs and financial forecasts. Most of the organisations distinguish between some employee groups for offering compensation & benefits services. In general almost all organisations offer variable and/or performance related pay but a large number of the organisations indicate that this is true only for some employees. The same counts for offering a cafeteria and/or flexible benefits model.

In Austria most organisations (over 80%) regularly use external compensation & benefits benchmarks for reflecting their policies with the external market.

### ***Training & Development***

In all countries about 80% or more of the organisations have formalised training, development and learning programmes (and budgets) for at least some of the employee groups. Also, the majority of organisations monitor the effectiveness of at least some of the trainings at the individual and organisational level and use their training programmes to anticipate future strategic changes.

In this respect it is remarkable that many organisations invest in the development of employees but do not yet seem to have the right mechanisms in place to adequately deploy employees.

### ***Human Resources Information System (HRIS)***

Only in Austria (47%) and Poland (63%) do the majority of organisations have fully integrated HRIS systems implemented (i.e. HRIS systems that cover various HR processes and make it possible for one-time data administration per employee). In these countries respectively 38% and 30% of the organisations use various HR administration systems that are not necessarily linked, which leads to multiple-data entry of employee data.

In the Czech Republic, Hungary, Slovakia and Slovenia integrated HRIS is not widely used and most organisations (40% to 50% of the participants) use various HR administration systems. In these countries only about 25% of the organisations use an integrated HRIS.

### ***Occupational health & safety***

All participants follow regulations and therefore promote health and safety protection. In Austria, Poland, Slovakia and Slovenia about 70% of the organisations monitor employee work satisfaction. In the Czech Republic this is only roughly 60% and in Hungary only 45%.

Participants were asked which benefits they provide to employees to improve employee well-being. Most organisations provide benefits which are more compensation based than supporting employee and organisation wellness. The majority of organisations provide:

- restaurant vouchers,
- contribution to holidays/recreation,
- travel allowance,
- insurance benefits,
- health care.

Benefits that are focused on employee and organisation wellness provided by 50 – 60% of the organisations are:

- sport and activity programmes,
- company team building,
- flexible working hours.

Benefits that are particularly focused on employee and organisation wellness but are not common include:

- work-life balance,
- working from home,
- parental leave,
- child assistance.

#### ***4.4 Future outlook***

In all countries the majority (between 60% and 80%) of organisations expect “no change” in the HR budget for the next fiscal year. A minority (between 10% and 30%) of organisations expect a decrease in the HR budget.

The same response was received for a change in the number of HR staff. Again a majority (between 60% and 90%) of organisations expect “no change” in FTE of the HR staff in the next fiscal year. A “decrease” in HR staff is expected by 10% to 30% of the participants. However, when asked what the situation will be 3 to 5 years from now the number of participants that expect a “decrease” remains the same but more participants expect an increase.

The table below shows which HR processes are expected to have the greatest demands. We have shown the HR processes with the top 3 percentages per country. In the EU accession countries it appears that the major focus and demand is expected to be on performance management, compensation & benefits, training & development as well as internal communication, while in Austria the focus is on HR policy development, training & development, HR planning and employee counselling/coaching. The latter two topics are in Austria, as mentioned above, currently indicated by none of the participants as a main responsibility for line management.

**Table 4. Priority demand for HR processes**

	Austria	Czech Rep.	Hungary	Poland	Slovakia	Slovenia
HR Policy Development	31%					
HR Planning	31%					
Recruitment & Selection					70%	
Performance Management			45%	26%		80%
Training & Development	31%	36%		26%	75%	80%
Compensation & Benefits		33%	36%	32%	80%	80%
Change Management			36%			
Employee Counselling/Coaching	31%					
Internal Communication		34%		35%	70%	
Employee Relations						80%

## 5. Organisation of human resource controlling within companies

One of the most intrinsic factors affecting the efficiency and effectiveness of human resource controlling as a helpful tool in the process of human resource management in companies is the organisational manner which has as its aim:<sup>6</sup>

- precise range of task and the competency as well as determining the responsibilities of the human resource controller or those for whom are accountable for this function,
- assigning specific activities to the appropriate organisational divisions by human resource controlling,
- to determine where these divisions can be most effective within the organisational structure of the company.

Generally, it can be said that the role of the controller in companies is to above all, implement human resource control systems and to then monitor

<sup>6</sup> A. Poczowski, J. Purgał-Popiela, Controlling..., op. cit, p.189

their on going effective functioning. Responsibilities of the human resource controller are very wide and the administration of these activities more than often bring with them a great deal of accountability. Therefore, an absolutely vital function is to determine the individual personality, talent and ability along with the necessary qualifications such a controller should have in order for this person to realise his/her personal goals and achieve market success. It is necessary that the controller's profile within the function of personnel and other functions have analytical, persuasive, motivational and interpersonal and management skills. Also of importance is that professional training includes the understanding of the concepts, instruments and techniques involved with human resource management as well as company economics, concepts of business planning, budgeting and balances. P. Świerkula states that the model controller should be an open minded person who is able to detect and identify the most important information quickly and effectively in order to analyse and present it to interested organisations<sup>7</sup>.

The basic role of the controller within the function of human resource management should include<sup>8</sup>:

- choosing a specific method, time and range of planning for personnel within a company,
- control the true realisation of processes connected to the area of human resource management as well as their progress in achieving desired goals,
- „bottle neck” analysis, where human resource management can identify the weaker areas of the company and define ways for them to be eliminated,
- coordinate work associated with the controlling process and to work through a coherent timetable and programme for human resource managers,
- establish the information needs for staff function,
- measurement and reporting of internal and external concerning employment,
- assistance and training for upper management and human resource manager.

The appropriate positioning of controlling staff within the organisational structure is an important factor in achieving high performance

---

<sup>7</sup> P.Świerkula, Controller- rola i zadania:  
[www.controlling.info.pl//artyk/pokaz\\_artykul.php3?nr=14](http://www.controlling.info.pl//artyk/pokaz_artykul.php3?nr=14)

<sup>8</sup> Z. Sekuła, Controlling..., op. cit., p.387-390

and effectiveness in activities carried out. The human resource controlling department can be located at head office where it deals with upper management only<sup>9</sup>. The second location would be working with middle management on the same level as other management. A high human resource controller position within the company hierarchy allows for them to be in a favourable position to promote organisational issues of internal human capital, permitting independence and access to a variety of information of great strategic company value. Thanks to this structural position, the controller can fulfil the function of advisor although not having the ability to make or carry out decisions. In the second position, the controller works much closer with all company divisions which have an essential effect on the regularity and speed of the decision making process and carrying out of tasks. Z. Sekuła states that it is possible in such a situation of using human resource controlling which doesn't present an independent controlling position but rather its function is passed on to the human resource department<sup>10</sup>.

Of course the factors which determine the location of human resource controlling staff within the organisational structure of companies are also quite wide and the specifics of its activity, already existing organisational structure and the company level of expansion shouldn't be forgotten. In small business the function of controller is taken over by the owner or the director whose role is to support the process of management via the attainment of information and fulfilling a consulting function<sup>11</sup>. In mid range business the role of controlling is carried out by organisational divisions created for this purpose. Whereas in large companies, the position of controller emerges as either the head of the department or directly responsible to upper management.

The firm Cap Gemini Ernst & Young undertook a questionnaire among company owners regarding the use of controlling staff within their company. The results were published in the report Human Resources Management 2002/2005 Bedeutung, Strategien, Trends. Presented in Chart 2<sup>12</sup>.

The research was carried out on a group of 100 companies of which over 60% responded that their controlling staff were located in the personnel department. Every 3<sup>d</sup> person also identified controlling staff within the personnel department and the financial department. Only 6% of respondents

## 6. Conclusion

In conclusion it should be stated that human resources controlling represents an essential tool in the assistance of the human resource management process within companies. They are necessary as this form of instrument management, results in mainly a greater meaning as to how not only staff work but their work within the company itself. Thanks to the effective use of their ability and qualifications, companies are in the position to follow through earlier plans, minimize or completely eliminate threats or difficulties which may appear in the near future.

The use of human resources controlling allows for recruitment rationalisation, taking into account the staff number realistically required by companies, limit accidental activities in the process of human resource management, eliminates the repetition of work by several members of staff, counteract incorrect decisions which are often expensive and carry out systematic appraisals of all activity connected with personnel policies realized within the company. All of these activities on significant levels effect the ability of companies to achieve results and to enhance its market performance. In order for these tools to be totally effective and provide the

desired results, it is vital that managerial commitment and also abilities are utilized by the company to adapt to market changes.

Thanks to the information provided by the human resources controlling, improvements in human resource management occur and the consequences of this are represented by the companies results and stronger financial position.

The success of these adoption processes allow for controlling solutions which are dependant mainly upon the personal characteristics of the controller and also how important the process of human resource controlling is for upper management.

## **Abstract**

*After the Revolution of 1989, Romanian economy went through an important transformation process from a planned economy to a functional market economy. The changes which occurred in the labor market (the increasing rate of unemployment), the market of goods and services (the emergence of foreign companies) and in the capital market forced many Romanian companies, which already existed before 1989, to change their field of activity in order to survive. The company S.C. ALCOM S.A of Cluj-Napoca is in the same situation. It used to be the greatest company of distribution and logistics in the county of Cluj. As the competition on the wholesale market increased due to the emergence of super and hypermarkets chains such as Metro, Selgros, Carrefour, Billa, Plus, Auchan etc.), the company was forced to reorient itself to the real estate market. This reorientation brought about the laying off of more than 500 employees as well as the giving up to the logistics equipment. Moreover, the frequent changes in the fiscal legislation forced the managers to adopt a strategy of company division into 14 micro-enterprises. In this article, we shall tackle on the changes that merged at the national level and the reaction mode of the managers at the micro level.*

**Keywords:** labor market, distribution, logistics, hypermarkets, legislative changes

## **1. Introduction**

The transition to the market economy has eventually been understood as a movement from the public sector – controlled by administrative levers – to the private sector, where the managerial posts seem to go first. The most significant function held by the management within this transition is enforced by the necessity to create an overall capacity of innovation, flexibility, and, even under the circumstances of an unstable business environment, a certain stability that should ensure success in the most difficult or extreme situations will be needed.

Within the given context, the theoretical and furthermore, the methodological approach to a theory of the commercial management, which makes the object and the topic of this project brings distinct, practical bonds. Throughout this study, we will seek to emphasize, while building a case in point, the need to switch the traditional, managerial mentality over the economic activities to a marketing vision, which calls forth on the primary necessity of any company to detect the demands and the wishes of the aimed consumers / customers and give forth / satisfy their complacencies in an economic manner that should be more efficient than the competition's offer.

The method of underlining the manners and the means that allowed the achievement of an efficient improvement of the commercial management, situation that applies to the company analyzed throughout this paperwork, and under the impact of the major changes appeared during the transition process, implied certain conceptual and methodological disentanglements regarding the essence of that process, the analysis tools and the evaluation markers.

## **2. Changes in the national economy after 1980**

In order to recall the bonds of the economic science, it will be enough quoting John Maynard Keynes's words: "The theory of the economic sciences does not furnish a complex of invariable conclusions, with direct application in politics. It is a method, not a doctrine, a mental instrument, a thinking technique that helps its users reach the right answer" (Conrad Hilton – "Be My Guest", Ed. Prentice Hall Press, New York, 1987, page 278). Therefore, we will focus on the fact that, in order to elaborate efficient development strategies, the management of any business must set as its main goal the economic analysis, relating permanently to a given business environment, while permanently noticing and explaining the economic cycles.

The overall categories of competitive management, undauntedly envisioned, will be approached by highlighting the technical solutions meant to improve the profitability of the company, considering that the success of a deal is possible only through a full insight into the environmental factors.

Conceptually, and considering the process of applying the theoretical principles to the practical area, the transition from a **centralized economy**, with the state propriety as its main feature, to a **market economy**, turned out to be a very complex matter. Due to the lack of precursory conditions, necessary for the good functioning of the economic body that relies on self-adjusting mechanisms, the transformation of the over-centralized system appeared to be a very difficult process. The major restrictions that affected the process of transformation in order to create the market self-adjusting mechanism are as follows:

- The idleness of various structures (social, economic, institutional);
- The lack of financial provision (the inhibition of the process of forming the in-land capital and the insignificant draw of foreign capital due to a general mistrust in the newly-formed markets);
- The insufficient development in the sector of services;
- The gap between the speed of the implementation of the banking, financial and currency policies and that of achieving the absolute economic basis of the transition (management buy-out, management, capital, labor force);
- The existence of serious structural mismatches in the areas of social protection and labor force;
- The scarcity of knowledge held by the formers of the economic policies, both at the macro and micro-economical levels.
- The economic thinking is divided into embracing two different opinions regarding the means of passing to the **market economy**: the so-called **shock therapy**, and the **gradual transition**.

The shock therapy brings forth its own disadvantages:

- It diminishes the time factor, the cold existence of the gap between the moment of the institutional reform and the

moment of the adjustment of the micro-economic sector to the institutional changes;

- It neglects the national feature of the economies in transition;
- It totally disregards some events pointing at the changes in the international climate (the disappearance of the URSS, the breaking-up of the CAER, the national-separatist movements);
- Its fundamental thesis - modifying the institutional system would automatically bring radical changes in the society and the economy's structure, behavior and function – is false.

In Romania, as well as in other former communist countries, due to the above mentioned conditions, the concept of gradual therapy, according to which the best transition strategy is combining the stabilizing policies (short-term policies) with those that promote the reforms and the reorganization (long-term policies) has been gradually developed. Today, when in Romania the management buy-out process has not been accomplished yet, most authorized opinions state that it has proved to be a wrong solution, which has excessively delayed the reform.

Ignoring the management buy-out process, the main components of the transformation process into market self-adjusting mechanisms, were:

- The creation of the market institutions and the organizational structures needed for their well-functioning: stock exchanges, banking system;
- The liberalization of prices and their evolution which was mostly determined by the demand-offer ratio;
- The creation of the main components of the market: the labor market, the goods and the services market and the financial market.

The management buy-out is a fundamental condition to meeting the demand of turning the structure of economic agents and of adjusting their behavior to the self-adjusting mechanism of the economic system. The management buy-out is not a goal per se, but it is the basic means by which the competitive structures of the environment of the market economy are created. It implies two major goals: the development of the private propriety and the building-up of organizational structures that would create and consolidate the competitive environment, as well as ensure the conditions for raising the business profitability.

The following analysis will briefly revise the way in which the company - subject to our case in point has adapted itself to this process of transition to the market economy.

### **3. Case study – S.C. ALCOM S.A.**

The “ALCOM” S.A. Company has been founded on the former structure of the Wholesale Trade Company (I.C.R.A.), being a Romanian legal person that operates according to the laws of the country, legally organized as a share company, with business quarters in the city of Cluj-Napoca.

In its first years of life, S.C. “ALCOM” S.A.Cluj functioned as a company with entirely state-held capital, carrying on the main activity of its predecessor (I.C.R.A.), the queue handling and the distribution of alimentary goods to its customers; these operations were carried out so as to meet the customers’ demands or according to the assignments and decisions made by its board. Afterwards, following the creation of the two types of funds, The Fund of State Propriety (FPS) and The Fund of Private Propriety (FPP), the company’s capital was divided 70% to the F.P.S., namely to the state capital, and 30% towards the population in propriety certificates, handled by the F.P.P. Thus legally organized, the company functioned until 1992, with the General Shareholders Assembly as its board. The General Shareholders Assembly was not strongly motivated in taking decisions that should point at a real development of the company mainly because it consisted of representatives of the F.P.S., of the F.P.P. and of the employees, being a heterogeneous board from every point of view (business interests, professional training and involvement).

In 1993, the Company’s employees created a non-profit company, a legal person whose only purpose was to buy the shares held by F.P.S. and F.P.P., therefore the management buy-out of the “ALCOM” S.A.Cluj Company, renamed “ALCOM” P.A.S. Cluj (Employees Action Program). The board of “ALCOM” P.A.S. Cluj negotiated the buy-out of all the “ALCOM” S.A.Cluj shares for the employees with the two Funds, and got the deal.

In 1994 there the share buy-sell contracts were signed; thus, the entire joint stock of 991,8 millions lei, divided in 9918 shares of 100.000/ share face value, entered the private propriety of the employees, and the “ALCOM” S.A.Cluj Company became a company with entirely private capital.

- The activity of lab analysis for all the products commercialized by the company as well as for other companies;
- The activity of getting together encasements, their reworking and capitalization through restitution and through selling to tierces;
- The activity of renting available camp sites to tierce legal persons in order to judiciously administrate the existing camp sites;
- The activity of maintenance and repair (by their own personnel) of en-gross camp sites, of their own shops, their own means of auto transport, their cargo handling appliances, of the machines, aggregates, apparatus, installations.

The “ALCOM” Company functioned according to the laws no. 15/1990, 31/1990 and to the Company’s Order - approved by the General Shareholders Assembly, within the space of goods camp sites, which add up to over 30.000 square meters, and which are adequately prepared for the mechanized handling of good where thousands of commercial companies used to get their supplies and where 10.000 – 12.000 bills, more than 2.000 taking – ins, more than 10.000 transfers to its own en – detail shops were operated, by using more than 60 transportation vehicles.

As the company’s logical diagram / organization chart shown in the Annex no. 1 points out, the supreme collective organism that makes the company’s decisions is the Shareholders General Assembly. The Administration Board of S.C. ALCOM S.R.L. is made up of 5 members, appointed by G.S.A. for a period of 4 years. While dealing with tierces the company is represented by the president of the Board who is also the General Director / Manager and who, together with his administrative directors operates the company’s management.

**The Commercial Department** is made up of two commercial departments, one for the en-gross activities and a commercial office for the en-detail activity, this being the engine of the company, taking care of both supplying the goods from various providers, thus concluding economic contracts which they monitor, they supervise the delivery of these products to their own chain of shops and take care of the prompt customer demands brought forth by the salesmen.

According to art. 6 of the company's statute, the company's main object of activity refers to commercial deeds and commercial activities that follow the legal stipulations of the Romanian Commerce Book in force and the terms of the other regulations on the company's activities, terms agreed on by its shareholders.

The company's main activity involves traditional commerce, the en-gross type, with food and other products. Immediately after its buy-out, a chain of company-owned en-detail stores that have gradually counted 33 units was created.

With more than 30 years experience in the field, the company has accomplished its main goal, mainly by developing the following activities:

- Conclude mutually beneficial transactions with providers, producers or distributors of food and different types of non-food products.
- Conclude mutually beneficial transactions with the users – the company has signed more than 600 transactions with various customers, legal persons from Cluj County and the nearby counties.
- Regularly supply its own store houses and stores with a great variety of food products and food components.
- Organize the management of the products' qualitative and quantitative taking-over.
- Provide the stock supplies.
- The efficient management of the goods transportation while stocking and distributing them.
- Coordinating the activities of supplying the storehouses and the regional stores and managing the expenses involved.
- Obeying the legal terms while organizing and managing the operative evidence, the accounting handling, handling the analytic and synthetic accounting, efficient handling of the legal documents and of the operations generated by each activity.
- The efficient management of the camp sites.
- The activity of roasting the green coffee and of pre-packing the roasted coffee.

- The activity of pre-packing a series of products delivered in bulk by their producers.

By the implementation of the already exposed organizational structure, by making use of the logistic data base and especially by adopting a strategic management, the company that we have monitored / analyzed, as emphasized by Table no. 1.1. registered between 1999 – 2000 an upwards evolution of both its rate of turnover and of its profit earning capacity indicators, although it has continuously been threatened by keen competition in the field. The study sighted out a total of 40 Romanian companies which had a similar start and status in 1990, a total of 37 having a different, downwards course.

**Table 1.1. Sales Evolution at National Level and at S.C. ALCOM S.A.**

Years	National Economy			S.C. ALCOM S.A.	
	Inflation Indicators	Whole sale food goods – billion Lei (current prices)	Evolution Indices(%)	Sales – Billion Lei (current prices)	Sales Evolution Indices
0	1	2	3	4	5
1993	395,5	666,6	100,0	1,204	100,0
1994	161,7	1083,2	100,5	2,351	120,76

*Source: The statistical annual of Romania 1991 – 2004*

Having in view the conditions of the nowadays market economy competition becomes an objective necessity, it becomes one of the most important rules of the market strategies, stimulating the need to maximize, diversify and improve the quality of the goods offer in order to align it to the market standards, namely to the customers' demands.

The transition period in Romania – transition which we have summarized in the opening part of this paperwork – marked an uncontrolled use of the unfair competition, of the underground economy, phenomena widely generated by the activity of a series of economic agents who constantly broke the terms of the legislation in force. The legislation in every field has been gradually modified in order to keep the pace with the demands of the free market.

The fiscal legislation has met with multiple and repeated changes itself. Therefore, whether the period before 1989 considered it important just because of the tax rate that affected the goods sales and established a different percent for each group of products, beginning with the 90's the tax rate on profit was introduced, initially demanding a totally unrealistic 42% / percent. This percent has eventually decreased in time to a 39%, then to a 25%, to ultimately come to a 16%, as a consequence of the amendment of the rules of the Fiscal Book this year. Beginning with 1993 the new element of the economic market appeared in the shape of the VAT (value added tax) which has been standardized for most of the products or services to a quote of 22%. The food tax equaled a rate of 11% for a while, a tax rate of 9% being applied to the so-called basic food products. During the last 6 years a 19% tax rate has been applied / demanded.

Although Alcom S.A. has tried to promote and enforce by its owners' associations and through the Romanian Department of Commerce certain law trends meant to stimulate a faster development in the sales sphere where it operates, in order to improve it and make it ready for the great competition caused and run by the international commercial concerns ( Metro, Billa, Selgros, Auchan, Aldi, etc) and which, immediately after 1990 have shown a particular interest for the Romanian market, attempts that have finally failed.

Under the given circumstances, the company management focused on the continuous evolution of the market and on the legislation amendments, trying to dwell on activities, products or departments which have proved to register a plus / a growth of their profitability level, by making an effort to choose strategic alternatives that should provide the company competitive advantages.

The excessive revenue legislation, the evolution of the inflation which during 1991 – 1993 registered a percentage of 322.8, 299.2, 395.5, and 251.4, in 1997 have led to a decapitalization of the company. This period registered a growth of the bank credit up to a level of 200% even during the years in which the inflation went under the already mentioned barriers, fact that cost the company unforeseen losses. In spite of these rough conditions S.C. Alcom S.A. has managed to achieve profitability. As far as its activities are

concerned the company has accomplished its objectives and reinvesting the dividends of its stockholders it managed to pay off the installments stated by the buy – sale agreements on the already mentioned shares.

Rid of these contractual terms, here included the clauses regarding the main activity of the company and the need to keep all its employees up to the date of the final payment of the shares, the company which makes the object of the present paperwork implemented a different strategy: realizing its impossibility to compete with the chain of international stores, it has gradually reduced its activity of commercializing food products in the favor of producing goods (spice production, poultry, chicken breeding).

It has also had in view the revamping of its assets and their exploitation by renting them or by applying certain policies / strategies of association. While giving up certain traditional activities the company oriented itself to new activities, with a greater potential, such as civil building and real estate business.

Taking advantages of the legislative stipulations regarding the micro-corporations that should not pay any taxes on their profit and whose tax rate equals 3% (from a previous 1.5%) the company divided itself into 11 new commercial companies, each considered a micro-enterprise, each administrating just one asset of the initial company, each understood as an independent profit gathering center.

The need to adjust itself to the demands of the European Union has gradually turned the production activities into a costly business. First, the necessity to get and use a computer program that should allow a daily evaluation of the company stock became urgent. Secondly, the company had to draw a new project on packing its products so that the wrapping should now provide information on the bar code for each product, the cost of which not being easily swallowed by the amount of the whole manufacturing / production process.

#### **4. Conclusion**

Aiming not only at its survival but also at its adjustment to the demands of the market economy S.C. Alcom S.A. has been forced to adopt a series of strategic decision.

We consider the following to have had an enormous impact on the future development of the company: the company's management buy-out, the creation of its own chain of en-detail stores, the development of a series of profitable activities, the change of the company's traditional main activity into a new, required activity, the division of the company into 11 micro-

enterprises and other strategic decisions regarding the efficient management of the company's assets, managerial efforts that followed the requirements of Romania's integration into the European Union.

## **Abstract**

*In the centre of this paper is the analysis of the financial superstructure, namely to study how and in what extent the financial structures developed by political, economical and financial factors have an influence on the economic growth of a national economy/region. In the last two decades Europe has experienced a significant expansion of financial markets. The international comparative analysis of the bank oriented- and market based financial structures is in search of the explanation of the shift towards the market-based financial structure and the changing role of the relationship-based and arm's- length financing. In the focus of cross-country comparison are primarily the EU countries, especially the new EU member states, where time series analysis can emphasize the relationship between financial structure changes and economic growth.*

**Keywords:** *financial structure; financial intermediation; financial markets; banking*

## **1. Introduction**

“One of the most important problems in the field of finance, if not the single most important one, almost everyone would agree, is the effect that financial structure and development have on economic growth” Goldsmith [1969]

My study is divided into three parts. In the first part, I give an overview of the major factors affecting financial structures, and the evolution of the various financial architectures characteristic of the individual countries. The second chapter is the comparative analysis of market-based vs. bank-based systems and relationship-based vs. arm's length financing systems. In the third part, I take a closer look at the financial structure indexes (size, activity, efficiency) characteristic of certain countries / groups of countries – mainly the Anglo-Saxon countries and the old and new EU member states – during the period between 1997 and 2003. These indexes are suitable for examining trends of change in the relative ratio of banks and markets, as well as the effects on economic development and growth.

## **2. History of the financial structure's evolution**

When examining financial superstructures, we can differentiate between two basic types: bank-based and market-based structures. In a bank-based financial structure, the banks have an intermediary role, collecting deposits and providing loans primarily to the corporate sector. In collecting deposits, they can largely rely on households, as their willingness to take risks is low, and they mostly prefer bank deposits to the various securities. The asset side, on the other hand, is dominated by corporate loans, thanks to the fact that funds acquired from banks is an almost exclusive, and by all means primary means of acquiring external funds. Market financing (equity or bond issues) is only supplementary. The above-mentioned structure is typical mostly of Germany, France and the majority of EMU member states (the Netherlands can be mentioned as an exception), as well as Japan. The other group of countries is characterized by the market-based system, where, due to the highly-developed securities market, businesses give preference to corporate bond or equity issues to funds acquired from banks. For this, however, is only possible if households are more willing to make savings, and give preference to the more risky market assets over bank deposits that grant a fixed return. A small part of household savings appears on the market directly, whereas the larger part appears through institutional investors. Accordingly, the dominance of these institutions compared to banks is

detectable on the market. The market-based structure is typical of the USA and England.

Most publications (e.g. Asli Demirguc-Kunt and Ross Levine [2002]) lead to the conclusion that, whereas the degree of development of the financial system has a profound influence on economic results and economic success, the dominance of one or the other financial structure is of lesser importance in this respect. No close connection can be pointed out between the dominance of any type and the success of the economy. The publications suggest that decision-makers should pay attention to the legal and regulatory environment and the reforms that may be necessary in that area, rather than to the prevalence of market-based or bank-based structures. It can be observed, however, that the financial systems of richer countries are much more developed, and therefore the stock exchanges of these countries are far more active and efficient as compared to banks. When examining the legal regulatory environment, the general conclusion can be drawn that the financial systems of countries where shareholders' rights are strongly defended, accounting regulations are well-structured, less emphasis is put on the protection of deposit holders, and the level of corruption is lower, are usually more advanced. On the other hand, countries characterized by weaker protection of shareholders' and loan provider's rights, low-level accounting regulations, high corruption, high inflation and restrictive banking regulations usually have less developed financial systems.

Many economists have studied the connection between financial development (well-functioning financial markets and intermediaries) and growth, leading to the conclusion that the high level of financial development has a strong positive effect on economic growth. The primary function of financial systems (financial markets and intermediaries) is to forward funds from the savers to the market players, who have productive investment opportunities. This basic function can be split up into three partial functions: the mobilization of savings, the acquisition of information and risk management. By performing these functions, financial systems increase both the quantity and quality of real investment, and thus they also increase general welfare. Financial systems can influence economic growth through three different channels. First, the commissions of financial services motivate the mobilization of the savings of small market players. The financial system can achieve capital and productivity increase through better efficiency, and it contributes to economic growth by cutting the liquidity risk of corporations. Second, better analysis and monitoring by loan providers leads to the more efficient distribution of resources. Third, the improvement of risk sharing aids the launching of innovative projects through the increase of the saving ratio.

Most researchers draw the conclusion that financial intermediaries and financial markets are complementary to each other in providing financial services. Both market-based and bank-based systems have comparative advantages. Financial markets are better at financing new technologies and projects where there is much disagreement concerning the issue of corporate financing, whereas banks are more efficient in handling the conflicts between lender and debtor (moral hazard).

### **3. Relationship lending versus arm's length financing**

Based on the events of the last 20 years, a clear shift towards market-based structures can be observed. As a result of globalization, deregulation and technological development, the size of efficient operation has grown significantly. Disintermediation and the securitization had a negative effect on the profitability of banks, and entailed the necessity to lay off superfluous capacities. Traditional lines of business proved insufficient to maintain profitability, therefore it became necessary to provide supplementary banking services. Since the 1980s, the investment products division has gained increasing importance as part of the banks' core activities, and contributed to their increasing efficiency. Most banks recognized that it is more worthwhile to keep their clients by making investment products available than to lose their deposits. They considered it much more important that the disintermediation process slows down greatly if banks are able to meet the demands of their clients as regards their financial services. In the mid 1990s, numerous studies showed that client retention depends directly on the number of products and services offered by the bank. Gackle [1994].

The market-based and bank-based intermediary systems are difficult to mark off for several reasons. In countries where the structure is traditionally bank-based, like Germany and Japan, there is a stable and long-term relationship between bank and corporation. This is called relationship-based financing. In German banks, the investment division has acquired an important role alongside traditional banking, and now we can speak about the system of powerful universal banks. Through their investment banking activities, the banks can monitor the way corporations enter the capital market. Beyond the loan provider's position, the regulatory environment also makes it possible for banks to hold stakes in corporations. Japanese banks own 20% of corporate shares, whereas German banks have a package of cca. 10%. The same ratio is around 2% in the United States.

**Table 1 Indicators of financial development in 1980 and 2000**

Country	Bank Loan to Private Sector		Stock Market Capitalization	
	1980	2000	1980	2000

*Source: ECB (2003) Rajan and Zingales*

In relationship-based financing, the financier (who can be an owner, a sole or primary creditor, a supplier or a customer) makes an attempt to ensure the return on investment by establishing a certain degree of monopoly at the financed company. The lack of regulation and system transparency means that other players have only limited access to the market, and the cost of entering the market is significant. In “arm’s-length” financing, however, the financier is protected mainly or exclusively by an explicit contract. In the relationship-based system, the bank has a close relationship with the financed company either because of their past contacts or because of its role as a stakeholder. Therefore, beyond the loan applicant’s current liquidity, the bank also inspects its long-term solvency, as well as numerous other factors not mentioned in the contract that help the bank enforce repayment. The current interest rate is negotiable, and is not necessarily in line with the extent of the project’s actual risk. In the case of arm’s-length financing, the loan applicant can choose from a wide range of creditors, thanks to the accessibility of relevant financial information. The loan contract is concluded for a specified period, the interest rate is competitive, and in line with the risk factor and period of the loan. As the relationship-based system is characterized by the lack of competition, transparency and publicity, the

decision-making involves no realistic price signals. As opposed to arm's-length financing, where the loan providers are in competition with each other, and make independent assessments of the project cost, the cost of the loan in the relationship-based system depends on the negotiations between the loan provider and the borrower.

There is no doubt some overlap between bank-based/market-based and relationship-based/arm's length approaches when it comes to the classification of structures / systems of financing. The bank-based structure is primarily, but not exclusively, characterized by the relationship-based system of financing. Venture capital financing is typically relationship-based, despite the fact that it is not a typical banking activity, and can be seen mostly in market-based countries. Similarly, the client's diverse banking relations lead to loss of strength for the individual banks, and point to the formation of a system that shares quite a few features of the arm's-length system. R.G. Rajan, L. Zingales in: ECB [2003]

#### **4. Cross-country financial structure index comparison**

For the comparison of financial structures between countries, I used the indexes as in Demirgüç-Kunt and Levine (2002). The authors performed a comparative analysis involving 130 countries using the 1997 data. With the help of these data, they classified the countries by the relative development of markets and banks (size, activity and efficiency) as market-based, bank-based and undeveloped financial structures (the latter term means that both banks and markets are developed below the average level of the examined countries).

For lack of data, the study does not include the new member states that joined the EU in 2004. The database of the characteristics of the individual countries' financial structures already contains the relevant country data for the period 1997-2003<sup>1</sup>. At the comparative analysis of the financial structure indexes of the different groups of countries, I was interested in whether the financial structure of the new member states (whose growth rate is higher than that of the EU-15) has become similar to that of the old member states, and whether it shifted towards the market-based structure during the seven-year period.

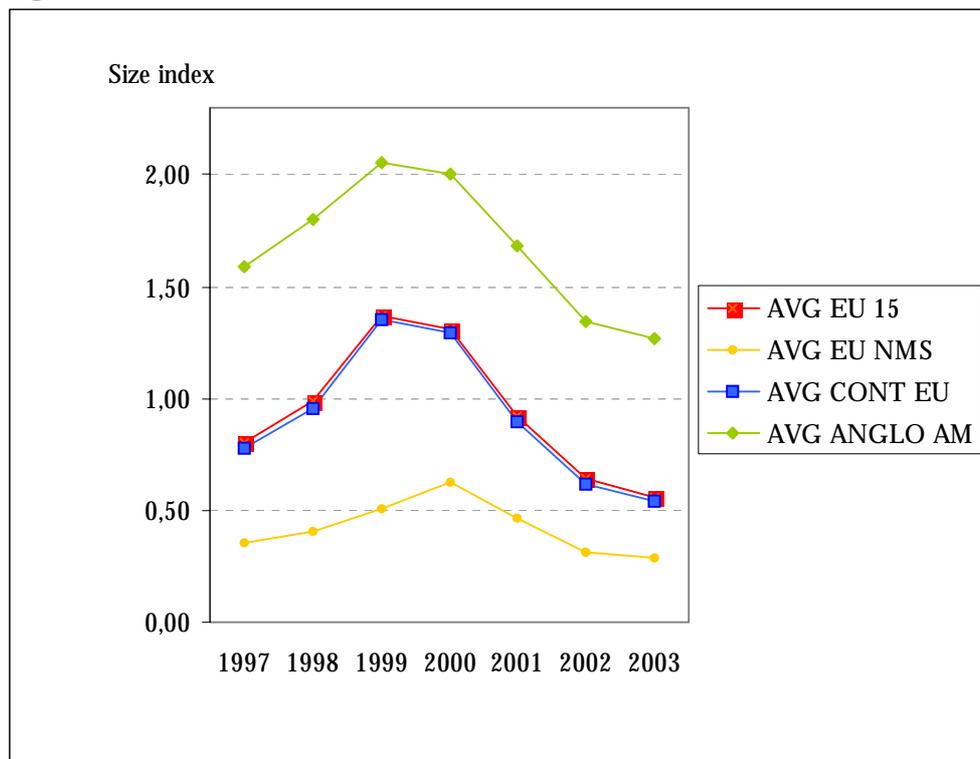

I examined the relative size of banks and the stock market with the capitalization vs. banks indicator, which is the quotient of stock market capitalization and the domestic assets of deposit money banks. To be more precise, it equals stock market capitalization/GDP divided by domestic assets

---

<sup>1</sup> The World Bank Group: Financial structure and economic development database

of deposit money banks/GDP. The growth of the resulting indicator shows the relative increase of market capitalization as compared to the size of banks. The examined groups of countries were the following: old EU member states (EU 15), new member states (NMS), Anglo-Saxon countries (United Kingdom and United States), and “continental Europe”, i.e. the old member states without the United Kingdom. The chart shows the average index values of the different groups of countries in the given period. Up to 1999 – or up to 2000 for the new member states -, a clear shift towards the growth of the market at the expense of banks is detectable, fitting into a 20-year trend. In the periods 1999-2003 and 2000-2003, however, the trend clearly turned, and the relative size of banks grew at the expense of markets.

**Figure 1 Financial structure size index**

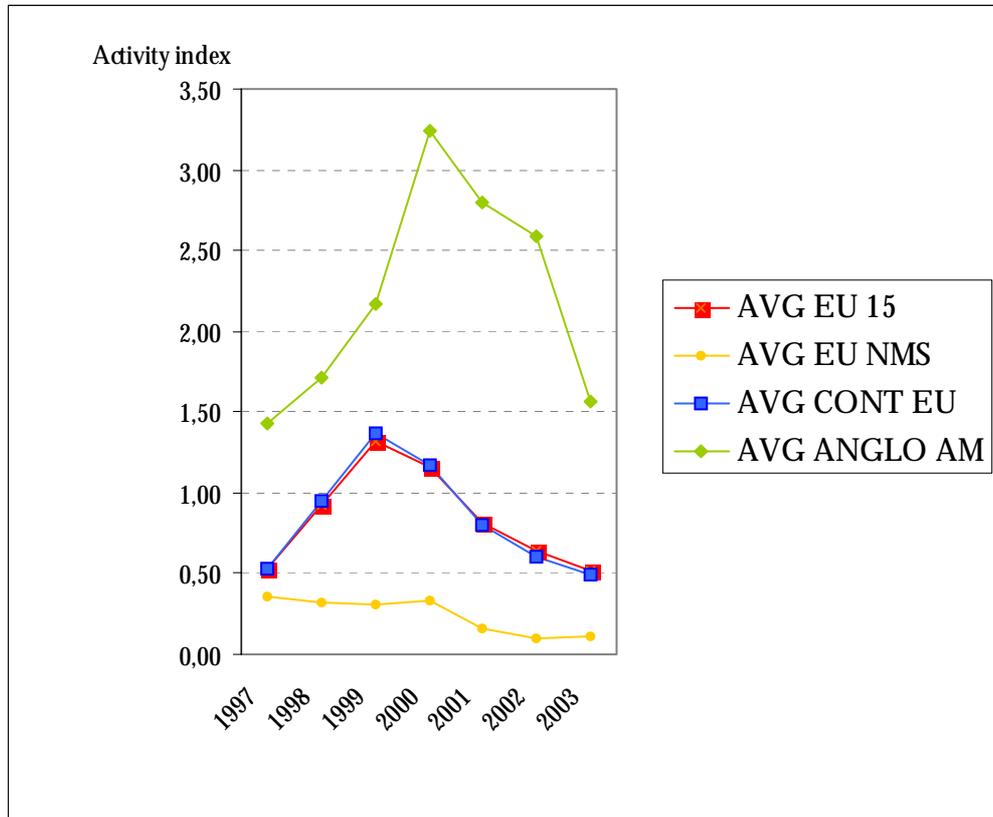

*Source: Author's calculation*

I interpreted the relative activity of stock markets and banks as the quotient of the stock market indicator ‘total value traded/GDP’ and the bank indicator ‘claims of deposit money banks on private sector/GDP’. The rise of the resulting indicator shows the increasing activity of the stock market as compared to the banks. In Anglo-Saxon countries, this phenomenon can be observed up to 2000, whereas in old EU member states / countries with fundamentally bank-based financial structures it lasted till 1999. The

indicator started to fall after this in the above-mentioned groups of countries, whereas in new member states it was on the fall almost throughout the examined period.

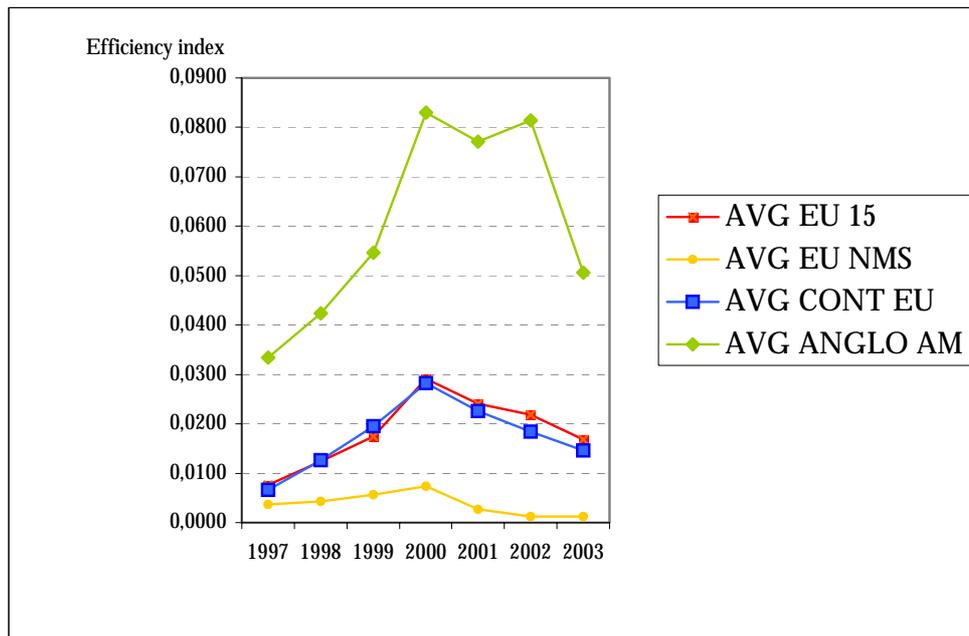

**Figure 2 Financial structure activity index**

*Source: Author's calculation*

The efficiency indicator is constituted by the product of the 'total value traded/GDP' and the 'net interest margin/total asset' indicators. The rise of the resulting indicators shows the increasing relative weight/efficiency of the market-based structure, as the increase of net interest margin is indicative of the decreasing efficiency of banks, and thus implicitly indicative of the growing relative efficiency of markets. Drawing a chart of the average indexes of the different groups of countries as a function of time, a clear growth in the relative efficiency of markets can be observed up to 2000. After that, a decreasing trend can be seen in both old and new EU member states, which is strongly characteristic of Anglo-Saxon countries only after 2002.

**Figure 3 Financial structure efficiency index**

*Source: Author's calculation*

Obviously, quite a few factors must be taken into consideration for the assessment of the indexes. Naturally, the fall of equity prices must have had a great influence on relative size, activity and efficiency. Earlier studies pointed out that in higher income countries, the activity and efficiency of domestic stock markets grows in comparison with the activity and efficiency of domestic banks. The higher growth of new EU member states as compared to the old member states did not result in a category rise in the World Bank's classification (low income, lower middle income, upper middle income, high income countries) On the basis of the used financial structure indexes, the rise of the activity and efficiency of domestic stock markets as compared to the activity and efficiency of domestic banks is not detectable during the whole period. Up to 2000 relative activity almost stagnated and efficiency was on the increase, whereas after 2000 the values of both indicators fell. However, considering the relative activity and efficiency index of the former and the new member states, there is a clear phenomenon of convergence. The financial structure of the new member states has become similar to that of the old member states.

## 5. Conclusion

The comparative analysis of bank-based and market-based financial structures can be performed from numerous aspects. The relationship lending/arm's length financing approach enables the more thorough study of the above-mentioned categories. The indexes used for describing the financial structures of the different groups of countries are suitable for analyzing the relative size, activity and efficiency of markets and banks. Based on the trend of the last 20 years, which shows a shift towards market-based financial structures, it can be observed that the relative weight of markets was falling as compared to banks in the years after 2000. However, considering the old and the new EU member states there is a convergence of relative activity and efficiency of markets versus banks.

## **Abstract**

*There are two main objects of this paper. The first object is to compare the most important theories and opinions about competition, monopoly and antimonopoly policy. The second object is to summarize some monopoly regulation of this economics theories. All these theories are subdivided into five parts started from the oldest time, e. g. from Aristotle, through mercantilism, early capitalism, theories of A. Smith to the classical Ricardian theories. There is discussed the competition and the origin of the first framework of anti-trust legislation at the break of the 19<sup>th</sup> and 20<sup>th</sup> centuries, the Karl Marx's and his followers' theories, the origin of imperfect competition and the system of neoliberal politics. This project was financially supported by the Internal Grant System of Silesian University, IGS SU Nr.15/2005.*

**Keywords:** *competition; monopoly; antimonopoly; regulation*

## **1. Introduction**

The main aim of this paper is to summarize and compare the attitudes towards imperfect competition, special towards monopoly and monopoly regulation of some economics theories. It stands to reason that the attitudes of several theories coherent with monopoly and antimonopoly policy were very different during the process of evolution. Above all the evolution of the last century was focused on the theory of dynamic competition. It was made out that monopoly is also limited by the process of making prices. These findings were the sources of new state regulations activities. It is the point, why to analyze the present situation of monopoly regulation and try to find a new arrangement which will make whole economics more competitive.

## **2. The oldest theories of monopoly**

It generally known, that the first man, who wrote about monopoly, was Aristotle. He has introduced a monopoly of marketable goods. There was a man in Sicily who used a sum of money deposited with him to buy up all the iron from the iron foundries, and afterwards when the dealers came from the trading-centres he was the only seller, though he did not greatly raise the price, but all the same he made a profit of a hundred talents on his capital (Aristotle, Politics, 1997, p. 57). It seems to be clear there were a discussion about monopoly in Antique time. The Greece word has two parts – „mono“means one and „polein“ means to sell.

The word monopoly is derived from Greek words meaning one seller. If one company is the only manufacturer of a product, that company has a monopoly. It is able to set its own quality standards and establish selling prices. It can also control middlemen, such as wholesalers and truckers. This does not mean that the monopolist will set the highest possible price for his goods. Market demand will decrease as prices rise. Therefore, the monopolist must set prices that the market will bear in order to make the highest possible profit. The prices will normally be far in excess of actual manufacturing costs and above a normal return on investment.

One-company monopolies are not common in the industries that manufacture products. However, we can have several single-firm monopolies in public utilities—companies that supply gas, electricity, and telephone and telegraph services. In spite of the breakup of the telephone and Telegraph Company, several regional telephone companies have virtual monopolies on service in their areas. In many nations these services are operated by

governments. Public transportation is normally a government monopoly as well. In some countries the government also owns the airlines.

Public utilities in the United States are usually investor-owned firms, similar to other corporations. Although they may be monopolies within their geographic areas, they are regulated by government. Thus the rates they can charge and the quality of service they offer are both subject to standards set by commissions or legislatures.

Adam Smith is writing about monopoly in his *An Inquiry into the Nature and Causes of the Wealth of Nations* like about an individual or a trading company. This company has the same effect as a secret in trade or manufactures. The monopolists, by keeping the market constantly understocked, by never fully supplying the effectual demand, sell their commodities much above the natural price, and raise their emoluments, whether they consist in wages or profit, greatly above their natural rate.

The price of monopoly is upon every occasion the highest which can be got. The natural price, or the price of free competition, on the contrary, is the lowest which can be taken, not upon every occasion, indeed, but for any considerable time together. The one is upon every occasion the highest which can be squeezed out of the buyers, or which, it is supposed, they will consent to give. The other is lowest which the sellers can commonly afford to take, and at the same time continue their business (Smith, A., *An Inquiry into the Nature and Causes of the Wealth of Nations*, 1976, p. 78).

In the accordance with was written above, wrote Smith that only state could stop the evolution of beginning monopoly. It helped to creative the origin of the first framework of anti-trust legislation.

As Smith was averse to restrains on international trade, so also he was opposed to those on domestic commerce and with colonies. In an age when restrictive preferences, privileges and state grants of monopoly were commonplace, he opposed them all. He also opposed private combinations of producers and workers, although, in a characteristic aside, he noted that there were more laws against combinations by the sellers of labour than against the similar practice by the merchants and manufacturers who employed them. He was not, however, entirely optimistic as to the possibility of contending with private combination. The impulse to such association was strong. In another deathless passage he observes that people of the same trade seldom meet together, even for merriment a diversion ends in a conspiracy against the public, or in some contrivance to raise prices. It is impossible, he says, to prevent such meetings, by any law which either could be executed, or would be consistent with liberty and justice. But though the law cannot hinder people

of the same trade from sometimes assembling together, it ought to do nothing to facilitate such assemblies, much less to render them necessary.

A century later, what Smith thought impossible would, after a fashion, be attempted in the United States, and the effort would continue for another hundred years. The Sherman Act and later legislation would forbid those of the same trade, even when gathered for merriment and diversion, from discussing, much less agreeing upon, prices. The prohibition would encounter not a few of the difficulties that Smith foresaw.

From Smith has come the commitment to competition as a principle in all capitalist societies – competition that is presumed to ensure optimal industrial performance. Considerably less influential has been Smith's warning as to the institution that, along with the state it might destroy competition. This was the state chartered company – the corporation. Where it had monopoly privileges, as in the colonial era, he was especially critical. But he also thought little of its efficiency. He would be appalled at a world where, as in the United States, a thousand corporations dominate the industrial, commercial and financial landscape and are controlled by their hired management, something Smith thought especially to be deplored. He says, that being the managers' father of other people's money than of their own, it cannot well be expected, that they should watch over it with the same anxious vigilance with which the partners in a private copartnership frequently watch over their own (Galbraith, *A History Of Economics*, 1987, p. 70).

### **3. First framework of antitrust law on the break of the 19<sup>th</sup> and 20<sup>th</sup> century**

On the break of the 19<sup>th</sup> and 20<sup>th</sup> century was necessary to start managing the regulation of the monopoly. The competition necessitated to its own destruction. The biggest companies tried to make the lowest prices as was possible and wanted to get exoteric market. So they tried to place another market with new products and services. Because of stronger and stronger competition these companies' costs were pushed lower. The levels of these costs were lower than the demand enabled.

Monopoly as defined above is better termed absolute monopoly and is the opposite of perfect competition. Perfect competition exists when there are large numbers of sellers and buyers of a homogeneous commodity. Each seller accounts for a relatively small share of the market; he cannot, therefore, influence the market price by varying his output, and he cannot increase his price above the market price because buyers would shift to other producers.

Although the concepts of absolute monopoly and perfect competition are useful for the purpose of illustrating economic principles, they seldom if ever occur in reality, where actual conditions range between the extremes of near monopoly and nearly perfect competition. In common usage the term monopoly is often employed to signify a state in which the degree of competition is restricted (but still present), whereas competition is used to denote a state in which competition is less restricted (but still not perfect). The precise dividing line between monopoly and competition used in this way is a question of definition. One generally accepted definition of monopoly is that embodied in British antimonopoly legislation, according to which a monopoly exists if at least one-third of the supply of a particular product or service is controlled by one enterprise or by several enterprises acting in concert with a view to restricting competition. Another name for a market in which a small number of sellers may each substantially affect prices and one another's behavior is oligopoly. Oligopolies often tend to act in concert or, when permitted by law, to form cartels with formal agreements on prices and supplies.

The arguments in favour of monopolies are largely concerned with efficiencies of scale in production, as for example the arguments that in large-scale, integrated operations, efficiency is raised and production costs are reduced; that by avoiding wasteful competition, monopolies can rationalize activities and eliminate excess capacity; that by providing a degree of future certainty, monopoly makes possible meaningful long-term planning and rational investment and development decisions. Against these are the arguments that, because of its power over the marketplace, the monopoly is likely to exploit the consumer by restricting production and variety and by charging higher prices in order to extract excess profits; and that, in fact, the lack of competition may well work against efficiency and lower production costs, with the result that the factors of production are not used in the most economical manner.

It has been one of the principles of free-enterprise economic philosophies that monopolies are, as a general rule, undesirable and need to be strictly controlled. This is not to say that the advantages of monopolistic supply in certain specific areas have not been recognized; it is rather a case of ensuring that monopolies are restricted to these areas and, at the same time, taking the necessary steps to prevent them from exploiting the consumer. A case in point is the natural-gas industry. It is clear that a situation in which individual consumers could obtain their gas supply from competing companies, through competing pipelines and distribution systems, would be a highly wasteful form of competition. The idea of a single supplier, therefore, makes sense in economic terms. In order to prevent the consumer from being

exploited, the monopoly's ability to control prices and supply needs to be restricted. This has generally been the view taken of firms operating as public utilities or in technical fields that invite a natural monopoly.

The owners of monopoly fixed the prices of their commodity with exclusive reference to the immediate net revenue which they can derive from it. The increased use of their commodity will before long recoup them for their preset loss. So it is clear that is wanted of calculations by which monopolists should govern their actions, on the supposition that he regards an increase of consumers' surplus as equally desirable to them. In case that the customer's surplus is added to the monopoly revenue derived from it, the sum of the two is the money measure of the net benefits accruing from the sale of the commodity to producers and consumers together. And if the monopolist regards a gain to the consumers as of equal importance with an equal gain to himself, his aim will be to produce just that amount of the commodity which will make this total benefit a maximum. The amount which the monopolist will offer for sale will be greater and the price at which he will sell it will be less if he is to any extent desirous to promote the interests of consumers (Marshall, Principles of Economics, 1961, p. 402). These conditions conveyed to the origin of the first antitrust legislation. The first most famous law led to curb concentrations of power and restrict trade and reduce economic competition were proposed by Sen. John Sherman.

Accordingly, most free-enterprise economic systems have an elaborate framework of laws and regulations aimed at controlling monopoly. The oldest and probably the most vigorous monopoly control legislation is represented in the U.S. antitrust laws. Consisting primarily of the Sherman and Clayton antitrust acts and the Celler-Kefauver Act, they are aimed at preventing agreements among suppliers, the effect of which would be to limit competition, and at preventing mergers between and acquisitions by and of firms, the result of which would be to lessen competition or to create a monopoly. The legislation provides for stiff civil and criminal penalties, and most administrations have tended to enforce the laws vigorously. In areas where monopoly is countenanced, such as in public utilities, a considerable degree of public control is exercised to ensure that monopoly power is not abused. In Great Britain the basic aims of the anti-monopoly legislation are similar to those of the United States, but much greater weight is given to the concept of the public interest. In the United States, any agreement or act that limits competition is regarded as undesirable, but in Great Britain and other west European countries such acts are accepted if they can be demonstrated to be in, or not to be against, the public interest. In general terms, the degree of monopoly tends to be relatively small in the United States; it is considerably more pronounced in Britain, France, and other parts of Europe, where among

operating monopolies are a large number of state-owned enterprises (Encyclopedia Britannica Online, <http://search.eb.com/eb/article?tocId=9067322>).

The Sherman Antitrust Act of 1890, which declare illegal all attempts to monopolize any part of trade or commerce in the U.S. initially used against trade unions, it was more widely enforced under press. Theodore Roosevelt. In 1914 Congress strengthened the act with the Clayton Antitrust Act and the formation of the Federal Trade Commission. In 1920 the U.S. Supreme Court relaxed antitrust regulations so that only “unreasonable” restraint of trade through acquisitions, mergers, and predatory pricing constituted a violation. For instance we can mention some others antitrust acts: The Clayton Antitrust Act of 1914 outlawed unfair price discrimination, interlocking directorates, and holding companies , as amended in 1936 by the Robinson-Patman Act, prohibits discrimination among customers through prices or other means; it also prohibits mergers or acquisitions whenever the effect may be to substantially lessen competition. A 1950 amendment to the Clayton act forbade a corporation to purchase another corporation's assets or stock, if doing so would reduce competition. Labour unions are also subject to antitrust laws (Encyclopedia Britannica Online, <http://search.eb.com/ebc/article?tocId=9378482>).

In the absence of competition, the supplier usually restricts output and increases price in order to maximize profits. The concept of pure monopoly is useful for theoretical discussion but is rarely encountered in actuality. In situations where having more than one supplier is inefficient (e.g., for electricity, gas, or water), economists refer to natural monopoly. For monopoly to exist there must be a barrier to the entry of competing firms. In the case of natural monopolies, the government creates that barrier. Either local government provides the service itself, or it awards a franchise to a private company and regulates it. In some cases the barrier is attributable to an effective patent. In other cases the barrier that eliminates competing firms is technological. Large-scale, integrated operations that increase efficiency and reduce production costs confer a benefit on firms that adopt them and may confer a benefit on consumers if the lower costs lead to lower product prices. In many cases the barrier is a result of anticompetitive behavior on the part of the firm. Most free-enterprise economies have adopted laws to protect consumers from the abuse of monopoly power. The U.S. antitrust laws is the oldest examples of this type of monopoly-control legislation; public-utility law is an outgrowth of the English common law as it pertains to natural monopolies. Antitrust law prohibits mergers and acquisitions that lessen competition. The question asked is whether consumers will benefit from increased efficiency or be penalized with a lower output and a higher price.

#### **4. Karl Marx and his followers**

Marx was unaware of the existence of monopoly in the British economy of his day. He treated monopolies not as essential elements of capitalism but rather as remnants of the feudal and mercantilist past which had to be abstracted from in order to attain the clearest possible view of the basic structure and tendencies of capitalism. It is true that, unlike the classicists, Marx fully recognized the powerful trend toward the concentration and centralization of capital inherent in a competitive economy. His vision of the future of capitalism certainly included new and purely capitalist forms of monopoly. But he never attempted to investigate what would at the time have been a hypothetical system characterized by the prevalence of large-scale enterprise and monopoly.

By accidental monopoly we mean a monopoly which a buyer or seller acquires through an accidental state of supply and demand. The assumption that the commodities of the various spheres of production are sold at their value merely implies, of course, that their value is the centre of gravity around which their prices fluctuate, and their continual rises and drops tend to equalize. There is also the market value—of which later—to be distinguished from the individual value of particular commodities produced by different producers. The individual value of some of these commodities will be below their market-value (that is, less labour-time is required for their production than expressed in the market-value) while that of others will exceed the market-value. On the one hand, market-value is to be viewed as the average value of commodities produced in a single sphere, and, on the other, as the individual value of the commodities produced under average conditions of their respective sphere and forming the bulk of the products of that sphere. It is only in extraordinary combinations that commodities produced under the worst, or the most favourable, conditions regulate the market-value, which, in turn, forms the centre of fluctuation for market-prices. The latter, however, are the same for commodities of the same kind. If the ordinary demand is satisfied by the supply of commodities of average value hence of a value midway between the two extremes, then the commodities whose individual value is below the market-value realize an extra surplus-value, or surplus-profit, while those, whose individual value exceeds the market-value, are unable to realize a portion of the surplus-value contained in them (Marx, K., *Capital Vol III.*, London, UK: ElecBook, 2001, <http://site.ebrary.com/lib/oulu/Doc?id=2001686&page=235>). It does no good to say that the sale of commodities produced under the least favourable conditions proves that they

are required to satisfy the demand. If in the assumed case the price were higher than the average market-value, the demand would be smaller.

Finally, if equalisation of surplus-value into average profit meets with obstacles in the various spheres of production in the form of artificial or natural monopolies, and particularly monopoly in landed property, so that a monopoly price becomes possible, which rises above the price of production and above the value of the commodities affected by such a monopoly, then the limits imposed by the value of the commodities would not thereby be removed. The monopoly price of certain commodities would merely transfer a portion of the profit of the other commodity-producers to the commodities having the monopoly price. A local disturbance in the distribution of the surplus-value among the various spheres of production would indirectly take place, but it would leave the limit of this surplus-value itself unaltered. Should the commodity having the monopoly price enter into the necessary consumption of the labourer, it would increase the wage and thereby reduce the surplus-value, assuming the labourer receives the value of his labour-power as before. It could depress wages below the value of labour-power, but only to the extent that the former exceed the limit of their physical minimum. In this case the monopoly price would be paid by a deduction from real wages (i. e.. the quantity of use-values received by the labourer for the same quantity of labour) and from the profit of the other capitalists. The limits within which the monopoly price would affect the normal regulation of the prices of commodities would be firmly fixed and accurately calculable (Marx, K., *Capital Vol III.*, London, UK: ElecBook, 2001, <http://site.ebrary.com/lib/oulu/Doc?id=2001686&page=1153>).

Engels, in some of his own writings after Marx's death commented on the rapid growth of monopolies during the 1880s and 1890s, but he did not try to incorporate monopoly into the body of Marxian economic theory. The wholesale merchant, Engel, says quite correctly, that efforts of the syndicate are intended to create a monopoly for itself and to eliminate the wholesale trade entirely. Naturally prices will not be any lower for the retailer. If the motives were not to obtain for the factory and the syndicate the same benefits which accrue to the wholesale merchant, the whole movement would be without purpose (Hilferding, R., *Finance Capital*, London, 1981, p. 416).

The first who incorporate monopoly into the body of Marxian economic theory was Rudolf Hilferding in his important work, *Das Finanzkapital*, published in 1910. But for all his emphasis on monopoly, Hilferding did not treat it as a qualitatively new element in the capitalist economy; rather he saw it as effecting essentially quantitative modifications of the basic Marxian laws of capitalism. We must recognize that competition, which was the predominated form of market relations in nineteenth-century

Britain, has ceased to occupy that position, not only in Britain but everywhere else in the capitalist world (Baran A. P., Sweezy, M., *Monopoly Capital*, Suffolk, 1966, p. 416).

Rudolf Hilferding writes about protective tariff, which means a constriction of the economic territory, and hence an interference with the development of the productive forces, since it reduces the size of industrial plants, discourages specialization, and impedes, finally, that international division of labour which brings about a flow of capital into those branches of production for which a given country is best suited. This is all the more important in the case of the modern high protective tariff since the tariff rates are frequently fixed less of regard for the technical conditions of production which prevail in particular branches of production, than as the outcome of a political struggle for power among various industrial groups whose influence upon the state ultimately determines the tariff structure. The tariff is a brake upon the development of the productive forces and hence of industry. It means direct deprives industries which are capable of being cartelized of their monopoly of the domestic market, if that monopoly is not already assured by protected freight rates in the case of coal or by a natural monopoly in the case of German potash production (Hilferding, R., *Finance Capital*, London, 1981, p. 312).

## **5. Neoclassicism**

In the market for consumer's goods a relatively small number of sellers face a large number of buyers, so that the imperfection of competition tells in favour of the sellers. In the labour market the position is reversed. Thus the share of labour in total output is ground between the upper and the nether millstones of monopoly and monopsony. This account of the matter bears a close resemblance to the theory of Lexis, quoted by Engels in the preface to Volume III of *Capital*. He writes that the capitalist sellers, such as the producer of raw materials, the manufacturer, the wholesale dealer, the retail dealer, all make a profit on their transactions, each selling his product at a higher price than the purchase price, each adding a certain percentage to the price paid by him. The labourer alone is unable to raise the price of his commodity, he is compelled, by his oppressed condition, to sell his labour to the capitalist at a price corresponding to its cost of production, that is to say, or the means of his subsistence. Further he writes therefore that capitalist additions to the prices strike the labourer with full force and result in a transfer of a part of the value of the total produce to the capitalist class. Engels gives (though grudgingly) his approval to this formulation which amounts to the same thing as the Marxian theory of surplus-value. Lexis thus provides a bridge between Marx

and the later theory. For Marx's scheme under-capacity working is impossible and the limit to the output of any concern is set, not by the imperfection of the market, but by the capacity of capital. The post dated theories exposed many relatively minor defects in capitalism which Marx, concentrating on major issues, was content to ignore.

The theory is good enough for purposes of a general discussion of the nature of the system. Where outright monopoly rules, or where a group of commodities is produced by a few powerful firms, there is great scope for individual variations in policy, and it is hard to make any generalization at all as to what governs the margin of profit per unit of output.

All this makes a serious breach in the smooth surface of the orthodox theory of value, and it seems that economic science has not yet solved its first problem – what determines the price of a commodity?

In this first statement of the theory of value Marshall wrote, that the great central law of economic science is that producers, each governed under the sway of free competition by calculations of his own interest, will endeavour so to regulate the amount of any commodity which is produced for a given market, during a given period, that this amount shall be just capable on the average of finding purchasers at a remunerative price, a remunerative price being defined so as to allow for normal profits on capital. This statement may be taken to mean two quite different things. It may mean that each producer, governed by calculations of his own interest, endeavours to maximize the profit, at each moment, on his current rate of output, by balancing marginal cost against margin gain.

The other interpretation is that each producer endeavours to fix, not the price which maximizes his current profit, but the price which will be remunerative in the long run. This at first sight seems plausible, but it entirely begs the question of normal profits on which, as we have seen, academic economics fails to provide any theory which is relevant to the real world. Moreover, even if the question of normal profits were settled, it would still remain to inquire what level of utilization of equipment is normal in the long run. Generally speaking, the lower the level of utilization, good years with bad, the higher the gross margin required to bring in any given level of profits. But the higher the gross margin, other things equal, the lower the level of utilization, for given the expected fluctuations in demand, the amount of capital seeking employment in the industry is governed by the gross margin established in the market. And the amount of capital employed influences the average utilization per unit of capital. The three determinants, profit per unit of output, profit per unit of capital, and capital per unit of output, are all interdependent, and the whole analysis dissolves in a haze of doubt.

The Marxian theory might yield the explanation that the development of trade-union power has been just sufficiently rapid to prevent the rate of exploitation from rising with the productivity of labour, while the academic theory suggests that a secular rise in monopoly has been just offset by a relative fall in raw-materials prices. Both explanations are somewhat lame, and the mystery of the constant relative shares remains as a reproach to theoretical economics (Robinson, J., *An essay on Marxian economics*, New York, 1967, p. 81).

## **6. Ordoliberalism and dynamic theory of competition**

The determination of the value of the monopoly is a special problem, and in solving it we must not forget that in the normal circular flow no motive to form such a value exists, hence the gain is not to be related to any other magnitude. However all this may be, the monopolist can at any rate never say, that they make no profit because they ascribe an extremely high value to their monopoly.

In a discussing Lauderdale's theory of interest Böhm-Bawerk also comments upon the case in which a labor-saving and hence profit-yielding machine is monopolized. He emphasizes rightly that this machine will be so dear that no profit, or only the minimum which will just induce people to purchase or hire it, will be connected with its employment. Yet a profit is undoubtedly connected with its production, which is as permanent as the patent. It might be said that the monopoly position is for the monopolist something analogous to a productive factor. Imputation takes place with reference to the services of this quasi-factor of production just as with reference to other factors. The machine as such is not a source of surplus value, nor is its means of production, but the monopoly makes it possible to obtain a surplus value with the machine or its means of production. Obviously nothing is changed if we allow producer and user to coincide in one person. There would be a source of surplus value the existence of which would be explained by the theory of monopoly; there would also be a reason for the assignment of a return to monopolists; and finally the fact that neither imputation nor competition annihilates the return would be explained. However, such monopoly positions do not occur regularly and numerous enough for this explanation to be accepted, and moreover interest exists without them.

There are several designs for escaping market discipline, including that imposed by younger, more adaptable, more aggressive competitors. The first is a return to tariff protection. Faced with foreign competition, the great

industrial corporation seeks tariffs and also quotas that will release it from the pressure of market constraints. After ceremonial praise of the free market, the need for a worthy exception is urged. A revival of protectionist sentiment and legislation in the older industrial countries having already occurred in the present, it will do so to even greater degree in the future. Once protective tariffs were for infant industries, now they are for the old and putatively senile.

A second well-established design for dealing with competition is simply to take it over. This is the purpose of the international or multinational corporation. It has long been thought that the latter is an instrument of aggression, even imperialism, on the world stage. Far more important is its protective purpose, its profoundly important service as an escape from the constraints of the market.

Evading market discipline is increasingly apparent in a third design, this is for the older bureaucratically and intellectually more rigid enterprise to assign to firms in the newer industrial lands work that can no longer be performed competitively in the older countries.

Another and final recourse available to aging and inefficient private enterprises is to seek forthright intervention by the government. This, in practice, goes far beyond protection from foreign competition. In the United States the Reagan administration has repeatedly set aside its free market rhetoric to come to the rescue of failing banks and needful exporters and, at unprecedented costs, to protect farmers from the free market. Again there is first the speech on the eternal verities of free enterprise and then the case for the particular exception (Galbraith, J., K., *A History Of Economics*, London, 1987, p. 294).

We conclude that sunk costs, unlike fixed costs; can constitute a barrier to entry. In particular, we argue now that fixed costs need not have any detrimental welfare consequences, unless they also happen to be sunk. In an industry whose firms use only capital on wheels or winks, some or all of that capital may be fixed, but it is not sunk. This means that in the absence of other entry barriers, natural or artificial, an incumbent, even if he can threaten retaliation after entry, dare not offer profit-making opportunities to potential entrants because an entering firm can hit and run, gathering in the available profits and departing when the going gets rough. Such a situation fits our definition of a contestable market, that is, a market vulnerable to costlessly reversible entry, even when it is currently occupied by an oligopoly or a monopoly. The contestable market is a generalization of the case of pure competition, and it offers many of the same benefits. Even if it is run by a monopoly, a contestable market will yield only zero profits and offer inducements for the adoption of Ramsey-optimal prices; in addition, it will

enforce efficiency of production, the adoption of new improved techniques as they become available, and avoidance of cross subsidy in pricing .

This resolves the apparent contradiction between our conclusion that fixed costs of sufficient magnitude permit the incumbent to adopt entry preventing prices and the preceding assertion that, in themselves, they constitute no barrier to entry. The availability of sustainable prices does permit the incumbent to preclude entry. But he can do so only by offering the public the very same benefits that actual competition would otherwise have brought with it. With entry barriers, supernormal profits, inefficiencies, cross subsidies, and no optimal prices all become possible. But in a contestable market, which is perfectly consistent with the presence of fixed costs that are not sunk, matters change drastically, and government intervention can contribute far less, if anything, to the general welfare (Galbraith, J., K., *A History Of Economics*, London, 1987, p. 292).

## **7. Conclusion**

Finally, we come to a variety of artificial sources of unsustainability which result from special disadvantages imposed by public policy upon incumbents over entrants, either intentionally or unintentionally. Examples include regulatory rules on depreciation policy, which force prices for some periods to fall below the pertinent marginal costs; deliberate imposition of cross subsidies designed to benefit groups considered particularly meritorious, environmental regulations, if they are more severe for incumbents; and rules against price discrimination, which prevent adoption of sustainable Ramsey prices. Any of these measures, as we have seen, can lead to unsustainability. The way to deal with such artificial sources of unsustainability is fairly obvious. One simply avoids the measure that give rise to them. For one thing, incumbents and entrants should always be treated similarly in any cost-imposing rule. For example, internal cross subsidies, such as those for the elderly should be replaced either by direct government grants or by funds obtained from the imposition of a tax that falls on an equal basis on all firms in the industry.

## **Abstract**

*The period of transition from a totalitarian regime and a supercentralized economy to a democratic state with a social market economy has been and it still is marked with great difficulties and obstacles, both objective and subjective, still coping with a prolonged structural crisis. As far as the unemployment structure in Romania is concerned, we may notice the following features: The unemployment rates by sex had an interesting dynamics; The evolution of unemployment by residential average was relatively stable in the course of time. It had the highest intensity in the urban area. The analysis of the unemployment structure by age groups shows that young people of 25 are the most affected.*

**Keywords:** *transition, centralized economy, unemployment structure*

## 1. Introduction

In the countries with a consolidated market economy unemployment is regarded as a natural phenomenon which, if maintained within certain limits, may even bring about positive effects by fostering a competitive climate on the labour market; this is an objective element of any market economy, irrespective of its level of development.

It is important to know that unemployment cannot be eradicated; it can only be *improved* and brought to reasonable limits economically and socially.

In Romania, unemployment emerged with the transition to the market economy though the estimations of various authors<sup>1</sup> indicate rates of hidden unemployment reaching 4 – 5 % around the year 1989.

## 2. Unemployment in Romania after 1989

The economical regressions accompanied for a long time by the prevalence of passive politics, reactive of labour market, have generated the explosion and the perpetuation of unemployment, the beginning of long-term unemployment and the segmentation of labour market.

Because of all these, unemployment has been assimilated in the individuals' mentality and at the level of community quite heterogeneously and not always correctly and coherently, as follows<sup>2</sup>:

- As a *traumatic phenomenon* affecting the *individual*, his personality, the social relations; it may even lead to individual's marginalization;
- As *transitory*, with effects on the individual's professional evolution;
- As *privileged*, providing the individual with certain advantages derived from the combination of social security and the possibility to obtain some other income on the informal market (undeclared work).

Among the main *causes*<sup>3</sup> of unemployment in Romania, we would like to mention:

---

<sup>1</sup> Goga, P.A., Mărginean Ș., *Restructurare. Ocupare. Șomaj Restreucturing. Employment. Unemployment*, P.S.P. & Co SRL Bucharest 2001, pg. 123

<sup>2</sup> Pert, S., *Piața muncii în România [Labour Market in Romania]*, CIDE, Bucharest, 1994, pg. 112

- Continuous reduction of social production (which represented in 1999 about 60% of the production level registered in 1989) under the influence of the thorough restructuring processes in the real economy, the standards imposed by Romania's joining the EU as well as other serious errors in the elaboration and enforcement of policies at the macroeconomic level;
- Inexistence of an economic and social development strategy which should have represented the starting point in directing the future structures of employment;
- The difficult start of economy restructuring process and its adaptation to the market economic mechanisms;
- Permanent lowering of solvent demand and the aggregate demand which, not supported by active policies, the investments from the state and the economic agents, brings about the decrease of the activity in many economic units and the increase of unemployment, especially the technical unemployment;
- Almost complete lack of internal investments and the insufficient mobilization of foreign capital.

Internal investments are in they greatest part reduced drastically by the decline of the national economy, the insufficiency of accumulation as well as the perpetuation of a galloping inflation and the starting of a consumption psychosis at the level of population and the economic agents. As far as the mobilization of foreign investments is concerned, the essential elements are not constituted of the richness of resources of the factors of production, but the dimension of the internal market and the economic and political stability.

As the dimension of internal market depends on the solvent demand, we can see that foreign investors are still reluctant.

In Romania after 1989, due to the breaking-up of the traditional structures responsible for the production of raw materials, the reduction in the volume of production, the decrease of supply of goods and services and the reduction of demand for labour force, unemployment increased incredibly fast as the current state of economy was not able to provide with a real social security.

---

<sup>3</sup> Pert, S., the work cited, pg. 129

It is painful that the Romanian citizen once able to meet the basic requirements to support himself and his family finds, in the current social and economic circumstances, with astonishment, revolt and even desperation that he is no longer capable to do it.

Unknown officially until 1990, unemployment registered a boom in 1991 after the promulgation of the Law 1 / 1991 (at the end of the year 337, 440 unemployed people were already registered, which indicates an increase of 267 thousand persons as compared to February 1991), an unemployment rate of 3% respectively. In the period between 1991 and 1994, the evolution of unemployment was rapid, reaching a climax of 1, 223, 925 unemployed people (at the end of 1994). After 1994, it started to decrease slowly due to the beginning of a process of economic stimulation. From 1996 a new ascending trend began which reached at the end of 2000 the figure of 1,007,131 unemployed workers. From this year, the quota of unemployed workers began to lower again, only 659 thousand unemployed persons being registered in 2003 (see table 1.1 and figure 1.1). Not denying that this evolution which has been registered in the last three years is a direct consequence of economic stimulation, we appreciate that the reduction of unemployment rate as a trend is to be reflected in the increase in the quota of the newly employed people. Nevertheless, figures show that the quota of the unemployed people decreased much more as compared to the quota of the newly employed people. This reality leads us to the following conclusions: either the unemployed workers are no longer registered or they are working without a labour contract.

This evolution of unemployment was the result of the simultaneous action of numerous economic, demographic and social factors. Among these, the economic factors and especially the economic decline played the most important part as well as the reduction of the economic activity, in general, and the industrial activity, in particular.

All the same, the demographic factor is extremely important. Unemployment, as the result of a continuous balancing between the demand and supply of labour, has increased, on the one hand, by the compression of the first, and on the other hand, by the increase of the latter due to massive lay-offs of workers as well the entering on the labour market of secondary and higher education graduates and other categories of unemployed people respectively.

As mentioned above, the information sources regarding the labour market are represented by the administrative ones (M.M.S.S.S.F.)<sup>4</sup> and the

---

<sup>4</sup> Ministry of Labour, Social Security and Family

AMIGO inquiry to complete the first. As a result of using various criteria (the BIM criteria in the case of AMIGO inquiry and the criteria of lack of a place of work and the registration with the M.M.S.S.F. administrative sources), the following differences are emphasized.

In the analyses presented below, to dispose of information in a range as large as possible of characteristics, we shall use both sources and we shall, of course, mention both the source of information and the methods applied (B.I.M. and M.M.S.S.F.)

**Table 1. Quota of unemployed persons and the unemployment rate at the registered level and according to B.I.M.**

*Source: The statistical annual of Romania 1991 – 2004 and AMIGO 1996-2004, I.N.S.*

As we can notice from the Table1.1, there are some differences in the area covered by the “Unemployment rate” indicator registered with the employment agencies and the unemployment rate calculated according to B.I.M. methods of AMIGO. The specialists<sup>5</sup> explain the difference between the two series of data in the following manner: there are persons who, while registered as unemployed with the employment agencies, they work outside the legal framework.

<sup>5</sup> Pert, S., *Piața muncii în România [Labour Market in Romania]*, CIDE, Bucharest, 1994, pg. 132

As far as *the unemployment structure by sex* is concerned, until 1996 it could have been seen that the women's unemployment was higher.

**Figure 1. Evolution of the unemployed persons by sex in the period 1991 – 2003**

*Source: It was accomplished based on the information taken from the Statistical Annual of Romania for the years 1991 – 2004.*

Everywhere around the world, the level of education and vocational training of women is continually growing. Despite of all these, when the general employment decreases, the labour force represented by women goes through a faster and more intensive erosion than the one represented by men. The factors of such an evolution derive from the particularities of this type of labour force (involved in the process of demographical reproduction) but also of mentalities, behaviours of the economic agents or other economic reasons.

In most of the cases, the dissipation of the productive, creative and participating potential of women's labour force by unemployment is greater as compared to the men's, indicating effects both on the family life and in

providing the inter-generation with a demographic balance and training of future generations<sup>6</sup>.

In absolute terms, the unemployment level by sex had the dynamics shown in the Table 1.2.

In the period between 1992 and 1996, as an absolute unemployment term and rate (the Table 1, 2 and the Figure 1), the women's unemployment was constantly higher than the men's unemployment.

On this background of 1997, an extremely interesting and rather paradoxical trend emerged: *the decrease of women's unemployment* and the corresponding increase of men's unemployment.

**Table 2. Absolute and relative unemployment by sex (1992-2003)**

	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003

The causes of such a surprising unemployment reversal in the structure by sex are based on demographic, economic and psycho-social factors, their simultaneous action rendering difficult the precise quantification of the influence of each<sup>7</sup>.

Basically, we *appreciate* that it is the question of:

- Cutting down of women's labour supply and the corresponding increase of men's labour force. In the years following the year of 1997, according to the official sources, both the population employed and the women's unemployment were decreasing; moreover, the supply of men labor force increases as a result of lay-offs and reduction of activity on several economic branches (especially the

<sup>6</sup> Pert, S., *Piața muncii în România [Labour Market in Romania]*, CIDE, Bucharest, 1994, pg. 133

<sup>7</sup> Mihăescu, C., *Populație. Ocupare, Trecut, Prezent, Viitor [Population, Employment, Past, Present, Future]*, Economica Publishing House, Bucharest 2001, pg. 306

processing and mining industry); these were the branches where the population employed and later laid off was preponderantly represented by men.

- Development of clothing industry, garments and shoes, where the labour force is mostly represented by women;
- Women started entering in the occupational atypical structures) part-time jobs, authorized social services, etc. or the “underground” economy.

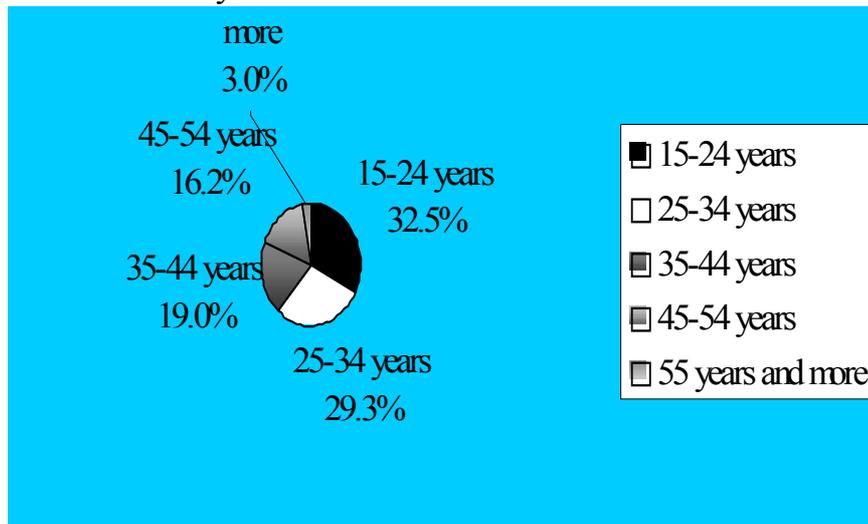

As far as the structure of unemployment *by residential environment is concerned*, the evolution was relatively stable in the course of years, the highest intensity being registered in the urban area where (according to the AMIGO data) the unemployment rate was, on average, 2,4 times higher than in the rural area.

The analysis of unemployment structure *by groups of age* shows that the young people under 25 are the most affected (Figure 2). The lack working places for the young people (though the labor legislation is stimulating for the employers to hire young people) remains one of the most serious and most difficult to solve economic and social problems of transition.

Another aspect to be mentioned is as follows: while a greater number of young people acquire the skills and qualifications required for the various trades, the number of working places does not increase accordingly. Young people who have recently completed a certain stage of education must compete on the labour market with other people with higher qualifications and longer work experience and thus are forced to accept positions of an inferior level, less paid or even enter in the circuit of unprotected labour (undeclared labour); this situation isolate them from society before allowing the to make the first steps in the professional and family life.

The next age group greatly affected by unemployment is the group 15 – 24 years, followed by the group 25 – 34 years which is the main category of population intended for industrial restructuring.

**Figure 2. Structure of category of age of the population unemployed as of the year of 2004.**

Source : Based on the data from “Labor Force in Romania. Employment and unemployment in 2004”, INS, 2005.

By examining the unemployment according to its *duration*, we come to the conclusion that in Romania, though the unemployment became apparent only at the beginning of year 1991, it remained permanent even chronic in only a few years, by the increase of *long – term unemployment*.

The long-term unemployment is the effect of an ever deeper economic and social crisis which has been inducing the reduction of employment and labour force supply.

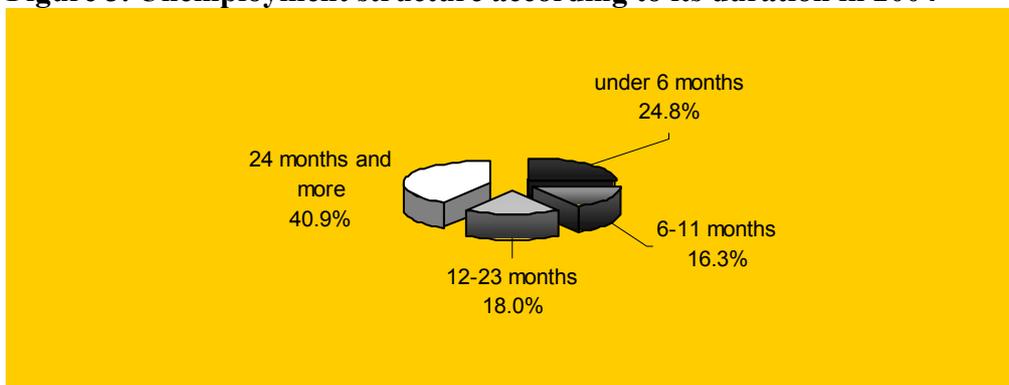

After 1992, it has been noticed that (according to the AMIGO inquiry) year by year, the average duration of unemployment shows increasing trends: from 16, 3 months in 1995 to 17, 9 months in 2001, to 21, 2 months in 2002 and 22, 4 months in 2004.

In 2004, more than the half of the total number of unemployed people (59, 9%) have been inactive for more than 1 year as compared to a percent of 43, 2% in 1999.

The categories of persons that could be most directly affected by the perspective of unemployment becoming chronic in our country are the workers over 50, the women, the young graduates and the individuals with a little level of qualification.

The structure of unemployment as of the end of 2004, according to its duration (expressed in the number of months) is shown in the figure bellow (Fig. 3.)

**Figure 3. Unemployment structure according to its duration in 2004**

Source : Based on the data from “Labour Force in Romania. Employment and unemployment in 2004”, INS, 2005.

Another form of long-term unemployment which is registered in the official records is the *discouraging unemployment*.

An alarming phenomenon is that the young are the most affected by this type of unemployment. According to the AMIGO<sup>8</sup> inquiry on the integration of the young people on the labour market, at the end of 2004, more than 30% of the total number of people discouraged were young persons, between 15 – 24 years.

Both the discouraging phenomenon and the long-term phenomenon generate serious social effects which, if prolonged, may acquire dimensions difficult to keep under control.

The analysis of unemployment according to the *occupational-professional* structure and *qualification of the unemployed workers* (Table 3) broadens the knowledge area of this phenomenon, suggesting solutions for the increase of employment in the fields that require professional retraining and re-qualification.

---

<sup>8</sup> The persons discouraged, in the sense of AMIGO, are the inactive persons, willing to work for the following 15 days, who do not have a job and have stated that they are looking for a job but they have not done anything on this purpose in the last 4 weeks or they are not looking for a job for the following reasons: they are not trained from the professional point of view, they think they won't be able to find a job because of their age or they have looked for a job somewhere else and they did not find one.

According to the M.M.S.S.F. records, the occupational-professional and qualification structure is composed of:

- Workers;
- Personnel with secondary studies;
- Personnel with higher studies.

The data in the Table 1.3 shows the massive concentration of unemployment in the category of workers. The quota represented by them (of almost 80% until 1996) gradually lowered, reaching 72, 5 % in 2001, as other categories began to be affected by unemployment. A significant change is also seen in the category of the unemployed workers with secondary studies, the quota of which shall double by the year 1991. In 2002, 2003 the quota of the unemployed workers in the category workers has increased as the quota of category of persons with secondary studies has decreased.

**Table 3 Structure of unemployed workers on their training level in the period 1991-2003 (%)**

	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
Workers	84,1	87,0	85,6	83,5	81,1	79,6	75,9	74,7	73,0	72,1	72,5	76,8	75,1
- of whom women (total of unemployed women)	82,6	85,8	84,4	82,2	79,6	76,2	69,7	67,8	65,3	65,5	65,0	71,0	69,4
Persons with secondary studies	12,9	11,1	12,8	14,9	17,4	18,8	21,7	22,8	24,1	24,7	24,1	20,0	20,7
-- of whom women (total of unemployed women)	14,8	12,5	14,1	16,3	18,8	22,1	27,7	29,3	31,4	30,8	31,1	25,0	25,2
Persons with higher studies	3,0	1,9	1,6	1,6	1,5	1,6	2,4	2,5	2,9	3,2	3,4	3,2	4,2
- of whom women (total of unemployed women)	2,6	1,7	1,4	1,5	1,6	1,7	2,7	2,8	3,3	3,7	4,0	3,9	5,4

*Source: calculus based on the data in the Statistical Directory of Romania I.N.S., 1991-2004.*

The quota of the unemployed with higher studies was rather changing during this period, oscillating between 1, 5% and 5, 4%, as the clear tendency from 1997 being an increasing one.

From the M.M/S.S.F. data, the most affected by unemployment are the trades in the processing industry (manufacturers-fitters of metallic structures, operators of polishing-rectifying machines, fitting mechanics and machine menders, electricians, fitters and trouble shooters of electrical wires, motor-vehicle mechanics and repairmen). The least affected by unemployment are the economists, the social workers, computer operators.

A deeper analysis of this typology may have positive effects in promoting some retraining and refresher courses, professional reorientation to trades which are actually on demand on the labor market.

### **3. Conclusion**

Concerning the unemployment in Romania, we observe the following characteristics:

- Concerning *its evolution*, we observe that the unemployment registered an explosion in 1991, having a fast evolution and reaching a peak of 1.223.952 unemployed at the end of the year 1994. After 1994, it starts to slightly decrease, on the background of a new process of economic invigoration. In the period 1996-2000 a new ascendant trend started to take place, reaching 1.007.131 unemployed at the end of 2000. Starting with this year, the number of unemployed started to decrease again, reaching 659 thousand unemployed in 2003.
- Without denying that this evolution from the last years is a consequence of the economic invigoration, we consider that reducing the unemployment rate as a tendency is also found in the increase of the number of employees. At the level of numbers, though, the number of unemployed decreased much more compared with the number of those newly employed. This reality leads us to the idea that either the unemployed have gone out of evidences, or were employed without working contract.
- The level of unemployment *on sexes* had an interesting dynamics; in the period 1992-1996, as absolute value and as unemployment rate, the feminine unemployment has been permanently higher than the masculine one. Starting with 1997, a very interesting and somehow paradoxical tendency

occurred: the decrease of the feminine unemployment weight and the corresponding increase of the masculine one;

- The evolution of unemployment on *residential averages* was relatively stable in time, having the highest intensity in the urban area, where the unemployment rate was 2,4 times higher on average than the one in the rural area;
- The analysis of the unemployment structure on *age groups* shows that young people under 25 years old are the most affected;
- The analysis of unemployed *according to its duration*, leads to the conclusion that, in Romania, although the unemployment phenomenon occurred only at the beginning of the year 1991, it became permanent in just a few years, it became chronic, through an increase of the long term unemployment; in 2004 more than half of the unemployed (58,9%) were inactive for more than one year compared to a percent of 43,2% in 1999;
- The analysis of unemployment according to the *professional employment and unemployed qualification structure* indicates the massive concentration of unemployment in the workers' category; a significant change is emphasized within the category of unemployed with medium studies, whose weight doubles compared to the year 1991.

As a *general conclusion*, we consider that the labour force market from Romania after 1990 was characterized by significant mutations. People were obliged to pay very high the transition to a market economy, very many of them loosing their jobs as a result of the imposed restructuring at macro and microeconomic level.

## **Abstract**

*The paper is based upon the last report regarding the global development new vistas lay down by the International Monetary Fund and made public in April this year, which is optimistic regarding the chances of overtaking the world recession. Fields of economy like agriculture and industry will be deeply affected by the new structural changes. The International Monetary Fund's report shows the weakness of the economies from euro area and it proposals regarding the solutions that could be put into practice. The experts are predicting that the most of the countries will intensify their efforts for attracting new foreign investments. The competition is rising, the investments playing an essential roll in the economical development of a region. For 2005 – 2006 is anticipating an increase of the beneficiaries of the foreign investments, comparatively with the last year. The liberation process of the markets will be expanding so that as many economies as possible should benefit by the foreign investments. In developed economies, the liberation process will have a smaller roll, but the orientation of funds towards the top domains will be more obvious as ever.*

**Keywords:** *foreign direct investment, challenges, Romanian agriculture, Romanian industry, and liberalization*

## 1. Introduction

Global economic integration is not a new phenomenon. Some communication and trade took place between distant civilizations even in ancient times. Since the travels of Marco Polo seven centuries ago, global economic integration—through trade, factor movements, and communication of economically useful knowledge and technology—has been on a generally rising trend. This process of globalization in the economic domain has not always proceeded smoothly. Nor has it always benefited all whom it has affected. But, despite occasional interruptions, such as following the collapse of the Roman Empire or during the interwar period in this century, the degree of economic integration among different societies around the world has generally been rising. Indeed, during the past half century, the pace of economic globalization (including the reversal of the interwar decline) has been particularly rapid. And, with the exception of human migration, global economic integration today is greater than it ever has been and is likely to deepen going forward.

Three fundamental factors have affected the process of economic globalization and are likely to continue driving it in the future. First, improvements in the technology of transportation and communication have reduced the costs of transporting goods, services, and factors of production and of communicating economically useful knowledge and technology. Second, the tastes of individuals and societies have generally, but not universally, favored taking advantage of the opportunities provided by declining costs of transportation and communication through increasing economic integration. Third, public policies have significantly influenced the character and pace of economic integration, although not always in the direction of increasing economic integration.

These three fundamental factors have influenced the pattern and pace of economic integration in all of its important dimensions. In particular, this paper discusses three important dimensions of economic integration: (1) through human migration; (2) through trade in goods and services; and (3) through movements of capital and integration of financial markets. After examining how fundamental forces have influenced economic integration in these dimensions, the paper concludes with reflections on three issues of general importance to the future course of global economic integration: the importance of communication as an influence on integration; the possibility that we may see a sharp reversal in the general trend of increasing integration, as occurred in the interwar period; and the apparent end of imperialism as a mechanism of integration. Before turning to this agenda, however, it is important to emphasize a key theme that will recur in

subsequent discussion: the main factors that drive the process of economic integration exert not only independent influences but also interact in important and complex ways.

## **2. Interactions Among the Fundamental Factors Driving Economic Integration**

Although technology, tastes, and public policy each have important independent influences on the pattern and pace of economic integration in its various dimensions, they clearly interact in important ways. Improvements in the technology of transportation and communication do not occur spontaneously in an economic vacuum. The desire of people to take advantage of what they see as the benefits of closer economic integration—that is, the taste for the benefits of integration—is a key reason why it is profitable to make the innovations and investments that bring improvements in the technology of transportation and communication. And, public policy has often played a significant role in fostering innovation and investment in transportation and communication both to pursue the benefits of closer economic integration (within as well as across political boundaries) and for other reasons, such as national defense.

The tastes that people have and develop for the potential benefits of closer economic integration are themselves partly dependent on experience that is made possible by cheaper means of transportation and communication. For example, centuries ago, wealthy people in Europe first learned about the tea and spices of the East as the consequence of limited and very expensive trade. The broadening desire for these products resulting from limited experience hastened the search for easier and cheaper means of securing them. As a by-product of these efforts, America was discovered, and new frontiers of integration were opened up in the economic and other domains. More recently, if less dramatically, it is clear that tastes for products and services produced in far away locations (including tastes exercised through travel and tourism), as well as for investment in foreign assets, depend to an important degree on experience. As this experience grows, partly because it becomes cheaper, the tastes for the benefits of economic integration typically tend to rise. For example, it appears that as global investors have gained more experience with equities issued by firms in emerging market countries, they have become more interested in diversifying their portfolios to include some of these assets.

Public policy toward economic integration is also, to an important extent, responsive to the tastes that people have regarding various aspects of such integration, as well as to the technologies that make integration possible.

On the latter score, it is relevant to note the current issues concerning public policy with respect to commerce conducted over the Internet. Before recent advances in computing and communications technology, there was no Internet over which commerce could be conducted; and, accordingly, these issues of public policy simply did not arise. Regarding the influence of tastes on public policy, the situation is complicated. Reflecting the general desire to secure the perceived benefits of integration, public policies usually, if not invariably, tend to support closer economic integration within political jurisdictions. The disposition of public policy toward economic integration between different jurisdictions is typically more ambivalent. Better harbors built with public support (and better internal means of transportation as well) tend to facilitate international trade—both imports and exports. Import tariffs and quotas, however, are clearly intended to discourage people from exercising their individual tastes for imported products and encourage production of domestic substitutes. Sadly, the mercantilist fallacy that seems to provide common-sense support for these policies often finds political resonance. Even very smart politicians, such as Abraham Lincoln (who favored a protective tariff, as well as public support for investments to enhance domestic economic integration) often fail to understand the fundamental truth of Lerner's (1936) symmetry theorem—a tax on imports is fundamentally the same thing as a tax on exports.

### **3. Human Migration**

Evidence from DNA has established that all modern humans are descended from common pre-human ancestors living in Africa roughly one million years ago. From that time until a few centuries ago, the most important mechanism for interaction among and integration of the activities of different human societies was undoubtedly people moving from one place to another, predominantly by foot. In the great span of pre-history up to roughly fifty thousand years ago, humans walked out of Africa and settled across the Eurasian land mass. Settlement of the Americas came later; my mother's Native American ancestors probably walked across the land bridge between Asia and North America now submerged under the Bering Strait roughly ten thousand years ago.

Throughout most of historical time, extending back roughly five thousand years, human migration has remained the predominant mechanism of interaction and integration of different societies. Use of the horse and other beasts of burden changed somewhat the technology of human movement (and had a larger effect on methods of warfare), and boats were used to cross water barriers. However, most people most of the time continued to travel by foot. Although migration was slow (by the standards of present speeds of

human transport) and often posed considerable risks, it proceeded on a vast scale. Indeed, even for many societies that pursued agriculture (as well as hunting and gathering) migration was a very common phenomenon up until quite recent times—as is testified to by the waves of migration out of Asia and across Europe extending up to roughly 1000 AD.

What fundamental factors were driving these waves of human migration? Relevant technologies (e.g., use of horses) presumably had some effect, and changing tastes may also have mattered somewhat. But, the key factor was surely public policy. In some cases a society would see that it was exhausting the productive opportunities in a particular location and decide to move on. Also, if one society thought it had the military might to improve its welfare by taking over the territory and other property of one of its neighbors, and, perhaps also enslave its citizens it would launch an attack. Seeing discretion as the better part of valor, the society under attack might decide to move on—and perhaps attack somebody else.

For the victor who succeeded in subjugating or driving out a rival society, the result would probably be an improvement in economic welfare. The loser, of course, would lose. The overall result presumably was negative sum. Indeed, in the first work in the entire field now known as social science, Thucydides opens his *History* on the Peloponnesian War with the following observation:

“...it is evident that the country now called Hellas had in ancient times [i.e., well before 400 BC] no settled population; on the contrary, migrations were of frequent occurrence, the several tribes readily abandoning their homes under pressure of superior numbers. Without commerce, without freedom of communication either by land or sea, cultivating no more of their territory than the necessities of life required, destitute of capital, never planting their land (for they could not tell when an invader might not come and take it all away, and when he did come they had no walls to stop him), thinking that the necessities of daily sustenance could be supplied at one place as well as another, they cared little about shifting their habitation, and consequently neither built large cities nor attained to any other form of greatness. Their richest soils were always subject to this change of masters... The goodness of the land favored the enrichment of particular individuals, and thus created faction, which proved a fertile source of ruin. It also invited invasion.”

This ancient observation remains highly relevant today. It reminds us that good governance at the national and international level—especially maintenance of reasonable security for peoples’ lives and property—is essential for economic progress. It also reminds us that not all forms of

economic interaction among different societies are necessarily beneficial. Globalization by means of the sword, the gunboat, or the slave ship is very different from globalization through voluntary movements of people, goods, services, and physical and financial assets.

Turning to human migration in more recent times, it is useful to distinguish between mass migrations which have continued to occur in response to wars and political and social turmoil, and migrations of individuals and families undertaken primarily for economic reasons. Of course, the two categories are not completely distinct; individual and family decisions about migration are often affected by both economic and non-economic factors. Nevertheless, events such as the mass migrations in Europe that occurred during and immediately after World War II clearly reflect different fundamental factors than those that were primarily at work in influencing migration to the United States during the past two centuries.

#### **4. Economies of scale and agricultural production**

Johnson and Ruttan (1993) examined the experiences of large-scale agricultural projects in six different developing countries: the Tanganyika Groundnut Scheme (1947 to 1949); the Molinos Nacionales sorghum project in Venezuela (1964 to 1966); the Dez agribusiness program in Iran (1968 to mid-1970s); Projeto de Jari forest and rice project in Brazil (1967 to the present); the Philippine Corporate Farming Project, started in 1974; and the Hershey's Hummingbird Farm in Belize (1976 to 1992). The key assumption underlying these projects is economies of scale - gaining a more than proportional increase in output for a given increase in all inputs. Economies of scale arise due to the following:

The use of lumpy inputs, such as machinery or management, might lead to economies of scale in the short run. Over the long run, the minimum scale of operations is likely to increase, with the result that the economies disappear. Biological and chemical inputs are likely to be scale neutral.

External economies of scale allow larger farms to buy inputs such as capital, storage, transport and marketing and distribution services at a lower price than is possible for smaller farms. This means that larger farms may have an advantage over smaller ones without necessarily being more technically efficient.

In some situations, Johnson and Ruttan (1993) say scale diseconomies might exist, and this has been used as a justification for land reform. Situations where this can occur are where labor markets might not exist,

where transaction costs in labor markets are high and where the effort of hired labor is affected by level of supervision.

Johnson and Ruttan conclude that the consensus is that agriculture is generally not characterized by economies of scale. In the US, changes in the relative price of capital and labor led to a substitution of capital for labor. If there are no economies of scale, then this substitution will occur at all farm sizes. A large part of the capital that is used in the US is machinery. Since machinery allows farmers to work larger areas of land, it may not be all that surprising that farm sizes have been increasing. The seasonal nature of the production cycle limits the opportunity for gains from specialization and division of labor. This is seen by some as a reason for limited opportunities associated with expansion beyond the size of the family farm. Further reasons favoring the family farm are that family labor is inherently more productive than hired labor. Monitoring costs are likely to be much lower with family labor than is the case with hired labor. Further, decisions on the spot are part and parcel of agriculture. With no managers around, hired labor might be unwilling and/or unable to make a decision. As risk increases, it has been argued that farm size should decrease. However, Johnson and Ruttan (1993) note that little work has been done on this relationship. Related to this, it has been observed that it is not a good idea to pool risk across farmers in a given area because of the high covariance of their natural risk. Hence, in risky environments, small farms may be better than large ones. Wealth tends to offset this in the sense that wealthy farmers have been found to be more immune to risks imposed by the weather. Industrial projects are generally perceived to be less risky in developing countries than agricultural projects, with the result that the more industrialized the agricultural project, the less risky it is considered to be.

## **5. International trade and environment**

The impact of international trade on the environment has been a contentious issue since the early 1990s. The debates over the North American Free Trade Agreement (NAFTA) and Uruguay Round of trade negotiations, which led to the creation of the World Trade Organization (WTO), stimulated a great deal of economic research on the ways in which international trade might be environmentally harmful or environmentally beneficial, along with case studies of many industries and sectors.

The last fifteen years have seen major developments in both the theoretical and applied economic literature on trade and the environment. Such issues are also of increasing policy relevance. U.S. Executive Order 13141 and the U.S. Trade Act of 2002 require environmental assessments of

trade agreements during the negotiation process. In the European Union, sustainability impact assessments of trade agreements are required as part of trade negotiations.

This special issue of the *Agricultural and Resource Economics Review* contains papers from a workshop on international trade and the environment that was held in Halifax, Nova Scotia, in June 2004, following the joint annual meetings of the Northeastern Agricultural and Resource Economics Association and the Canadian Agricultural Economics Society. The objective of the workshop was to stimulate research and discussion to improve our understanding of the complex interrelationships between international trade, natural resource use, and the environment, particularly as they relate to agriculture, forestry, and fisheries.

The paper by Brian Copeland in this issue reviews recent work on the implications of endogenous policy responses for the impacts of trade on the environment. As Copeland demonstrates, the effects of trade on the environment can be quite different in the case where the environmental policy regime is assumed fixed and in the case where it adjusts in response to changing economic and environmental conditions.

## **6. What are some of the critical global change issues?**

Over the past two decades, a number of specific issues have gained significant attention and served as the foci of global change research. Critical issues attracting attention include:

*Climate Change and Greenhouse Warming*, which relates to the potential for greenhouse gases and aerosols emitted as a result of human activities to alter the global climate and cause significant impacts on the natural environment and societal activities;

*Ozone Depletion and UV Radiation*, which relates to the effects of emissions from human activities on the atmospheric ozone layer, and the consequent reduction in the ability of the atmosphere to screen out ultraviolet (UV) radiation; and

*Significant Variations of the Seasonal Climate*, which relates to the agricultural, economic, and related effects on human activities of sharp fluctuations and variations in the seasonal to inter-annual climate, particularly the extended heavy precipitation and drought episodes associated with El Niño-Southern Oscillation (ENSO) events in the tropical Pacific Ocean.

These three issues are by no means the only issues of global environmental concern. Extension of agriculture and rapid increases in population are leading to major changes in land use, including deforestation

and dry land degradation, which often have detrimental effects on the resilience and complexity of ecosystems. The development of coastlines is altering beach processes, reducing coastal habitats, and making communities more vulnerable to severe weather and sea level change.

To meet the challenge of a changing environment, it is essential to continue to undertake research to improve the predictions of consequences and the effectiveness of options for responding to the impacts of global change.

***Keywords:** e-economy, financial services, electronic banking, information and communication technologies, artificial intelligence, distribution channels*

## 1. Introduction

*The future of banking sector belongs to companies which can not only offer products and services fallen with needs of an individual client, but can provide them at any time and anywhere as well*

*Tom Peterson*

An increase in social expectations in relation to subjects rendering financial services, dissemination of new technologies, more developing technical culture of society, an increase in importance on information technology in economy, business globalization, consolidation of banks and an increase in competitiveness are only a few reasons which had an influence on a type and quality of services rendered by banks.

An abstract feature of financial products, which undergo dematerialization rather easily, possibility of their connection with information exchange (due to the developing market of new technologies) and an introduction of the electronic signature influenced significantly

---

<sup>1</sup> Paper is published due to the Czech Grant Agency support (grant GAČR No. 402/05/2758 Integration of the financial sector of the new EU member countries into the EMU).

easiness of reaching wide ranges of targeted groups and increasing the distribution of financial services.

The work deals with new possibilities of the distribution of financial services by banks on basis of selected channels – internet banking and virtual banking, which are especially important problem during integration of the financial sector of the new EU member countries and their way into the EMU.

## **2. New economy and its dimensions**

The new economy, also called e-economy, is the most frequently used term in economic and technical literature, discussions of scientists, businessmen and politicians beside globalization and information technology society. Three planes of understanding of the new economy can be distinguished:

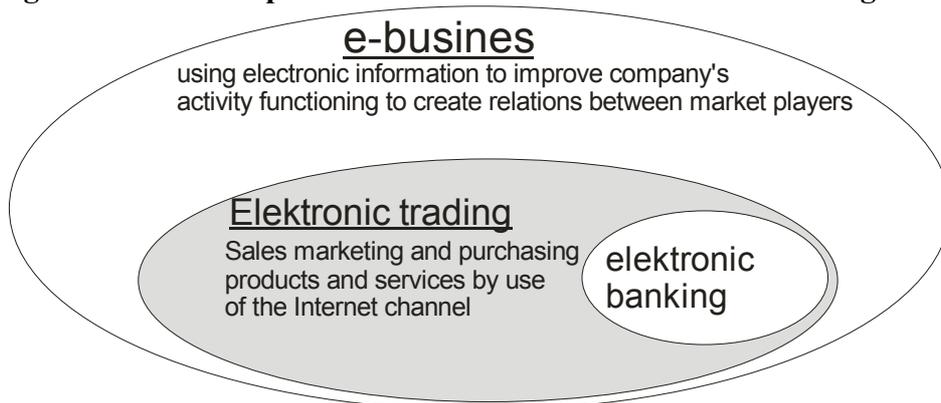

- as a system of new principles explaining how economic subjects function on the market;
- as activities of economic subjects in the strongly changed conditions. Owing to the dynamic development of technical progress, especially in information technology economic subjects change completely strategy of their activities many times. Information and knowledge as main economic categories, which are the basis of the contemporary business, are the foundation of activity. Another term is assigned to this understanding, namely knowledge-based-economy.
- new economy treated as a subject, namely determining activities of an enterprise in the IT sector.

Considering economy as knowledge-based is the most adequate to the contemporary trends in the economic processes. Innovations in the advanced technology and globalization of worlds' markets changed our economy to such extent that we are forced to think and act in a different way in it. It is connected with searching for new sources of quick growth, making structural changes in the development of information technologies, and above all, quick commercialization of the Internet. Owing to new technologies, and particularly the Internet network, the economy is characterized by high degree of transparency, there is a technical possibility to compare economic results, competition results and prices of products with ease. In fact, three channels of influence of those technologies on the economy can be distinguished:

- accelerating an increase in work productivity in sectors manufacturing equipment of new technologies and an increase of their share in the National Gross Product;
- fall in prices and an increase in demand for this type of equipment, what results in an increase in investment level and the National Gross Product;
- changes in a way enterprises function in new market conditions and accelerating work efficiency and capital productivity.

Therefore, *the new economy*, also called *cyber- economy*, constitutes a new paradigm of business. On this virtual market E-business is a new form of an exchange of resources by means of information technology systems and internet technologies, conducted *on-line* through electronic connections and an information exchange by use of electronic multimedia such as Internet, cable and satellite television, telephony, electronic cards, Intra and Extranet at the national and international level. It consists of electronic trading, business intelligence and technological capacities to self-service business processes conducted. For that reason e-business is a new source of speed, innovation initiatives, efficiency and new ways to create values in the organization, Fig.1

**Figure1 Relationships between e-business and electronic trading**

*Source: our own work*

It contains three areas of activities:

- *involvement*, namely needs to create cost effective commercial websites and applications, directed at marketing, network advertising and promotion tools;
- *trading*, conducting *on-line* business with safe and measurable execution of orders;

- *analysis*, concerning understanding of attitudes of customers and motives directing purchases and use of this knowledge to improve quality of services rendered.

Transactions on the electronic market are performed in the following relations:

- business-to-business, B2B, it refers to the co-operation between companies (e.g. transactions between companies), distribution of information, goods and services and relations between commercial companies and public administrations institutions (e.g. paying taxes) ;
- business-to-customer, B2C, co-operation between companies and customers in a scope of retail sales of products and services (e.g. banks, internet shops) and between customers and public administration institutions (e.g. making payments to treasury offices, city halls etc.);
- customer-to-customer, C2C, it concerns transactions concluded between private persons (e.g. auctions, electronic “notice boards”);
- customer-to-business, C2B, concerning transactions concluded by customers directly with firms. Prices of products are determined by customers, a firm can accept them, or reject e.g. potential customers offer a price which they are ready to pay for a flight, whereas the airlines can accept it, or turn down the offer. This type of market has not achieved that level of development as B2B, B2C or C2C yet;
- business-to-administration, B2A, it concerns relations between a company and the state administration. Companies via the Internet can participate in public tenders, pay taxes and other dues to the state. Whereas in the opposite direction – subsidies or returning of taxes reach a company;
- customer-to-administration, C2A, instead of business parties there are consumers, who via the Internet settle taxes with the Treasury Office, receive tax refunds, compensations or allowances.

The development of electronic business takes place in phases. In the first phase the Internet is web enabled to conduct activity, whereas in the second one business is web based totally. The fact to which phase countries belong to depends on the internet infrastructure and communication channels they have. Europe comparing to the USA is backward about two years and it is still in the phase of building infrastructure.

### **3. Electronic banking as an element of e-business**

Electronic business is a complex and dynamically developing sector. It is not only limited to access to World Wide Web and information exchange. In order to achieve success in it, different requirements must be met, and they are such as: safe information processing concerning transactions, winning customer's trust, skillful management of intangible products. Electronic business is of particular importance in the finance sector. It comprises both a scope of customer service and a transfer of funds and mutual co-operation of institutions. Necessity to introduce comprehensive electronic business results from, among others, a level and scope of competition present on world financial markets nowadays. Banks wanting to maintain an appropriate position on the market face challenges which force them to use solutions increasing effectiveness of their activities. In this system of market forces even commercial networks offering their own credit cards and financial institutions not having a status of a bank, but offering less expensive services of the same kind constitute a threat and competition for banks.

Financial sector activity, including banks, is not connected with manufacturing physical products, but it is business based on information using telecommunication and information technology achievements on a wide scale. Management of finances becomes more and more management of information about creditability, purchasing power and financial position of persons and institutions [9]. New technologies are directed to manage relations with customers, to improve internal integration of systems and internal operations of banks, but not as in the previous period to increase inner efficiency and development of distribution channels. Those factors cause that the bank sector is prepared best to function in the electronic environment and develop electronic economy. Information and communication technologies (ICT) can be used in any type of bank activity and they are the main factor of changes in the whole sector of financial services. In that economic situation only those banks, which will use different distribution channels and variety of services and modern technological solutions will be basis of their long-term strategy, will achieve success. Problems of electronic economy became a key element of initiatives undertaken by European Union within the framework of the Lisbon Strategy. The main aim of the Lisbon Strategy, within the e-Europe initiative accepted in Seville in July 2002, is to transform the European economy to 2010 into the most competitive world's knowledge-based economy. One of the assumptions of the strategy is to make electronic banking development more dynamic – a fundamental factor to create an integrated European market of

financial services. It is possible due to liberalization of the telecommunication services market, what will have an advantageous influence both on development of this sector and development of electronic services rendered by the banking sector. For that reasons the Lisbon Strategy emphasizes the market liberalization, development of the telecommunication sector and it defines clearly a role and place of financial institutions and capital market in UE. The Polish banking sector has been obliged to undertake activities aiming at creating an integrated market of financial services until 2005. Detailed activities are included in the document Financial Service Action Plan (SAP).

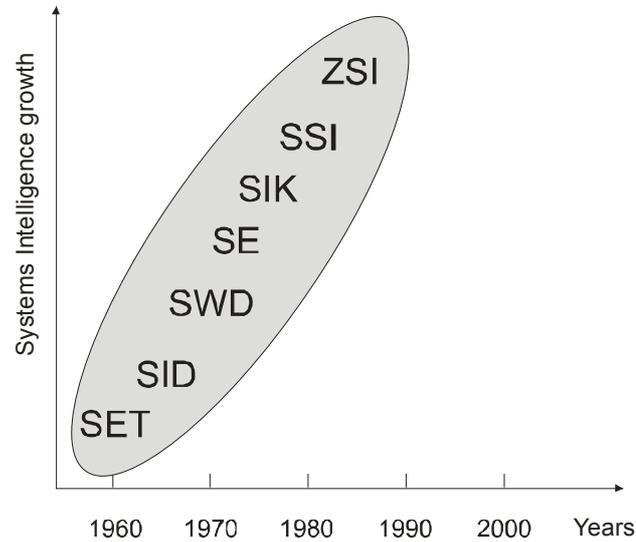

#### **4. Artificial intelligence in e-banking**

The growth of the accessibility of the new e-banking solutions, new banking tools (for instance card to buy in the internet, EMV card - Europay-Matercard-Visa) is the result of building bank position on the market and competitive superiority. This can be seen in the methods of the access to the financial means on the account proposed by the bank, the way of using bank tools as well as their new functions, using mobile solutions (for instance *m-banking*) and lowering bank commission for its service. These actions may encourage new clients to use the service of the certain bank and gained clients to stay with their choice, on the other hand it should enlarge competitive position of the bank. To achieve the planned goals by the banks may be possible by making the society aware of benefits related to new bank solutions, constant growing of technical culture of the society as well as the most favorable decision making on the highest managing level.

The main influence on the achievement of competitive advantage by the banks have advanced information systems which rise the bank services for the corporate and individual clients. It is necessary to mention that the usage of new technologies in not a must related to the current trends but it is important tool in bank strategy, which cause its rising position. If the bank lacks the vision of supplies for new services then the most advanced investments in new technology will be only the serious cost not the profits for the bank. It is important to use the golden rule of the new economy, market position and competitive advantages, which says that commonness of the solution does not cause long-term and stable position of the enterprise on the market. That is why the usage of the new information technologies in the bank in the essential component of banking e-business. The matter of this issue is of great importance because in the age of necessity of processing

large information data and making decision based on them, current banking systems are not enough, Fig.2.

**Figure 2. The changes of the intelligence level of information managing systems<sup>2</sup>**

It is the most important in the field of supporting the essential decisions which are at the same time the most difficult, strategic related to banking *Top Management*. Traditional information systems which support the process of managing are related to gaining from the computer concrete answers to the given questions and nowadays they become less effective. The difficulty is in the proper explicitness of the question on the basis of large amount of possessed information, often uncertain and unclear. We do not know which features will cause success or failure of the concrete business strategies. The mentioned features cause that the typical tools of information support of process support decisions are less effective. That is why it is necessary to use different techniques and tools of artificial intelligence such as expert, neuronal systems of processing natural language.

In the literature of this subject there are different terms of this issue such as AI is the part of information technology related to designing intelligent computer systems [E. Faigenbaum], AI is the system which

---

<sup>2</sup> SET – List- & Transactional Systems; SID – Informative and Decision Systems; SWD – Decision Support Systems; SE – Evaluation Systems (macro- & micro- economical models); SIK – Executive Information Systems; SSI – Computer Network Systems, ZSI – Computer Integrated Systems

demonstrates the abilities of understanding similar to those of a human in order to improve life conditions and economy competitiveness [Japan AI Centre]<sup>3</sup>. Other definition of this issue points out on the problem solving related to natural action and cognitive processes of human beings by means of computer programmes which stimulate them [Encyclopaedia PWN]. There are two different approaches to AI in the literature of the subject:

- Symbolic one where the systems are based on logic( PROLOG) as well as the systems with the base of knowledge (expertise);
- Computational one where neuron net, evolution system, systems with unclear logic as well as intelligence without presentation are used (Project COG).

## **5. Distribution channels of the products and e- services in e-banking**

In new economy conditions managing financial institutions is connected with the change of the ways of services selling, providing information to clients as well as with the change of their function and noticing the key competence. The standard of work in banking area has been related to the usage of solutions based on information, knowledge and new technologies which give the clients access to financial means collected on the bank accounts and the possibility to make different transaction there. It has led to distinguishing great variety of e-banking channels such as:

- Cash dispensers,
- Phone banking;
- Banking based on separate network - home banking ( Corporate banking),
- Call Centre,
- Voice-IVR,
- Internet banking (with the type, limited to virtual sphere, virtual banking),
- Mobile banking (SMS banking – make possible to manage the bank account by means of textual news SMS as well as WAP banking – allowing for interactive contact of the client with the bank by means of mobile phone using protocol WAP<sup>4</sup>),

---

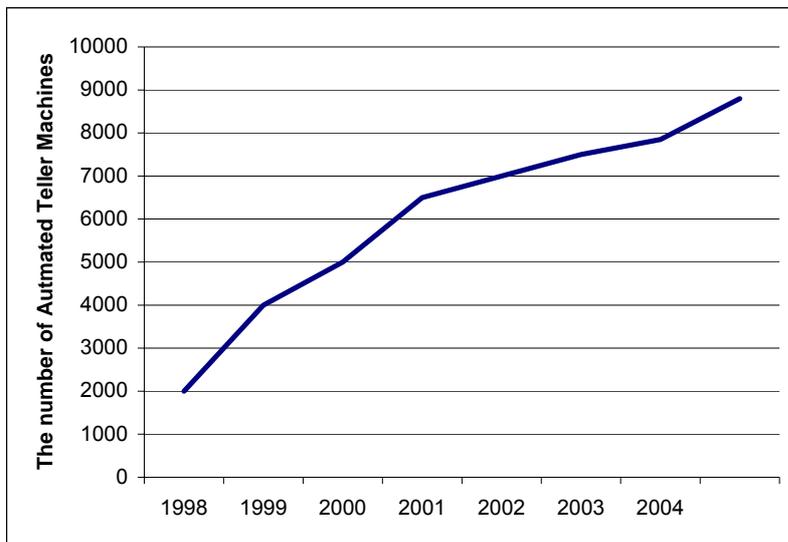

<sup>3</sup> VIII Forum bankowości elektronicznej, Warszawa 2004

<sup>4</sup> WAP (ang. Wireless Application protocol).

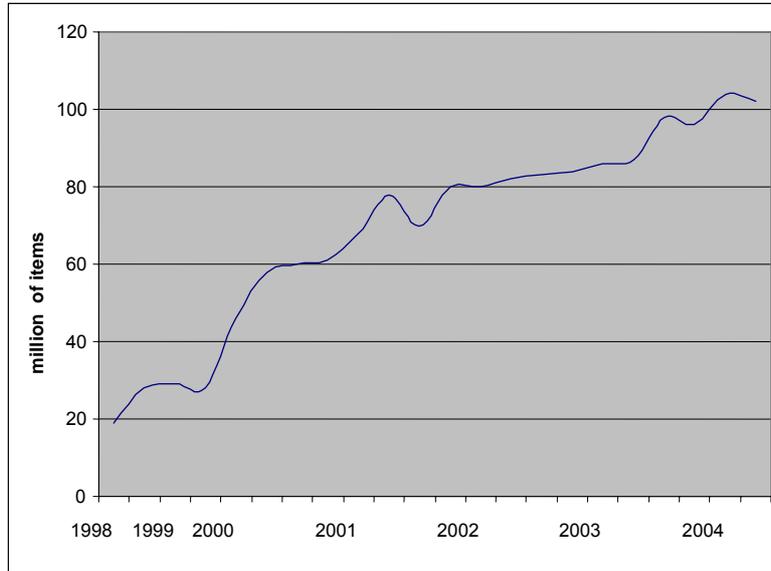

- TV-banking – allowing access to the bank account by means of TV set and telephone
- Multimedia kiosk.

The usage of these channels in the banking sector vary and depend on the level of entanglement of the services offered by them, offer of banking financial tools as well as strategies used by the banks. Cash dispensers are the most popular channels. It results from the easiest way of operating and the possibility of doing different services by these machines. In Poland the network of ATM is constantly developing. In 2004 7850 items have been installed (Fig.3), 107 million transactions have been made (Fig. 4) and their value has been on 32 milliard zloty, Fig. 5.

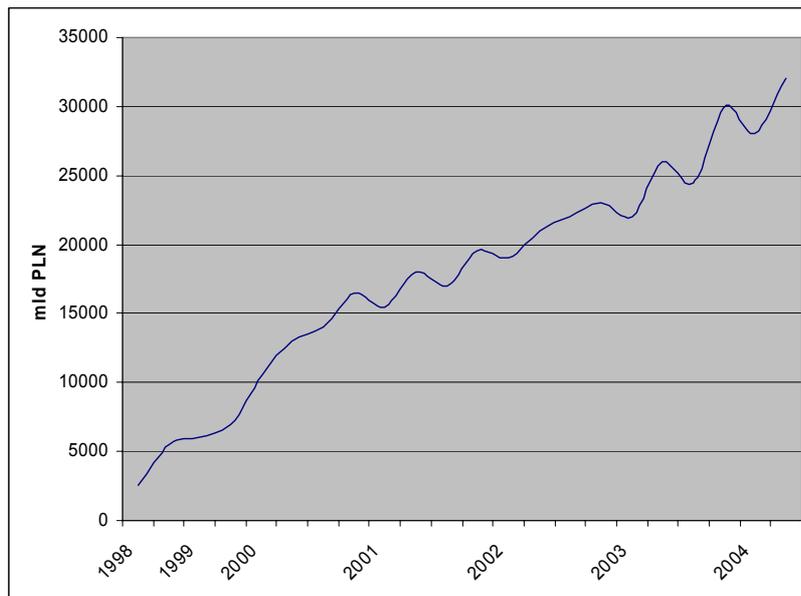

**Figure 3 Changes of the number of ATM in Poland in 1998-2004**

**Figure 4 Changes in the number of transaction in cash dispensers in million items**

**Figure 5 Changes of value of transactions in cash dispensers in milliard zł**

Nowadays many of the cash dispensers functioning on the Polish market are the multi functioning machines and the owners of the cards can use them 24 hours. In spite of the fact that year by year there is a growth of

cash dispensers their location is not steady. Further growth of the popularity of this banking channel will be possible when the financial tool such as chip cards EMV will become more common. The internet becomes the e-channel which is developing very fast these days. Its advantages as the channel for distributing the products and services in e-banking were used in 1995 by SFNB bank (*Security First Network Bank*)<sup>5</sup>. Despite the e-banking leads to segmentation of the market, products and services (this may derive from the level of service complication, its value and the security of transactions), it allows to enlarge the receivers. It is caused by:

- Conducting simultaneous and fast bank service for large number of clients,
- Individualisation of bank offers, creating of individual client wallet on the basis of information gained about him for instance preferences.
- Conducting service of client by the bank 7 days a week as well as 24 hours (without time limit),
- Enlarging geographical reach – bank without borders (borderless bank), which allows to realise the order from different place (without space limit),
- Enlarging market research,
- Realisation of the orders on-line,
- Quick support of bank workers in case of emergency,
- Lowering the cost of single transactions and commission for the services,
- Enlarging client satisfaction this can lead to the growth of his loyalty towards the bank.
- Enlarging the competitiveness of the bank on the market of bank services.

The growth of the interests in services offered by this channel was the reason of creating by the banks, in terms of their structures, internet branches which are mainly responsible for the development of e-services, Table 1. The success of the internet branches have been gained by traditional banks with strong and stable position on the financial market and with wide consumers base. It resulted from the compromise between the habits of clients to traditional form of transaction realisation in the bank and the solutions of 21<sup>st</sup> century standards (internet channels).

---

<sup>5</sup>In the process of communication between the client and the bank the protocol http lub https was used.

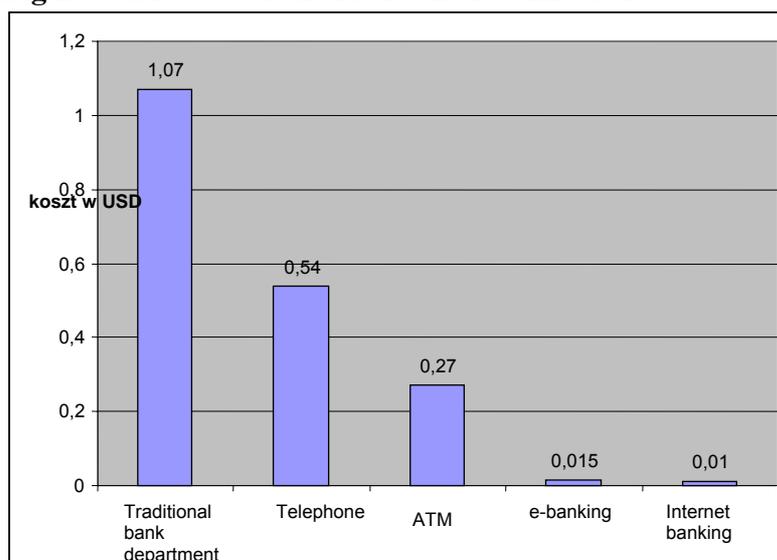

**Table 1 Internet branches of the biggest financial institution in Europe**

Founder's bank	Name of the internet brunches	Number of on-line clients (million)	Type of the service

Source : J. Pietrzak, „Wpływ modelu dystrybucji na konkurencyjność banku”, *Bank i Kredyt*, nr 3, str. 35-43, marzec, 2002

In the new economy conditions banks intensifier the actions towards lowering the costs of running a business (the transaction make in the internet is 100 hundred times cheaper than the same transaction made in the bank), or commission for the bank service<sup>6</sup>, Fig. 6.

**Figure 6 The cost of distribution of bank services**

Source : Booz Allen Hamilton Inc.

<sup>6</sup> Rport firmy doradczej Booz, Allen & Hamilton

The savings gained from the clients' service by e-banking are restricted at great financial cost for the promotion campaign connected with gaining new and maintaining present bank's clients. The survey of the e-banking shows that the expected savings from the clients' service are reached by gaining the proper number of clients-called the critical market mass. The amount constitutes 600 thousands clients. However, 6<sup>th</sup> E-Banking Forum – CPI states that the earning capacity of the account led by Internet is gained by 1600 zł of the monthly payments. In comparison to the traditional bank, the earning capacity is about 1298 zł.

Resulting from easily gained benefits, as far as on-line banking is concerned, typical, virtual subjects originated, rendering services to people by internet. Such kind of activity which is the simplification of the multi-channel distribution (*bricks and clicks*) fits in the model– *clicks only- virtual banking*, Table 2.

**Table 2 The costs of those subjects which offer virtual service**

The name of the subject	Costs in Euro(mln)
Egg	310
First-e	58
IKANOBanken	25
OnBanca	20
Sainsbury's Bank	47
VZ Bank	30
VirginOne Bank	30

Source: *The Banker*, March 2000 p. 11

The fight for incomes among virtual banks, maintaining the stable competitive overbalance leads to the double functioning –financial service deliverer, as well as, broker-the service distributor of financial institutions: banking, insurance or brokers. On the way of their activities, one can notice the principle that – ‘*Clients don't care where the products are from. They are to meet their needs.*’ [<sup>7</sup>]. The example of such strategy is bank *Egg.com* – on-line company which belongs to British financial Prudential Assurance Co. which assembles about 3 mln clients in the 4<sup>th</sup> areas: banking, insurance, capital market, and on-line shopping. The other example is *First-e* which is the broker, the distributor of products and other institutional services. It's

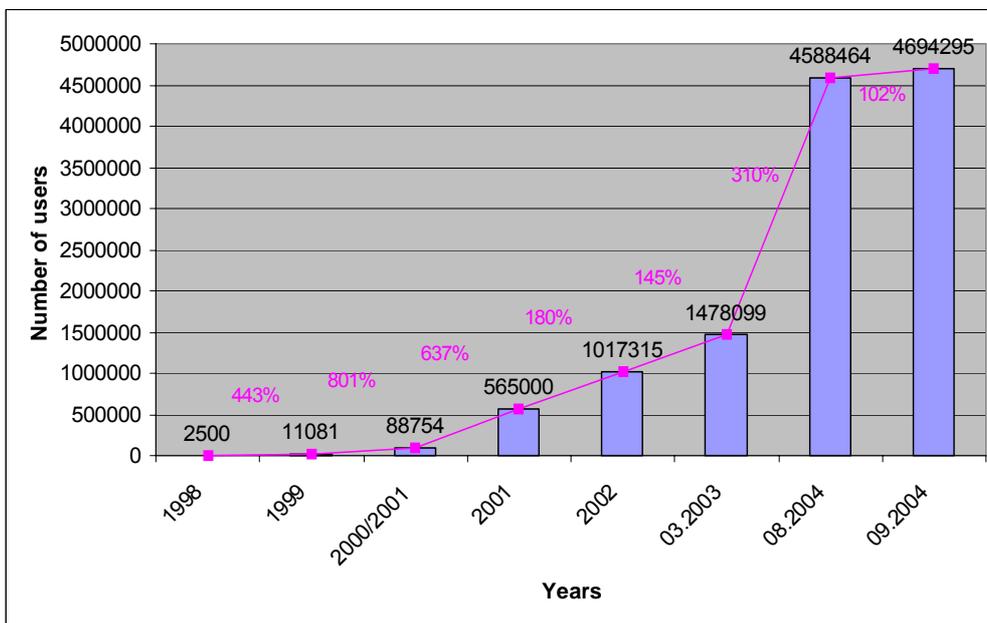

---

<sup>7</sup> Pietrzak J.: „Wpływ modelu dystrybucji na konkurencyjność banku”, *Bank i Kredyt*, nr 3, str. 35-43, marzec, 2002

functioning as portal, directing clients to the best products, transactions, mortgage credits, credit cards and stocks and shares.

The success of internet banking in the world was the stimulator of banking development in Poland. The growing commonness of internet thanks to improving Teleinformation, infrastructure, as well as, the changing law regulations. In the last 6 years 1998-2004 the number of clients using the access to bank by internet increased by 1835 times which yearly average amount is 400% Fig. 7. The biggest pace of the increase of the e- banking clients was between 1999 and 2000/2001 - 801% and 637% between 2000 and 2001. At present, in Poland there are 18 banks rendering internet banking services with 4694295 clients<sup>8</sup>.

**Figure 7 The number of e-banking clients in the years 1998-2004**

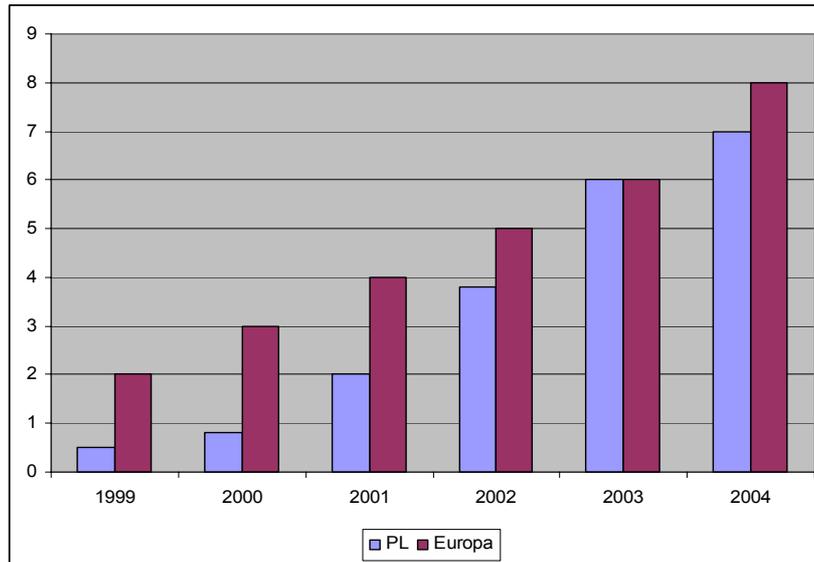

*Source: Own elaboration on the basis of E-Banking Committee*

The measurable benefits of using on-line banking caused the situation in 2002 that every invested zł was the result of internet being used and according to K. Pietraszkiewicz until 2005 the number is supposed to double. In spite of the great interest of internet service, Poland is still on the further position against the background of Europe. Fig. 8. One should indicate that

<sup>8</sup> VIII Forum bankowości elektronicznej, pp. 34, Warszawa 2004

the pace of the changes is one of the biggest among new admitted European Union countries.

**Figure 8 The percentage of clients using e-banking by internet / mobile**

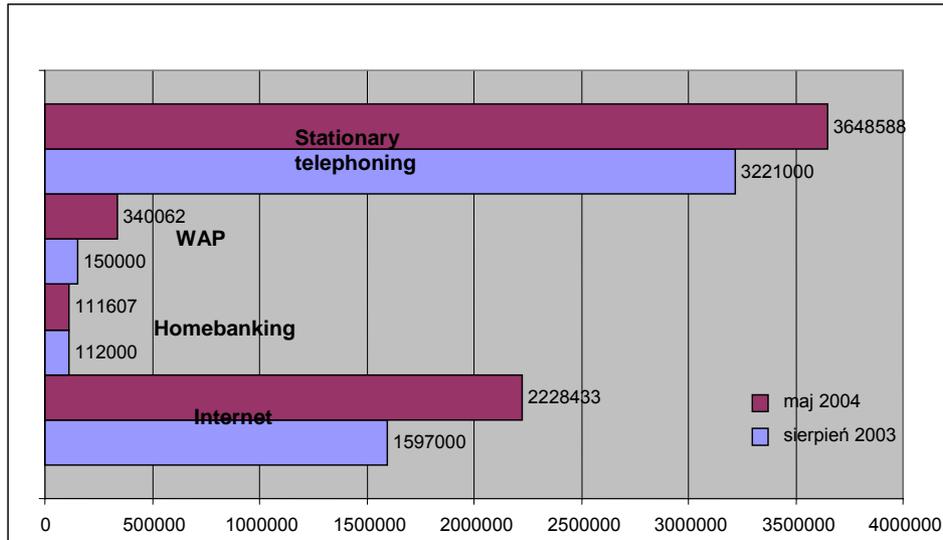

Source: Own elaboration on the basis of<sup>9</sup>

Such great growth in internet banking sector results from the comfort of using banking services on-line, as well as, the growing clients' consciousness, the growth of security, beneficial financial conditions and the improving technical conditions. Along with internet banking development, the other accessible channel is spreading out, Fig.9

---

<sup>9</sup> Stryczyński Jacek, Zarzyki Tomasz, *Raportu EDS „Bank ery gospodarki elektronicznej”*, Bank 09/2000, pp 57

**Figure 9 The changes of the clients number using e-banking**

*Source: Own elaboration on the basis of ZBP data*

It takes place due to economical regards e.g. the decrease of expenses in traditionally managed banks, as well as, the increasing number beyond banking field. Teleinformation users e.g. mobile telephoning or WAP. At present about 80% of the net clients are using mobile telephones<sup>10</sup>. In Poland, from August 2003 until May 2004 mobile telephoning WAP indicated the biggest growth. (the increase of clients 'number using internet banking amounts 126,71%, the increase of zł transactions amounts 112, 55%, and the average amount of transfer is 58,37%). However, mobile banking didn't succeed so much in spite of optimistic surveys and banks' efforts in offering their service. According to Forrester Research in 2002 in Great Britain only 100 thousands out of 300 mln WAP users used mobile banking.. Such phenomenon one can observe in Scandinavia, with the biggest mobile telephones market in the world. However, in the USA there are 800 thousands cordless banking users. PDA and PalmTop –other mobile devices are included in this number.

The phenomenon of low interest, as far as mobile banking is concerned, caused the resignation from using WAP by internet banks and revival to traditional, popular forms of contact such as: SMS. The main cause of not using functional WAP and UMTS technologies results from inappropriate level of mobile telephoning development. It is estimated that there is 2-years -lateness in case of Europe in relation to Japan and South

<sup>10</sup> Górski P.: „E-banking dla Kowalskiego”, e-Fakty – wszystko o gospodarce elektronicznej” nr 4, Instytut Logistyki i magazynowania, str 22, 2004

Korea, where 3G telephoning is successful and mobile banking is massive. In the western Europe the short-term reduction of investment is planned in such places where there is lack of rapid investment development. There is a reduction tendency, as far as the number of clients is concerned, in case of Homebanking – 0,35%. It may result from technological restrictions and increasing costs ( in a bank), Table 3.

**Table 3 Changes of particular accessible channels.**

Accessible channel	August2003	May2004	Growth
<b>HOME BANKING</b>			
The number of clients using e-banking	112.000	111.607	-0,35%
The number of monthly transactions	9.370.000	9.637.289	+ 2,85%
The amount of transactions in zł	64.484.656.000	84.250.295.251	+ 30,65%
Average amount of payments in zł	6.882	8.742	+ 27,03%
<b>INTERNET</b>			
The number of clients using e-banking	1.597.000	2.228.433	+ 39,54%
The number of monthly transactions	2.579.000	5.696.185	+ 120,87%
The amount of transactions in zł	6.327.100.000	10.018.233.859	+ 58,34%
Average amount of payments in zł	2.453	1.758	-28,33%
<b>STATIONARY TELEPHONING</b>			
The number of clients using e-banking	3.221.000	3.648.588	+ 13,28%
<b>MOBILE TELEPHONING– WAP</b>			
The number of clients using e-banking	150.000	340.062	+ 126,71%
The number of monthly transactions	2.327	2.685	+ 15,38%
The amount of transactions in zł	2.043.000	4.342.355	+ 112,55%
Average amount of payments in zł	1.021	1.617	+ 58,37%

*Source: Own elaboration on the basis of ZBP*

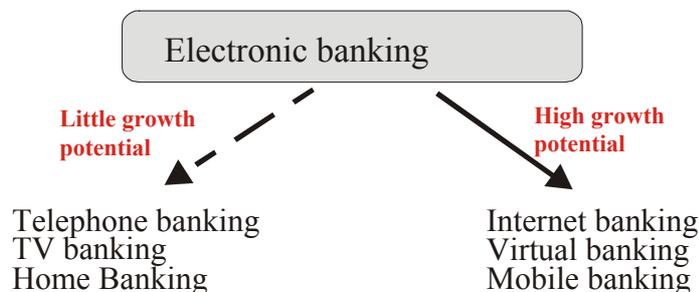

One of the newest solutions in the field of communication between client and bank is TV banking, with the usage of satellite TV, cable TV, telenewspaper and telephoning. The client may check his account in the telenewspaper. However, it should be proceeded by telephone contact with bank. After giving the account password, the client receives the number of page in the telenewspaper or by sending coded data by digital TV ( decoder is necessary in this case. Those who already possess such device are able to contact with bank in this new way (satellite TV and telephone). However, it will depend on the percentage of the amount in the account. The commonness of this channel depends on whether the client possesses interactive digital TV, the device which is still quite limited. According to Forrester Research, the growth of digital TV in European Union is expected up to 44 % in 2007 in comparison to 2002 when it was only 11%. The example of the country in which TV banking is popular is Great Britain,

where more than 770000 digital TV users take advantage of bank service. The most popular bank is *Egg bank* and *Sky TV*. Because of technological and economical barriers such communication is still not popular in Poland. The only Polish bank which offers TV banking is InvestBank within *Invest-Account channel*. The client may receive information about his balance, operations within basic service whereas within interactive service one can do transfers or become the user of lawful regulations. Technological barriers and little clients' interest stop the development of such services in EU countries and in Poland as well. TV banking is rather only treated as technological piece of information and banks investments should be limited until digital TV becomes a giant.

TV transmission with the bank's consultant and real-time services e.g. chat banking belong to new communication solutions. (Chat is a real-time conversation with the bank's worker on a special channel proceeded with login of the client). Such solution is mostly used by bank in order to give a piece of advice.

The participation in e-banking differs and depends on the access to technology, the infrastructure development, lawful-administrative regulations, banking culture, e-banking culture and the costs of exploitation. Such factors influence distributive channel groups with a different growth potential. Little growth potential: little functioning, (telephone banking) or high cost of exploitation ( TV banking and Home-banking), as well as, high growth potential: ( internet banking, virtual banking, mobile banking ) with low exploitation costs. Fig.10.

**Figure 10 E-banking access channels and their growth potential**

*Source: own elaboration*

New technological solutions qualified the characteristics of clients' behaviour. Getting to know clients' needs made it possible to adjust the kind

of offered service in case of communication. In the result, the bank organisation changed from interactive, where the contact with the client was limited into proactive, thanks to which the client is supported<sup>11</sup>.

## **6. E-banking services**

Thanks to multiplicity of channels, banks use multichanneled strategy which offers many distributive channels to clients along with financial service which seems to be attractive. The level of complicated service changed from simple marketing service into complicated interactive service thanks to new information technologies and information techniques. It also influenced bank functioning from interactive into proactive, supporting the client (the concept of partnership e-banking). The changes of e-banking led to creation of new e-services dependent on used accessible channel such as:

- Bills payments,
- Funds transfer among accounts ,
- Orders instructions,
- stocks and shares trade,
- credits acceptance,
- accepting credit cards applications,
- reviewing the calendar of dates and deadlines,
- reviewing the history of carried out operations,
- tax accounts,
- sending orders and messages by means of text message system,
- aggregation of financial services

as well as associated financial services i.e. insurance, leasing, investment or retirement services. Table 4.

*Source: Centeno, C. Adoption of Internet Services in the Enlarged European Union from the Internet ranking case. June 2003.*

With the development of e-economy new payment instruments were introduced on the market. These new instruments made it possible to conduct transactions on the Internet and in the mobile environment. In Poland the market of pay cards was created only in the 90ties of the last century following the reforms initiated after the change of political system in 1989. These reforms radically transformed Polish banking sector. In this initial period demand for modern payment instruments was moderate. There was no sufficient technical infrastructure which would accept electronic payments. The year 1994, however, saw considerable increase in demand which was a result of rapid changes on Polish financial market and was determined by potential customers' needs.

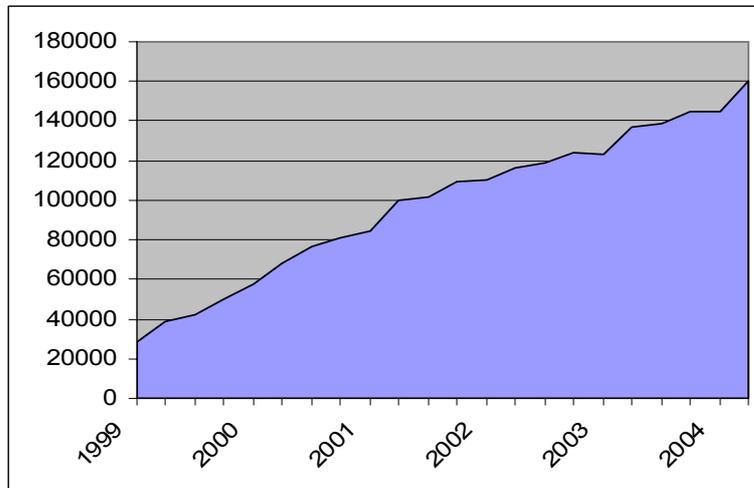

In the second quarter of 2004 the number of issued cards amounted to 159400 and there was 16044930 transactions made with them. All these transactions were worth 38480800 PLN. 80% of them were withdrawals from cash machines. The number of cards issued between 1999 – 2004 together with the number and value of transactions made with them is shown in Figs. 11, 12 and in Fig. 13.

The future of banking and financial services is associated with EMV microchip card. Currently in the EU there are 25 different kinds of electronic money based on microchip cards. In Poland there are no such systems but there are attempts at creating a system based on a central institution of electronic money. The big asset of microchip cards is greater level of transaction security when compared with cards with magnetic strip (better protection against “Freud” and functions giving access to banking and non-financial services). Such cards can be used in health care, transport or e-Government. Another important factor is the microchip potential to process information and store a few thousand times more information than a magnetic strip. Having recognised these new areas of EMV cards application the EU is currently promoting activities aimed at popularising microchip card solutions making it a priority of Europe programme.

A solution gaining big popularity in Europe (especially in Belgium and Luxembourg) is the so called electronic purse. It is an intelligent chip card used *off-line*, by means of which it is possible to settle small payments for services worth less than 10 USD in cashless way (in Poland from 1 grosz to 100 PLN).

The European Committee claimed e-purse proves to be essential in creating the Economy and Currency Union. It was also pointed out that thanks to low costs electronic payments can replace cash in member states

where the local currency is weak. E-purse standard is being created in co-operation with CEPS (*Common Electronic Purse Specification*), VISA, Proton and a number of European financial institutions. This project is partly stimulated by introduction of the European currency Euro. It is expected that all national enterprises connected with e-money wanting to go internationally will join CEPS. Combination Euro-CEPS can be the greatest driving force towards adoption of e-money.

Another solution based on e-money concept is a credit card:

- a) *post-paid-cards*: the issuer covers the costs incurred by the card holder for purchasing goods or services. The card holder can purchase goods or services by means of his credit card and its authorisation in *Authorisation Centre* before he actually pays for them. If the payment is settled through the Internet, the card holder must provide his card number as a part of the crypto-graphic procedure.
- b) *prepaid cards* with determined credit value reflected only on central server. Payments are settled anonymously (registration is not required).

Popularisation of the Internet Channel in business activity created a demand for payment instruments adjusted to network environment – network money and software money. There are two kinds of network money:

- c) money on a microchip card whose reading is carried out on a PC of its holder. The PC, however, must be equipped with a special programmed reader (i.e. pre-paid card- e-purse).
- d) Money on a computer disc: E-Cash, DigiCash<sup>12</sup>, stored on the hard disc and used in networks (e-cash is of single-use type which means that once a banknote with a given number has been used it is invalidated by a bank).

These systems are similar to the solutions used a cash card or money transfer. Their special feature is innovative opportunity to send money by SMS, e-mail or Internet websites. Taking as a criterion the addressee of the payment the systems can be divided into two groups:

- systems which allow to make a payment only to a business person (person to merchant);
- open systems allowing for transferring payments between market users (person to person). To these open systems belong banking institutions and other non-banking subjects.

---

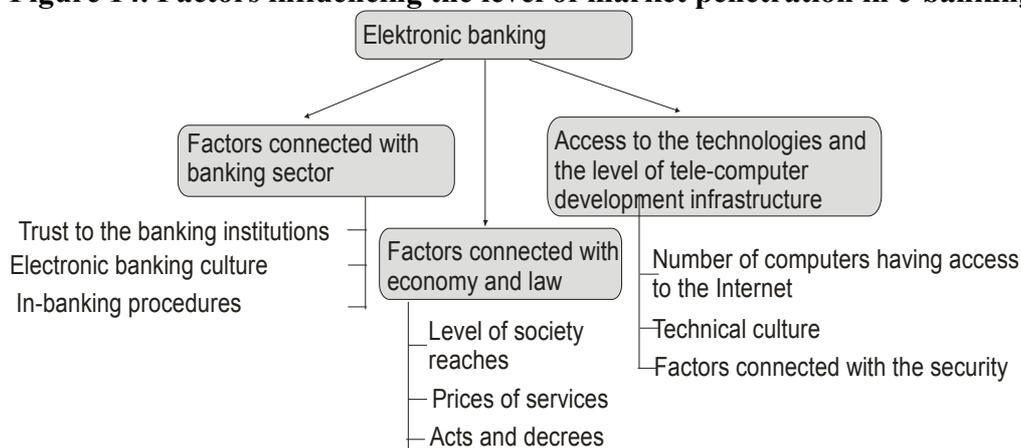

<sup>12</sup> DigiCash was the first company which offered e-cash Internet technology.

These opportunities are used by PayPal – the Internet payment system. There are not many similar solutions on the European market. It is used by a Dutch bank ING – product Way2Pay, Robobank – system Minitix. In Poland system PayU is getting more and more popular. There are however some barriers of legal nature. Polish legal system does not recognize systems based on central server as e-cash systems. Consequently it creates a situation in which this payment instrument is treated as a instrument different from e-cash instrument.

## 7. Factors influencing absorbing of e-banking services in the world and in Poland

E-banking is not developing evenly. The pace is different in different countries of the world. It does not entirely depend on the economic development of a country, it is rather an outcome of many factors influencing absorbing of these services but also of many barriers which arise in the context of new electronic technologies and related risks and illegal activities such as dirty money washing, selling non-existing bonds and hacker activities. Hence, this issue being a very complex one should be analysed from three points of view (Fig. 14), taking into consideration such factors as the total number of users of e-banking, level of market penetration as a percentage of all clients of a bank, level of market penetration as a percentage of the population and finally level of market penetration as a percentage of the Internet users.

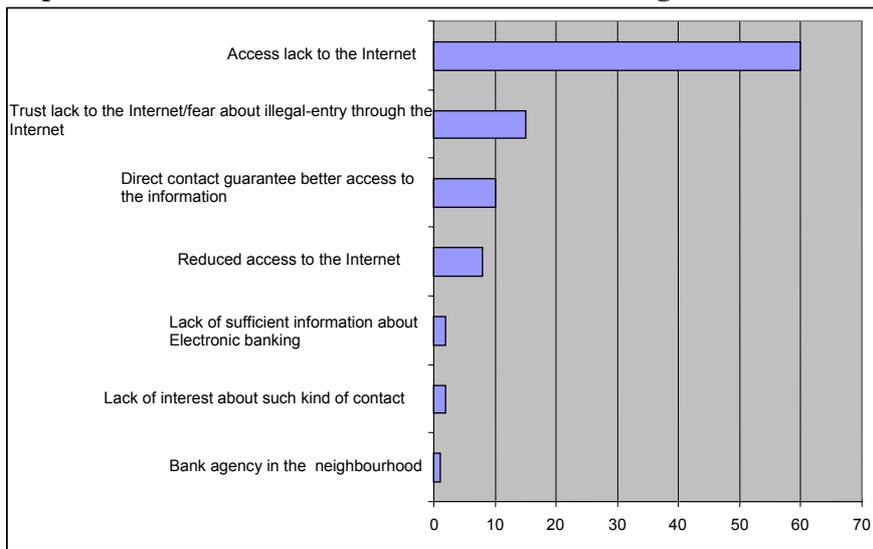

**Figure 14. Factors influencing the level of market penetration in e-banking**

*Source: own work based on*

The basic factor influencing absorbing the services is the access to technologies and the level of development of tele-computer infrastructure. This development is closely connected with the wide availability of Personal Computers and the Internet Channels which, in turn, has an impact on technical culture of information society. This was confirmed by Mentor-Telebus research which showed that the lack of access to the Internet creates a barrier and the reason to reject e-banking methods for nearly 60% of respondents, Fig.15.

**Figure15. Reasons for lack of interest in e-banking among Polish respondents who do not use the Internet banking**

Source: Mentor-Telebus, April 2003<sup>13</sup>

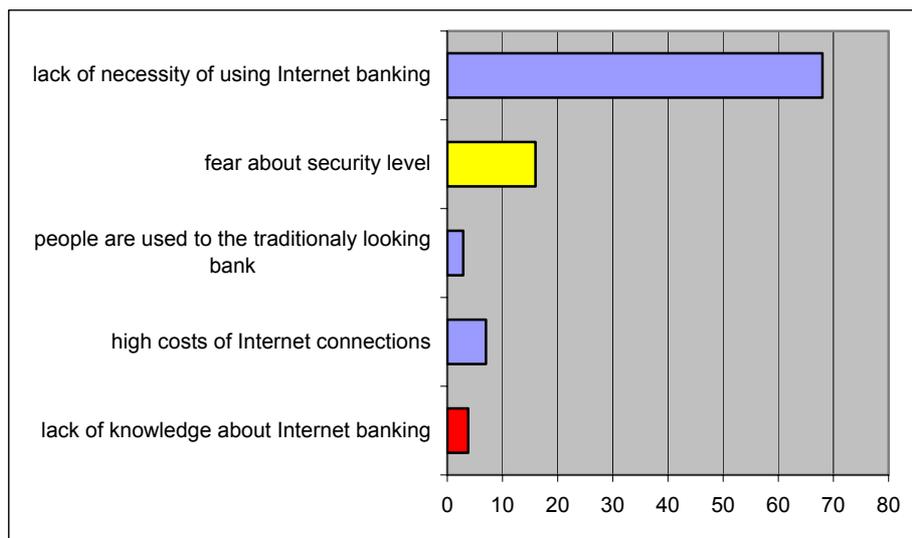

The indirect factor of e-banking services absorption are costs related to creating the access to new developments in technology, mainly using the telephone line and wide-wavelength access to the Net. Another salient issue is the so called level of saturation of the access to the internet. The critical point is 30% saturation of Internet services, after which a considerable rise in interest in Internet banking can be observed. We cannot speak, however, of free Internet access to use e-banking services without liberalisation of telecommunication market. In new EU member states it creates the greatest barrier for e-banking development together with low availability of the Internet. The liberalisation process helps create new measures in telecommunication sector such as: competition, implementation of new techniques and convergences, increase in demand for services and

<sup>13</sup> Szyszka G, Śliwczyński B at al., *Elektroniczna gospodarka w Polsce*, Poznań 2004

globalisation processes. The acceleration in development of telecommunication sector and economy in general through breaking up the monopoly and the presence of new operators caused many positive phenomena such as: price reduction for telecommunication services, increase in the number of services delivered, higher quality of services, their flattening and postalisation of tariffs. The above mentioned phenomena has a considerable influence on e-banking development.

Another important issue is the trust customers have in e-banking services. According to Forrester Research the fear of using the Internet banking is diminished with the time of usage of the Internet channel. The number of e-banking users who were previously Internet users consists of 50 % after 5 years of experience with the Internet channel and only 19 % after 2 years. It may be the outcome of growing awareness of depositing financial resources in the so called “invisible bank”<sup>14</sup>, growing technical culture of customers and lack of information on the scale of losses banks have as a result of Internet crime. This statement can be confirmed by research in which 15% of respondents share this opinion<sup>15</sup>, Fig. 16.

**Figure 16 Reasons limiting e-banking development among the Internet users.**

*Source: own work based on I-Metria, lipiec 2003.*

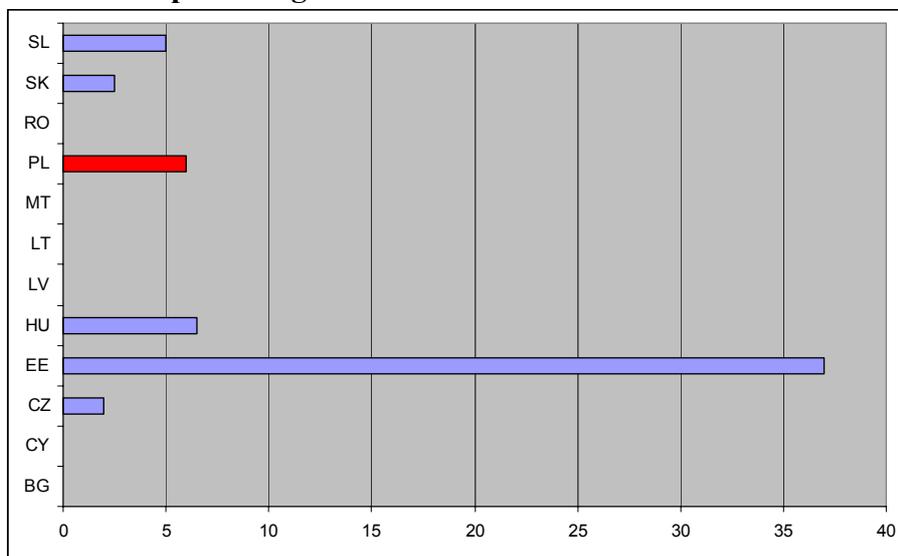

<sup>14</sup> J. Stryczyński, T. Zarzycki, „Bank ery gospodarki elektronicznej”, Bank, nr 9(96), 09.2000

<sup>15</sup> Mentor-Telebus, 04.2003

Another group of factors connected with penetration of Internet banking services are: confidence to financial institutions, electronic banking culture and internal procedures of banks' operations. However, Internet banking is frequently used in those countries where bank transfers are more popular.

Various researches show that confidence to banks and culture of electronic banking vary a lot. In Poland, due to significant technological backwardness, technical culture of Polish clients is not high. As compared to other EU countries, the ratio between a number of Internet banking users and a total number of bank account owners places Poland on the third position, after Estonia and Hungary, Fig. 17.

**Figure 17 Penetration of electronic banking in new-accessed EU countries in percentage relation to a total number of bank clients**

*Source: ECB 2002b, 2001 data for CY, MT, RO, SK, SL, Albassera, Sep 2002 for CZ, HU, PL Bank Association, 2002 for PL, HansaBank, 2002 for LV, LT, UNCTAD, 2002 for EE; Population 2000; Eurostat.*

The third group includes the following economy factors: service prices, level of clients' affluence, scale and pace of society education. However, using systems and ICI tools in operations of financial institutions, including banks, are regulated by according law acts and rules, for instance:

- act of 18 July 2002 about performing services by electronic means (operative since 10 March 2003), which institutes the European

Parliament and Council of European Union directive, number 2000/31 of 8 June 2003 (directive concerning electronic trade)

- act of 12 October 2003 about electronic paying tools. The act meets the European Union standards in respect to consumers' protection regarding bank services and limits clients' responsibility in case of a theft or loss of a card. The main part of the act is connected with using paying cards. It also touches electronic banking regulations and puts an obligation on banks to provide proper security and confidentiality when conducting operations.
- act of 18 September 2001 (operative since 08.2002) about electronic signature.

Apart from exemplary law acts many ordinances have been decreed, for instance:

- Ordinance of the Cabinet of 25 February 2003 concerning the rules of making, recording, storing and securing bank documents made on electronic means of information.
- Ordinance of Finance Minister of 24 September 2003 concerning the way, scope and time-limits of storing electronic money by institutions and banks as well as data on issuing electronic money. This ordinance is an addendum to the law act of 12 September 2002 about electronic paying tools and the way, scope and time-limits of transferring data to the National Bank of Poland.
- Ordinance of Finance Minister of 24 September 2003 concerning the way, scope and time-limits of transferring data on paying cards issued by competent institutions.
- Ordinance of Finance Minister of 24 September 2003 defining security procedures, permissible risk of operations of Electronic Money Institutions and area of its use. It also defines types of financial tools and regulations with respect to investing funds coming from obligations assumed while issuing electronic money, as well as other rules applicable while reducing risk.

It must be pointed out, however, that the above mentioned factors can also hinder development of electronic banking services. In many cases law acts do not follow the pace of electronic economy development and are not precise enough. In Poland two ordinances of Ministry of Finance can serve as the examples:

- Ordinance of 5 December 2000 concerning the way of collecting payments and returning tax payments as well as the way of conducting tax payment registration which do not allow making these payments by electronic means. This ordinance is in contradiction to:

Administration Procedure Code, Section II, Chapter I, Article 63, Clause 1, and Electronic Signature Law Act that aims at introducing electronic document in administration and economy.

- Ordinance of 15 September 2001 concerning definition of “cash payment form specimen and tax office money transfer form”. While introducing a new payment/transfer form, the legislative board overlooked the fact that almost all small, medium and large businesses make their payments via electronic transfer.

Another normative act that includes wrong regulations, contradicts the Polish Constitution, and the European Union Law, and hinders introducing necessary ordinances is the act of electronic signature of 16 August 2002. According to the PIIT opinion, wrong regulation says that the certificate document can be issued exclusively by institutions co-owned by the National Bank of Poland, which leads to the monopolization of the market (in June 2002 these condition were fulfilled solely by Contrast). PIIT representatives also believe that banks aim at gaining areas that are not strictly connected with their activity. It concerns, for example, limiting electronic money clearings (changing money to electronic impulses collected on cards) only to bank authorities, and hinders such operations from other companies. Banks conditioned exclusivity to clearing operations for the period of a year from the moment of issuing the regulations about electronic payment tools.

In practice it means complete lack of possibilities of issuing parking cards or public transport tickets by other companies but banks. Also, some other proposed changes in telecommunication regulations dealing with service prices at “a moderate price”, yet based on real costs, arouse concern among PIIT representatives.

The second group of factors that have a restraining effect on development of electronic banking consist of internal banks’ procedures that are not tailored to substantial, organizational and time aspects.

Development of modern bank services is also hindered by lack of unified security standards used by bank institutions. Each bank has its own systems, which is costly and time consuming. The solution to the problem might be the use of electronic signature that according to the law act guarantees:

- confidentiality of documents through their ciphering and at the same time their inaccessibility by third parties,
- integrity of documents so that their contents cannot be changed or counterfeited,

- authorization of a sender through exclusivity for his signature
- affixed electronic signature put down on a document becomes unquestionable fact.
- civil law aspect – the rule of equipoise of legal consequences as regards electronic signatures based on qualified certificates with manual signature is in power (except for some legal actions requiring particular form such as notary acts)

According to bankers and researches conducted by OBOP, development of services is also hindered by lack of Internet access and customers' habit of using traditional channels of bank services distribution.

## **8. Conclusions**

The end of the 20th century is the period of impetuous changes ongoing in the way of functioning in Europe and in the world. This is a period of continuous challenges, economic co-operation and implementation new ways of management. The changes include reducing time of carrying out business processes, their wider scope, more flexibility and reliability of operations, and increasing level of client service. In the near future, e-economy will revolutionize business activities in almost all sectors of economy. It has already marked its presence in financial services sector, including banks and, therefore, proves that further, comprehensive development of electronic bank services is inevitable. It leads to a necessity of bank strategies modification imposed by costs reduction, change of clients' consumption patterns, dynamic development of new technologies, and polarization of clients because of their ability to use the Internet and positive attitude towards electronic media. As a result, clients will gradually change their perception of bank sector institutions. A new quality of bank services is being provided, where a client becomes a subject and not an object as it used to be in traditional banking.

Modern e-banks take a particular place in e-economy. Their importance for development of new economy has been emphasised in the e-Europe programme, that is one of the Lisbon Strategy principles. E-banking makes it possible to perform such services as: electronic tax clearings, unemployment benefit or scholarship payments.

According to many Polish bankers, there is a strong belief that multi-channel activities and modern technological solutions will contribute significantly to the improvement of profits coming from banking operations. It means that the importance of both Internet and virtual banking on financial markets will be gradually increasing. The researches led by IPSOS show that

about 84% of the banks plan to introduce new solutions to bank-client relationship management. Other key enterprises of banking sector include: popularisation of mobile banking technology based on GSM technology with main access channel via Short Message Service –SMS (on a smaller scale, via WAP) and introducing Straight Through Processing Systems (STP).

## **Abstract**

*In view of the European Union accession, a large number of reforms are taking place in the member countries, especially in the “new” members. It is one from the priorities to develop modern, robust and efficient payment systems. Bodies, which are interesting in this goal are among others the central banks of the members countries, including the European Central Bank. The process of building of the new methods, used in the payment systems is influenced by changes in using of payment instruments. These changes are evoked not only as a result of changes in the legal, regulatory and institutional environment, but as a result of the national traditions and of the historical reasons, too. More than ten years, which has flowed from the beginning of the negotiations about the accession of the European Union, has influenced the development in the accession countries. There are not differences between payment systems and payment tools used today in the “old” and “new” members; there are differences in level of using of common instruments and tools. The development in the both parts of the European Union is today very similar.*

**Keywords:** *payments, cheques, credit transfer, payment card, direct debit*

## **1. Introduction**

This speech focus on the use of various payment instruments in the European Union. The main source of it is possible to find in the ECB statistics, especially in publications, which are named „Payment and securities systems in the European Union“ and „Payment and securities systems in accession countries“. Short name, used for these two publications and its addendum incorporating the last figures is „Blue Books“. In these publications is possible to find many informations about payment systems in all Member States and in countries, which were preparing for membership in the EU, ten of which have since become Member States of the European Union .

What is the aim of this speech? To compare data about using payment cards, cheques, credit transfers and direct debits in part of members of the European Union and to describe differencies and/or resemblances between old and new members of the Euroiepan Union in the field of payments.

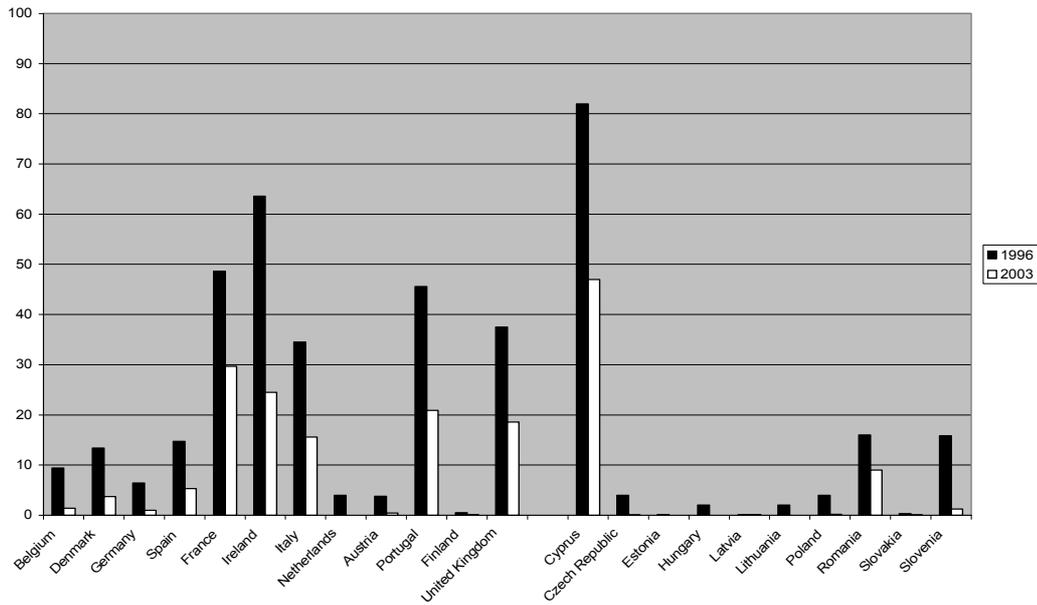

There are two reasons, why figures are not done for all Member States – data are not available for all countries in all categories and all years and the methodology is changing in some countries during time.

## **2. Cheques – traditional payment instrument**

In next two bar charts the data about using cheques are shown. The term “cheque” includes traveller’s cheques, eurocheques and bankers’ drafts. Commercial bills are included only if funds transfers can be made on the basis of these, without using another medium. The first of picture show us figures, which give us information about volume of used cheques in comparison with other payment instruments, the second one give us information about value of used cheques in comparison with other types of payment instruments.

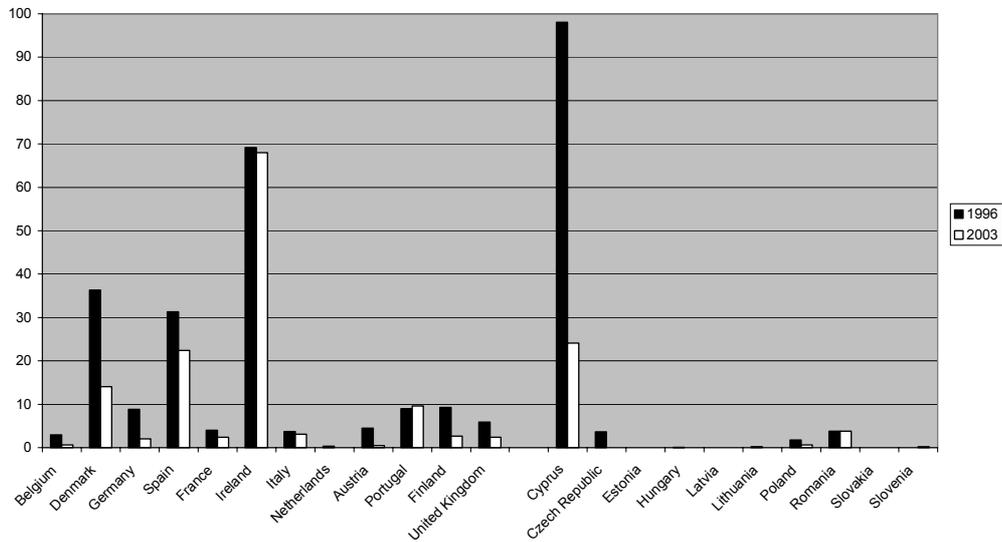

Cheques were traditional payment instrument in many countries. Cheque as payment instument has many advantages – it reduce using of cash, necessary for bussiness making. Customers consider them easy to use, either for remote payments or face-to-face transactions, and they are free of charge for the drawer. The cheque is still the most widely used payment instrument in some countries, as for example in France, Ireland or Portugal. Facing it – in other countries, as for example in Germany, Austria or Finland cheques has never become as important as in many other countries of the western world. In new member countries using of cheques had never tradition and nowadays this instrument is not using in any new members, excluding Romania (which are going to be a member of the EU very soon).

**Figure 1 Relative importance of cashless payment instruments - cheques  
(% of total volume)**

Source: Author's calculation according to Blue Books

**Figure 2 Relative importance of cashless payment instruments - cheques  
(% of total value)**

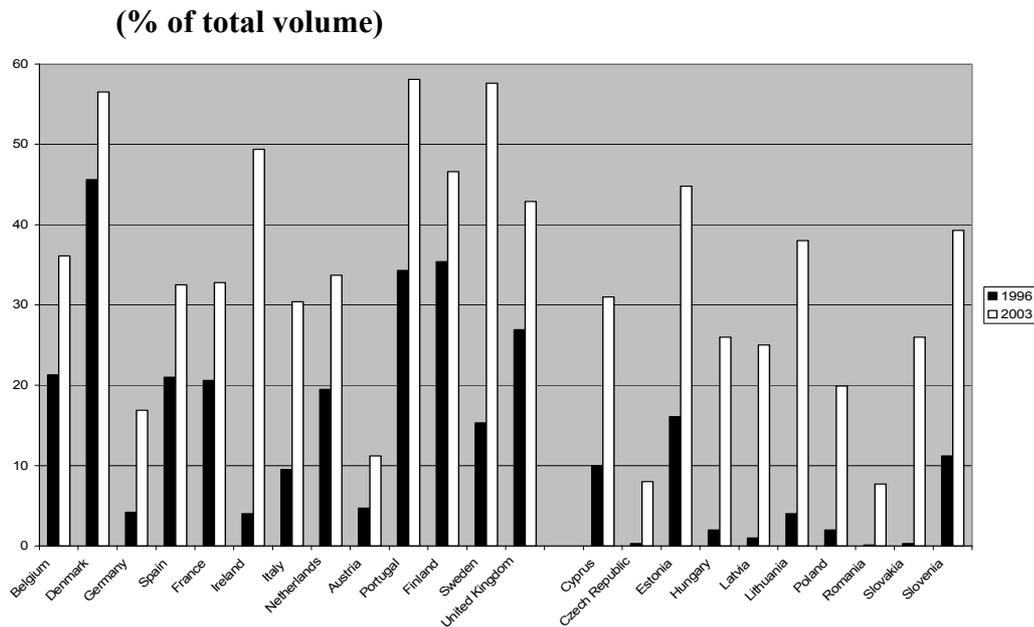

Source: Author's calculation according to Blue Books

One interesting moment is possible to explore in previous graphs – if number of using cheques makes from this instrument in some countries relatively important part of portfolio of payments instruments, the value of payments executed by cheques is higher only in four evaluated countries and only in Ireland the importance of cheques should be higher in future. In this four countries using of cheques has long tradition. In other countries, with the automation of cashless payment transactions, the fact that a cheque is a payment instrument which is payable at sight has proved to be one of its key disadvantages – above all the fact, that cheque must always be collected and presented in paper-based form.

### 3. Credit cards – a new dimension of payments

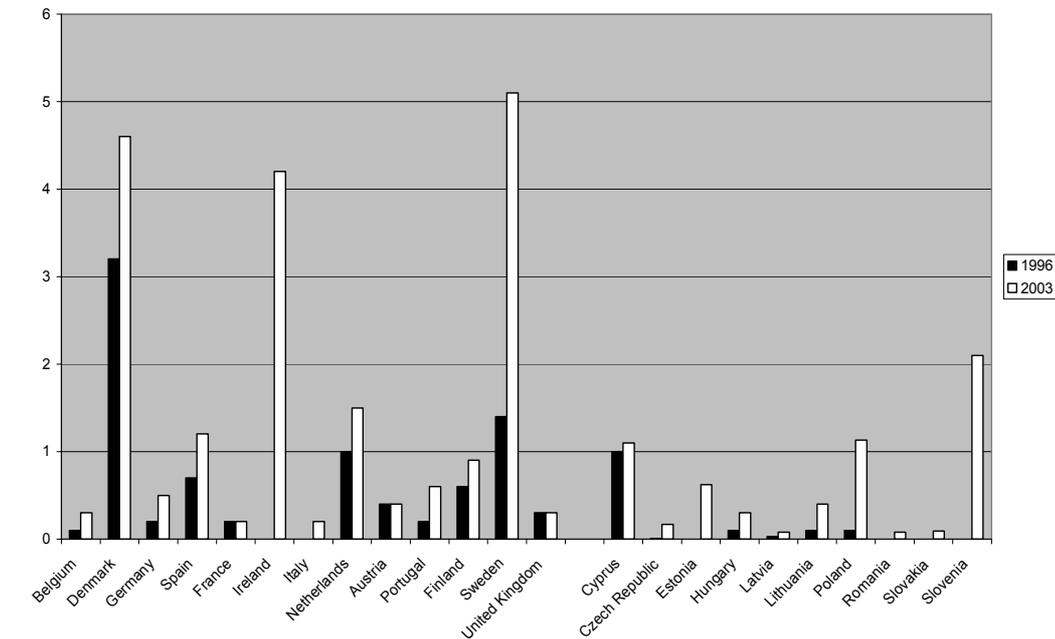

Payment cards in any possibilities (credit cards, debit cards, charge cards, elektronik purses and so on) plays more and more important role in payments in all countries. Relative small percentage of used credit cards in some countries can be influenced by specific factors – for example, in the Czech Republic play (see figures 7 and 8 ) big role direct debits. In absolute figures the number of payment operations with cards is the same as in other new member states, in relative figures it seems to be less.

**Figure 3 Relative importance of cashless payment instruments - payment cards**

Source: Author's calculation according to Blue Books

**Figure 4 Relative importance of cashless payment instruments - payment cards**  
(% of total value)

Source: Author's calculation according to Blue Books

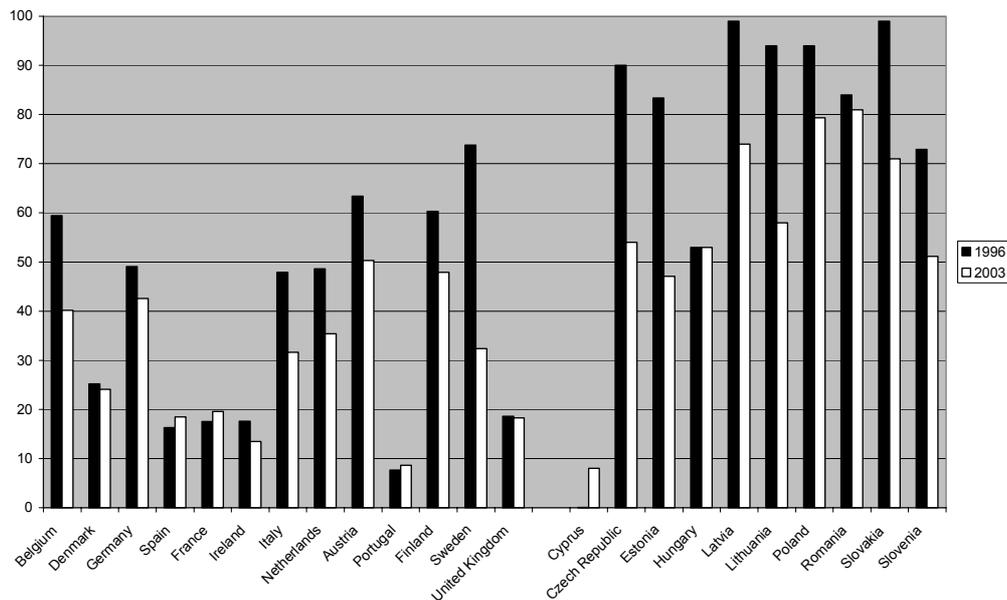

Figure 3 has shown us information about volume of cards in comparison with other payment instruments, the second one has given us information about value of used cards in comparison with other types of payment instruments.

Payment cards played bigger role ten year ago in old part of the European Union. In the eastern part of Europe using of small pieces of plastic, called payment cards, was in beginning. But after seven years the situation has rapidly changed. The figures, which inform us about volume and value of using cards in new Member States are similar to figures in old part of the EU. One notice is possible to say now. If cheques are used in bigger volumes in a few countries, cards are typical retail instrument, used by small clients for personal payments. Maximum level of percentage of using cards (if we compare value of operations with cards) is between four and five percent in three countries. In the other countries cards are used only in one percent of value of payments. One from the reasons of this fact should be found for example in small limits, which are given for majority of cards for its day or weeks using.

#### 4. Credit transfers – tradition with long future perspectives

Credit transfer is a payment order or possibly a sequence of payment orders made for purpose of placing funds at the disposal of the beneficiary. It is really traditional payment tool. Credit transfers have traditionally been the predominant form of payment transaction. However, their share of the total volume of payment transactions has decreased in recent years because more suitable payment instruments are used for certain purposes.

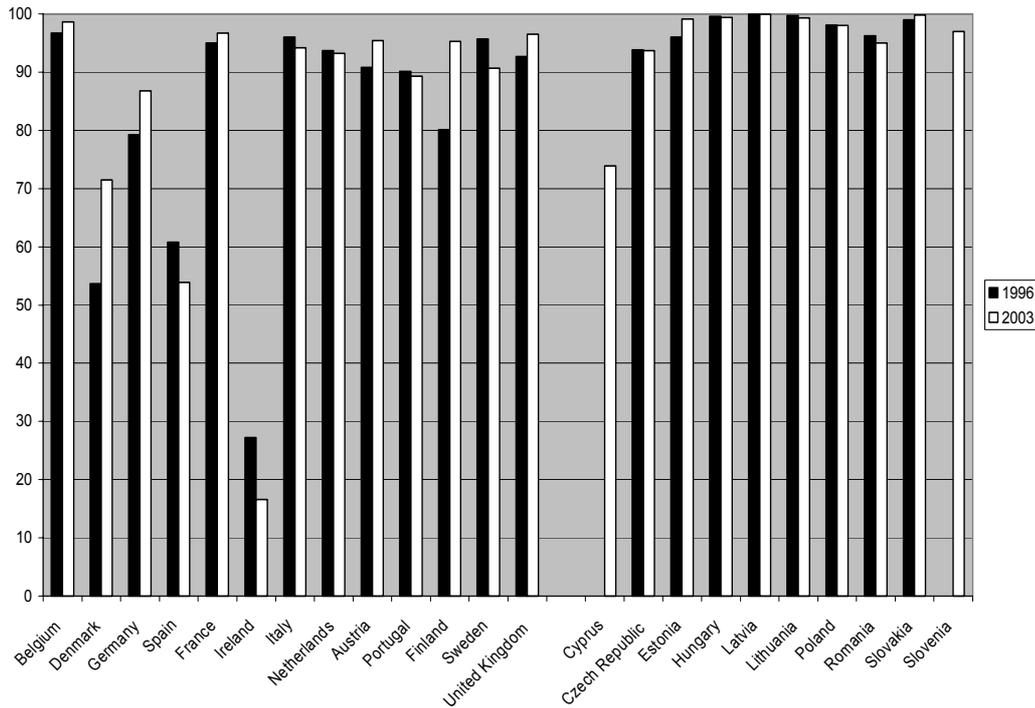

**Figure 5 Relative importance of cashless payment instruments - credit transfers (% of total volume)**

*Source: Author's calculation according to Blue Books*

In last decade has grown the role of one new product, which support the using of credit transfers – e-banking. A significant development can be seen in the growing popularity of electronic forms of payment orders made by customers in parallel with the growing popularity of self-service banking and home banking products. More and more clients, including big firms, are communicating their payment orders via magnetic media or telecommunications. It should be the reason for big percentage of value of payments, done by credit transfers.

**Figure 6 Relative importance of cashless payment instruments - credit transfers (% of total value)**

*Source: Author's calculation according to Blue Books*

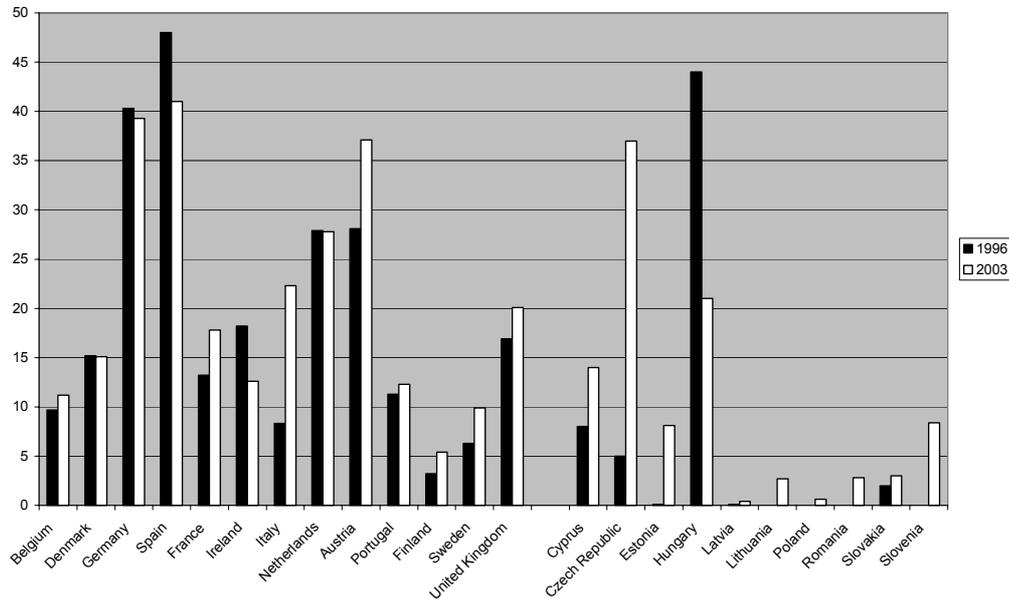

## 5. Direct debits – last but not least

The term „direct debit“ means a pre-authorised debit on the payer’s bank account initiated by the payee. Initiators of direct debits must be approved by a bank. They must also obtain signed authorisation from the payer, which is then moved to the payer’s bank.

Direct debits are used generally for recurrent payments such as electricity, gas, telephone and water bill payments, and for monthly income tax payments, mainly in the larger urban centres. Direct debits offer advantages to bank (processing costs are relatively low thanks to automation), as well as to the utility companies (by simplifying their accounting administration) and to individuals (by simplifying the payment). Legislation in some countries make possible „legal“ direct debits – i.e. direct debits on the basis of legally valid and enforceable decisions of courts, court executors and administrative bodies of the state budget – as well as direct

debits for the payment of interest or charges for banking services. The use of direct debits is in average increasing.

**Figure 7 Relative importance of cashless payment instruments - direct debits (% of total volume)**

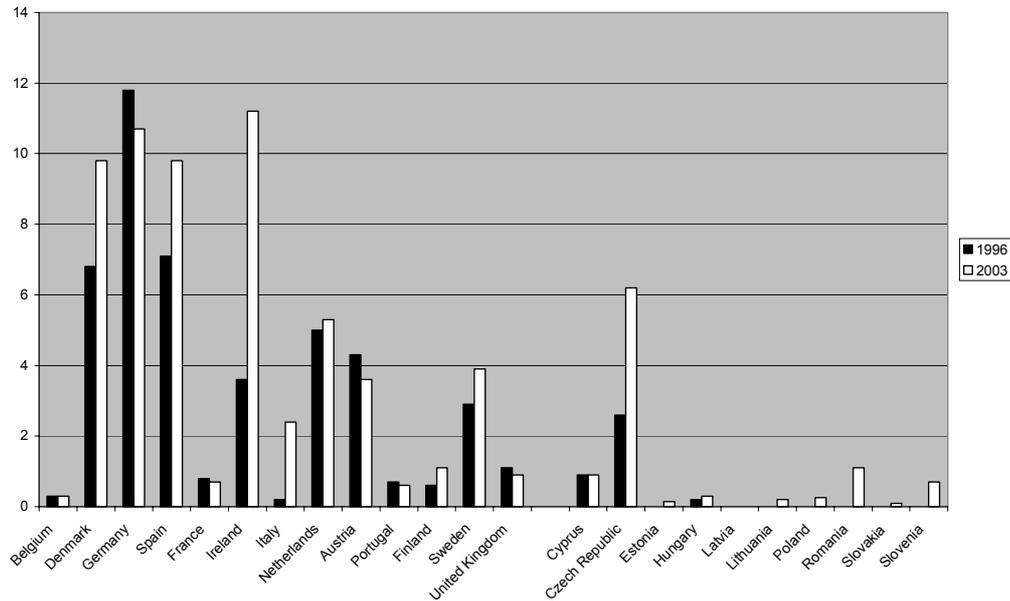

Source: *Author's* calculation according to Blue Books

Two partial conclusions is possible to do, if the statistical data from individual countries are compared.

At first – direct debits are very often used in most of old mebers of the European Union. In a new part of the EU this type of transactions is not so popular and so frequently used (with one exception in the Czech Republic). The reasons can be different. For example, in Poland direct debits were introduced by the National Bank of Poland in October1997 and the first transactions were effected I July 1998, its use is increasing, but this instrument still plays a marginal role in retail payments. The similar situation is in Romania, Latvia or Lithuania.

At second – direct debits are used for big volume of payments, but average value of these payments is very small. It's a reason, why – for example – 45 % of volume of payments in the Czech Republic reperesents only 6 % of total value of payments in 2003. The value of regular direct debits is influenced by its purpose and probably will not change in a future.

## 6. Conclusion

Two big groups of countries existed a few month before the best change in history of the European Union. One of them was group of 15 „old“ members from which 12 countries have created Eurozone with one currency. Second group was created by twelve accession countries, ten of which have since become Member States of the European Union .

It is possible to say, that it was a symbolic situation. Fifteen years ago majority of this groups were enemies. First changes started as a result of political changes. West and East Europe have started to cooperate. But differences between these two groups of countries were so deep, that ten years were not enough for their covering. Aproximately ten years ago the negotiations about accession to the European Union have started. Influence of that fact is probably the main factor, which caused, that now accession countries use the same instruments and methods as are common in the EU. Differences of course still exist. But what is important, that there are differences in level of using of common instruments and tools in common systems and that these differencies are going to be lower and lower during

the years. There are not differences in using systems and it is reason for optimistic view to common Europe future.

## **Abstract**

*Implementation of the European legislature into the Czech system of law in connection with preparation of the Czech Republic into the European Union and its own entry on May1, 2004 participated on changes in the legal frame of the system of payments. This contribution is focused on considering benefits of related changes for clients –a consumer of the system of payment services (domestic and foreign) and a holder of electronic means of payment. Except the indisputable importance, which harmonizing legal regulations have for improving the legal position of a client, possible financial benefits resulting from this process not only for a small client, but also for small and middle firms are reviewed. Concretely it concerns the amount of charges for cross-frontier payments and reduction of the responsibility of a credit card holder for financial losses arising in connection with its loss or theft.*

**Key words:** *implementation; law on the system of payment; cross-frontier transfers; financial arbitrator; electronic means of payment;*

---

<sup>1</sup> The paper is published due to the Czech Grant Agency support (grant GAČR No. 402/05/2758 „Integration of the financial sector of the new EU member countries into the EMU“).

## **1. Introduction**

Cross-frontier system of payment specification in terms of the European Union is modified mainly by the Directive of the European Parliament and the Council no. 97/5/ES on cross-frontier transfers of assets and the Directive 98/26/ES on irrevocability of settlement in the systems of payment and in the systems of settlement of securities dealings. Orders of the European Parliament and the Council (ES) no. 2560/2001 on cross-frontier payments in EURO, which by May 1, 2004 has become the part of the system of law of the Czech Republic without the necessity of its transposition modifies rules for cross-frontier transfers, which are denominated in EURO and Swedish crowns.

Regularization of issuing and using electronic means of payment comes out of the Directive 97/7/ES on protection of the user in case of a contract concluded at a distance, the Recommendation 97/489/ES on transactions carried out by electronic means of payment and the Directive 2000/46/ES on approach to the activity of institutions of electronic money.

Mentioned European legal rules emphasize the protection of the user and of system of payment regulation. Their importance consists in the fact that transfers are the most used service in the domestic and foreign system of payment. Electronic means of payment as well, namely credit cards, admitted also considerate expansion.

## **2. Law on the system of payment**

By January 1, 2003 the Law no. 124/2002 Coll. on transfers of finances, electronic means of payment and systems of payment (the law on the system of payment) as amended by changes under the Law no. 257/2004 Coll. came into force. By May 1, 2004 those provisions of the Law, which were as for the time bound with the entry of the Czech Republic to the European Union, came into force.

### ***2.1 The subject of adjustment***

The Law adjusts

- a) carrying out transfers of finances on the territory of the Czech Republic in the Czech currency (domestic transfers in crowns) and carrying out cross-frontier transfers, regardless the currency in which accounts of an ordering customer and a beneficiary are conducted,
- b) issuing and using electronic means of payment,

- c) origin and carrying out systems of payment .

## ***2.2 Domestic and cross-frontier transfers***

The second part of the Law implements the Directive 97/5/ES on cross-frontier transfers. The aim of the Directive and even the Law as well is the protection of a small user. The cross-frontier transfer means the transfer of finances from one member state of the European Union or from the state making the European economic space to another member state of the European Union or the state making the European economic space in the domestic currency of any member state of the European Union or the state making the European economic space up to the equivalent amount of 50 000 EURO. Restriction of the sum of the transfer to the amount of the equivalent of 50 000 EURO was taken from the directive only for the cross-frontier transfers. The directive does not apply on domestic crown transfers, and therefore the Law insures the same terms of transfers and further obligations regardless of the amount of the sum of the transfer.

The Law regulates only settlement form of payment and it does not imply to the collection form of payments. Rules for providing collection forms of payments are set by the Regulations of the Czech National Bank no. 62/2004 Coll., by which the way of providing the system of payment between banks is set, accounting on accounts at banks and technical, procedures of banks at corrective clearing.

### **2.2.1 Informative duties**

To insure transparency of conditions of providing transfers and improving informedness of a potential client the Law sets the transferring institution the duty to publicize introductory information on basic conditions on which transfers are provided. The Law also sets the transferring institution the duty to announce the following information after realization of the transfer unless a client renounces a claim on this information.

The transferring institution informs the public clearly and comprehensibly in a written way in its premises whereas information must always include:

- a) the term necessary for putting a sum to the credit of the account of the beneficiary's transferring institution,
- b) the term necessary for the sum of this transfers to be credited for the benefit of the beneficiary's account,
- c) the amount or the way of setting the amount of the price, which the client will settle for providing transfers,

- d) procedures for settling complaints including all information on procedures for solving conflicts.

The bank has a duty to give the client introductory information on the price of the transfer or the way of setting its price. At the domestic transfer such information is available. By the entry of the intermediary institution at the cross-frontier transfer the amount of charges becomes uncertain. According to the explanation of the Czech National Bank transferring institutions will fulfil informative duty sufficiently, provided it is stated in conditions that the price composes of the price, which is counted by the institution and further from prices of all intermediary institutions, which are not known, and a client will be charged at the concrete transfer. This way is valid for the way of payment so called OUR, when the ordering customer covers the price of all transfer and the sum must be credit in full amount to the beneficiary.

### **2.2.2 Terms of providing transfers**

Provided the transferring institution of the ordering customer carries out the transfer on the territory of the Czech Republic in the Czech currency:

- a) among different transferring institutions, it is obliged to ensure putting the sum of the transfer to credit for the benefit of the beneficiary's transferring institution account at the latest the following bank working day after the day of force of the transfer order, unless a shorted term has been agreed on,
- b) within the same transferring institution it is obliged to provide the sum of transfer to the beneficiary on the day when the force of the transfer order took effect or the following bank working day,
- c) provided the transferring institution of the ordering customer carries out the cross-frontier transfer, it is obliged to ensure putting the sum of the transfer to the credit for the benefit of the beneficiary's transferring institution account in the term agreed on by the ordering customer and provided such term is not agreed on, within 5 bank working days from the day of force of the transfer order.

The beneficiary's transferring institution will put a sum of the transfer to the credit for the benefit of the beneficiary's account at the latest the following bank working day after the day when the sum of the transfers was put to the credit of its account. This term is cogent and relates to both domestic and cross-frontier transfers.

Mentioned terms are obligatory even in cases when a transferring institution provides conversion between the currency of the transfer and the currency of the ordering customer's account or the beneficiary's account. Terms

set by the law for domestic crown transfers are cogent and cannot be prolonged by the contract.

Terms of cross-frontier transfers are dispositive, the agreement of contracting parties has the preference. Provided only the term is not agreed on, the law sets the five-days term of the cross-frontier transfer.

### **2.2.3 Ban on transacting deductions from transfers**

It concerns only transfers, at which the price of transfers is covered by the ordering customer of his transferring institution, that is so called payments OUR. Provided the ordering customer does not set the price for the transfer or its part is covered by the beneficiary (so called. payments BEN, SHA), the transferring institution is obliged to use the way of charging OUR. The objective is to prevent double charging.

### **2.2.4 Obligation in case of unsuccessful transfer**

Provided the transfer is not realized in the set term after the force of the transfer order, not even the sum of the transfer was returned, and the ordering customer asks for that, the transferring institution will provide him the sum of the transfers and further the punitive interest and from the price for transacting the transfer which the ordering customer has already paid. The institution will satisfy the obligation within fourteen bank days from the day of delivering the request of the ordering customer.

Another procedure is valid for the cross-frontier transfer. In case of the cross-frontier transfer the mediatory transferring institution is obliged to return the transferring institution, which gave it an instruction to carry out the transfer, the sum only to the equivalent of 12 500 EURO and further the punitive interest and the price for providing the transfer, which it received. Settlement of the remaining sum over 12 500 EURO is solved according to the Czech system of law.

### **2.2.5 Solving conflicts**

The provision comes out from the article 10 of the Directive97/5/ES, which placed the member states a duty to ensure appropriate and effective procedures of handling complaints and redressing conflicts between clients and transferring institutions. With conflicts arising between transferring institutions and their clients at carrying out transfers of finances according to the law clients can appeal to institutions for solving conflicts effecting under the special legal regulations. In the Czech Republic it is a financial arbitrator. The right of the client to appeal to the court is not violated.

### **3. Prices of cross-frontier transfers**

Cross-frontier transfers, however, only those which are denominated in EURO and Swedish crowns, except the law on the system of payment are modified also by the Enactment no. 2560/2001/ES, which is the part of the Czech system of law.

The Article 3 of this enactment establishes the principles of equality of prices for domestic and cross-frontier payment operations:

- 1) With force from July 1, 2002 prices charged by institutions for cross-frontier electronic payment operations provided in EURO up to the amount of 12 500 EURO are the same as prices charged by the same institution for corresponding payments in EURO carried out in the member state in which the institution carrying out the cross-frontier electronic payment operation is settled.
- 2) With force from July 1, 2003 this enactment is valid for all cross-frontier transfers, regardless to the form of giving the transfer order.
- 3) With force from January 1, 2006 the amount of 12 500 EURO increases to 50 000 EURO.

For the practical transaction of the cross-frontier system of payment it is important the provision of Article 5 par. 2 of the Enactment, which sets that the bank can charge additional prices provided the client does not use IBAN (International Bank Account Number) of the beneficiary and BIC (Bank Identification Code – swift code) of the beneficiary's bank. IBAN is an international standardized format of the account number and its implementation supports making the foreign system of payment and its automation more efficient. The Code BIC serves for the correct routing of payments in the international system of payment.

#### ***3.1 Price of cross-frontier transfers in the CR***

Prices for cross-frontier payments in EURO are not in any way related to prices for domestic payments in Czech crowns. However, it is the reality that approximately 70% of accepted and transmitted foreign payments is denominated in EURO and a decrease of related charges has importance for clients and mainly for small and middle enterprises trade intensively with foreign partners. The condition is not to exceed the sum of 12 500 EURO in one payment and correct setting of codes IBAN and BIC.

Československá obchodní banka decided as the first to accede to advantaging this category of payments, Komerční banka and Česká spořitelna

followed. In the course of the year 2005 other banks joined gradually. From the chart 1 it is obvious that not all the banks did so and the difference in charges charged in single banks is so distinctive.

Some banks, namely Česká spořitelna, ČSOB, GE Money Bank, Komerční banka and Raiffeisenbank, define types of transfers, to which price advantaging applies, by the comment in the price list.

**Table 1 Prices of cross-frontier transfers of chosen banks**

<i>Bank</i>	<i>Position of a client</i>	<i>Charge [CZK]</i>	<i>Price of the transfers of the sum 12 500 EURO</i>	
			<i>[CZK]</i>	<i>[EURO]</i>
<i>Citibank</i>	ordering customer	1% (min. 300,- max. 2 000,-)	2 000,-	66,70
	beneficiary	free of charge	free of charge	free of charge
<i>Česká spořitelna</i>	ordering customer	220,-	220,-	7,30
	beneficiary	100,-	100,-	3,30
<i>Československá obchodní banka</i>	beneficiary	250,-	250,-	8,30
	beneficiary	150,-	150,-	5,00
<i>eBanka</i>	ordering customer	1% (min. 200,- max. 1 500,-)	1 500,-	50,00
	beneficiary	1% (min. 100,- max. 1 000,-)	1 000,-	33,30
<i>GE Money Bank</i>	ordering customer	220,-	220,-	7,30
	beneficiary	220,-	220,-	7,30
<i>HVB Bank Czech Republic</i>	beneficiary	250,-	250,-	8,30
	beneficiary	200,-	200,-	6,70
<i>Komerční banka</i>	ordering customer	225,-	225,-	7,50
	beneficiary	225,-	225,-	7,50
<i>PPF banka</i>	ordering customer	1% (min. 200,- max. 1 200,-)	1 200,-	40,00
	beneficiary	1% (min. 100,- max. 1 000,-)	1 000,-	33,30
<i>Volksbank CZ</i>	ordering customer	1% (min. 300,- max. 1 700,-)	1 700,-	56,70
	beneficiary	0,5% (min. 100,- max. 750,-)	750,-	25,00

<i>Raiffeisenbank</i>	ordering customer	220,-	220,-	7,30
	beneficiary	220,-	220,-	7,30
<i>Živnostenská banka</i>	ordering customer	0,8% (min. 200,- max. 1 500,-)	1 500,-	50,00
	beneficiary	1% (min. 200,- max. 1 500,-)	1 500,-	50,00

*Source: Tariffs of mentioned banks.*

*Commentary to the Table:*

- 1) *For the calculation it is used approximate conversion 1 EUR= 30 CZK (even on ten cents).*
- 2) *Data are taken from the price list of in October 2005. There are charges for transfers ordered by the bank offered forms of direct banking.*
- 3) *In case of different rates in dependence on the size of the client and dividing expenses between the ordering customer and the beneficiary the chart shows charges for natural persons, respectively small and medium firms with the variation SHARE.*

#### **4. Issuing and using electronic means of payment**

The third part of the Law implements in the introductory stated European legal regulations. Principles and rules included in the Recommendation 97/489/ES are included in the Exemplary business conditions of the Czech National Bank (Česká národní banka), which contain the adjustment of mutual rights and obligations of issuers and holders at issuing and using electronic means of payment. Exemplary business conditions do not have the character of legal regulations, but recommendations of the central bank issued by it with the aim of increasing the protection electronic means of payment holders. In the introductory provisions of its business conditions the insurer is obliged to inform explicitly whether the conditions correspond to exemplary business conditions of the Česká národní banka, and what is the content of possible divergences.

##### **4.1 The holder's responsibility**

The article VIII of Exemplary business conditions of the Česká národní banka determines the holder's responsibility for financial losses suffered in consequence of loss or theft of the electronic means of payment. It sets the deductible limit of the holder on the existing financial loss and also the moments of the transfer of responsibility from the holder to the issuer of electronic means of payment. Specifically this problem is solved by the Exemplary business conditions of the ČNB as follows.

- 1) The holder bears the responsibility up to the moment of reporting loss or theft that is in maximum up to the amount of 4.500Kč. In case when the

holder committed gross negligence, he violated contractual obligations or dealt fraudulently bears loss with in full amount.

- 2) The holder does not bear any responsibility after the moment of reporting loss or theft of electronic means of payment, with the exception of cases, when he acted fraudulently.

As it is obvious from the chart, mentioned banks limit in various ways the moment of the transfer of the responsibility from the client to the bank. Some banks prolong the interval of the client's responsibility even after the moment of receiving the report of loss or theft of the card. They all accord in the fact that to the decisive step the client bears the responsibility for loss in full extent. Identically they also insist on the fact that the owner bears all responsibility for transactions carried out by lost, stolen or misused card provided PIN was used at these transactions.

**Table 2 The moment of transfer of the responsibility from the client on the bank**

<i>Bank</i>	<b>Responsibility transfer</b>
<i>Citibank</i>	To the moment of reporting loss or theft of the card in full amount. In case of an electronic card then even to passing one hour after reporting loss or theft, again in full amount.
<i>Česká spořitelna</i>	Till the moment of reporting the card into the file of bans.
<i>ČSOB</i>	Immediately after the telephone announcement with the exception of transactions at which the transaction time from the receipt or from the authorization systems is not ascertainable. At this type of transactions the responsibility of the account owner expires at 24:00 hours of the day when the event was reported by phone.
<i>eBanka</i>	In case of the credit card Maestro/Elektron in the course of an hour after reporting loss or theft. In case of the credit card Standart/Classic, Business or Gold till 24:00 hours of the day of reporting loss or theft.
<i>GE Money Bank</i>	Till the moment of reporting theft or loss of the card in full amount.
<i>HVB Bank Czech Republic</i>	<i>Till the end of the day in which he bank received the instruction carrying out the blockage of the card fulfilling al specified requirement.</i>
<i>Komerční banka</i>	Immediately after receiving the order for introducing the card oh the stop list of the KB head office, except the transaction at which the transaction time is not ascertainable from the receipt or from the authorization systems. At this type of the transaction the cardholder bears the risks of damage until the following calendar day (that is till the midnight of the day of reporting loss/theft).
<i>PPF banka</i>	Identically with the ČSOB.

<i>Volksbank CZ</i>	After passing the calendar day in which the theft or loss was reported. At credit cards MasterCard the cardholder deductible even for the transaction carried out after reporting loss/theft of the card that is in the amount set by the Scale of charges up to 10.000, -Kč.
<i>Raiffeisenbank</i>	Till the moment when theft or loss or misuse of the card was invincibly reported. .
<i>Živnostenská banka</i>	By the beginning of the calendar day which follows the day in which theft or theft of the card was reported to the bank..

## **5. Law on the financial arbitrator**

The institution of the financial arbitrator of the Czech Republic is a special body out of court settling conflicts, which can occur between providers of the system of payment services and their clients or between the issuers and users of electronic means of payment. It was established within harmonisation of the law of the Czech Republic with the European Union countries, as the Directive no. 97/5/ES on cross-frontier transfers requires ensuring rapid and effective settlements of clients' conflicts with transferring institutions by extra judicial way. The objective is a higher protection of a client – a user. Member states of the European Union and other states (USA, Canada, Australia) have ombudsmen and other extra judicial bodies and institutions with variously broad competence and responsibility.

The Law no. 229/2002 COLL. on the financial arbitrator was amended by the Law no. 558/2004 Coll. with the legal force from January 2005. In his activity the financial arbitrator is bound by the Law no. 124/2002 Coll., on transfers of finances, electronic means of payment and the system of payment (the Law on system of payment).

The financial arbitrator decides about arguments occurring between institutions and their clients. They are conflicts occurring at implementation of domestic and cross-frontier system of payment and conflicts between holders and issuers of electronic means of payment. Especially it concerns abidance of by the law provided terms and conditions for accounting of single system of payment transactions. The amendment of the Law on the financial arbitrator extended its force on adjust accounting and the collection form of payment on the territory of the Czech Republic which are modified by implementery legal regulations to the Law on the system of payment, namely by the Edict no. 62/2004 Coll., by which the way of providing the system of payment between banks, accounting on the accounts of banks and technical procedures at adjust

accounting is set. From the Law the financial arbitrator is authorized to solve conflicts at cross-frontier transfers up to the equivalent amount of 50 000 EURO. This competence of his began to be valid by the moment of the entry of the Czech Republic to the European Union.

The advantage of the client at making the complaint at the financial arbitrator is quick and simplified hearing. From the Law it implies among others the obligation to provide the submitter with the right to lead the proceedings in the language in which his contract was drawn and which was used in the mutual contact between him and the transferring institutions, namely an insurer of the electronic means of payment. Proceedings between the financial arbitrator is free of charge. Only expenses on interpreting and translating are paid by the aggrieved transferring institution. Other expenses of the proceeding before the financial arbitrator are born by every party separately. On the request of the submitters the financial arbitrator gives them help at drawing, submitting or completing the petition.

### **5.1 Results of the activity of the financial arbitrator**

In the year 2004 the financial arbitrator solved altogether 130 cases compared to 66 cases solved in the year 2003. In the year 2004 the number of justified cases increased to 77 cases compared to the previous year, when there were only 27. In the year 2004 the financial arbitrator issued 42 findings in total from which whole 69%, that is 29 findings, were issued for the benefit of the institution. Remaining 31%, that is 13 findings, were issued for the benefit of the submitter.

**Table 3 Justified cases solved by the financial arbitrator**

Spheres of conflicts of solved cases	<b>2003</b>	<b>2004</b>
<i>Finances transfer</i>	9	18
<i>Misuse of electronic means of payment total</i>	18	59
<i>from that - using electronic means of payment in ATM</i>	--	28
<i>- using electronic means of payment by businessmen</i>	--	19
<i>- other problems with electronic means of payment</i>	--	12
<b>Total</b>	27	77

*Source Annual reports of financial arbitrator years 2003, 2004*

## 6. Conclusion

It is obvious that acceptance of new regulations and amendment of existing ones governing the sphere of system of payment services, brought many beneficial changes, evoked especially by the obligation of the Czech Republic to harmonize the system of law with the law of the European Union. Especially the level of transparency of offered services increased and the legal position of the client when using these services was reinforced. Also certain financial benefits of clients indirectly resulting from this process were recorded. On the contrary the degree of the client's responsibility for financial losses resulting in connection with misusing electronic means of payment remains relatively high.

## **Abstract**

*The book keeping is presently IT based, including the correspondence with the clients. The traditional tools are also IT based and new techniques are emerging such as: the ATM and home banking. The beginning of the 3<sup>rd</sup> millennium is highly influenced by the expansion of the Internet used as tool for communication affecting also the relations between the banks and their clients. The lack of a banking service represents a handicap for the banks intending to gain corporative clients and, in the perspective for those specialized in development of retail services. As banks expand their service channels to include Internet service, call centers, and mobile banking through wireless devices, they can easily be drawn into piecemeal solutions which impose a penalty in quality of service and in cost of deployment. There is a strong competitive advantage in acquiring solutions that integrate the channels used and enable a unified management view of customer interactions for all bank services.*

**Keywords:** *IT Banking, Romania, ATM, home banking, Internet banking*

## 1. Introduction

Credit institutions through their activities are offering a wide range of banking products and services so that a better mobilization of the temporary available capitals in economy should be achieved followed by their transformation in borrowed capital.

The banking product represents the basic element of the bank's activities and operations, its lack leading to the elimination of the credit institution itself. The credits and the bank deposits are the main banking products, used by the credit institutions to borrow capital.

Banking services are completing the banking products as their components in the operations accomplished by the banks at clients' request such as: accounts receipts and payments, currency operations, etc. or are independent of the capacity of banking product such as financial-economics consulting operations.

The separation between the two banking assets, products and services, imposes from the point of view of the understanding the credit institutions within the economic and financial system as well as from the point of view of the interpretation and assessment of the activities and the functioning of the credit institutions in economic environments. The products of the bank (the banking products) are offered by the banks to their clients and the services are the goods requested by the clients to the credit institutions.

The range of the banking products is very wide, some of these being given as an example in that follows:

- Loaning short, medium or long time secured credits, for the needs of the clients, of the economic agents or the natural persons;
- Formation of the sight, notice or collateral deposits;
- The placement of stocks and shares
- The release of the deposit certificates or savings books
- Performing the carrying over operations with titles of the financial market, etc.

As being banking services some operations are included:

- Operations in current accounts, transfer settlement
- The emission and the acceptance of the payment documents;
- Currency services

- The emission and the acceptance of coverings
- The emission of the banking guarantee letters on different purposes
- Banking and financial consulting
- Credit card issuing

The diversification of the banking products and services is determined mainly by the subjects to who are addressed to: natural persons, legal persons, financial institutions other than banks, other credit institutions and the state. Comparing the credit conditions for natural persons and those for the legal persons, one can say that for the latter there is no standardization. Generally, the time interval for what the credit is loaned, the amount of money and the grace period are depending on the credit time length: short, medium or long time credit.

Specialized credit institutions offered a single product or banking service till now, presently are diversifying continuously their activities, offering new products and banking services to better meet the needs of the clients. Also, there are attempts to penetrate new markets where previously the credit institutions had no access. The credit institutions, similar to any other institutions, are expecting short-time results, the development being imposed by new client segment conquest and the reordering of the items that are implied in profit.

Given these conditions, the signals coming from the clients and the potential business partners of the credit institutions, the intensification of the competition have reoriented the activities towards new products and banking services such as: leasing, factoring, the credit account, monetary cash money transfer, inter-banking compensation, client's reliability assessment services, bank deposits and credits for pupils, the transmission of information using modems, phone and computer banking services, etc.

Despite all affirmed above, the products and banking services very present in the activity of a bank are: the credits, the bank deposits, the incomings and payments in accounts, performance bonds, currency operations, deposit certificates or savings book. The increase of nongovernmental loaning in the products portfolio addressed to the clients by the credit institutions operating on Romanian market meant a diversification of the loaning. The balance sheet for the first 6 months of the year 2003 shows that, for the structure of the credits loaned in the Romanian banking system, the main credits are the consumer credits, loaned to the economic agents for the usual activities followed by those for the industry and service companies. The private sector receives 75% from all credits and 25% goes to

the state companies. The highest growth rate is recorded for the real estate credits. From the dynamics point of view but also as percentage in the structure one can notice that the interest of the credit institutions is to loan the building and trading domains.

The credit institutions cannot elude the problems of the financial equilibrium. The increase of the interest caused by the inflation, obtaining the resources and using the placements are redefining the management techniques and also sectors of the banking strategy.

In competition conditions, the fight is engaged within the banking market mainly on the clients generating high interest and commissions.

The last studies made by National Bank of Romania regarding the internal market of banking services and products have shown that a part from the bank offer is at a basic stage of development as follows: investment credits, agricultural credits, the credits for Public and Local Administration, credits for Small and Medium Sized Enterprises and derivative financial instruments.

## **2. Factors that are slowing down the development of banking services and products**

The credit institutions are facing presently with some factors that are slowing down the development of the services and banking products such as:

The instability of the macro economical environment, impeding the activities of the economic agents and therefore of the credit institutions in assessment the business plans with a low degree of credibility from the point of view of the creditor.

The legal inadequate environment has a negative impact on the financing activity

The behavior of the participants on the market: lack of transparency regarding the real situation of the patrimony of the economic agents, the low level of the background in economy and especially in banking of the effective and potential consumers, the inexistence of professional background of the credit institution's personnel impedes the achievement of a highly efficient communication between the two parts;

The macro economical instability has impeded the long time assessment of the results that will be generated by the investments for what credits are requested, leading to the limitation the possibility to loan credits for investments under high security conditions. The volatility of the economy, the uncertainties related to the correct assessment of the

RON/USD, RON/EUR exchange ratio, high levels of the interest rates represented major obstacles in the augmentation of the credit portfolio for medium and long term. The unfavorable macro economical conditions have an impact on the credit institutions regarding the medium and long term deposits in national currency that generated the decrease of the credit financing sources volume for the investments, credits loaned in national currency and of the mortgage credits. The main factors that contributed to the decrease of the number of credits for the agriculture were, principally, the low efficiency and productivity in agriculture, the delayed reformation of this sector, but also the very poor implying of the state in the unfavorable situations. Also, one can notice a poor representation in the offer of the credit institutions of the long term credits loaned to the SMSE, having as possible causes the macro economical instability (the inflation rate), the high degree of uncertainty regarding the life expectancy of the SMSE and the lack of the long term financing sources.

The presence of an undeveloped legal environment and also of costly and time consuming legal procedures for the recovering of the claims through the execution debt enforcement has a negative impact over the funding activity. The inexistence of a legal protective environment for the credit institutions in the case of the guarantees compulsory sale, the high amount of time and slow procedure to force sale collateral stopped the mortgage credits. The mortgage credit weight in the total amount of the credits loaned by the credit institutions has recorded very low levels due to some limitations imposed by the law, as follows: the computing method of the reference index of the interest for the mortgage credits had to be established by the Government, fact that never materialized, thus the mortgage credits were loaned in national currency only and the minimum term for the population was 10 years. These malfunctions have been solved through a government resolution for the changing of a law referring to the mortgage credit for the real estate investments. The approval of the law package due to that the agricultural producers took benefit of credits with the interest supported by the state had a negative impact over the evolution of the agriculture credits.

It has been observed that among the most important factors that have stoooped the development of the products and banking services is the behavior of the market competitors.

The credit institutions are not willing to face with the risks resulting from the medium and long term credits, preferring to loan short term credits. Usually, short term credit refers to the funding of the current activity of a company and those with medium or long term are reserved for the investment funding. The lack of long term crediting resources determined the apparition in the balance sheets of a miscorrelation among the maturity of the mortgage

credits (generally long and medium term credits) and the funding sources of those credits (mainly short term sources such as banking deposits having the due term within 1 year).

The existence of this miscorrelation implies the bank to assume high risks, especially referring to the interest rate risk and liquidity risk, justifying the prudence of the credit institutions in loaning mortgage credits.

In addition, the investment plans and reliability studies presented to the credit institution are not properly made and aren't taking into account all the investment costs, thus influencing the sizing of the financial resources needed to implement the investment projects. Under this conditions the banks are preferring to train and use their own raters in order to analyze the feasibility of the businesses and to asses the mortgage guarantees of the credit applicants and to offer consultancy services to the clients, that implies supplementary costs (for the investment credits or mortgage credits). The availability and the volume of the credit financing funds depends on the agreements between the Romanian credit institutions and the international financial institutions (BERD, BEI, PHARE), the majority of the credits of the type being sustained through external financing, implying supplementary eligibility conditions for the final beneficiaries (activity sector, the duration of the projects, co-financing percentage) and much rigorous assessments made by the banks. For instance, the crediting programs for the SMSE aren't unreled by all the branches of a credit institution. These limitations of the banking infrastructure are hardening the access of the SMSEs to this financing manner, generating in some geographical areas a lack of competition among offerers with direct implications over the crediting cost supported by the SMSEs. The credit institutions are facing with a crisis of information referring to the business behavior of the clients, situation which is generated especially by the inexistence of the records describing the prior relations with creditors.

On the other hand, the clients of the credit institutions are reticent referring to the credits, due to the following aspects: high interest rates, low level of the banks popularity in Romania, the majority of the business community considering the banks not being potential partners and consultants.

### **3. Measure to be taken in order to stimulate banking activity**

Starting from the causes that are slowing down the development of the services and banking products, the National Bank of Romania identified the possible measures to be taken in order to stimulate the banking activities, such as:

- The acceleration of the reform in the real sector of the economy so that the healthy weight of the economy to increase, the only part that can be credited by the credit institution in safety conditions;
- The modification of the legal environment in order to protect to a greater extent the rights of the loaners
- The increase of the training in economics of the persons that request the loaning of a credit, developing the training centers for entrepreneurs and the programs offering consultancy in order to elaborate business plans to loan credits
- Taking drastic measures in order to penalize banking frauds, taking into consideration the impact of those frauds over the banking system;
- The improvement of the macro economic system, under predictable conditions, so that the degree of thrust of the business plans to increase from the point of view of the funding person as well as from the point of view of the beneficiary and the funding to be carried on under high security conditions.
- The increase of the competition in the banking system and the finalization of the privatization for the banks suited for this process

The attitude of credit institution on the market, under the conditions of high competition among banks must be offensive and not be limited to the passive expecting of the demands of the clients but to promote constantly new products and banking services. Through the extension of a range of such products and services, the credit institution will be able to respond much better to the options of the economic agents, evolving in connection with the market demands.

Breaking of new banking products has on the basis studies, information referring market situation, the conditions under what the credit institution, that offers the product, carries on the activity. A determination of the capability of the credit institution to use at maximum its capacity to make this product and to sell it has to be done. The promotion of new banking products implies a very complex activity including the digitization of the accounting information, products trading, attracting a high number of clients, promoting using advertising of a favorable image. In addition it is necessary to establish the priorities lying at the basis of the activity of the credit institution with new products and banking services. These priorities refer to

the profit, the degree of satisfaction of the clients, the risk, the quality of the products and impose the reorganizing of the functional structure and the increase of the capacity to react to changes.

#### **4. New banking products in Romania**

Much and much credit institution are intending to extend their crediting activities by means of new instruments such as the credit cards. This market has a huge potential of development. It till 2002 were only five card types issued by four credit institution, now there are eight types of such instruments, issued by seven credit institutions. The potential of the market is the main reason that determined other credit institutions to include new products in their offer.

The year 2003 affected the overall market cards, the number of the cards in Romania being twice greater than the cards issued in 2002. Despite all these, from the total of 4,2 million cards, only 200.000 are credit cards.

In Romania, there are several payment systems with cards having magnetic stripes or chips, such as:

- The CardAvantaj card (with magnetic stripe) issued by the Finansbank bank (Romania), card with a loyalty program, allowing shopping from the Bucuresti Mall complex store, the credit being covered in monthly rates.
- The chip PetromCard card, issued by the Petrom company, dedicated to the legal persons (company card). With this card you can buy gas only from Petrom oil station.
- The Fill&Go card issued by the Rompetrol company is a credit card with chip and pin code for the legal persons carriers which can buy gas, products and services only from Rompetrol stations, within the framework of much complex service package.

On the other hand, all card operations are financial loss risk generators, frauds and disputes over the transactions.

The financial loss risk appears to all the actors implied in a card transaction: the card owner, the trader, the issuing bank and the bank that accepted the card.

Current frauds are: using a lost or stolen card, the cloning of the card, on purpose denying of the transaction or the denying that the person has received the product. Frauds can be generated also by the personnel of the

bank that has access to confidential data and can use this data in order to clone cards or to obtain a different identity.

In the present days, only 5-10 percent of the card owners from Romania use these payment instruments to buy from the goods. If the cards are not going to be used the card will be an investment not very rewarding.

In order to support the use of the credit card as payment instruments, the government of Romania took a series of decisions, for instance the resolution no. 193/2002 that stipulates that economic agents that are supplying services of public interest, the public institutions that are cashing impositions, taxes, surcharges, interests, penalties and other payment obligations, and also the traders with turnover greater than 1000.000 euros are forced to accept cashing through debit cards and credit cards from the natural persons.

Even if Romania is high in the top of the credit card owners, having a 15% quota, a full development is estimated in the following 3 or 4 years.

In Romania, in the year 2003, the number of Internet users represented 24% of population, the number of PCs was 2,1 millions and the number of Internet services providers is 400. These data indicates the existence of an impressive infrastructure capable to offer the services needed for the development of the e-Commerce in Romania.

The payment instruments used in electronic commerce are the bank cards, electronic drafts, electronic credit letters and electronic transfer orders.

The e-Commerce developed in Romania in the last few years having two main forms:

- Internet products traders with the payment on delivery: impose the existence of a product catalogue with descriptions and prices, each client having a shopping basket. The products are delivered at home and the payment is done at the delivery of the products with cash, draft, banking transfer, using cards, using mobile POS, etc. This is the first form of electronic commerce that was used in Romania.
- Traders accepting real time card payments using 3-D Secure protocol. In order to be able to use this system, the traders must underwrite an Internet trader contract with a bank and the owners of the cards issued by the Romanian banks willing to use shop anywhere in the world using these system, must be registered in the system.

The year 2003 marks the apparition of the remotely accessed payment instruments, such as internet – banking and mobile banking, allowing the clients to use from distance the services of the credit institutions. Presently, 19 banks have 1 year authorizations for the use of remotely accessed payment instruments; other 2 banks have temporary authorizations. The offer is often varied the client being able to choose the most advantageous solution for his needs, taking into account the status of legal or natural person. Through these remotely accessed payment instruments the clients save time and money, performing operations that are usually made on the spot but with commissions 50% smaller.

Internet banking is a service available to every person, allowing to perform banking operations through Internet. The service is made especially for the natural persons and it's offered free of charge by the majority of the credit institutions.

In order to use this service the Internet site must be accessed and the option Internet banking has to be chosen.

The vast majority of the firms prefer the home-banking services, because it allows to many people within the same company to use the service, having different access levels. To benefit from this service the firms must have a direct connection with the credit institution through a regular phone line or through a modem.

Mobil banking is a service that allows the user to obtain financial-banking related information, no matter the day or the hour of the day, using only the mobile phone, the user not being forced to go to the credit institution, to an ATM or forced to use a computer connected to the Internet. For the activation of this service an adaptation of the mobile phone is needed, that implies the replacement of the SIM card a contract with the credit institution that offers the service.

## 5. Conclusions

The credit institutions offering presently almost the whole range of products that can be commercialized, products adapted to the development stage of the local economy. From the clients point of view the Romanian banking market is limited. There are still a lot of Romanians that are not working with the banks. The explosive development of the loaning especially of the consumer credit is a sign of development of the consumer society.

The diversification of the product and banking services offer in order to cover the whole range of needs of the economic agents, no matter there the size of the enterprises (corporations or small and medium sized enterprises) is a constant preoccupation for the credit institutions. Given, on the one hand, the complexity of the offer for legal persons and on the other hand the increase competition among the credit institutions operating on the market with services for natural persons, the credit institutions focused on the latter.

## **Abstract**

*The increasing presence of the Internet in every day's life changes the way business, including banking, is done. This applies also to the business practice in Slovakia. The aim of the article is to present the research results of the e-banking usage in Slovak companies in years 2003 and 2004. It was measured on the sample of 117 companies in 2003 and on the sample of 390 companies in 2004. The research was conducted by means of questionnaires. The usage was studied according to the company size (measured by the number of employees) and in year 2004 also by sectors and legal form of companies. Their impact on the e-banking usage was analyzed by the logistic (multinomial) regression. Both bivariate and multivariate approaches were used. The article offers some possible explanations of the results and ideas for the further research.*

**Keywords:** *e-banking; empirical research*

## **1. Introduction**

The Internet is still more present everywhere including Slovakia. Its increasing presence changes also the way business is done. The banking is no exception. More on payment systems can be found e.g. in (Delina, Vajda, 2005, pp. 100-116). The euphoria witnessed towards the end of last decade surrounding the use of the Internet in service provision was based primarily on the notion of infinite scalability (the ability to serve increasing numbers of customers at low incremental costs). This notion justified high valuations of Internet firms from venture capitalists. E-banking within the information-based environment of financial services made infinite scalability appear even more promising compared to other types of e-commerce.

The often unrealistically optimistic projections regarding Internet use, however, led to the dot.com shakeout that came with the dawn of the new millennium (Mahajan, Srinivasan, ind, 2002). One example for such a dot.com failure is the Irish internet-only bank “first e” that filed for bankruptcy at the end of 2001 with the customers being unable to access their money for days. In the US, at the end of year 2000 only 19 % of the US commercial banks and savings institutions offered e-banking services, a number that shrank even further in 2001.

However, a number of success “survivor” stories make it clear that e-banking is here to stay. What is needed are new business models that suit the new business environment. The Internet has become a part of everyday life with tens of millions online every day engaging in various Internet activities, 50 % of which include e-commerce. (See a special issue of *American Scientist*, 2001, and of *Communications of the ACM*, 2001, for trends and statistics.)

The article presents the research results of the e-banking usage in Slovak. The research was conducted by questionnaires on the sample of 117 companies in years 2003 and on the sample of 390 companies in 2004. The usage was studied according to the company size and in year 2004 also by sectors and legal form of companies. Their impact on the e-banking usage was analyzed by the logistic regression in case of one factor and by multinomial regression in case of more than one factor. Both bivariate and multivariate approaches were used.

## **2. E-banking usage in Slovak companies**

The impact of several factors on e-banking usage will be discussed in the following subchapters. The factors are company size (measured by the number of employees), sectors and legal form of companies. The test and

confidence intervals are calculated and interpreted on the confidence level  $\alpha = 0.05$ . The confidence intervals are not symmetric since the exact formula (not the approximation using normal distribution) was used.

## 2.1 Company size

There are more possibilities to measure company size. Obviously, the simplest one is according to the number of employees. This could be also combined by the profit or the turnaround of the company. Since we tried to keep questionnaires as anonymous as possible and because of the previous experiences, we decided to divide companies only by the number of employees. Actually, there will be presented two divisions throughout the paper. The first one is compatible with the Statistical bureau (tables 1 and 3) and the second one is according to the Slovak law no. 231/1999 (tables 2 and 4).

E-banking usage was measured on the sample of 117 in 2003. The results according to the organizational statistics are presented in the table 1.

**Table 1 E-banking by organizational statistics (2003)**

	<i>yes</i>	<i>no</i>	<i>percentage</i>	<i>confidence interval</i>
<i>up to 9</i>	12	10	54.55 %	$\langle 32.21 \% ; 75.61 \% \rangle$
<i>10-19</i>	11	6	64.71 %	$\langle 38.33 \% ; 85.79 \% \rangle$
<i>20-49</i>	14	3	82.35 %	$\langle 56.57 \% ; 96.20 \% \rangle$
<i>50-249</i>	30	2	93.75 %	$\langle 79.19 \% ; 99.23 \% \rangle$
<i>250-499</i>	10	1	90.91 %	$\langle 58.72 \% ; 99.77 \% \rangle$
<i>500-999</i>	6	1	85.71 %	$\langle 42.13 \% ; 99.64 \% \rangle$
<i>1000+</i>	11	0	100.0 %	$\langle 71.51 \% ; 100.0 \% \rangle$

*Source: Author's calculation*

There are statistically significant differences in e-banking usage among the groups in this table (p-value = 0.002 413). These are the differences between the companies with less than 10 employees on the one hand and companies with 50-249 (p-value = 0.001 003) and with 1000+ employees (p-value = 0.012 902) on the other hand. The third difference is between the companies with 10-19 and 1000+ employees (p-value = 0.015 045).

The data as in the table 1, but according to the Slovak law no. 231/1999, are presented in the table 2.

**Table 2 E-banking by law no. 231/1999 (2003)**

	<i>yes</i>	<i>no</i>	<i>percentage</i>	<i>confidence interval</i>
<i>small</i>	37	19	66.07 %	⟨52.19 %; 78.19 %⟩
<i>medium</i>	30	2	93.75 %	⟨79.19 %; 99.23 %⟩
<i>large</i>	27	2	93.10 %	⟨77.23 %; 99.15 %⟩

*Source: Author's calculation*

Obviously, statistically significant differences exist also here (p-value = 0.000 638). They are between small companies on the one hand and medium (p-value = 0.003 690) and large companies (p-value = 0.007 219) on the other hand.

The research was repeated in 2004. There were 390 companies in the sample but only 383 of them supplied the number of their employees. The results according to the organizational statistics are presented in the table 3. There are again statistically significant differences between groups (p-value = 0.035 002).

**Table 3 E-banking by organizational statistics (2004)**

	<i>yes</i>	<i>no</i>	<i>percentage</i>	<i>confidence interval</i>
<i>up to 9</i>	65	25	72.22 %	⟨61.78 %; 81.15 %⟩
<i>10-19</i>	49	8	85.96 %	⟨74.21 %; 93.74 %⟩
<i>20-49</i>	61	11	84.72 %	⟨74.31 %; 92.12 %⟩
<i>50-249</i>	70	11	86.42 %	⟨77.00 %; 93.02 %⟩
<i>250-499</i>	19	5	79.17 %	⟨57.85 %; 92.87 %⟩
<i>500-999</i>	21	2	91.30 %	⟨71.96 %; 98.93 %⟩
<i>1000+</i>	34	2	94.44 %	⟨81.34 %; 99.32 %⟩

*Source: Author's calculation*

These are the differences between the companies with less than 10 employees on the one hand and companies with 50-249 (p-value = 0.025 260) and with 1000+ employees (p-value = 0.007 092) on the other hand.

We may want to compare the differences of e-banking usage also in time. The multinomial regression model with the year and the size is significant (p-value = 0.000 499). But the only significant factor in it is the size (p-value = 0.000 277). The effect of the time is not significant (p-value = 0.316 420).

The same data as in the table 3, but according to the Slovak law no. 231/1999, are presented in the table 4. But the differences between the groups do not seem to be significant (p-value = 0.100 132).

**Table 4 E-banking by law no. 231/1999 (2004)**

	<i>yes</i>	<i>no</i>	<i>percentage</i>	<i>confidence interval</i>
<i>small</i>	175	44	79.91 %	⟨73.98 %; 85.01 %⟩
<i>medium</i>	70	11	86.42 %	⟨77.00 %; 93.02 %⟩
<i>large</i>	74	9	89.16 %	⟨80.41 %; 94.92 %⟩

*Source: Author's calculation*

When we use the multinomial regression model with the year and the size, it is significant (p-value = 0.002 157). The only significant factor is the size (p-value = 0.000 865). The effect of the time is not significant (p-value = 0.302 846).

So, in both models there is enough evidence that there are differences in e-banking usage according to the size of the company but there is not enough evidence about the change between years 2003 and 2004.

## 2.2 Sectors

There was a closed question on sectors in the questionnaire. There were the full names of sectors according to the Slovak classification called OKEČ. The names were shortened in the table 5 in order to fit the table. 380 (out of 390) companies supplied data on the sector.

**Table 5 E-banking by sectors (2004)**

	<i>yes</i>	<i>no</i>	<i>percentage</i>	<i>confidence interval</i>
<i>agriculture</i>	6	3	66.67 %	⟨29.93 %; 92.51 %⟩
<i>forestry</i>	1	2	33.33 %	⟨0.84 %; 90.57 %⟩
<i>mining</i>	2	1	66.67 %	⟨9.43 %; 99.16 %⟩
<i>industry</i>	74	7	91.36 %	⟨83.00 %; 96.45 %⟩
<i>energy</i>	4	1	80.00 %	⟨28.36 %; 99.49 %⟩
<i>construction</i>	35	11	76.09 %	⟨61.23 %; 87.41 %⟩
<i>commerce</i>	71	18	79.78 %	⟨69.93 %; 87.55 %⟩
<i>transportation</i>	22	3	88.00 %	⟨68.78 %; 97.45 %⟩
<i>finance</i>	9	0	100.0 %	⟨0.00 %; 33.63 %⟩
<i>insurance</i>	6	2	75.00 %	⟨34.91 %; 96.81 %⟩
<i>other</i>	81	17	82.65 %	⟨73.69 %; 89.56 %⟩

*Source: Author's calculation*

In case we consider the possibility "other" to be a sector, there is not enough evidence that there are statistically significant differences between groups (p-value = 0.055 211). But since "other" represents a mix, we suggest not to include it as a sector. Then there is enough evidence that there are statistically significant differences between e-banking usage by sectors (p-

value = 0.035 407). These differences are between industrial and construction companies (p-value = 0.031 668); between industrial and commerce companies (p-value = 0.049 574).

### 2.3 Legal form

There was a question on legal form of companies in the questionnaire. 378 (out of 390) companies filled supplied data on the legal form. E-banking usage according to the legal form is presented in the table 6.

**Table 6 E-banking by legal form (2004)**

	<i>yes</i>	<i>no</i>	<i>percentage</i>	<i>confidence interval</i>
<i>v.o.s.</i>	6	0	100.0 %	⟨54.07 %; 100.0 %⟩
<i>k.s.</i>	1	0	100.0 %	⟨2.50 %; 100.0 %⟩
<i>s.r.o.</i>	158	24	86.81 %	⟨81.02 %; 91.36 %⟩
<i>a.s.</i>	93	12	88.57 %	⟨80.89 %; 93.95 %⟩
<i>cooperative</i>	3	2	60.00 %	⟨14.66 %; 94.73 %⟩
<i>sole entrepreneur</i>	55	25	68.75 %	⟨57.41 %; 78.65 %⟩

*Source: Author's calculation*

There are statistically significant differences in e-banking usage among the groups in the table (p-value = 0.003 000). These are the differences between the sole entrepreneurs on the one hand and s.r.o. (limited companies, p-value = 0.000 754) and a.s. (publicly traded companies, p-value = 0.001 385).

### 2.4 Summary

Data from the research conducted in 2004 were analyzed only by the bivariate approach in the previous subsections. Generally, one could expect that the bigger the company the more probably it uses e-banking in conducting business. Maybe someone would expect, since industrial companies have historically more experience with automating their processes, that they will automate also banking in greater extent than companies in other sectors.

And actually, all the factors seemed to be fairly significant. But the factors are not independent. All the commerce companies are small and medium enterprises. Every insurance company and bank has to have a legal form of a.s. Industrial companies are rather large and so on. Therefore it is important to use a multivariate approach to identify the really significant factors.

In case we use the organizational statistics in measuring the company size, the multinomial regression model (data on 276 (out of 380) companies

(rows in data table) because only they supplied all the required information, 97 (out of 276) rows are unique) is significant (p-value = 0.033 229) but none of the factors is significant (p-value of the size = 0.816 450, p-value of the sector = 0.218 832 and p-value of the legal form = 0.129 954).

In case we use the Slovak law no. 231/1999 in measuring the company size, the multinomial regression model (data on 276 (out of 380) companies because only they supplied all the required information, 71 rows are unique) is significant (p-value = 0.015 745) but only the legal form is significant as a factor (p-value = 0.034 595). Other factors are not significant (p-value of the size = 0.842 960, p-value of the sector = 0.178 129).

So, the legal form is probably the main factor influencing the usage of e-banking by Slovak companies. But it has to be noted that only three factors were analyzed. There are certainly many more relevant factors. The suggestion for the future research in this area is to try to add at least the proportion of foreign equity. Because the factor seemed to be about as important as the legal form in the research of decision support system usage (Sudzina, 2005).

### **3. Conclusion**

Since banks all over the world invest billions in the Internet infrastructure (for example Deutsche Bank invests approximately half a billion USD per year), customer satisfaction and customer retention are increasingly developing into key success factors in e-banking. From the bank's point of view, profitable e-banking requires a strong focus not only on the acquisition of new customers but also on the retention of existing customers, since the acquisition costs in online banking exceed that of traditional off line business by 20-40 % (Reibstein, 2002; Reichheld and Scheffer, 2000). Consequently, establishing long-term customer relationships is a prerequisite for generating positive customer value on the Internet.

During the last few years, these findings have led to the development of simple banking web sites into comprehensive e-banking portals offering a great variety of services in addition to traditional bank products and thereby enabling customers to gain financial advice from merely one source. Thus, the user ideally no longer needs to make use of several different web sites. The great variety of portal resources available also creates incentives for longer site visits during each use.

Offering a broad range of financial services and features at one single site has been noted as the most important development in e-banking (Jun and Cai, 2001; Strieter, Gupta, Raj, Wilemon, 1999). According to Jun and Cai

(2001), most Internet banks are still lagging behind their customers' quality expectations. In order to enhance customer loyalty, portals are required to put a strong emphasis on their customers' quality demands, which are steadily increasing over time due to the growing competition in the internet banking industry (Jun and Cai, 2001). Most importantly, loyalty has been recognized as a key path to long-term profitability. These findings hold especially true for the financial service sector, where reducing the defection rate by 5 % can boost profits by up to 80 % (Reichheld and Sasser, 1990).

Our findings suggest that the most important target customer for acquisition in case of Slovakia is a sole entrepreneur since they use e-banking the least (69 % compared to 87 % at s.r.o. and 89 % at a.s.). Other discussed factors are not significant. In case the research is repeated, we suggest adding the proportion of foreign equity as another factor. We assume that the effect of time can be significant in the case of bigger research samples.

Based on what was mentioned before, we suggest to evaluate also the quality of e-banking portals through the customer satisfaction measured e.g. by the Likert scale. This means also adding a question to identify which bank's service is used.

## **Abstract**

*Nowadays, a time of massive banking in which the great majority of people and of economic agents has become the banks' clients, on terms of the amplification of bank operations and of the development of the subsidiaries and agencies network, the banking activity implies the large-scale use of computer science and telecommunication. Within the present development phase of electronic trade, certain banks take on a positive attitude towards e-banking services, while some others remain reserved. Any bank willing to invest in e-banking services must make sure that introducing a new distribution channel of e-banking services is possible and viable.*

**Keywords:** *electronic payment, e-banking, computer science, telecommunication*

## 1. Introduction

In close connection with the expansion of commerce and international investments, the financial-banking activity has become one of the peak fields of the globalization process. The globalization of commerce is accompanied by the development and institutionalization of banking institutions. Actually, the internalization of the banking activity takes place on two plans:

- on one plan, institutionally, the commercial banks and business banks develop their operational network by setting up new units on the territory of other states.
- on the other one, at an operational level, the products and services are also offered in other currencies except the national one.

As the society has grown, the banks have evolved from the emission bank to the transfer, deposits, business banks, from a regulation institution to the electronic bank. Traditionally, the commercial banks' activity consisted mainly in three main spheres: the attraction of deposits, credit granting and the monetary transfers' operation. Gradually, banking transfers diversified by engaging in some operations, once under the management of other specialized banks or financial societies and by performing new services existing in the neighboring area with other financial operators<sup>1</sup>.

The unfolding of the payment flow, their appropriateness, slowing down and speeding up actually depend on:

- the payment capacity of the entities;
- the policy of making payments carried out by the economical entities;
- the efficiency of technologies and the organizational abilities of the payment systems carried out through banks<sup>2</sup>.

Under the present conditions, in developed countries it is noticed that there ended a long time ago "the banking" process, process in which the largest majority of companies and persons have opened accounts in banks, which allows making payments through banks, by transfers or virements among banking accounts respectively.

In the process of the introduction of the new technologies based on telemathics, information technology, there have been reconsidered the traditional payment tools: the cheque and the bill of exchange, by their adjusting to the electronic transfer demands of funds. The evolution of the payment instruments is characterized by the accelerated decrease of base

<sup>2</sup> Basno, C., Dardac, N., *Payment system, compensations and settlements*, Publishing House, Didactica si Pedagogica R.A., Bucuresti, 2003, I.S.B.N. 9730-30-274103, p. 5

paper documents and the rapid increase of dispositions and payment orders expressed in electronic messages.

Nowadays, the human society meets the most profound transformations from its entire existence, in which information technology plays a determinant part and has begun to transfer to the networks most of the common activities. We can talk at present of teleconferences and workgroups going on by the intermediary of computer networks, newspapers distributed in networks, funds' transfer systems and network commerce, all these services being a reality of the biggest and more impressive means of communication between people which has become the Internet.

Along with the entrance in the Internet and in the e-business age, of the new economy, in general, certain fundamental transformations of the social-economical structure are produced.

The development of the interconnectivity of computers in the internet, in all segments of society, has led to a more obvious tendency of companies to use these networks in order to carry out a new type of commerce, the electronic commerce, through the internet<sup>3</sup>.

The new economy or the digital one, resulting from the interaction between the personal computer, telecommunications, Internet and electronics, is characterized by a range of features completely different from the traditional economy and is subjected to the principle according to which "*the more people involved the bigger the benefit for everyone involved*". The micro and macro economical effects of the new economy have as foundation the general principles of its development, which are<sup>4</sup>:

- awareness;
- accessibility;
- availability;
- affordability;
- appropriateness.

The electronic commerce (e-commerce) offers the consumers and the companies alike information regarding the merchandise and the services available in the whole world, prices and sale conditions, giving them the option to take the best decisions in management.

The internet can be used in commercial transactions, either in business to business transactions, that is between companies or from company to company or from business to consumer, because a commercial transaction

<sup>3</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 303

<sup>4</sup> [www.gandul.info.ro](http://www.gandul.info.ro)

can be divided in three main stages: the advertisement and research stage, the contracting and payment stage and the delivery stage, and any of these may be accomplished successfully through their intermediary.

This new type of commerce has stimulated nevertheless the demand for new appropriate payment methods. The development of the communication network between computers, into what some people call “*the global village*”<sup>5</sup> allowed the introduction and use on an ever larger scale of electronic payment systems. The electronic commerce offers the possibility of doing network commerce by consulting electronic “on” catalogues on the WEB or “off” catalogues on CD-ROM and by paying with credit cards or electronic wallets.

The convenient, fast and safe transfer of the money has become one of the fundamental demands of viability of the new concept of the electronic system of payment. The replacement of the traditional cash forms with the e-money offers a better flexibility to the payment systems, in the conditions of the increase of the safety level of all participants in the system. The replacement of coins and bills with electronic money leads to the lowering of costs involved by the issuance and maintenance in circulation of the cash<sup>6</sup>. In the electronic payments systems, most of them working online, the payer and the beneficiary communicate with banks during the payment transactions.

Using the electronic money, electronic cheque and the unfolding of the repeated exchanges of data through the networks, makes it compulsory to insure the confidentiality of transactions, by the safe authentication with digital signature and certificates.

Until recently, the banking branch was considered the only delivery channel for the banking services. Despite that, during the last few years the unconventional channels have won over the customers’ preferences because of :

- the increased costs for the building of the banking branches;
- large delivery costs for the conventional channels;
- the decrease of the communication costs and of equipment;
- the increased demand for better and easier services.

According to the covering quota of the banking business, the distribution channels also include<sup>7</sup> :

<sup>6</sup> www.byte.ro

<sup>7</sup> Mihai, I., *The technique and the management of banking operations*, Publishing House, Expert, Bucuresti, 2003, I.S.B.N. 973-8177-91-X, p. 344

- Telephone banking and home banking, covering a larger business quota;
- Internet banking, characteristic to payments for standardized products and services;
- Mobile Banking- little used variant.

The physical and the juridical persons alike have the freedom of choosing from an entire range of channels such as: the ATM, the telephone, the terminal at distance, the mobile phone, the internet.

The advantages of the e –banking use are:

- for the effectuation of different operation the client doesn't have to go to the bank;
- the removal of the manual preparation of documents;
- the automatic processing of the payment orders;
- the payment orders are valid, the electronic signature being guaranteed by the bank;
- the access to the e-bank can be made every 7 days, 24 hours a day.

Mobile Banking is destined to the clients of the bank that own credits and are mobile phone users and presents the following advantages:

- comfort and time saving by the use of the telephone in order to connect with the bank;
- the access to information about credit card and the transactions made by ATM;
- the safety and confidentiality of operations;
- financial-banking information on-line.

The EU Banks have as central strategic objective the reduction of costs in order to improve the results by the reorganization of activities and the bringing outside of bank of the support activities (information activities, card processing). Another European banking strategy represents the maintaining of the various distribution channels (the network of unities especially), to the detriment of the Internet Banking, which continues to develop and to represent a solution of decreasing of costs and increase of the operational effectiveness<sup>8</sup>.

### ***1.1 The payment and discount systems in EU, USA and Japan The UE:TARGET payment system [Trans European Automated Real-Time Gross Settlement Express Transfer]***

The payment systems of the EU countries are very diversified at present there existing more than 25 payment systems, while in the USA there are only two, CHIPS and FEDWIRE.

TARGET [Trans European Automated Real-Time Gross Settlement Express Transfer] represents a system stipulated in the Maastricht Treaty by which it is realized the transfer of the euro resources among the accounts from the central banks. TARGET is formed of a communication network and a whole range of common procedures that insure the effectuation of payments.

TARGET contributes to the integration of the monetary market and by this to the implementation of the unique monetary policy in Stage III of the European Monetary Union. The objective is to allow the payments in the euro region (especially the ones closely linked to the monetary market) to be realized at low costs, at a minimum risk and in a very short processing time<sup>9</sup>.

In the USA there are two funds transfer systems of great value<sup>10</sup>:

- a) The transfer system of the FEDWIRE funds, operated by the Federal Reserve System which is a system of interbank funds transfer, in real time with gross settlement and connects 12 Federal Reserve banks to the participant financial institutions and to federal governmental agencies;
- b) The CHIPS system( Clearing House Interbank Payment System) operated by the New York Clearing House Interbank Association (NYCHIA), a transfer system of the credit payment instruments, but which clears many-sidedly the funds transfers and settles at the end of the day the net calculated positions. The participants to this system are the commercial banks, certain corporations, investment companies or banks affiliated to a commercial banking institution that has its headquarters in New York.

The Japan banking system offers a large variety of payments, services which operate in more institutions for the establishment of some internet networks, such as<sup>11</sup>:

<sup>10</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p.87

- a) The local clearing houses of bills and cheques;there functioning around 700 local houses;
- b) The Zengin Data Telecommunication System which is managed by the Tokyo Bankers Association and is organized on two separate operating centers, Tokyo and Osaka respectively;
- c) The Foreign Exchange(Gaitame) Yen Clearing System (FEYES).The system is operated by the Bank of Japan as part of BOJ NET which performs the settlement and clearing of transactions;
- d) Bank of Japan Financial Network System (BOJ- NET) is an online system introduced in 1988 for electronic fund transfers to the financial institutions, including the Bank of Japan, which manages this system and establishes its regulations.

### ***1.2. International Payment Modalities and Instruments***

The international payments are realized by banks which hold and transfer the sums in corresponding currencies for the extinguishing of the payment obligations from the concluded commercial contracts.

The payment modalities comprise the banking procedures, the mechanisms and the techniques, by which the importers transfer the sums in foreign currency corresponding to the received goods or to the carried out services<sup>12</sup>.

#### ***The international settlements by SWIFT and MONEW GRAM***

SWIFT is a commercial society created in 1973 by American, Canadian and European banks in order to accelerate the international payments by processing the information with the help of information systems.

The transfer represents the most used payment modality in international transactions among the companies from the developed countries. The classical means used by banks to realize the international funds transfers were the courier and the telex.

The unfolding of an operation by payment order supposes the existence of a document, typified form. Its remittance by the principal bank to the paying bank can be made<sup>13</sup>:

---

<sup>11</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 96

<sup>12</sup> Voinea, GH., *The mechanism and the international exchange and financial techniques*, Publishing House, Sedcom Libris, Iasi, 2004, I.S.B.N. 973-670-067-4, p. 185

<sup>13</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 120

- by letter-when the payment can be made on the basis of the standardized form;
- by telegraph-when the payment is made on the basis of the instructions received in a telegram;
- by telex or SWIFT- represents the most modern and the fastest way.

The international settlement by SWIFT (Society for Worldwide Interbank Financial Telecommunications) presents the following advantages<sup>14</sup>:

- contributes to the reduction of the settlement time;
- the means of information processing are equipped with detection and error correction programs;
- the international settlements by SWIFT involve more reduced expenses;
- the messages exchanged among the accumulators at a national level and the processing centres are recorded on computer.

The Money-Gram Service represents a fast and safe modality to send and receive money in any country by its own network of agents. This service is available in banks, exchange houses, tourism agencies, postal offices and in some countries in the supermarkets, airports and railway stations.

The Western Union System carried out through the Eurogiro network insures the safe transfer of the sums of money in any corner of the world where its own agents operate. The Euro-Giro system is a form of cooperation mainly between the postal organizations and other organizations and credit institutions interested in the funds transfer at the international level<sup>15</sup>.

The following settlement means can be used in the international payments: the letter of credit, the documentary incasso, the cheque, the card and others.

**a) The letter of credit-** represents the firm commitment assumed by a bank, at the order and in its client account, the importer, to pay a sum to the exporter, against the documents attesting the fulfillment of obligations by the latter, at the terms established by the importer<sup>16</sup>.

The unfolding mechanism of the payments through the letter of credit is regulated in the brochure “Uniform Regulations and uses regarding the

---

<sup>14</sup> Voinea, GH., *The mechanism and the international exchange and financial techniques*, Publishing House, Sedcom Libris, Iasi, 2004, I.S.B.N. 973-670-067-4, p. 211

<sup>15</sup> Basno, C., Dardac, N., *Payment system, compensations and settlements*, Publishing House, Didactica si Pedagogica R.A., Bucuresti, 2003, I.S.B.N. 9730-30-274103, p. 213

<sup>16</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 182

letters of credit” elaborated by the Chamber of International Commerce from Paris, modified in the years 1983 and 1993 and issued under the name Publication no.500.

In connection with the other settlement means, the letter of credit represents the preferred modality both by the letter of credit principal and by the beneficiary because it is a form of guaranteed settlement, the bank being the guarantor. Even though the exporter is the one who profits first of the advantages of the letter of credit, as settlement modality, this insures the importer as well a protection measure, taking into account that the exporter will be paid only after presenting the documents that certify the goods’ delivery conforming to the terms and conditions of the letter of credit.

**b).The documentary incasso** is a settlement modality that is based on the payment modality of the buyer assumed by the commercial contract, without presenting a payment commitment from the banks involved in the unfolding of the operations<sup>17</sup>.

As a payment modality used in the international economic exchanges, the incasso is regulated in the document entitled “Uniform regulations for the incasso”, known under the name Publication 522, revised in 1995 with practicability from 1996.

The payment mechanism by incasso can be used in the case in which the exporter trusts the reliability and the correctness of the importer, or if there exist certain interdictions in the legislation of the importer’s country or due to some common practices on certain markets. Because the payment by incasso doesn’t suppose any obligation or payment guarantee, beside the obligations assumed by the buyer through the commercial contract, the conclusion would be that the incasso is a risk source not to be ignored by the seller.

In the common practice, the risks of the unfolding of the payment operations by incasso documentary are: the risk at the payment delay, the risk of not being paid, the risk of the diminution of the cashing, the risk of the goods’ loss<sup>18</sup>.

**c) The cheque** represents a written order given by a client (credit holder) to his ban by which he requires this one to pay a certain amount,

---

<sup>17</sup> Mihai, I., *The technique and the management of banking operations*, Publishing House, Expert, Bucuresti, 2003, I.S.B.N. 973-8177-91-X, p. 132

<sup>18</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 182

either to him for the cash withdrawal, or to a person specified by the client, for the payment of a debit<sup>19</sup>.

The cheque is a payment instrument which links, in the process of its formation, 3 persons: the drawer who issues the card, the drawee who pays the cheque and the beneficiary that is the legitimate owner who cashes the cheque.

In the specialized literature there are more criteria of cheques' classification: from the point of view of the beneficiary (nominative cheque and bearer cheque), from the point of view of the cashing modality (uncrossed cheque, crossed cheque, transfer cheque); other types of cheques: circular cheque, traveller's cheque, the eurocheques.

In addition to its advantages (simple use, operativity), the cheque presents also a series of risks (doesn't present guarantee against the commercial risks, can be without covering).

The electronic cheque represents an electronic payment instrument which removes the existence of paper support in the settlement of the international transaction, replacing the traditional cheque with an electronic equivalent. These were developed in a project of FISC – Financial Services Technology Consortium – a group of international financial institutions that suggested the creation of a project: E-Checks. This project improves the safety of settlements through the classic cheque as it follows<sup>20</sup>:

- because of a system of information encoding, the participants to the transaction benefit of the confidentiality and increased safety;
- the reduction of the transaction duration and the clearance terms.

The electronic cheques are created in order to realize payments and other financial functions of the paper cheques; by the use of the digital signatures and encoded messages, on the Internet network support. For protection against theft and illegal utilization of the electronic cheque, a smart-card is also used.

As a debit transfer instrument, the cheque involves, in addition to the credit institutional risk the risk that the payer might not have sufficient monetary funds in his banking account in order to cover the cheque value. If the cheque is not guaranteed in any way, the financial institution of the payer might not honor it, so the payment might not be realized. A research performed by The International Regulation Bank on the use of the

---

<sup>19</sup> Basno, C., Dardac, N., "*Payment system, compensations and settlements*, Publishing House, Didactica si Pedagogica R.A., Bucuresti, 2003, I.S.B.N. 9730-30-274103, p. 108

<sup>20</sup> Paraschiv, M., D., "*Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 131

international payment means utilization points out the fact that the two countries from the top of the four first countries with the biggest non-cash payment level on inhabitant-USA and France-use to the largest extent the cheque for the purpose of carrying out of the payments. In Germany the transfer is preferred (45%) to the cheque (10%).

*d) The card* is a payment instrument without cash by which the authorized holder can settle the equivalent value of the goods bought from the tradesmen, or can benefit from the services carried out by third parties and who are empowered to accept it and use it and also allows the acquiring of liquidities from the issuing bank, managing in fact the current account of the credit holder<sup>21</sup>.

The banking cards fulfill multiple functions, the most important ones being the following<sup>22</sup>:

- e) the function of funds withdrawal;
- f) the payment function;
- g) the credit function;
- h) the guarantee function.

The largest majority of the banking cards fulfil multiple functions of funds withdrawal, payments, credit and guarantee.

The credit market as an integrant part of the world finance is subjected more than any other activity, to a rapid globalization process, in addition to the two great payers (VISA International and Master Card International), an active role in the globalization of the credit market plays Europay International as well, American Express, Dinners, Club International, JCB (Japan Credit Bureau)

The itinerary covered from the full-bodied currency, with intrinsic value, to the paper currency has been incomparably longer than that from the paper money to the electronic money, which was achieved in a very short historical period of time.

On the mature markets (The West European market, American market) and on younger markets as well (The Central and East-European markets, to which there belongs also Romania) there is a multitude of card types, which are basically nothing more than variations of the three fundamental credit types: the debit card, the credit card and the charge card overdraft.

---

<sup>21</sup> Basno, C., Dardac, N., *Payment system, compensations and settelements*, Publishing House, Didactica si Pedagogica R.A., Bucuresti, 2003, I.S.B.N. 9730-30-274103, p. 121

<sup>22</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 153

The e-money represents the value stored electronically on a device, either in an electronic support, or in the computer memory, and which can be recharged, with the possibility of its use to a multitude of goals<sup>23</sup>.

The beginning of cards in Romania goes back to the year 1997, when the unresiding foreign persons visiting the country had the privilege that at certain hotels, restaurants, shops, stores, to use as a payment means, the card. Once with the passing to the market economy the Romanian commercial banks began to issue their own cards. During the last years the cards market in Romania has known a rapid development, being currently in full maturization process in all its segments.

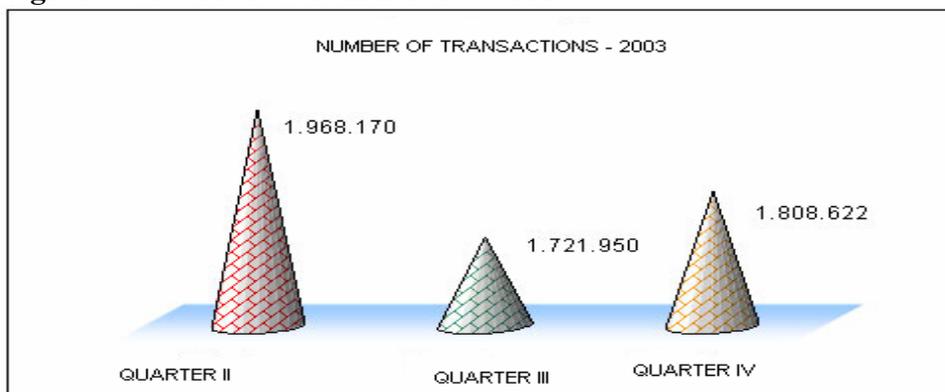

Conforming to a statistics drawn up by the National Bank of Romania, the situation of the number of cards users and the number of transactions performed by the intermediary of cards in the years 2003, 2004 and 2005 is presented in the following tables and graphics:

**Table 1 The situation of the number of transactions performed by card in the period 2003-2004**

**Figure 6 Users number of cards in 2005**

Starting from the fact that the smart-card is the card offering the possibility of processing and stocking of the value units by the means of an integrant processor (chip) and, by comparison with the magnetic band card, this one can effectively store funds transferred from a banking account or from another smart-card(card to card operation), as well as information regarding the balance due , the payment realized with this type of card being realized on the spot, we can assert that the future belongs to the smart-card.

Expression of the technological progress, the card, instrument of economic and social identity of the person within the systems that insure the

globalization of payments by cards, is subjected to a continuous improvement process.

## **2. The mobile financial services**

The Internet economy is already a reality, a fact of everyday life and is in continuous progress in Europe, being estimated an increase of the Internet users number of over 200 million in 2008.

The extent of the electronic commerce in Europe will be slightly different from that of the USA. Reflecting the penetration factors of personal computers, mobile phones and cable TV, there will be carried out in a proportionate way in Europe more transactions on non PC type devices, such as for instance the mobile phones, other portable equipments and web connected television

At a world level, the mobile communications represent the latest distribution channel of financial services which is estimated to have a huge impact in the future over the way in which the consumers will use and manage finances.

The m-banking applications will comprise from the simplest mobile banking operations to the possibility of effectuating financial operations for any transaction of the e-commerce type by the intermediary of a portable device. The analysts estimate that the base services of the retail-banking type will be followed by complicated applications of mobile financial services, as well as by stock market operations and financial facilities of transaction and commerce.

The users of the mobile financial instruments benefit from services such as the possibilities to make payments and to check the banking account balance.

The mobile telephony operators will confront in the future with a dramatic decrease of the income on user if they remain within the framework of the present services(voice services), and for this account they try to conclude partnerships with different institutions in view to diversify the services in order to maintain the income level or for registering an increase of these ones.

Before the future Internet banking expansion, the mobile banking offers very simple services, such as informing the client through his own mobile telephone about the situation of the current account balance, of deposit or of card accounts, through the sending of SMS messages.

The reasons for which the telecommunication companies need the financial institutions in the on-line sector/mobile banking are: the lack of the know-how and the absence of the mark image in the banking field. On the other side, the financial institutions pursue the attraction of new clients, a very attractive segment being the clients of the telecommunication companies eager to enter direct banking relations.

### ***2.1. The mobile financial services (m-banking and the interactive television (ITV banking)-alternatives for Internet Banking***

The main reason for which the Romanian large banks launched harder Internet-Banking services is the reduced number of potential clients, because of the weak penetration of Internet services.

The reduced number of personal computers in Romania and the relatively high cost of telecommunications generated that situation that leaves space to new alternatives to Internet access such as : Interactive TV (ITV) and mobile Internet.

The offer of e-banking services on all he three platforms (m-banking ITC and PC based internet) will allow a bank to attract clients using more platforms in order to carry out their transactions.

In the Western Europe it is estimated: an average increase of 140% yearly for the exclusive ITV users and of 221% for the m-banking users, increases which are clearly superior to the average increase ratio of the PC based e-banking users.(37%)<sup>24</sup>.

Nevertheless, a TV is a good used by the entire family, without existing a sufficient confidentiality level for the operations performed using the ITV-banking operations. This distribution channel for the e-banking services is a channel for the customers for which the cost of the access to these services has a great importance and for the regions with a relatively low number of Internet users. In Romania the potential of development of this type of services is extremely promising because the Romanian market is price –sensitive and there is a great numbers of users of TV channels.

The mobile financial services (m-banking) give the clients the possibility to realize transactions anywhere and anytime, and the size of the screen and the fact hat the mobile phone is a personal use object insures a maximum confidentiality degree to this e-banking service. The m-banking services will have a much larger number of active users and the transaction

---

<sup>24</sup> Paraschiv, M., D., *Technique of international payments*, Publishing House, Economica, Bucuresti, 2003, I.S.B.N. 973-590-932-4, p. 268

volume will top clearly the volume of transactions for the ITV users and even PC-based e-banking.

Conforming to a certain opinion the e-banking services involves risks which the Romanian banks are not ready to face<sup>25</sup>:

- conformity risk
- strategic risk;
- operation risks (among which the piracy);
- Crediting risk (accentuated by the client recognition);
- The liquidity risks, of interest rate, and of market volatilisation);
- Th reputational risk.

It is essential for any bank eager to invest in e-banking services to be able to offer these services on any of the three platforms. Even if at present the PC based e-banking potential users are the most important ones, this situation is about to change in the near future, and the banks must insure that the introduction of a new distribution channel of e-banking services is possible and viable.

These new payment procedures allow the convenient, safe and very fast transfer of the money among the business partners. In addition to this, the replacement of coins and paper money with electronic money leads, apart from the reduction of issuance costs and maintaining in circulation of the cash, to the increase of flexibility and safety of the payment systems.

### **3. Conclusion**

Any of the payment modalities presented hereby involves risks and in order to insure themselves against these, the involved parties must get to know very well these payment modalities, their unfolding mechanisms and the documents necessary to be requested. Apart from the banking regulations, the successful carrying out of the transactions requires good faith from the part of everyone involved.

The continuous evolution of the payment means and the passing to the electronic money (e-money) can be considered a revolution, because they generate changes within the banking system (modern services, the legal financial frame adjusted at the international level. The Romanian banking system is subjected to a reorganization process, characteristic, in fact, to the entire national economy in transition not only to the market economy, but also to the Internet economy or new economy.

---

<sup>25</sup> Turcu, I., The operations and banking contracts, 5th edition, Publishing House Luminalex, Bucuresti, 2004, ISBN 973-588-824-6, p.173

It can be noticed that the payment means are in a permanent evolution determined by the economical development and the appearance of the new technologies, the money preserving, however, their essential functions. The passing to the electronic money causes changes both at the level of the banking infrastructure and at the level of the consumer behaviour as well.

*Motto: "The computers are useless. They can only offer you answers", said Pablo Picasso. The utility levels of the electronic currency and what we will offer ourselves by its mediation is about to unveil the future for us.*

*The world of money is a world of caution and any hidden thing (a code, an address), can generate suspicion.*

## **Abstract**

*The main purpose of all economic activity is to satisfy the clients' needs. Everything that happens in connection with the bank must follow this objective. If certain banks neglect their clients' needs, then certainly it will be the rival banks to take care of them. We consider that success is always on the side of the bank that manages to find the answer to the question How can we improve the bank-client relations? Since 1990, numerous changes have taken place in the Romanian financial-banking system. The banks have opened for the public as well, they have introduced numerous new products and services, new processes have been established, new regulations have appeared, the foreign banks have opened new branches, the informational technology has been updated. Under these circumstances, it is vital that the banks be to a greater extent marketing- and management-oriented, more precisely client-oriented. They must be aware of the rapid changes in the banking environment and to be able to adapt and change their plans and strategies, to introduce products and services compatible with the new demands and transformations. The practical activity tells us that the banks offer services similar to those of their competitors'; that is why, in order to be more competitive, a bank always needs to find something to differentiate it from its rivals. Always situating the client as the first priority, anticipating his needs and problems, responding to the services that he requires are the strategies with this result. We must also mention that, as the clients' expectations increase and as they become more and more demanding with every service granted, the bank must be always ready to comply.*

**Keywords :** *the bank-client relations; Romanian banking system; competition*

## 1. Introduction

The main purpose of all economic activity is to satisfy the clients' needs. Everything that happens in connection with the bank must follow this objective. If certain banks neglect their clients' needs, then certainly it will be the rival banks to take care of them. We consider that success is always on the side of the bank that manages to find the answer to the question *How can we improve the bank-client relations?*

In the countries with a tradition in the field, one can observe the tendency of the clients to appeal to several banks—a phenomenon called multi-bankarization, the tendency to recede from the banks when it comes to savings products (resorting to insurance products, financial products offered by the monetary authorities or to derived products). Under these circumstances, the administration of the institutions, the personnel and, in general, the businessmen implied in financial-banking services activities have shown particular interest in knowing as many aspects as possible concerning the domain in which they evolve.

Since 1990, numerous changes have taken place in the Romanian financial-banking system. The banks have opened for the public as well, they have introduced numerous new products and services, new processes have been established, new regulations have appeared, the foreign banks have opened new branches, the informational technology has been updated. Under these circumstances, it is vital that the banks be to a greater extent marketing- and management-oriented, more precisely client-oriented. They must be aware of the rapid changes in the banking environment and to be able to adapt and change their plans and strategies, to introduce products and services compatible with the new demands and transformations.

The human society is confronted at the beginning of the third millennium with a series of vital and unprecedented issues. That is how the Romanian banking system finds itself in a transition process that creates the conditions for a turbulent environment for the banks functioning in the system. It is likely that this environment will continue to exist for a period of time while the economy continues to develop.

As a natural consequence, the competition in the banking system will increase. Several well-known foreign banking corporations have entered the banking market, new private banks have appeared and a part of the banks in the Romanian state sector have undergone a process of privatization. In this context, satisfying the clients' interest by offering a variety of banking products and services has become a must. This will lead to an increase of the

clients' loyalty and of the reputation of the bank, thus insuring the clients' fidelity and stability.

The practical activity tells us that the banks offer services similar to those of their competitors'; that is why, in order to be more competitive, a bank always needs to find something to differentiate it from its rivals. Always situating the client as the first priority, anticipating his needs and problems, responding to the services that he requires are the strategies with this result. We must also mention that, as the clients' expectations increase and as they become more and more demanding with every service granted, the bank must be always ready to comply.

## **2. Conditions specific for Romania**

### ***2.1 Limits of development of the banking market and of the relationship bank-customer. Macroeconomic conditions***

The instability of the macroeconomic environment represents an obstacle for the well development of the activity of the economic agents (especially in the case of the entrepreneurs), but also of the banks, through the fact that, in much less predictable conditions, the business plans, which are at the basis of lending, have a lower degree of credibility from the financier's point of view.

Also, the still significant gravity of the inefficient companies diminishes the degree of safety of the lending activity. Thus, the delays registered in the restructuring of the actual sector determine many of the economical agents not to be eligible for granting credits.

### ***2.2 The inadequate, insufficiently developed legal environment***

The existence of an inconsequent and incomplete legal environment, as well as of some judicial and extrajudicial procedures for recovering the debts by forced, expensive and long lasting execution, has a negative impact over the financing activity.

### ***2.3 The behaviour of the market participants***

The partnership bank-customer has to suffer because of:

- the lack of transparency of the real situation of the patrimony of economical agents, which allows correcting the performance indicators afferent to their activity within the solvency analyses

for granting the solicited funds. In this context we must mention the embellishments produced by annulment, re-phasing of the debts of state companies, without taking into consideration the objective principles such as competition ;

- the non-promotion of the corporate management;
- the weak use of the instruments specific to risk management.

Moreover, the reduced level of economical and especially banking education, of the actual and potential consumers of products/banking services, as well as the professional training, which is still adverse, as an average in the banking system, of the staff of the credit institutions hinders the achievement of an efficient communication between the two parties. Thus, on one hand, many economical agents with funding necessities do only appeal to banks as a last resort, and on the other hand, there are still banks which do not give sufficient importance to the aspects regarding the introduction in their offer of consulting services for their customers.

The analysis pointed out the fact that, regarding the efficiency of the activity in the banking system, as an ensemble, supplementary efforts are necessary on behalf of credit institutions in order to be able to handle the level of competition in the European Union.

Thus, the degree of banking intermediary in Romania, expressed as banking assets/inner gross product, represented at the end of 2002 only half of the level registered in Poland and a quarter of the one reported by the National Bank of the Czech Republic in the same period. Regarding the productivity of the banking activity (banking assets/employees in the banking section) this was in Romania, in the previously mentioned period, three times smaller than in Poland and six times smaller than in the Czech Republic.

### **3. Customers for Romanian Banks. General characteristics**

The principal goal of any economic activity is satisfying the customers' needs. If the organizations do not take care of their own customers, then their competition will. The bank must understand its customers' necessities and the process of their decision taking.

The analysis of the customer's behaviour is a key component of marketing research. By understanding this behaviour, the Romanian banks anticipate the probable reaction of a customer and can influence the structure and planning of the services provided by the bank. The customers represent the most obvious barometer in the evolution of a bank. The presence of an increasing number of commercial companies or individual entities in the offices of the bank, confirm the quality of the bank's services, while the

migration of the same customers to other banks serves as proof for the unit's weaknesses.

In a broader acceptance, a customer is defined as a legal or individual entity, who frequently or sporadically asks for the services of the bank in order to satisfy their needs and producing economical effects on the bank.

In a limited acceptance, a customer is defined as a legal or individual entity, with one or more open accounts at the bank, a clear name, well-defined headquarter or residence, legal judicial status, who constantly and frequently resorts to the products and services of the bank satisfying some of its needs and producing economical effects on the bank.

In the case of commercial banks in Romania, the high dynamic of their customers confirm the trust they have in the capacity to work of some banking units, in the quality of the staff and of the offer of products and services.

At the present time, among the customers of the banks there is an important number of commercial companies with state capital, different autonomous administrations, budgetary institutions, commercial companies with private capital, as well as individual entities.

In the last years, the counters of the banks have been assaulted by a big number of individual entities, especially for the fruition of the available funds, either by open deposit accounts, or by the deposit certificates, a very tempting capitalization instrument.

The bank's customers desire an ever better quality of the services and a diversified range of products. This is why competition becomes stronger together with the continuous development of the economy. It is vital, for any bank, that its products and services to be presented on the market successfully in order to obtain the increase, development and power in the financial-banking sector.

The relationship between the customer and the bank is very important and needs to be maintained in order to assure the loyalty of the customers and to develop long term relationships with them.

Attracting new customers can be more expensive than keeping the existing ones. It is universally known that, in market economy, the price for attracting new customers is four or five times bigger, in financial costs and effort, than developing and maintaining the relationship with the existing customers. For this reason, maintaining the existing customers content is a crucial side of the marketing strategy. The strategy must contain a component which is directed in maintaining and developing this customer content, by satisfying their needs.

Both actual and potential customers are important for the economic activity; losing one customer could not be very important, but losing more the bank would really have problems.

The quality of the services and the concern for the customer inevitably remain the key elements of the total offer of services, but conditioned by the constraints imposed by the cost control and maintaining the competition regarding prices.

The key of maintaining the customers' loyalty is to keep them satisfied. If a customer is satisfied, he will wish to continue the relationship with the bank, he will use more and more services to satisfy his needs and will recommend the bank to others.

Long term loyal customers will guarantee the income of the bank. The customer's loyalty improves the image of a bank and can be an excellent source of advertisement. The bank's customers will not wish to work with the bank's competition for similar services, even if sometimes they may offer cheaper services or may offer attractive interest rates.

Customers want consultancy regarding the ever bigger number of services and the best solutions for their objectives. The employers of the bank have the obligation to give the customers the best consultancy and clear information concerning the services which best satisfy their needs and demands.

The customers which are individual entities and legal entities have different needs and expectations from the bank they work with. Banks must give the customer – individual entity consultancies for the services they need and help him in organizing his personal incomes.

The customer - legal entity will need consultancy in preparing the business plans, adequate services for solving his business needs, money transfer services, etc.

The bank is interested in attracting its customers from the market and maintaining a relationship of long term collaboration with them. In this sense, performing financial consultancy services (free of charge) the bank must:

- strengthen the image of professionalism of the bank;
- eliminate the psychological barriers (preconceived ideas) of the customer;
- obtain as much information as possible about the customer, free of charge.

At the present time, serving the customer is the decisive starting point for many organizations and will become vital for the strategy of the Romanian banking system, while the competition becomes stronger and more

services are created. Any organization, which is aware of the quality of the services, aspires to overcome a minimum level of satisfaction and offer the customers more than they ask for. In the last decades the quality of the services has become such an important matter for banks, that none of them can neglect this aspect, as long as the others improve the level of their services.

It is important for those who deal with the marketing activity to understand the customer's behaviour and how the final buying decision is made. In the financial – banking service, the customer does not only choose the product, but also the bank he wishes to do business with. The understanding of the customer is vital for any marketing department.

The factors which influence the customer's behaviour (as a buyer) in relation with the bank are:

- trust in the banking system;
- the accessibility to acquisition of services;
- the reputation of the bank;
- the range of products and services;
- the quality of the services;
- the tariffs for the services;
- easy spotting the bank;
- the possibility to satisfy the needs regarding the financial-banking services;
- the presence of a friendly and capable staff.

In Romania competition continues to grow, new banks are founded, and this is why customers have the possibility to choose from the banks the one which satisfies their specific needs concerning the financial-banking services. Within the financial-banking department, the services and products are alike due to their effect, for this reason, a bank must maintain its competitive advantage. The quality of the services is a domain in which an organization is capable of acting and is the key for a future development. One of the secrets of guaranteeing the customer a good service is to understand his needs and wishes.

The commercial sector is the most complex in a bank. Despite all this, for many of the small businesses, accounting is made by individual persons and for this reason, the personal factors will probably have a bigger influence in their decisions, than in business confidences. It is important not to ignore the attitudes of the persons in large organizations, because they can influence the bank where the account is opened and which provides the services.

Reconsidering the preoccupation towards the customer implies:

- the concern for the granted time
- the concern for the moral values of the customer
- the concern for educating the customer (helping him in understanding the responsibility of the customer and the preoccupation of the bank for his needs)
- rough concern (identifying the moment when and how to say NO)

Today in marketing the accent begins to fall on keeping the clients in order to defend the market quota. The client is a productive resource, has its own contribution to the creation of quality, value and satisfaction and it also appears as a competition to the company.

If in the beginning of its activity, the bank offered its clients a reduced range of bank products and services, this confining to performing the cashing and payment operations through the bank accounts and giving credits to the economic agents and individual persons; as new products and new banking services were created, the range of clients has expanded, their number and the number of the accounts have increased from year to year.

The clients develop most of their activity through accounts opened at the bank. Their accounts and evolution provide an image on the banking activity. The evolution in time of the customers is crucial for two essential aspects: first of all because their interest towards the bank's services, the trust in the stability and safety that the bank provides and then the impact of these customers on the bank's resources, as a result of receiving an important number of Lei and foreign currency. The customer segment that had known the biggest development, both as number and as resources brought to the bank, is the population. Though the products and services especially created for this type of clients, the individual persons have manifested a great interest towards banks, this because of the reorientation of the population's economy to the bank deposits and as a result of the deponents' change in point of view, and that is, that the value of the earning is less important than the safety of the investment.

A client – individual person can be described as a person that holds a bank account for his/her personal use. This type of clients must respect the existing regulations, and the bankers must make sure that these people do not open nor use bank accounts for illegal purposes. The persons can open accounts only in their own name, with the possibility that the account holders authorize other persons too for the account signature. In other countries, the joined accounts (opened in two names), are very frequently encountered (for example, in a family, the husband and wife can open an account on both names).

Regarding the individual persons, the only thing that the banks must take into consideration, is the age of the persons that wish to change an account. It is taken into consideration that very young persons might not entirely know the consequences of operating certain transactions with the banks, and therefore, such persons are protected, in order not to be taken advantage of.

Also, it wouldn't be wise for the banks to engage in complex loan agreements with too young persons. Even if the law is not very clear at this point, the banks can have their regulations regarding the minimum age of the clients. In Romania as in most countries, beginning with the age of 18 individuals have the full exercise ability, and as such, can exercise their rights and they can assume the respective obligations to the legal reports that they close.

### ***3.1 Conditions for keeping the clients***

The clients that were admitted by the bank as a result of fulfilling some criteria, and that enter a normal and current relationship with the bank, will be permanently observed in the purpose of establishing to what extent they are keeping, enlarge or reduce their initial performances. In this way, during the business development and the different connexions with the bank concerning the clients, the following possibilities may occur:

- The clients maintain or enlarge their basic qualities, which were approved through the acceptance criteria. These clients are recommended as being very good, with high performances and, in these conditions, the bank and its regional units shall actively approach him/her.
- The clients change their performances, in the sense that they register low profitableness, the fixed assets are not in a very good situation (too big) towards the own capitals and the long term resources, they appeal to few of the bank's products and services, the customer indexes will be accepted continuously in a passive way and will be carefully followed and supported in order to be able to improve the general state in which they find themselves.
- The clients no longer qualify for the criteria they were accepted, no longer perform a profitable activity, have liquidities and a debt level no longer admitted, their activities and products are no longer accepted on the market, generally they find themselves in a determined situation which promises no future improvement.

The legal persons have always been encouraged and sustained by the banks in their efforts for productivity modernizations and change of the technology by granting a various range of credits in Romanian and foreign currency, that came in the completion of their own resources used in this purpose. In the course of their activities, the banks have given a special attention to the state enterprises that have not yet undergone privatization, as well as to the foreign investors that have shown interest in investing in economical activities undergone on the Romanian territory. The growth of the customers' number will be followed in parallel with the growth of the quality of the offered services, so that the clients' interest is satisfied by the bank in mutual convenient conditions. The client will still occupy the central place in the bank's activity, enjoying a special attention from its behalf, the bank pursuing the keeping of profitable clients' base and its expansion at maximum length, through attracting other big regional agents.

The place and the role of the client will be still kept in the centre of the bank's attention, observing its behaviour in accordance with whom the bank can better organize its activity. All this will be accomplished because for the employees of the bank, the clients represent a permanent priority, them being the most important part of the banking activity, those who put in motion the bank resources and without whom the bank would not exist.

#### I. The Conditions and the contents of the research

A group of professors (the co-authors of the paper) have realized a research project which was selected by the National Council of The Scientific Research of the Superior Education from Romania, as being part of the priority fields in research and developing regarding the Romanian integration in the Euro-Atlantic Structures.

In the project entitled **“Study regarding the banking environment in Dolj County and the identification of the improving possibilities of the bank-client relationship”** we proposed to make an analysis of the bank environment from Dolj County, in order to identify the opportunities of improving the bank – client relationship in the context of the reorganisation of the banking activity in Romania imposed by the alignment at the European banking standards.

As part of the research we appealed to the elaboration of a questionnaire for analysing the bank-customer relationship. We have made a pole based on the questionnaire based on the following major directions:

- Attitude towards the bank;
- The degree of knowledge of the banks in the county;
- The utilization range of the banking products and services;

- The motivation of bank change.

Following the development and the interpretation of the data obtained through statistic methods, we have reached a series of conclusions which we present in the following.

#### **4. General conclusions**

The bank market in Romania has known in the last two years a more pronounced change of the power equilibrium in the bank –client relationship, on behalf of the supplier of banking solutions towards the client. This change is more accentuated on that part of cooperative clients, where the number of the clients is still small, and the competition is big, and less notable in the bank’s relationship with individual persons. In this respect, the commercial banks have diversified their range of products, have become more flexible in the relationship with the clients and have decreased the interest rates.

Different approaches for different range of clients have appeared, but in the same time the innovation on the bank market has been quickly imitated. In this way, the “innovative” products become “standard” in a high speed.

Predictable evolution, sustained dynamics, a very high grade of competitiveness are just a few of the basic characteristics of the bank market specialized in companies. It is the place where the clients gain the hardest way and these are maintained with efforts and quality at the highest standards. Regarding the evolution of the financing products, in the last year we have noticed closeness in the financing conditions from the structural markets, a relative relaxation of the granting conditions, following the use of rating techniques, as well as the division of the activity between two or three banks.

Furthermore, together with the favourable evolution of the country risk, with the improved financial situation of the companies and the economic growth, the bank’s appetite for long term finance has increased. In this way after a period when the companies had mostly access to the short term credits, nowadays an increase of the maturity in the corporate credits towards 7-10 years is noticeable. The credit activity is headed towards the field of productive investments on longer terms that exceed five years and the credits for commerce activities have diminished. Under these circumstances, the commercial banks have evolved from short time financers, who offered only working capital for their clients, to suppliers that offer complete financial solutions.

In this way an intensive growth of the bank's portfolio is being accomplished, in parallel with the increase of the clients' portfolio. So, the lending products have diversified and financing structures have appeared meant to circulate the company's financial flux and to make risks easier to control. Furthermore, the credits for project financing will be more and more used, and there will appear new approaches of the complex projects.

Regarding the currency in which the credit is given, a sinuous evolution has been registered in the past few months. The credit in a foreign currency dominated in the first months of the year, but through the accentuated drop of the interests, through the nature of the operations of many companies and the elimination of the exchange risk, the credit in Lei becomes competitive.

The evolution in the last year of the financing conditions has been closely connected to the growth of the competition in the banking system. In this way, the accentuation of the competition has been determined by the very aggressive target of the majority of the foreign banks in increasing their market quota. In order to accomplish this objective, the commercial banks were forced to offer the corporate clients more convenient conditions. In certain geographical areas, the banking service offer obviously exceeds the request – especially on the segment of big companies and with a low risk – so that the competition to earn clients has become stronger and stronger.

The credit still represents the most important reason for which a company chooses a bank or another. The current offer regarding loans is relatively various, and the diversification possibilities are multiple, not only in the field of the lending, but also in the field of the monetary and capital market. We consider that on the market in general, the Romanian companies take little advantage from the possibilities of the banking sector of offering derivate products or finances through emission of obligations or commercial papers.

Although the banking products directed to the companies are almost standard, some of the banks present on the Romanian market try to differentiate the offer towards the competitors, and the good news is that in Romania innovation in the banking field is still possible, both regarding the products, as well as the offer characteristics. The adjustability to the specific needs of the company, the consultant and partner attitude towards the client, as well as the quickness and professionalism in the implementation of the offered banking services are the main attributes that we consider that differentiate one bank from another.

On the other hand, there are no magic recepies through which the banks can handle when facing the competition especially that the Romanian

market companies become more sophisticated and professional clients. They want dedicated solutions, a pragmatic approach and closer to their necessities, as well as bank counselling.

If it succeeds in being close to the client and in understanding its need, banks has chances in imposing itself on the banking market and win the battle with the competition.

## 5. Specific conclusion

The research was elaborated on the basis of a questionnaire that contains 38 questions and is structured in four main parts. The main conclusions that come from the research are the following:

I. The perception towards the banking activity:

1.1. Name the banks that you most often use or you know of:

Question

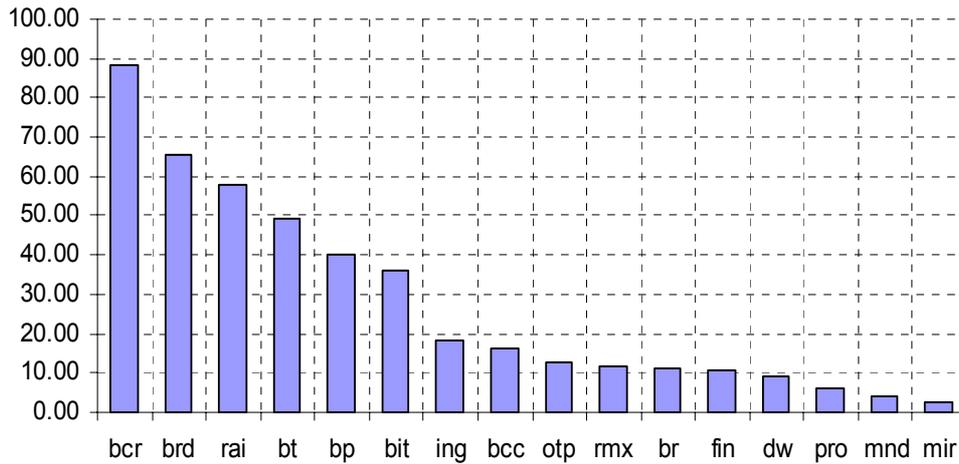

1.1.

No. of known banks

5

Banks' notoriety Ranking

position	1	2	3	4	5	6	7	8	9	10	Total
<b>bcr</b>	53	47	25	13	10	2	1	0	0	0	<b>151</b>
<b>brd</b>	17	30	15	26	13	9	2	0	0	0	<b>112</b>
<b>rai</b>	11	22	37	14	4	8	1	1	1	0	<b>99</b>
<b>bt</b>	9	18	15	15	14	5	7	1	0	0	<b>84</b>
<b>bp</b>	18	13	11	6	12	3	3	1	0	2	<b>69</b>
<b>bit</b>	15	8	13	11	3	8	1	1	0	2	<b>62</b>
<b>ing</b>	1	3	4	6	4	7	3	3	0	0	<b>31</b>
<b>bcc</b>	7	2	4	6	4	2	2	1	0	0	<b>28</b>
<b>otp</b>	10	5	2	3	0	1	1	0	0	0	<b>22</b>
<b>rmx</b>	8	3	3	1	1	0	2	1	1	0	<b>20</b>
<b>br</b>	1	3	2	1	4	2	1	3	2	0	<b>19</b>
<b>fin</b>	2	2	5	3	3	2	0	1	0	0	<b>18</b>
<b>dw</b>	9	1	0	0	2	2	1	1	0	0	<b>16</b>
<b>pro</b>	5	2	2	0	1	0	0	0	0	0	<b>10</b>
<b>mdn</b>	1	2	1	0	2	0	0	1	0	0	<b>7</b>
<b>mir</b>	2	0	1	1	0	0	0	0	0	0	<b>4</b>

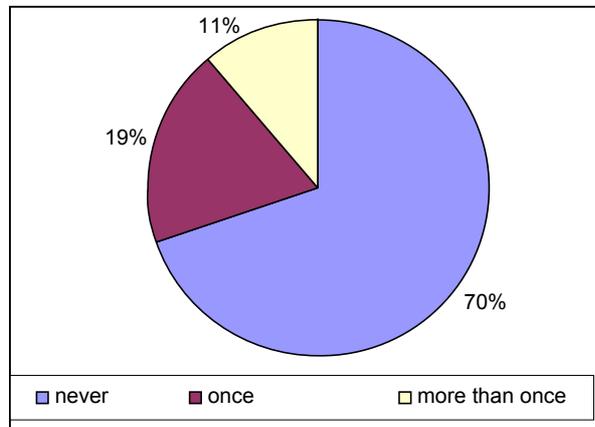

Thus, the degree of knowledge for ten banks, unassisted, places on the first three places the Banca Comerciala Romana (Romanian Commercial Bank), Banca Romana pentru Dezvoltare (the Romanian Development Bank) and Raiffaisen Bank

1.5 How many times did you change the bank you have been most frequently used in the last three years?

1. never;
2. once;
3. more than once.

1.5	
1	119
2	33
3	19
Non-response	0
Total	171

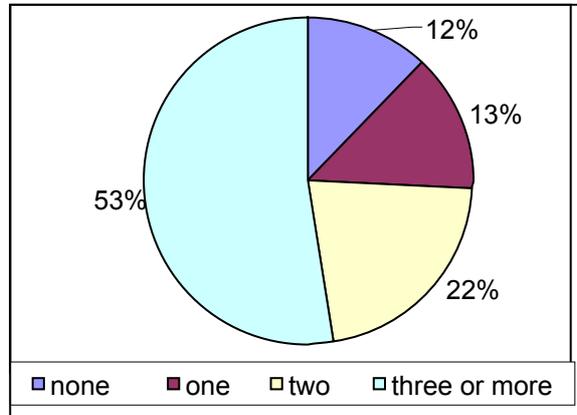

we discover that 70% of the interviewed clients have remained faithful to the bank they work with.

1.7. how many products or banking services do you use beside the running account:

1. none;
2. one;
3. two;
4. three or more.

1.7.	
1	21
2	23
3	37
4	90
Non-response	0
<b>Total</b>	<b>171</b>

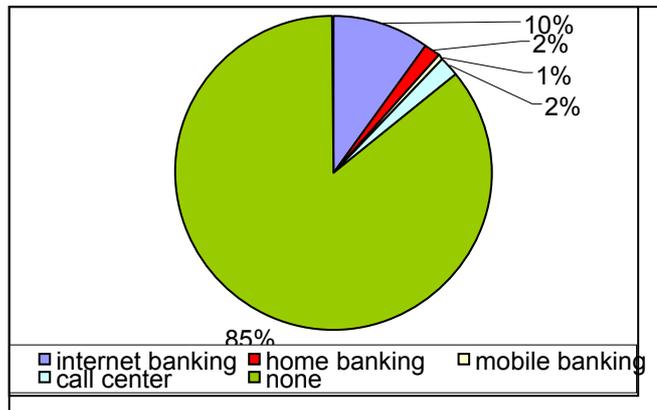

More than half of the interviewed persons specified that they use three or more banking products.

1.10. Which of the following products or services have you been using in the last 6 months?

1. internet banking ;
2. home banking ;
3. mobile banking;
4. call centre;
5. none.

1.10	
1	17
2	3
3	1
4	3
5	146
	170

Although the Romanian commercial banks spend important amounts of money to implement new products and services, we discover that 85% of the interviewed persons do not use not one even one of the new products.

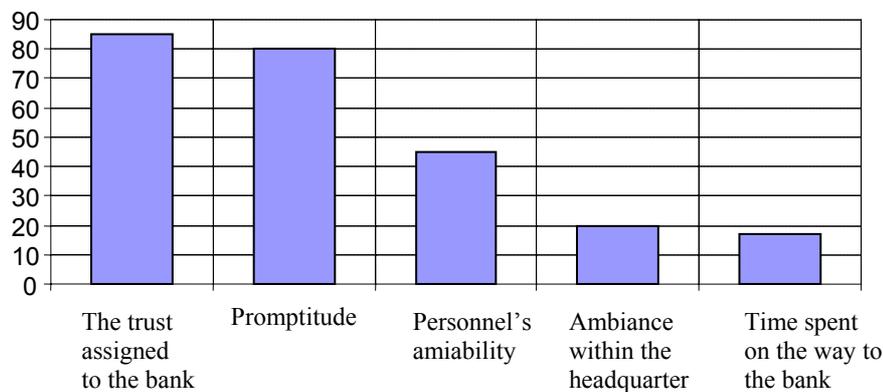

II. The attitude towards the banking services:

2.12. The greatest impact for you when choosing a bank is:

1. the trust you have in the bank;
2. the ambiance within the bank headquarter;
3. the amiability of the bank personnel;
4. the promptitude in solving your requests;
5. the time spent on the way to the bank.

2.12

1	85
2	20
3	45
4	80
5	17

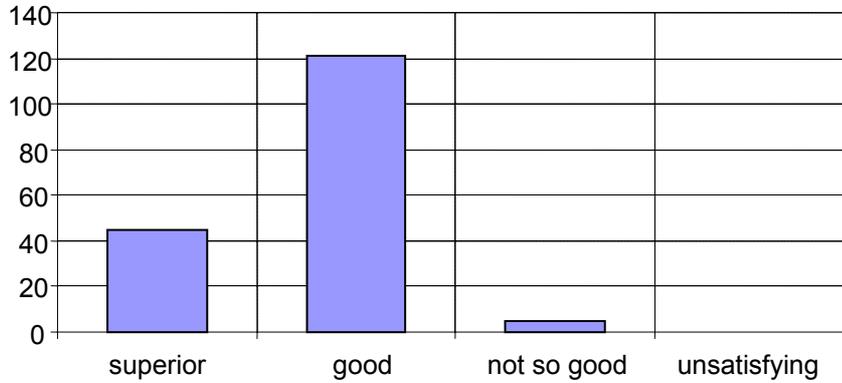

In Romania, when choosing a bank, the clients still take into consideration the trust they have in it.

2.20. You evaluate the efficiency of the process of solving your problems as:

1. superior;
2. good;
3. not very good;
4. unsatisfying.

2.20

1	45
2	121
3	5
4	0

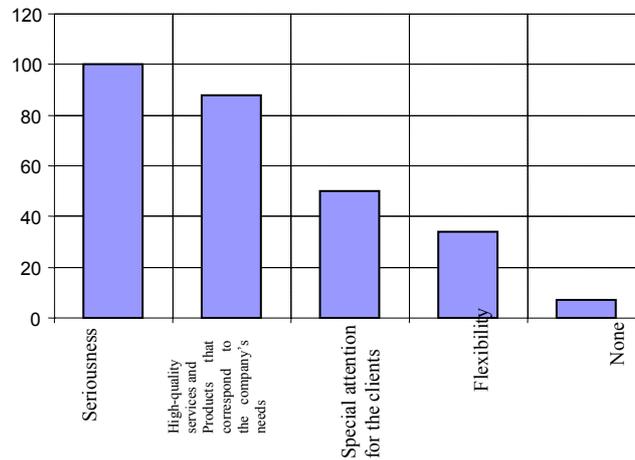

Although the banks make important efforts in order to improve the bank-client relationship, only 70% of the clients appreciate their relationship with the bank as good and only 23% of them consider it superior

2.21. Which of the following qualities match your bank:

1. seriousness;
2. high-quality services and products that correspond to the needs of my company;
3. flexibility;
4. special attention for the clients
5. neither.

2.21

1	100
2	88
3	50
4	34
5	7

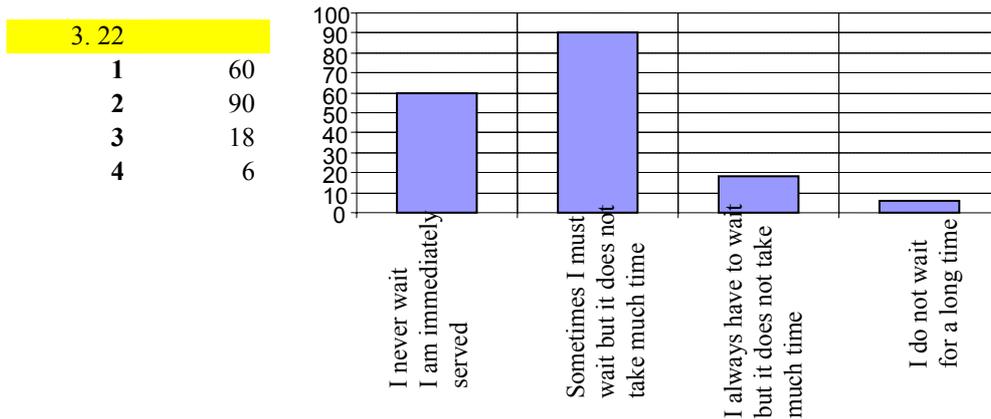

The main qualities appreciated by the clients are seriousness and high-quality services.

### III. The quality of the services and products

3.22. How do you characterise the waiting time at the bank:

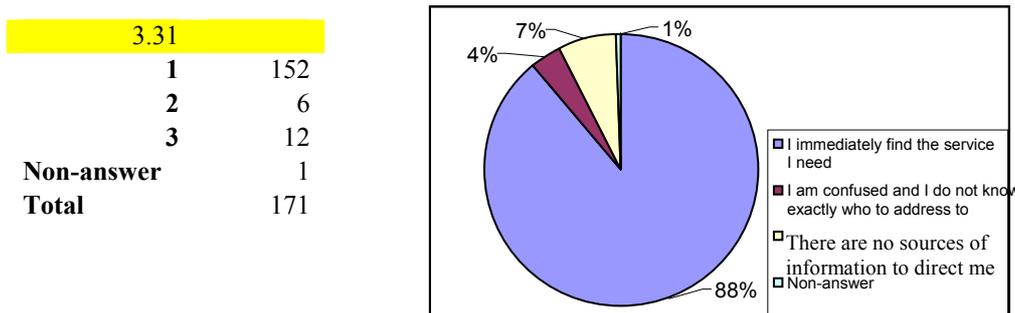

1. I never wait, I am immediately served;
2. sometimes I must wait, but it does not take much time;
3. I always have to wait, but it does not take much time;
4. I wait too much.

More than half of the interviewed clients consider that they sometimes happen to wait at the bank window, nevertheless, not for a long time.

3.31. How well are the signs and the posters directing you when entering the bank:

1. I immediately find the service I need;
2. I am confused and I do not know exactly who to ask for directions;
3. there are no sources of information to guide me, therefore I ask an employee for information.

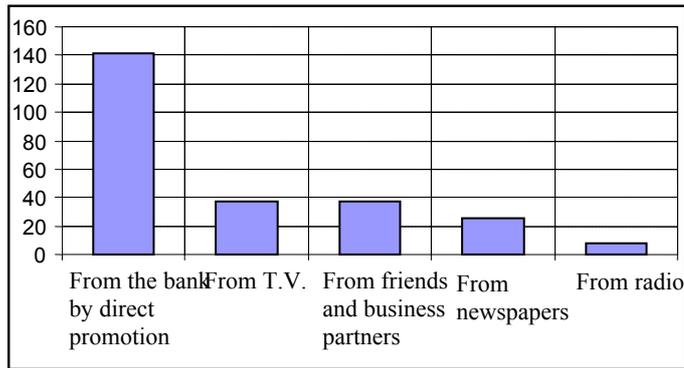

The clients can easily enter the locations where the services are performed, 88% of them being satisfied of the way the posters and signs within the bank direct them towards the services or the products they need.

3.33. You learn new information about new the banking services and products from:

1. the bank throughout direct promotion;
2. television;
3. radio stations;
4. newspapers;
5. friends and business partners.

33	
1	141
2	37
3	8
4	26
5	37

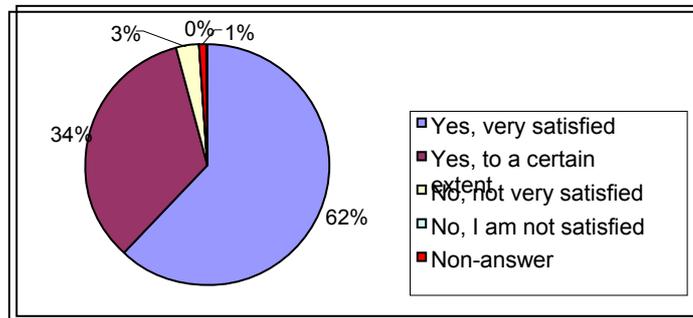

With the exception of the direct promotion, we find that a large number of clients learn about the banking services and products promoted by the banks from their friends and business partners.

IV. Clients' fidelity.

4.34. Are you satisfied by the bank-client relationship:

1. yes, I am very satisfied;
2. yes, to a certain extent;
3. no, I am not very satisfied ;
4. no, I am not satisfied.

4.34	
1	106
2	58
3	5
4	0
Non-answer	2

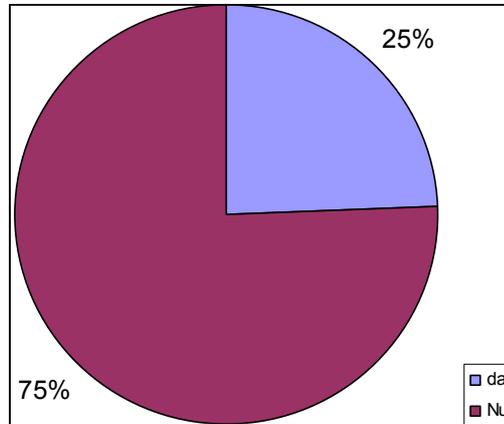

From the study we understand that most of the clients are satisfied about their relationship with the bank.

4.38. Did you know that there is a standard, respectively ISO 9004-2, that recommend the clear definition of the requests concerning the banking services:

1. yes, I did ;
2. no, I did not.

4.38	
Yes, I did	42
No, I did not	129
Total	171

As expected, the quality standard is familiar to approximately 25% of the interviewed persons; had the research extended also to the natural persons we consider that this degree of knowledge would have been even more reduced.

## **Abstract**

*The developments taking place in information and communication technology are affecting the financial institutions worldwide. This evolution had transformed the way banks deliver their services, using technologies such as automated teller machines, phones, the Internet, credit cards, and electronic cash. In this spirit, banking in Romania has been undergoing some changes. Many banks have been investing in Internet technology in order to maintain a competitive edge. This paper presents various aspects regarding the application of information and communication technology in the context of a developing nation.*

**Keywords:** *electronic financial services, electronic banking, Internet*

## 1. Introduction

In the financial sector, the last century has been under the sign of continuous liberalization and modernization. *The democratization of finances* (in an expression of Thomas Friedman) has been based in the first place on the development of the market of “commercial papers”(commitments that, since 1960, are sent to the public by corporations or even nations, introducing a sense of pluralism in the financial world and reducing the monopoly of banks). The democratization of investments has also been intensified on an international level when the set exchange rate and the strict control of cash flow system, that was founded in Bretton Woods after World War II, have disappeared at the beginning of the 1970’s. The moment when this system became more pliant, the developed countries democratized their financial markets, by opening them to the foreign participants, and the countries in the process of development followed the same example.

One of the most important revolutions “lived” by the banking sector has been set off by ... the new informational and communication technologies, “under the guidance” of the Internet. Under the impact of the new technologies, new types of banking services rose, the financial markets became more fluid and more efficient, and the consumers were able to choose from a number of offers – that often also come from other organizations than the banking ones.

The success of informational and communication technologies was bigger in the inter-banking transactions. Since many of the operations that take place between banks are standardized, their “digitalization” proved to be easy. In time, the important banks have developed their own ICT departments, have devised advanced networks and brought the informational operations that used to be externalized “in house”.

In the retail area, the ever growing power of the customer had the following effects:

- the ever growing variety of banking products;
- the cut in prices in the banking services;
- the increase of the quality of banking services etc.

All this came as a follow-up of the change of optic of the banking institutions, that have had to give up their traditional “pride” and become flexible, interactive, adaptable to customer’s demands.

But the ICT impact was not as large as in the inter-banking discount area. To choose a banking service is a complex decision, one that is hard to

make without direct contact with a bank employee. As a result, ICT have only been used by individual body customers in repetitive operations, such as taking out cash or visualizing the available sum in the bank account.

## **2. E-banking. General factors**

The financial-banking domain has known an uncommon evolution in the last few years; the increase in volume of the transactions in this field has been accompanied by a diversification of the services offered by the institutions in the branch. Under these conditions, the use of some IT solutions that were able to answer some more and more specific needs became a mandatory requirement for the growth of operational efficiency of financial institutions.

The banking service market is not exactly new. In Romania “electronic banking” was introduced since 1996, first by the foreign banks and then (starting from 1998-1999) by the local banks as well. The fact that since 2001 some of the banks have moved on to the implementation of “internet banking” could determine us to draw the conclusion that the Romanian market has matured and is offering services so as to cover the new needs of the customer. Even so, the obtained results do not come up to the expected level yet; practically, five years after the first home-banking service emerged in Romania, from the over six million customers of the banking system, the number of users of home banking services (whether we are talking about I-banking, e-banking, phone banking or mobile banking) barely comes close to 10.000<sup>2</sup>.

Because of the fact that the mass of banking service users in Romania is growing continuously, as are their skills in using Internet technologies, the expectations include modern services from the banks: accessible, with high performances and comfortable in Internet technology. The banks themselves need robust and advanced computing infrastructures that are able to integrate the existent applications, out of practical reasons, in an evolutionary rather than revolutionary manner. In Romania, right now, these tendencies are very much accentuated by the positive dynamics of the banking sector.

From a functional point of view, a high performance e-banking application should distinguish itself through easiness in navigation, meeting the customer’s demands, selective access to content based on needs/types of consumers, credit simulation and diagnostic tools and, of course, for the authorized customers, the whole set of banking operations for consultation and administration of the bank account and bank transfer.

---

<sup>2</sup> <http://www.no-cash.ro/sti/stiric15.html>, accessed in September 2005

Technically, response time and system reaction, pertinence and selectivity of the search engine are the important ones. The last, but not the least, the security of the application operation and of the traveling information should be built, maintained and monitored in a manner beyond doubt. For the business to business applications, which serve the really important transactions in the banking activity, the requirements are made to match. These applications have to change with each other an impressive amount of data and, furthermore, to react to a standard number of events with standard functions.

### **3. Risks for e-banking**

The companies from the financial sector that were interviewed by the Gartner analysts have showed that they intend to invest about 10% on average from the total IT budgets in risk management products and services. The analysts consider that in 2006 the risk management will continue to situate itself in the top of the priority lists of the companies from the financial sector. And as this subject becomes more important, the responsibility to build some risk management strategies is attributed to a higher level of the organization's management. The strategic responsibility is shifted from the individual department's level to the corporation's level.

Although for the financial companies the risk is becoming an element that needs to be kept under control under any circumstances, in the case of implementation of some IT projects, risk management becomes a key to success. The risk may come from the direction of businesses, of people or of IT elements. While certain risk elements are obvious, others are more difficult to identify. The risks may vary during the life span of a project and are, in general more significant in the last stages of the project. Still, risk management, the active and continuous process of risk identification, of analysis and reply to the risk factors, must begin even before initiating an e-banking type project. The organizations have to recognize the fact that risk management is a repetitive process, and that's why it takes regular risk reevaluations. IDC considers that at the core of IT projects failure there are many causes that are not immediately obvious.

### **4. The interoperability of e-banking solutions and the Web service market**

The interoperability of e-banking solutions is a mandatory requirement for the bank-implemented solutions, and necessary for ensuring the connection of the existing applications at the level of a financial institution and for the interoperability with various systems of the partners.

According to the estimates, the global market of Web services and that of the solutions dedicated to application interoperability was estimated in 2004 to approximately 3,4 billion USD. For the next years an important evolution is estimated for this sector, Web services covering a more and more acute demand of IT system integration. Thus, in 2008 the market of solutions based on Web services is estimated to approximately 11 billion USD. A consolidation of the market of solutions based on Web Services for the 2004-2008 timespan is foreseen. The defining of some evolved standards, as well as their acceptance by an ever-growing number of companies will contribute to the adopting of this technology on a wider and wider scale. Considering the transmission of relevant business information through the Web, the use of methods which allow the implementation of an enhanced level of security and which ensure data confidentiality is absolutely necessary. The achievement of standards as comprehensive as possible in the Web service field is a priority for the next years. The future versions of the Web service standards, available for now in the testing phase, will allow the encoding of data transmissions and the use of digital signatures. For the SOAP protocol, extensions for the attachment of identification elements will be available, ensuring an efficient control of the identity of the users which make the connections.

An example of implementation of the interoperability of IT systems on a national level in Romania is the electronic payment system implemented by BNR (National Bank of Romania). The process of modernization of the system began in 1995 with the improvement of BNR's ability to implement the monetary politics, the modernization of the payment on paper system and the nearing to a society predominantly without cash. Through the second stage of the process, which takes place in this period of time, the facilitation of the development of economy is targeted through the enhancement of security and of the efficiency of the inter-banking payment system, the passage to a society predominantly without cash, as well as the establishment of a well founded legal base for the payment and discount system. The project is operational in this moment, ensuring the interoperability on the level of IT systems from different banking institutions.

## **5. Romanian data and realities regarding e-banking services**

If the "Internet Banking" service has its beginnings somewhere around 2002 here, on a global level it has emerged since 1990, when the "Wells Fargo" Bank in California, USA, introduced the first service of this kind in the world.

According to the statistics of the Ministry of Informational Technology and Communications, the number of users of electronic payment systems with access from a distance is over 56.000, representing a growth of 26% compared with 2004. Also, the value of the payments expressed in euro equivalents has increased from 6,9 billion euros in the first trimester of 2004 to 12,6 billion euros in the first trimester of 2005.

Internet banking is a service offered to the customers by the banks, a service through which online banking operations are facilitated, from a distance. All that it takes is a computer, no matter its location and a connection to the internet. The access to this service is ensured all year round, 24 hours a day, 7 days a week. Except for its high availability, this service also offers the advantage of simplicity. Generally, surfing on the Internet-Banking dedicated sites is simple and intuitive, most of this product's interfaces being "user friendly".

In Romania, for a bank to be able to provide its customers with the Internet-Banking service, it has to obtain an approval from the Ministry of Informational Technology and Communications (MITC). In the present moment, according to the information on the MITC site, a number of 30 Internet banking, mobile banking and home banking services are approved. Most of the sites for these services are secured and guaranteed by the Verisign company, so that the customers are able easily recognize and verify its authenticity. Without trying to promote certain bank names in Romania, we present in the following table a few e-banking type functional products, as well as their main security features.

**Table 1 – Internet Banking Services in Romania**

<i>Bank</i>	<i>Product name</i>	<i>Security</i>	<i>Customers</i>
<i>Alpha Bank Romania</i>	Alpha Web Banking	Electronic signature A/S 400 & Midas	Corporate body
<i>Italo-Romena SpA Italia Treviso Bank</i>	WirWeb	Firewall against unauthorized access Communication channel secured through the SSL protocol with a 128 bites length of the encrypting key. Digipass type device that generates unique access codes.	Individual body Corporate body

<i>BancPost</i>	Internet e-bank	The data exchange takes place under a SSL3 secured protocol that uses an 128 bites encrypting key and 3DES Firewall algorithm and intrusion detectors at Internet access level The customer authenticates himself/herself through a Digipass 300 (token) security device	Individual body Corporate body
<i>BRD Group Societe Generale</i>	BRD-NET	For the encrypting of the transmitted data the SSL 128 bites security protocol is used BRD-NET is provided with 80 connections that can be made with the same password	Individual body Corporate body
<i>HVB Bank</i>	Online Banking	Data encoding 128 bites SSL Three security levels access system Digipass 300 security device

## 6. Conclusion

The Internet, phone, mobile or electronic banking offer on the Romanian banking market is in full development process, and the banks have to win the confidence of the individual and corporate body customers, taking into account the fact that the transactions that are made on the online system are perceived as incorporating a high risk factor. But the level of accessibility regarding the performing of banking operations straight from the company office or from home without depending on the opening hours of pay-offices determines a growing number of customers to resort to this kind of services.

A market is initiated and stimulated to grow and, in consequence, the banks have the role of getting involved in the forming of the future demand for this kind of services on the Romanian banking market, as the economy and the society develop. The role of banks is in this sense very important, consisting in the rise of the knowledge level in most modern practices, work techniques and in the adjustment of customers to these. In many cases, the Romanian customers do not resort to e-banking services because they are not familiar with them or because they don't understand them well enough.

On the other hand, the potential user's trust in the e-banking services is just one of the factors that influence the manner in which this market develops. Also here we can add the lack of information amongst the population, the legislation regarding the electronic signature, the national payment system.

## **Abstract**

*The field of mobile technologies has been particularly dynamic during the past few years. The number of mobile phone users has grown permanently. Mobile operators are involved in launching new technologies which allow for an ever faster and better data exchange. The degree of expansion of the mobile phone networks, fast penetration rate of handsets and the emerging use of banking services via the fixed Internet are the main reasons for a strong anticipated growth of mobile banking, a mechanism with a number of unique advantages. This paper discusses mobile banking services aspects, with specific attention focused on the development of a new model for analyzing mobile banking solution. The proposed model focuses on the customer's motivation and preferences. Also, there are presented the results of an investigation regarding mobile banking services in Romania, in the framework of the new model of analysis.*

**Keywords:** *mobile financial services, mobile banking, mobile Internet*

## 1. Introduction

The fulminatory development of the last decades in the informational technology has created a context in which global market has become a relevant arena for the economic competition. The commerce, the electronic and mobile business – radical innovations which have the potential to drastically change the current products and processes- have as a support this informational technologies' evolution and are an important element in the enlargement of globalization's action sphere.

The evolution of informational technologies continues in the same astounding manner and their communication component becomes more and more obvious. A foresight form the specialized literature<sup>2</sup> says that until 2010, the data communications will rapidly develop and will become more important than even the computer processing. They have gone hand in hand until now, but we are slowly moving from a computer era towards a communication era. This affirmation is supported by a score estimated by ITU: the number of mobile telephony users exceeded 1, 5 billion persons (a quarter of the Globe's population), in the middle of 2004.<sup>3</sup> The rhythm of development of mobile telephony surpassed the fix telephony one: the wireless communications develop six times faster than the fix telephony services<sup>4</sup>.

In this context, the mobile devices and technologies will continue their evolution too. All the progresses registered until now hardly represent, according to literature, **the first step in acquiring mobility**. The successful combination between services applications with added value, the developing capacity of transmission, the more and more extended development area, the better and better quality of services continue to impose mobile telephony as an indispensable comfort.

The continuing development, the happy marketing approaches and the harsh competition lead to a permanent development of mobile telephony. The financial services have achieved an important position within the mobile industry.

## 2. The mobile financial services

**The mobile financial services** are a *sub-set of mobile commerce* and include *the financial transactions carried out through the agency of portable devices*. Metaphorically speaking, they represent “an important step towards a cashless society”<sup>5</sup>.

There are three main categories of financial services that have been adapted to the business development mobile environment:

- Stock exchange transactions;
- The payment of goods and services counter value;
- Bank services.

### 2.1 Stock Transactions via Mobile Phone

**Stock Transactions via Mobile Phone** are an extension of the type of transactions practiced on the Fix Internet. When the stock activity is carried on on-line, the presence of intermediaries isn't required anymore. Relevant information about actions, obligations etc. can be obtained directly, by searching on the Internet, and the persons interested can express the desire to invest through the agency of the Internet. The strong competition in the field, combined with small transaction costs, has strongly reduced the taxes afferent to the brokers' services. As a result, the number of on-line investors has grown and is continually growing. With the help of mobile communication services, it is possible for new services destined to investors who possess a mobile device to appear, such as:

- the transmission of alerts/notifications to the persons interested, based on predefined factors: at a certain period of time or at the quotations' fluctuations between certain margins;
- the transmission of personalized news , selected according to the persons' interest field and delivered to them by SMS or with the help of a WAP portal;
- immediate consultancy services, at the request of the beneficiary of such a service; the administration of the portfolio and the titles' quotation evaluation.
- the buying and selling of financial titles.

## 2.2 Mobile payments

With the help of mobile devices, both the goods and services acquired in the mobile environment, and also the goods and services acquired in the “traditional” manner can be paid. We continue by presenting a series of classifications of mobile payments, meant to help examining and classifying the concept from different angles.

According to the *moment* in which they take place, the mobile payments can occur immediately (from a debit account) and even previously (from a pre-paid sum) to the acquisition moment. According to the *type (nature) of the acquired goods*, the payments are divided into payments for physical (real) goods, for digital (virtual) goods or for different services. From the *geographical* point of view, the mobile payments can be national or international. Taking into account the *currency involved in the transaction*, the payments can be carried out in national currency, in one or several currencies.

A more technical classification divides the mobile payments according to the place where the beneficiary’s account information is stocked: on a server from the financial institution network or a telephony operator, in the user’s mobile device or on a card inside the mobile device.<sup>6</sup> By analyzing in more detail, we identify three ways of stocking the client’s financial information in his mobile phone<sup>7</sup>:

- Mobile with only one chip : a bank application is stocked on the SIM card (elegant solution, dependent on an a certain bank and on a certain operator. The SIM card has also WIM functionalities (Wireless Identity Module) and other supplementary functions;
- Two cards are inserted in the phone – the one belonging to the mobile telephony (SIM) operator and to the financial institution (WIM), foreseen with PKI<sup>8</sup> and one for the mobile devices.
- Dual Slot: the phone has two slots, one for the SIM card and one for a normal dimension card.; in this situation, the user places the bank card in a card reader and then pays with mobile phone (it is a rather awkward alternative for an usual

<sup>7</sup> Kalliola, M., *Mobile Payments*, la [http://www.tml.hut.fi/Opinnot/T-109.551/2005/reports/Mobile\\_payments.doc](http://www.tml.hut.fi/Opinnot/T-109.551/2005/reports/Mobile_payments.doc)

<sup>8</sup> PKI – Public Key Infrastructure

person but can be used in the B2C sector – for the use of ambulant sellers or the delivery personnel, for whom the transportation of a normal card reader would be difficult). The Dual Slot Mobile was used by the French system „Payment sur Mobile CB”.<sup>9</sup>

Some payments can also be made through SMS, with a usual mobile phone, provided with only one SIM chip. Some operators can provide SIMs with payment applications. There are also mobile phones foreseen with a special key, through which a menu dedicated to the mobile parts is activated (the NTT DoCoMo I-mode key of Japanese mobile phones).

The mobile payments systems can also be classified in *closed and open systems*.<sup>10</sup> The closed systems characteristic, which is of a majority, is that both the phone possessors, and the traders have accounts at the same bank, this being connected with the mobile telephony operator that intermediates the payments. With the less numerous open systems, several banks and mobile operators can participate, with their interconnected networks. The transactions are mediated, in this case, by a payment services provider (mobile operator, a bank or an independent entity).

According to their purpose, the mobile payments can be used in three main fields: in the mobile commerce, within the banking mobile services, and also in the mobile payments of bills (mBilling). The three fields are superposed.<sup>11</sup>

Among the most common classification criteria in the specialized literature, there are the payment value and the place of payment.

According to the *payment value*<sup>12</sup>, there are:

- Micro payments (with a value of 10 euros or USD);
- Macro payments (in which larger sums than 10 euros or USD are involved).

The distinction according to the payment value is important especially for security reasons: in the case of macro payments, stronger procedures of payer's authentication are necessary (PIN, user name and password or even authentication certificates), while in the case of micro payments, the

<sup>12</sup> Mallat, N., Rossi, M., Tuunainen, V. K., *Mobile Banking Services*, in the magazine „Communications of the ACM”, May 2004, Volume 47, Number 5, p. 43

authentication can be made only according to the PIN checked by the operator or bank or can even be absent.

Taking into account the place of goods or the paid service, the following mobile payments categories can be identified:

- Local payments, to a device (POS <sup>13</sup> from a shop or a street automaton, provided with a special apparatus) found in the proximity of the mobile terminal's possessor. The user utilizes, most of the times, a prepaid account, of electronic pocket book type, and the discount is made between the bank that issued the pocket book and the accepting bank, that has the equipment to which the payment was made. A preliminary understanding is necessary between the network operator and the bank that issued the pre-paid accounts.
- Distant payments (through the agency of electronic networks). These payments are also called OTA payments (Over the Air). Distance mobile payments are made through the mobile operator, using usual telephony protocols (GSM, CDMA, GPRS etc.), SMS or the Internet access through WAP. The other actors are the issuing banks (that have control over the one who pays) and the accepting banks (where the traders' accounts are) and eventually, the intermediary (the payment services provider).

By combining the last two criteria we obtain several mobile payment categories.

The *micro-payments* made at the distance, through the agency of the telephony operator network, allow paying the informational content and the services acquired through the agency of a mobile device (different types of information, sounds, logos, digital format tickets for several events, participation at network games etc.) The micro payments to a POS found in the proximity of the user allow the direct or intermediated by a human operator payment of small value goods (newspapers, restaurant meals, goods offered by street automates etc.)

The issuing of immaterial shape tickets can be easily assimilated by the mobile payments. The person to person payment through the agency of the mobile phone is advantageous, for example, in the case of relatives who live in different countries.

---

<sup>13</sup> Point-of-Sale

*The micro payments* are intended for the payment of great value goods and services, bought on the Internet or in the traditional manner.

The numerous classifications presented above foresee the fact that mobile payments have found ways of various materialization, such as:

- The adding of the counter value of goods and services acquired at the mobile phone bill, modality that has the advantage of being familiar to the user. For example, the seller contacts the mobile phone operator, who supplements the value of the user's bill (the m-play Vodafone service functions in this way). In this category the added value payment by SMS is also included.
- The deducing of mobile payments from the user's credit account (Mobile Payment forum works at a standard for this type of payment); the mobile phone works as a credit card; a variant of this type of payment is the extraction of the due sum from a buyer's separate account, meant for mobile payments (the risks are reduced, but the user has the supplementary concern to administrate a new bank account);
- Payments from virtual accounts or from pre-paid SIM cards- the virtual sums are in fact the proof of the previous payment of a sum of money to a person who gives such payment solutions. The "loaded" sum can be spent through the agency of mobile technologies, and of course rebuilt by previous depositions. The payments from virtual sums are especially used by persons who do not have a bank account (such as children and persons living in isolated areas). Their advantage is the low risk, for all the payments involved in the transaction. The main disadvantage consists of the fact that blocking a sum of money in a virtual account does not bring any profit to the user, but rather to the provider of this payment solution; moreover, the depositing of the sum is a step forward in a transaction whose main trump is simplicity;
- Other ways of payment: the transformation of loyalty points in currency for several acquisitions; the payment according to use session (in the case of video-games for example)

### **2.3 The mobile bank services**

*M-banking* can be defined as "that part of products and services, of relationships established between banks and their clients or between banks

and other banks, based on a mobile device or which use as a transmission support a mobile telephony network.”<sup>14</sup>

The *m-banking* services are generally modified versions of Internet banking services type, which suppose to serve the bank’s client from a distance, through the agency of Internet technologies. Both types of services have as an advantage the decrease of bank transaction costs (there are providers of mobile payments technologies who claim they have reduced the transaction cost below 1 cent, very small value compared to the cost of a transaction through ATM -27 cents or with a cash transaction- 1.07 USD<sup>15</sup>.) From the user’s point of view, mobile-banking means making bank operations from your own mobile device<sup>16</sup>. The bank services can be divided in two distinct categories: basic services and advanced services.

*Basic services* have the same functions as the one met in the case of Internet:

The visualization of account extracts, of recent transactions, of interest rate and of exchange currency, fund transfers, the bill payment. The simplest form of m-banking is interrogating your personal accounts’ sold by SMS. It makes use of the person’s natural interest regarding his financial situation, offering him the possibility to find out conveniently and immediately his own financial situation, no matter the place where he is or the moment of the day,.

The services belonging to the fix Internet field must be adapted to the restrictions of mobile devices by using predefined forms and processed with an established course.

*Advanced services* must be capable to increase consumers’ loyalty and to differentiate the rest of current bank services, being especially designed for mobile consumers. A few examples of such services are: account extracts sent when the account reaches a certain limit, notifications related to the credit line, installment simulators, instantaneous contracting of consume credits etc.

Generally, the access to advanced services is conditioned by the use of a “smart” mobile phone, with Java, WAP, GPRS incorporated facilities.

### 3. The stage of development of mobile financial services

As far as the **stage of development of mobile financial services** is concerned, we appreciate the fact that among the facts that determined the proliferation of mobile solutions use in the field of financial services, there are:

- *The impressive penetration of mobile phones at the world level*, in a relatively short period of time;
- *The personal nature of mobile devices*, which make them appropriate for the administration of your own money funds;
- *Positive experiences of use of informational technologies and of financial transactions communications* (Internet banking, home banking).

Although the number and variety of contemporary mobile financial services are impressive, many of these are in an early stage of development and haven't reached the number of users which can ensure their success and survival. And generally, the degree of mobile financial transactions' penetration is reduced, both compared to the number of mobile devices possessors and also compared to the number of persons who have a bank account.

We continue by presenting part of the reasons for the weak development of financial transactions in the mobile environment.

- *The limits of the current technologies*. If in order to receive bank information by SMS only a usual mobile phone is necessary, the complex financial applications require technologies of an improved data transmission (GPRS, Java). The promised step towards third generation technologies (3G) will allow the development of these services' application, which will become faster and more comfortable, cheaper and more standardized;
- *The immaturity and deficiency of mobile devices*. Very often, in order to activate a financial application, complex settings of phones are required. From another point of view, complex settings of phones are necessary. From a different approach, there are not enough automates provided with technologies such as infrared rays, identification based on radio frequencies (RFID – Radio Frequency Identification) or Bluetooth, which accept the payment from a mobile device. For small sums, because of the simple reason of comfort, the cash payment is

preferred. All these technologic difficulties make the evolution of mobile payments hard to foresee.

- *The existence of a “negative publicity” phenomenon.* The profile press, not to become too excessively enthusiastic from the boodot.com period has treated the newly-come mobile commerce with reserves.
- *Security problems.* The payment through the mobile phone seems safer than providing the details of the credit card to a human operator. The security mechanisms such as digital signature and PKI contribute to the creation of a safety feeling. Nevertheless, the attackers of information have easily adapted their methods for the mobile telecommunication sector. Together with interceptions or mobile viruses, already in circulation, dangers of the identity stealing type can appear (by phishing and phreacking). Moreover, many times, especially for micro payments, the implementation of some supplementary security mechanisms would be too expensive.
- *The lack of safe and interoperable standards for the mobile payments.* The phenomenon is paradoxical: although there are a multitude of forums and the consorts constitute in the purpose of standard formulation, a general accepted model delays to appear. In this context, constituting a mobile payment global market is difficult.
- *In the area of micro payments, persons are not willing to pay for the information that can be found on the “traditional” internet.* The psychological threshold of payment accepting has been overcome only in the case of digital products (such as sounds or logos that personalize the mobile phone) that could only be acquired by buying them, ever since they appeared. Even those who pay for the goods acquired by mobile phone prefer to do this periodically, by subscription. Moreover, there are not many products which can be sold in exchange of small sums of money. This thing can be changed if we take into account initiatives such as Google<sup>17</sup> that intends to create a huge on-line library, project for which they are already collaborating with famous names such as Harvard or

---

<sup>17</sup> Hof, R., *Noua putere în tehnologie (The new power in technology)*, article „Business Week” taken in “Biz”, no 108, 8 - 20 July 2005, pp. 40 – 45

Michigan. Accessing information from virtual libraries or archives is made by payment, by using micro payments.

The estimation regarding the evolution of mobile payments is generally optimistic. It is estimated that towards the end of 2005 and the beginning of 2006, the effect of competition between Visa, American Express and MasterCard will be felt by the evolution of mobile payments, and in 2008 they will be adopted on a large scale in USA.<sup>18</sup> According to other previsions, in 2009 the incomes generated by mobile payments will be greater than 50 billion dollars.<sup>19</sup>

The immediate reality does not seem to confirm these expectations. While, according to the borings, more than a quarter of the Europeans are willing to pay with the mobile<sup>20</sup>, the USA banks have given up mobile services, because the number of users was not satisfactory. A possible indicator for the ulterior evolution of mobile payments is the current situation of North Korea- an excellent space of testing for the communication technologies. Here, tens of thousands of restaurants and shops have already terminals reading bank information from the phones, by infrared rays. The access to the subway or bus station is also paid by phone.<sup>21</sup>

#### 4. The place of mobile technology in the developing countries

The reality according to which different people, different cultures and areas within a nation do not have access in the same way to information and communication technologies, is referred to with the term *digital divide*-translated by “digital gap”, “digital disparity” or “digital division”. A term referring strictly to the differences between countries and regions on the globe regarding the access to TIC is *global digital divide*.<sup>22</sup>

<sup>19</sup> ARC Group, in Swann, J., *Read Works*

<sup>20</sup> AT & Kerney and Judge Institute of Management Studies, quoted in Muşătescu, M., *Schimbarea la față a mobilului* (The mobile’s change of look) „Business Magazin”, Nr. 23 (10/2005), 16-22 March 2005, p. 51

<sup>21</sup> Ihlwan, M., *Read Works*, p. 30

<sup>22</sup> Haag, S., Cummings, M., McCubbrey, D., *Management Information Systems for the Information Age*, 4th Edition, McGrawHill Irwin, 2004, p. 246

The phenomenon *digital divide* is persistently tackled in the specialized literature of the beginning of XXI century and is the object of concern for a great number of institutions.

The easiest way to “build a bridge” over the digital gap is providing the less developed countries with computers and the founding of consultancy centers. Samples of these initiatives can be found in great number in magazines such as “Business Week”, “The Economist” or “Harvard Business Review”. UNO, for example, has launched a “Digital Solidarity Fund” for financing the projects that address the “unequal use and distribution of TIC” and allow the “excluded countries and persons to enter a new era of informational society”<sup>23</sup>.

However, a contrary idea was recently discovered in the same magazines’ pages: providing persons with computers only builds a feeble bridge between the two margins of the imaginary gap. There still remain the serious discrepancies between incomes, the level of development and of education. The people from the countries in course of development have greater needs than those of desiring TIC, such as providing for food, taking care of their health and personal security.

Taking into account these fund elements, they reached the conclusion that mobile telephony has a much bigger potential of reducing the digital disparity than the more sophisticated calculation technique, because of the more reduced costs of devices and their use and of the fact that approximately 77 % of the world’s population already lives in areas covered by mobile telephony networks. The technologies of mobile data transmission seem to have a greater long term impact on the development of countries of the second world. In this respect, a study<sup>24</sup> of “London Business School” shows that an increase of 10 mobile phones per 100 persons has as a result an increase of 0,6 percentage points in the Gross Internal Product.

Their governments, who must support the free competition, are the first who can influence the development of mobile telephony in the countries in course of development. The device producers play an important role in providing the persons from countries in course of development with mobile phones. Although the biggest majority of their incomes result from selling sophisticated phones in the developed countries, the markets of these countries are becoming full. As a result, producers have oriented themselves towards the countries in course of development, offering rudimentary telephones, with long lasting battery independence, at very low prices. More sophisticated telephones also sell well in the poor countries, where they play

---

<sup>23</sup> \*\*\*, *The Real Digital Divide*, in „The Economist”, March 12th 2005, p. 11

<sup>24</sup> \*\*\*, *Calling an End to Poverty*, in „The Economist”, July 9th – 15th 2005, p. 51

the role of a social symbol and supply for other devices, such as radios or PCs.

The next table presents the factors with positive and negative implications on the m-readiness level in Romania.

**Table 1 A possible appreciation of m-readiness level in Romania**

<i>Positive factors</i>	<i>Negative factors</i>
The rate of mobile telephony penetration in Romania in 2004 was of 48% of the country's population. The estimated increase for 2005 is of at least 10%. The rate is visibly higher than the penetration of personal computers.	The penetration rate is still reduced compared to the higher than 100% rate reached in the developed countries
The main operators have already launched (Connex) or are intending to launch (Orange) 3G advanced data services (video calls, Internet files download, games, music, live TV etc.) They also address the companies with offers such as IP Data services, point-to-point services, or the wireless Internet access. In the future, the operators intend to introduce Unified Messaging as well.	For the time being, the pre-paid services (the use of cards) are the most common in the entire operator's activity. This fact shows a reduced level of mobile telephony users' incomes and questions the use of devices for the transmission of Data (other than the rudimentary way of SMS)
The operators have signed partnerships with content providers such as MTV or UEFA Champions League.	
The phones with advanced functions sell better and better in Romania.	In 2004, only 1-2 % of the phones sold in Romania were smartphones. <sup>25</sup>

Concluding, we can appreciate that although Romanians are some of the most open consumers as far as mobile telephony is concerned, the national market is not yet ready to adopt data services on a large scale.

<sup>25</sup> Antohi, D., *Românii preferă telefoanele cu ecran color și sunete polifonice (Romanians prefer phones with colored screen and polyphonic sounds)*, în „Biz”, no. 101, 21 March - 4 April 2005, p. 34

The only mobile services which have reached a certain level of development are the financial ones, analyzed in the following lines.

## **5. Adopting mobile payments in Romania**

As it was previously shown, many economical organizations, traditional players on the market of financial services and not only, have identified opportunities and niches in this area and have proposed solutions to these issues. Among the numerous projects, launched in very short periods of time, many don't overcome the pilot stage. Few applications were rapidly accepted on a large scale by the mobile telephones possessors (an example is the payment of small value digital goods by the mobile phones possessors by SMS). Because of this reason, the analysis of existent applications from the point of view of their beneficiary is considered appropriate. The necessity of this kind of analyses is obvious, if we take into account the fact that the attractiveness of a certain financial solution for the consumers determines its success and development.

Generally, the mobile financial services are appreciated by their users because of the independence from the place and time of their occurring and implicitly, as a synergetic effect of these two characteristics, because of the comfort they offer.

Beyond these general advantages, the characteristics of a mobile system that we consider relevant from the point of view of its potential user are:

- The necessity of adapting the mobile phone to the payment system- the importance of changing the SIM card or even the phone in order to be able to use the mobile solution can be considered a serious obstacle in the way of adopting the application.<sup>11</sup>;
- The necessity of registration- signing a contract may not be necessary (for example in order to pay some goods at the street automates) , it can be made through Internet or through the mobile phone or may obligatorily require the physical presence of the person; the users will accept more easily the systems for which the registration is easy, but only with the guarantee of the data confidentiality.
- The dependency of payment solution on a certain telephony operator can be a serious impediment in its implementation- the users will not easily accept to change the company they are subscribed at;

- The diversity of services that the payment instrument offers – some applications try to offer the user the possibility to pay through the mobile phone in a great number of circumstances, while others focus on a single type of payment;
- The complexity of the payment transaction itself, which depends on a series of aspects: the necessity of phoning a number at the beginning of the transaction, the necessity of communicating the transaction details to the user (by SMS, vocal call or the direct screen display of the transaction details), the manner of authenticating the user;
- The user's perception of the security of the transaction – mainly influenced by the manner of accepting the transaction by the user (\*by a PIN code established together with the solution provider during the registration period or through a PIN+ randomly generated unique code combination for each transaction) and by the transaction confirmation in the moment following immediately after the payment, by cash voucher in the case of traditional POS or by SMS or display on the mobile device screen;
- The occurrence of payments- the paid sum is subtracted from the client's bank account, from a sum prepaid to the payment solution provider or is added to the monthly invoice issued by the mobile telephony operator;
- The brand name attached to the payment system- can belong to the financial institution , to the mobile telephony operator, to the application provider- the more credible the brand is for the user, the bigger his trust in the system;
- The cost associated to the mobile transaction – can include the registration fee, a temporary subscription for the solution use, the payment of a solution for each transaction made, the cost of the phone call, of the SMS sent within the transaction etc.
- The transaction time- can be appreciated in comparison with cash transactions (in average less than 10 seconds) or with the card ones (about 30 seconds); the fact that the mobile transaction has the advantage of not depending on the time and place of payment, even if it doesn't last more, must not be neglected.

Starting from this theoretical background, we will continue by analyzing the *mobile banking* type of services from Romania<sup>26</sup>, which represent, in our opinion, the most developed segment of national mobile financial services.

As a result of the public information analyses from the web sites of the 38 commercial banks in Romania, we can express the following observations:

- The number of banks offering services of Internet banking type is of 68% from the total number of banks, optimistic percentage that shows a tendency of bank institutions towards the electronic sphere of their interaction with the consumer;
- In contrast, only 18 % of the total number of Romanian banks offer mobile banking services;
- All the banks that have certificates, according to the Communication and Information Technology Ministry's Order No. 218/2004 concerning the procedure of certifying the payment instruments with distance access (Internet Banking, Home Banking or Mobile Banking) have effectively implemented these instruments.
- According to the information on the Romanian banks' sites, accessed in April 2005, there is a number of 7 banks offering mobile banking services, alone or in partnership with national mobile telephony operators (see table 2); the distribution of individual and partnership solutions is evenly (4 individual solutions, 4 instruments offered together with a mobile telephony company);
- These services' characteristics differ considerably (see table 3).

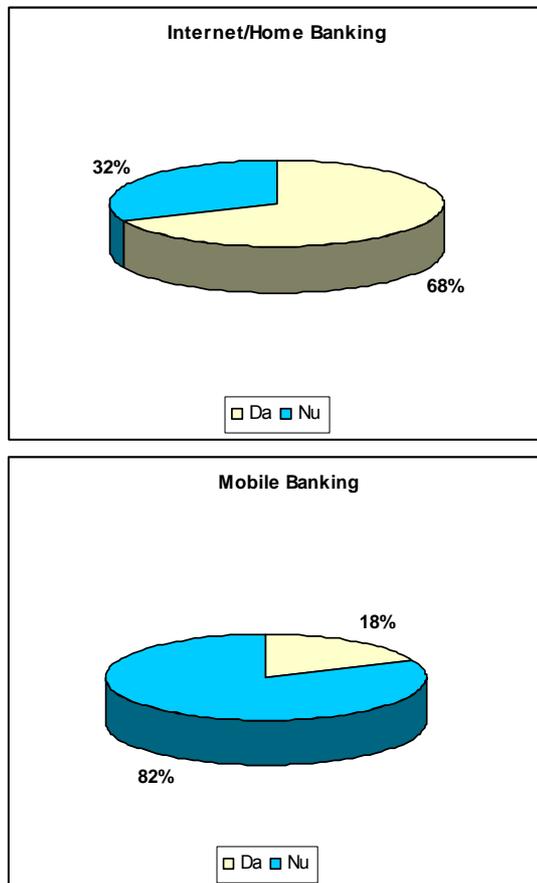

As far as the necessity to adapt the mobile phone in view of using the mobile banking application is concerned, two of the solutions analyzed propose the replacement of SIM card with a special card, which has the advantage of being free. The card is available only in a few towns, district residence, for at least one of these solutions. There are also two solutions which require an eventual adaptation of the phone- one for which a WAP phone is necessary (not very restrictive, taking into account that the greatest

---

<sup>26</sup> Their list was taken from the National bank's sites(<http://www.bnro.ro/>), and the Communication and Information Technology Ministry's site (<http://www.mcti.ro/1398.html>)

majority of phones have incorporated WAP facilities) and another for which a phone provided with a micro browser is necessary. The applications that don't require any phone or card adaptation generally offer basic services.

**Figure 1 The percentage of banks offering Internet Banking and Mobile banking in Romania**

**Table 2 Romanian mobile banking instruments**

<i>Bidder</i>	<i>Instrument</i>
Raiffeisen – Connex	myBanking
BRD - Orange	Mobilis
BCR – Connex, Orange, Zapp, Cosmorom	Smart Tel SMS and Smart Tel 3G SMS+ Browsing
Banca Italo Romena	Bank@You
Piraeus Bank Romania	MOBILBank
UniCredit	UniCredit Mobile Banking
BancPost	SmartTel, in three variants: SMS, 3G and WAP

A mobile solution which is not interoperable, in other words, functions in only one mobile network, will only have the success allowed by the limits of that network. After the SMS model, the success belongs to the applications independent of the network. Before accepting this assertion, we must look at the mobile telephony market context from Romania, where dominants are the Orange and Vodafone (the owner of Connex brand) operators, each one having an equal (and impressive) number of users. The two operators have each achieved, in partnership with a financial institution, an *m-banking* solution, comparable with the one of the competitor's.

Thus, a consumer of each of the two companies will always have at his disposal an m-banking application which may satisfy his needs. Problems appear only for users who have a bank account at a different financial institution than the one that the mobile telephony operator has made the m-banking solution with. Annulling the possibility of occurrence of this type of problems, five of the analyzed services offer applications independent of the network.

For the amazing majority of applications, it is necessary to sign a contract with the bank. In Romania, a bureaucratic country by excellence, this fact isn't necessarily negative, being considered a foregone conclusion. On the contrary, it even has positive connotations, increasing the consumer's trust in that service.

The m-banking Romanian applications have generally focused on offering basic services. Almost all instruments offer their user the possibility to visualize information about their own accounts (most of them in the easiest way- by SMS), to receive alerts/notifications regarding the transactions made in accounts and the possibility to make transfers between accounts. Only two solutions offer the payment service of bills to the providers (by providers meaning only mobile telephony operators who have made the application). However, this is not the fault of financial institutions offering the solution, but moreover the fault of utilities of other goods providers, who have to adapt their own informative systems in order to sustain the payment by mobile.<sup>27</sup>

Together with the basic services presented above, some banks also offer there services, destined to attract the consumer (see table 3).

---

<sup>27</sup> According to „Jurnalului Național”, in March 2005 Electrica carried out tests related to the possibility of bill payment through mobile telephony-Radescu , A, *Buying train tickets by SMS*, in „Jurnalul Național”, online version , 18<sup>th</sup> of March 2005, at <http://www.jurnalul.ro/modules.php?op=modload&name=News&file=article&sid=244105&mode=thread&order=0&thold=0>

**Table 3 The characteristics of national mobile banking type instruments**

<i>Instrument/ Characteristics</i>	<i>my Banking</i>	<i>Mobilis</i>	<i>Smart Tel SMS (BCR)</i>	<i>Smart Tel 3G (BCR)</i>	<i>Bank @ You</i>	<i>MOBIL Bank</i>	<i>UniCredit Mobile Banking</i>	<i>Smart Tel (Banc Post)</i>
<b>The necessity of adapting the phone</b>	Yes, special card	Yes, special card	No	Yes, phone with browser	No	No	Yes, WAP phone	No
<b>The dependency of a certain telephonic company</b>	Yes, Connex	Yes, Orange	No	No	No	No	Yes, Connex, Orange, Cosmoro m	No
<b>The necessity to register to the bank</b>	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
<b>The diversity of services offered</b>								
<i>Transfer between accounts</i>	Yes	Yes	Yes	Yes	No	No	Yes	No
<i>Information about your own accounts</i>	Yes, SMS	Yes, SMS	Yes, SMS	Yes, browsin g	Yes	No	Yes	Yes
<i>Alerts (Notifications) regarding the transactions made between the accounts</i>	Yes	Yes	Yes	Yes	Yes	No	No	No
<i>The payment of the bill to some providers</i>	Yes ( Connex)	Yes	No	No	No	No	No	No
<i>The request to block the card account</i>	No	No	Yes	Yes	No	No	No	No
<i>Information about the currency, interests, types of bank products</i>	No	No	No	Yes	Yes, currency	Yes, currency , interests	Yes, currency	No
<i>Currency exchange completion</i>	No	No	No	No	No	No	Yes	No
<i>ATM in the area</i>	Yes	No	No	Yes	No	No	No	No
<i>Bank in the area</i>	Yes	No	No	Yes	No	No	No	No
<i>Telephonic cards recharge</i>	Yes, Connex	Yes Orange	No	No	No	No	No	No
<b>Security</b>								
<i>Coding</i>	Yes	No	No	No	No	No	No	No
<i>Authentication by codes/passwords</i>	Yes	Yes	Yes	No	No	No	No	No
<b>Costs</b>								
<i>Monthly subscriptions</i>	0,5 €	No	No	1 \$	No	No	No	No
<i>Unitary cost(/message)</i>	0,15 € or 0,30 €	No	0,19 \$	0,19 \$	Normal message	No	No	No

From the point of view of transactions' security, the preferred method of authentication is the codes one. It is adopted only by three of the 8 analyzed solutions. One of the applications has implemented a method of coding information that circulates between the bank and the client. We consider the level of security ensured by the greatest majority of solutions as being unsatisfactory, especially taking into account that the information spread are part of the confidential category.

Regarding the m-banking services, the situation is heterogeneous: a part of the solutions offer services for a cost formed of subscription and unitary cost, per transmitted message, while others are free. The costs do not have a restrictive level, especially taking into account that the m-banking instruments do not address the large public, but, for Romania, to a population segment with incomes over the average.

## 6. Conclusion

In conclusion, mobile banking is an additional channel to the bank's traditional activity in Romania. The implementation of such a solution brings a plus of image to banks and mobile telephony operators involved, but do not represent, at least until now, an important source of income. Regarding the mobile data services, it is assumed that the national wireless market will have an explosive evolution, with increases between 30% and 60% from one year to another<sup>28</sup>. The beginning is promising: Information and Communication technology Ministry and the General Inspectorate for Information Technology are about to elaborate a strategy of clearing the 3,6 – 3,8 Mhz frequency band and to provide it, by auction to the operators who want to implement WiMax in Romania<sup>29</sup>, while Orange Romania has developed localization services<sup>30</sup>.

By using the mobile phones, the area or road where the mobile phone or the vehicle belonging to one of the company's employees is found can be discovered at any moment, from the computer's screen.

In this context, we can estimate that IMMs will be more and more interested in mobility, security, registration and stocking applications in Romania, while more and more Notebooks will be bought and the portable devices will be more and more appreciated. In this background, a

## **Abstract**

*Anti-money laundering (AML) has attracted highly focus from the mainland China government recently since it has been deeply involved with the faiths of the nation, economic stability, combating the serious flooding of nationwide corruption offences, especial the field of organized crimes. Due to the backward situation of AML mechanism in China, it is of great significance to develop a set of AML intelligence collecting and analyses system to reinforce the countermeasures fighting the ever-raging money laundering activities among local financial networks. Based on the business characteristics of Chinese financial systems, the paper proposed a framework of self-adaptive AML system which is composed of a 4-layer structure including 3 modules. Related procedures of feature selecting and strategies of analyzing and discriminating are discussed.*

**Keywords:** *data mining, anti-money laundering, self-adaptive, decision support system*

## 1. Introduction

Anti-money laundering (AML) has attracted a high focus inside mainland China financial and judicial fields nowadays. It has become a symbol of the capability of the central government and the faith of the nation, as well as an important measure fighting organized crimes and forestalling the flooding of nation-crossed corruptions. However, the construction of an effective AML mechanism is just at its startup which is far from perfect. Most of relevant technical tools, the developing and applications of monitoring and analyzing system are nearly blank, while legislation work is relative coarse and primitive, given the opportunities for the launders to evade the detections. For example, the threshold for the reporting of large-value foreign exchange transaction payment stipulated by the regulator is: as to cash payment, single transaction or accumulated to above US\$10,000 per day; as to credit payment, single transaction or summed up to US\$100,000 for individuals or US\$500,000 for enterprises. Such data reported by local financial institutions compose the main sources for AML intelligence database while other data below the threshold will escape from data collection. It is easy to infer that the launders will split large value funds into smaller pieces and disperse them into different bank accounts as an effective strategy, while a lot of clean and honest transactions above the amount given by the rule will be reported as enormous noises to the analytical procedures day by day and constitute the main body of the database. Though the board will keep perfecting the legislations to adapt the situation, both sides of regulators and offenders will obviously repeatedly play the game. Thus the main requirements of AML information system developing are: to pre-cleanse the immense data reported nation-wide everyday to refine the most valuable clues, to embed a mechanism of self-learning and self-adaptive into the information system to meet the continuously changing strategies of the launders. In this paper we propose a framework to construct an intelligent suspicious financial transaction discriminating system considering the complex situation in mainland China. The paper is organized as follows: Section 2 sets forth three urgent problems the self-adaptive system should solve. Section 3 proposes a whole framework based on the experiences of world-wide AML practices. Section 4 gives a group of preliminary algorithms and data structures to realize the self-adaptive requirements mainly based on statistical theory. The last section is a conclusion and further research jobs are listed.

## **2. Three Urgent Requirements an Effective AML System Should Meet**

Three urgent requirements are listed below that an effective AML system should solve. Such requirements are all derived from the status quo of AML practices among financial networks across mainland China.

### ***2.1 Providing automatic data filtering and checking functions for data reporting jobs of bank branches***

The monitoring and analytical data sources are reported by every commercial bank branch to the regulator—the People’s Bank of China. The data are generated from hand written cash payment dealing reports or electronic reports of SWIFT remittance system shared by all commercial banks. Far different from the credit payment style dominated in the western countries, Chinese people prefer cash payments which take a proportion of more than 80% over all transactions. Credit payments level in small or medium cities and rural areas is even lower than those in big cities. As a result it’s very difficult to pursue the trace of fund flow procedure for the investigators. Considering other factors existing in the commercial bank braches, including the shortage of professional AML talents, the procedures of suspicious data discriminating, collecting, analyzing is surely under an uncertain supervisory. A sound solution is to equip all such bank branches with data collecting computer software providing automatic data filtering and checking functions to ensure the quality of data reporting.

### ***2.2 Self-adaptive or self-evolving technologies***

Self-adaptive technologies in AML system are mainly adopted in two procedures:

First, the system will apply such technologies to regularly extract the data that can feature the customer’s financial transaction behaviors in different local areas, industries, organizations in order to reflect a real and continuously changing image of local economic development. The uniform reporting threshold of large-value payment stipulated by the Central Bank has obviously ignored the serious economic unbalances across mainland China. There exists a remarkable gap between the eastern coastal area and the middle and western areas, where the eastern coastal areas enjoy much higher economic development level. Enormous legal and normal large-valued transactions data are reported unconditionally in the southeast coastal developed areas while lots of abnormal data may be omitted in those backward areas just by the reason they do not reach the reporting standards though they have been apparently beyond the local economic normal level and show notable unusualness. Thus the reporting data filtering standard

should be stipulated by an overall statistical analysis based on local area or industries historical databases instead of a uniform nationwide standard. Furthermore this filtering standard should be self-adjusted along with the local developing level.

Second, achieve a data-mining ability to find out suspicious clues through series normal-likely transactions data. A critical characteristic of money laundering is that the launders will try all efforts through series complex and normal-likely transactions to explain the legitimacy of dirty funds. Their laundering strategies will be also continuously revised by the new AML policies. It is an essential requirement for a successful AML system to provide a learning mechanism which could automatic adjust the analytical and discriminating strategies to reflect the AML offenders' changing activities.

### ***2.3 Link analytical tools to promote the concentration of suspicious intelligences***

Most money-laundering cases are related with the investigations of law enforcement departments such as the Public Security Bureau, the Custom, the Tax Office and the Business Administrative Office, etc. It is proved to be a short cut to notably reduce the processing job size applying a link analytical tool embedded into the system which could tracing the transactions related with those accounts, suspects, corporations being investigated by law enforcement departments. Most literatures of international AML practices all recommend that an effective link analytical tool plays a key role in AML intelligence system.

## **3. A Macro Framework of AML Intelligence System Designing**

A macro framework of AML intelligence system is given as below based on experiences of leading AML countries joined with the status quo in mainland China.

### ***3.1 A 4-Layer Analytical Model***

The analysis procedures shall be divided into four layers from micro to macro, from local pieces to a wholly aggregation so as to acquire a particular and comprehensive results.

From inner to outside the four layers include: transaction layer, account layer, organization layer and link layer (link layer is also designated as ring layer in some literatures).

**3.1.1 Transaction layer:** separated or isolated single transaction records, such as cash deposits and withdrawals, cheques, electronic remittance, etc. Such records provide few analytical context because they don't constitute a data chain.

**3.1.2 Account layer:** A serial transaction activities should have all happened through a specialized account in a bank set up by a specialized person.

**3.1.3 Organization layer:** a main body of money laundering activities is more likely a corporation or an organization, covering multiple accounts and persons.

**3.1.4 Link layer:** investigation to a money-laundering mostly involves multiple levels of corporations, organizations and persons.

Different layers play different roles during the analyzing procedure. Data of Transaction layer and Account Layer are submitted from the root bank branches and have composed the fundamental sources. Only isolated intelligence may be derived from the perspectives of both inner layers. Organization layer and Link layer provide perspectives to take a comprehensive and aggregate discriminating and analyzing procedure to all data involved by multiple banks, areas and departments, to check, contrast, mine, judge and derive in all those data collected from varied channels. The later layers have much more advantages during macro situation judgment and relevant cases investigation.

## ***3.2 Three Main Bodies of the System***

### **3.2.1 Data collecting and filtering system**

The system will be applied in the root bank branches to aid the suspicious data collecting, filtering and transmitting job. It belongs to Transaction layer and Account layer.

### **3.2.2 Data integrating and analyzing system**

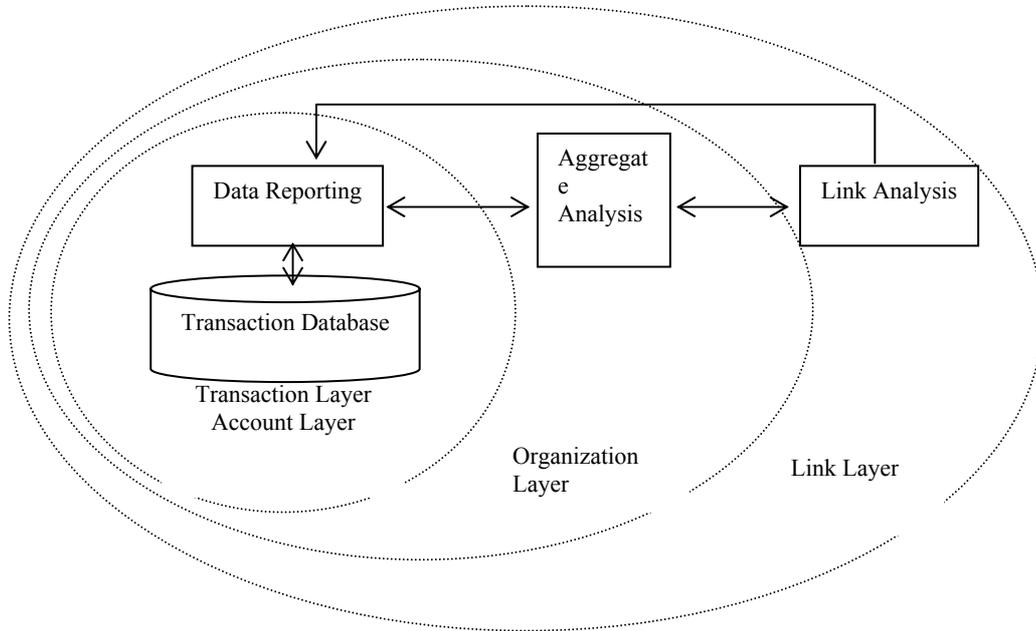

It will give a comprehensive analyzing process to the data collected from different channels at a integrative perspective to pick out most suspicious-like intelligence, as well as provide a wholly study from a macro and strategical perspective to derive the trends, migrations, and countermeasures of AML.

### **3.2.3 Link Analytical System**

The system can take advantages of the intelligence provided by law enforcement departments to tracing relevant persons, organizations and their accounts and transactions. The link tracing function may be integrated into

other systems to acquire an ability of automatic monitoring and analyzing given accounts and persons. The framework is shown as Figure 1.

**Figure1 Framework of AML Intelligence System**

## 4. Main Algorithms

### 4.1 Data Filtering

Data filtering is the essential function of data reporting system for local bank branches. The key technology is feature selection based on expert knowledge database. Feature selection job should give a relative accurate behavior profile reflecting the normal level standards of local financial transaction activities. A simple but practical algorithm is the famous Bayes decision method based on statistical theory. The central bank has set forth series unusual financial norms featuring money laundering in its suspicion reporting rules. But the standards are all ambiguous to operate. The judgment features include capital flow sum in a given period, frequencies of in and out the account, etc. But they are not recorded in the reporting database. Such features could be derived out by statistical method. Relationship may be described through a linear regression model.

Tag the register capital sum with  $f$  the sum of in and out the account during given period is  $s$   $f_i$  and  $s_i$  are corresponding attributes of account  $i$ . Assume that  $f$  and  $s$  have an approximate linear relationship:  $f = \alpha + \beta s + \varepsilon$   $\alpha$   $\beta$  are constants,  $\varepsilon$  obeys normal distribution  $N(0, \sigma^2)$   $\alpha$   $\beta$  may be estimated using least square method so we will get

$$\hat{\alpha} = \frac{n \sum_{i=1}^n f_i s_i - (\sum_{i=1}^n s_i)(\sum_{i=1}^n f_i)}{n \sum_{i=1}^n s_i^2 - (\sum_{i=1}^n s_i)^2} \quad \alpha = \bar{f} - \hat{\alpha} \bar{s}$$

The relationship between register capital of a given industry and the periodical flow sum in and out from its bank account could be estimated by above equation so as to filter out the abnormal data.

For those time series data from given bank account, the behavior profile could be also be inferred through statistical method as below:

Assume the periodical flow sum nearly obeys a normal distribution  $X \sim N(\mu, \sigma^2)$  the parameters  $\mu, \sigma$  may be estimated by median and range. The theorem tells that:

If  $Me$  is the median of samples series  $X_1 \square X_2 \square \dots \square X_n$ , then for any

$$\lim_{n \rightarrow \infty} P \left\{ \sqrt{\frac{2n}{\pi}} (Me - \mu) \leq x \right\} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt$$

$x$ , , we could assume  $\mu = Me$  if  $n$  is big enough.

Besides, the expectation and variance of range  $R$  are:

$$E(R) = dn\sigma \quad D(R) = vn2\sigma^2,$$

$$\text{So we could infer } \sigma = \frac{R}{dn}.$$

As the parameters have been concluded, give the single side degree of confidence  $\alpha$ , the confidence interval is  $(0, \mu + \mu\alpha \frac{\sigma}{n})$ . If the given transaction sum is big enough which has been located outside the interval, the transaction may be considered as unusual.

#### 4.2 Algorithms of aggregate analysis

Money laundering is a three-stage process that requires: placement--launderers place the dirty money into financial system. Layering, that is, disguising the trail to foil pursuit, with such techniques as shares, bonds, loans and other conduits. It usually consists of a series of transactions

designed to conceal the origin of the funds. This is the most complex stage of the process, and the most international in nature. The money launderers might wire transfer funds from one country to another, and then break them up into investments in advanced financial options or in overseas markets. The final stage of money laundering is termed integration, making the money available to the criminal once again with its occupational and geographic origins hidden from view. The aggregate analysis focuses on the layering stage by collecting all related data from different accounts, persons and transactions. Almost every mature data mining and pattern recognition algorithm such as neural network, genetical algorithms, etc. has been adopted in the financial analyzing systems in AML leading countries. Two solutions are put forward in this paper to meet the requirements during designing the analysis system: how to describe the relationships between different accounts, and how to reduce the immense data search range.

#### 4.2.1 Directed map data structure

A directed map structure can easily describe the relationship and the transaction details between two accounts as shown in Figure 2. Each node represents an account; each line links two accounts, what's more, it also records their transaction features such as frequency, sum, etc. The structure is described as below:

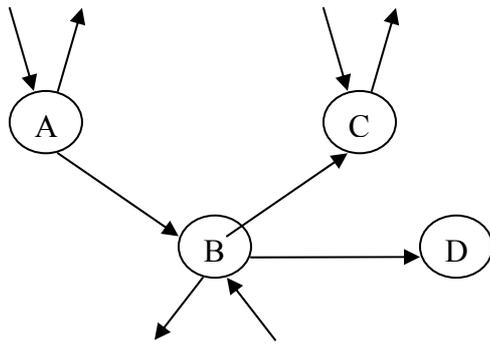

Node structure:

```
node{
    Accountid:long; //account no
    accountAttr:string;//description of attribution
    N:int;// count of out
    Out[1...N]:line;//line of out
}
```

Line structure:

```
line{
    Node:node;//direction node
    monSum:int;//monthly average sum of account
    monFreq:int;//monthly average frequency of
dealing
    monFreqs:float;// variance of the monthly
frequency }
```

**Figure 2 An illustration to directed map data structure**

#### **4.2.2 Suspicious score ranking method**

In order to effectively reduce the immense processing size on reporting records, we adopt a suspicious score ranking method. Construct a table of account score, give each account an initial score 0. Then construct a scoring rule table which provides the scoring value or norms given by professional experts or derived by statistical experiences. Suspicion scores can be computed for each record in the database (for each customer with a bank account), and these can be updated as time progresses. The table can then be rank ordered, and investigative attention can be focused on those with the highest scores or on those which exhibit a sudden increase.

### **5. Conclusion**

AML system designing and constructing is at its infancy now in China. The AML intelligent prototype proposed here is mainly based on the practical algorithms based on statistical theory. A further research work will introduce more effective self-learning capability, integrated with the training data set acquired from AML applications, and perfect the data storing structure for analyzing procedures.

## **Abstract**

*International integration produces many positive effects. Nevertheless, every coin has two sides. Liberalizing of international capital flows and making money transfers easier has also enabled new ways of legalizing dirty money. Fight against money laundering became a discussed topic mainly after terrorist attacks in September 2001. EU has followed the world struggle to stop money laundering and terrorist financing by creating a new anti-money laundering directive. The directive is in conformity with international conventions and standards related to that topic. It reflects the revision of FATF 40 recommendations. New directive proposes three forms of due diligence. It also deals with the role of national financial intelligence units. Aim of the paper is therefore to present the fight of EU against money laundering and terrorist financing and the influence of the fight on the financial sector. Institutional provisions regarding anti-money laundering rules will be also mentioned, i.e. role of financial intelligence units and international institutions that focus on money laundering.*

**Keywords:** *EC anti-money laundering directive; FATF; due diligence; financial intelligence unit*

## 1. Introduction

Integration processes have their positive and negative aspects. Single European market is based on the principles of non-discrimination, market access and competitive federalism. Thus the aim is to create market similar to domestic market. As to the free movement of capital and payments, EU has liberalized capital flows between EU member states and between EU and third countries. EU shall therefore take necessary measures to hinder money laundering as a negative aspect of integration process. European Union naturally follows international processes and standards of fight against money laundering. This shouldn't however mean that all the standards and measures should be adopted automatically without critical consideration of cost and effects of the measures.

## 2. Definition of money laundering

Most proper definitions give international agreements. Because of the topic of the paper, I have chosen EC directive whose definition follows international standards.

*'Money laundering' means the following conduct when committed intentionally:*

- *the conversion or transfer of property, knowing that such property is derived from criminal activity or from an act of participation in such activity, for the purpose of concealing or disguising the illicit origin of the property or of assisting any person who is involved in the commission of such activity to evade the legal consequences of his action;*
- *the concealment or disguise of the true nature, source, location, disposition, movement, rights with respect to, or ownership of property, knowing that such property is derived from criminal activity or from an act of participation in such activity;*
- *the acquisition, possession or use of property, knowing, at the time of receipt, that such property was derived from criminal activity or from an act of participation in such activity;*
- *participation in, association to commit, attempts to commit and aiding, abetting, facilitating and counselling the commission of any of the actions mentioned in the foregoing indents.*

*Knowledge, intent or purpose required as an element of the abovementioned activities may be inferred from objective factual circumstances. Money laundering shall be regarded as such even where the activities which*

*generated the property to be laundered were carried out in the territory of another Member State or in that of a third country.*<sup>1</sup>

As can be seen from the definition, money laundering is not only conversion or transfer of property but even possession or use of property that was derived from criminal activity, if the person knew that such property stems from criminal activity.

Money laundering has three stages: placement, layering and integration. In the placement stage, the aim of the launderer is to introduce the money into financial system, typically by breaking large sum to be laundered into smaller sums. The aim of this phase is to hide illicit origin of the money. In the second stage, the money is transferred from the accounts, used to set up shell companies so that the origin of the money appears clean. Last stage of the process is integration of laundered money into legitimate economy.

Total laundered volume can be only estimated. International Monetary Fund for instance estimated the volume as 2-5% of world GDP<sup>2</sup>. Money launderers don't use only bank sector to conceal the true origin of the financial sources, they use also currency exchange houses, wire transfer companies etc.<sup>3</sup>

### ***2.1 Why should we fight against money laundering?***

When talking about anti- money laundering (further in text "AML") rules, natural question arises. Is the fight against this phenomenon effective and shall we matter about this activity? When considering this topic, we should name negative effects of money laundering. From macroeconomic point of view, money laundering changes the demand for cash and thus influences monetary policy. Money laundering is a process of financing consequent criminal activity. Money laundering has also negative effect on financial institutions. Money laundering increases the probability that financial institution becomes corrupt or controlled by criminal interests and increases the probability of financial failure as a result of the institution being defrauded<sup>4</sup>. Money laundering also goes hand in hand with corruption<sup>5</sup>.

<sup>4</sup> see Bartlett, B. L. The negative effects of money laundering on economic development. Economic research report for the asian development bank. May 2002 Access from:

Money that stems from corruption must be laundered and to launder money, one sometimes has to corrupt employees of financial institutions. These are the most important arguments for pursuing illegally gained money.

There are also several arguments contra tracing dirty money. Some anti money laundering rules are in conflict with fundamental human rights (e.g. right to privacy, right to fair trial). To detect illegal money, financial institutions have to gather relevant information on financial transaction and on the customers. Data protection and breach of bank secrecy becomes a relevant problem in this context. Other problem is effectiveness of the activity of tracing illegal money. The effectiveness cannot be precisely measured and anti money laundering measures appear to be very costly.

There are however strong arguments for AML fight. When tracing criminal money, we can trace criminal activity as such and reveal criminal acts. AML fight also hinders development of criminal activity (illegal money serves as source of consequent financing of criminal activity). It gives a strong signal for potential criminals that “crime doesn’t pay<sup>6</sup>”. Another question is if money laundering shall be considered as a criminal act (in other words, if it is not punishing twice for one crime). It is to emphasize that many famous criminals have been convicted because of other crimes – tax evasion, money laundering<sup>7</sup>. Fight against money laundering is therefore not meaningless; the important question is scope and method of the fight.

## ***2.2 International standards of fight against money laundering***

Money laundering is an international problem. To cope with it in an effective way, it is necessary to cooperate on international level. Hence, international organizations try to set out world-wide standards for fight against money laundering. These standards shall include definition of money laundering as a criminal activity, measures taken by institutions in which money laundering occurs, state measures against money laundering and international cooperation in this field. Quality institutional and legal framework is essential.

<sup>5</sup> For detailed analysis of effects of money laundering, see Bartlett, B. L. The negative effects of money laundering on economic development. Economic research report for the Asian development bank. May 2002

<sup>6</sup> Many criminals count with the imprisonment as a price they have to pay for the money they have illegally gained. This changes if the possibility of confiscation of the money is very probable.

<sup>7</sup> One example speaking for all is imprisonment of Al Capone.

International organizations feel the need to combat this phenomenon. Thus, several anti money laundering conventions have been adopted. **Council of Europe** adopted the Convention on Laundering, Search, Seizure and Confiscation of the Proceeds from Crime (Strasbourg Convention). **United Nations Organization** adopted two conventions: UN Convention against Illicit Traffic in Narcotic Drugs and Psychotropic Substance 1988 (Vienna Convention) and UN Convention against Transnational Organized Crime 2000 (Palermo Convention). Aim of the conventions is to unify national rules on criminalization of money laundering and thus make the fight against this phenomenon more effective.

Banking sector also became active in fight against money laundering. **Basel Committee on Banking Supervision** focused on money laundering in several recent texts. The committee elaborated rules for customer due diligence (October 2001) and consolidated know your customer (KYC) management (October 2004)<sup>8</sup>.

**Wolfsberg Group**<sup>9</sup> drafted Wolfsberg AML Principles. The principles were agreed by major international private banks. The Principles set general guidelines for client acceptance. Categories of information that are essential to collect in order to comply with due diligence rules are named. The Principles also define situations that require additional diligence, give definition of unusual or suspicious activities, their identification and reporting. Banks are required to monitor account activities, establish regular management reporting on money laundering issues, establish a training programme on the identification and prevention of money laundering for employees who have client contact and keep records of anti-money laundering related documents. They shall establish department responsible for the prevention of money laundering.

There are also international organizations that focus expressively on AML rules. **Financial Action Task Force**<sup>10</sup> (further in text FATF) is a body created by states of G7 to combat money laundering. Main aim of the body is to *generate the necessary political will to bring about legislative and regulatory reforms in these areas*<sup>11</sup>. FATF examines the international

---

<sup>8</sup> See [http://www.bis.org/bcbs/publ\\_13.htm](http://www.bis.org/bcbs/publ_13.htm)

<sup>9</sup>Wolfsberg Group is an association of twelve global banks, which aims to develop financial services industry standards, and related products, for Know Your Customer, Anti-Money Laundering and Counter Terrorist Financing policies.

<sup>10</sup> For more information see official web sites on [www.fatf-gafi.org](http://www.fatf-gafi.org)

<sup>11</sup> Access from: <[http://www.fatf-gafi.org/pages/0,2987,en\\_32250379\\_32235720\\_1\\_1\\_1\\_1\\_1,00.html](http://www.fatf-gafi.org/pages/0,2987,en_32250379_32235720_1_1_1_1_1,00.html)> Accessed: <14. 10. 2005>

methods and trends of money laundering. The body also publishes a list of non-cooperative countries and territories<sup>12</sup>.

FATF created 40 recommendations to combat money laundering. Recommendations are divided into four parts: legal systems, measures to be taken by financial institutions and non-financial businesses and professions to prevent money laundering and terrorist financing, institutional and other measures necessary in systems for combating money laundering and terrorist financing, international cooperation. Recently, the recommendations have been amended by 9 special recommendations against terrorist financing.

First part of the recommendations defines minimal legal scope of money laundering offence. Then the recommendations focus on due diligence, record keeping and reporting suspicious transactions. Recommendations also define competent authorities that shall prevent money laundering. Countries shall establish financial intelligence units (centers for receiving, analysis and dissemination of suspicious transactions).

**Egmont Group** is an informal body that stimulates cooperation among financial intelligence units (FIU). FIUs, at a minimum, receive, analyze, and disclose information by financial institutions to competent authorities of suspicious or unusual financial transactions<sup>13</sup>. Nowadays, 94 countries are members, including the Czech Republic.

International organizations pay sufficient attention to AML phenomenon. Regional integrations must follow basic principles set by the most important AML conventions (UN conventions, Council of Europe convention, FATF rules) in order to combat money laundering effectively. Mainly FATF list of non-cooperative countries and territories creates an international environment in which it is not politically possible for a country to avoid international standards.

### **3. EU fight against money laundering**

To take action in some field of activity, European Union must have competence conferred by primary legislation. Fight against money laundering has two dimensions – economic measures and criminal prosecution. Economic dimension of money laundering falls in the scope of the first (supranational) pillar whilst criminal law belongs to the third pillar – cooperation in the field of justice and home affairs.

---

<sup>12</sup> The list of the non-cooperative countries and territories as well as report on observance of FATF recommendations is published also by IMF

<sup>13</sup> According to: [http://www.egmontgroup.org/about\\_egmont.pdf](http://www.egmontgroup.org/about_egmont.pdf) <7. 10. 2005>

At the beginning, the aim of the Communities was to combat drug abuse. Several resolutions of European Parliament dealt with that topic. European Union participated in the United Nations conference on Drug Abuse and Illicit Trafficking and became party to the Vienna Convention. Lately, EC has adopted the first anti – money laundering directive<sup>14</sup>.

Important political step in cooperation of European countries in AML fight was Tampere summit (1999). Aim of the summit was to create an area of freedom, security and justice. In Tampere, EU member states (MS) agreed on action against money laundering. MS shall implement Strasbourg Convention and FATF 40 recommendations. AML directive shall be revised. Further, summit conclusions focus on cooperation of FIU. MS agreed upon approximation of criminal law on money laundering (mainly on the scope of criminal activities, which constitute predicate offences for money laundering)<sup>15</sup>.

---

1. Council Directive 91/308/EEC, of 10 June 1991, on prevention of the use of the financial system for the purpose of money laundering. (OJEU L 166 of 28.6.1991 p. 77)
2. Joint Action 98/699/JHA, of 3 December 1998, adopted by the Council on the basis of Article K.3 of the Treaty on European Union, on money laundering, the identification, tracing, freezing, seizing and confiscation of instrumentalities and the proceeds from crime. (OJEU L 333 of 9.12.1998 p. 1)
3. Council Decision of 17 October 2000, concerning arrangements for cooperation between financial intelligence units of the Member States in respect of exchanging information. (OJEU L 271 of 24.10.2000 p. 4)
4. Council Framework Decision 2001/500/JHA, of 26 June 2001, on money laundering, the identification, tracing, freezing, seizing and confiscation of instrumentalities and the proceeds of crime. (OJEU L 182 of 5.7.2001 p. 1)
5. Protocol established by the Council of 16 October 2001, in accordance with Article 34 of the Treaty on European Union to the Convention on Mutual Assistance in Criminal Matters between the Member States of the European Union. (OJEU C 326 of 21.11.2001 p. 2)
6. Directive 2001/97/EC, of the European Parliament and of the Council of 4 December 2001, amending Council Directive 91/308/EEC on prevention of the use of the financial system for the purpose of money laundering - Commission Declaration. (OJEU n° L 344 of 28.12.2001 p. 76)

Access from <[http://www.europarl.eu.int/comparl/libe/elsj/zoom\\_in/26\\_en.htm](http://www.europarl.eu.int/comparl/libe/elsj/zoom_in/26_en.htm)>

<sup>15</sup> X. Special action against money laundering

51. Money laundering is at the very heart of organised crime. It should be rooted out wherever it occurs. The European Council is determined to ensure that concrete steps are taken to trace, freeze, seize and confiscate the proceeds of crime.

52. Member States are urged to implement fully the provisions of the Money Laundering Directive, the 1990 Strasbourg Convention and the Financial Action Task Force recommendations also in all their dependent territories.

The fight against money laundering is carried out by the Commission, mainly DG Justice and Home Affairs and DG Internal Market. The cooperation in the field of criminal justice is realized through Financial Crime Group of Europol.

### ***3.1 Why does EU have to harmonize AML rules?***

Fight against money laundering is important for proper functioning of the single market. Council expressed the peril that launderers could try to take advantage of the freedom of capital movement and freedom to supply services and stated that money laundering has evident influence on the rise of organized crime in general and drug trafficking in particular. Money laundering can constitute an existential threat to European integration<sup>16</sup>.

EU cannot combat the phenomenon isolated. Therefore, when drafting any anti money laundering measures, EU must take into account international AML rules listed above. European Union expressed this in the preamble of

---

53. The European Council calls for the Council and the European Parliament to adopt as soon as possible the draft revised directive on money laundering recently proposed by the Commission.

54. With due regard to data protection, the transparency of financial transactions and ownership of corporate entities should be improved and the exchange of information between the existing financial intelligence units (FIU) regarding suspicious transactions expedited. Regardless of secrecy provisions applicable to banking and other commercial activity, judicial authorities as well as FIUs must be entitled, subject to judicial control, to receive information when such information is necessary to investigate money laundering. The European Council calls on the Council to adopt the necessary provisions to this end.

55. The European Council calls for the approximation of criminal law and procedures on money laundering (e.g. tracing, freezing and confiscating funds). The scope of criminal activities which constitute predicate offences for money laundering should be uniform and sufficiently broad in all Member States.

56. The European Council invites the Council to extend the competence of Europol to money laundering in general, regardless of the type of offence from which the laundered proceeds originate.

57. Common standards should be developed in order to prevent the use of corporations and entities registered outside the jurisdiction of the Union in the hiding of criminal proceeds and in money laundering. The Union and Member States should make arrangements with third country offshore-centres to ensure efficient and transparent co-operation in mutual legal assistance following the recommendations made in this area by the Financial Action Task Force.

58. The Commission is invited to draw up a report identifying provisions in national banking, financial and corporate legislation which obstruct international co-operation. The Council is invited to draw necessary conclusions on the basis of this report.

<sup>16</sup> Mitsilegas, V. Money Laundering Counter-Measures in the European Union. A New Paradigm of Security Governance versus Fundamental Legal Principles. Kluwer Law International, 2003. ISBN 90-411-2131-5

new AML directive, stating that ... *money laundering is frequently carried out in an international context. Measures at Community level... have very limited effects.* And vice versa, ignoring the problem would lead to pressure of international organizations on EU states to take appropriate steps.

### **3.2 Anti money laundering directive**

First directive against money laundering was adopted in 1991 (directive 91/208 EEC on the prevention of the use of financial system for the purpose of money laundering). The directive defines money laundering in accordance with international conventions. Money laundering shall be prohibited. Then it sets rules for credit and financial institutions. Basic principle of the directive is thus “**know your customer**”. Credit and financial institutions shall require identification of transactions involving a sum amounting 15.000 ECU and more, keep evidence on the transactions and inform competent authorities of suspicious transactions.

The directive was amended by the directive 2001/97. Main change is the extension of the scope of persons covered by the directive on auditors, external accountants, tax advisors, real estate agents, notaries, independent legal professionals, dealers with high value goods and casinos.

New, **third text of the directive** was being prepared mainly as a consequence of terrorist attacks in September 2001<sup>17</sup>. The text of the directive focuses expressly also on terrorist financing. New text of the directive is considerably longer and more detailed than previous directive. Main principles of the directive stay the same<sup>18</sup>, though described in more details. Main aims of the directive declared by EU are as follows:

- including the funding of terrorism in the definition of money laundering
- extending application of the system to trusts and insurance intermediaries
- introducing a simplified due diligence system
- banning anonymous accounts<sup>19</sup>.

Important part of the directive is Chapter II – **Customer due diligence**. Due diligence is adopted according to risk-based approach.

---

<sup>17</sup> Commission proposed the directive on 30 June 2004.

<sup>18</sup> The directive extended the list of obliged persons on trust or company service providers

<sup>19</sup> see European Parliament. Money laundering. Access from :  
<[www.europarl.eu.int/comparl/libe/elsj/zoom\\_in/26\\_en.htm](http://www.europarl.eu.int/comparl/libe/elsj/zoom_in/26_en.htm)>

According to the directive, due diligence has three forms: simplified, enhanced and general.

**Due diligence** comprises identifying the customer and verifying his identity, identifying the beneficial owner<sup>20</sup>, obtaining information on the purpose and intended nature of the business relationship, conducting ongoing monitoring of the business relationship. Persons covered by the directive may however determine the extent of the measures on a risk sensitive basis<sup>21</sup>.

**Simplified procedure** appears when customer is a credit or financial institution covered by the directive, listed company whose securities are admitted to trading on a regulated market, beneficial owner of pooled account held by notaries or independent legal professionals and domestic public authorities, e.g. subjects with a very low risk. In case of credit and financial institutions, these are automatically not subject to due diligence. In case of other institutions mentioned, member state may allow by the way of national legislation not to apply customer due diligence.

**Enhanced customer due diligence** appears in case when risk of money laundering activity is very high, mainly in situations when the customer is not physically present for identification purposes, cross frontier correspondent banking relationships with respondent banks from third countries and transactions with politically exposed persons<sup>22</sup> residing in other state. Directive lists additional measures to prove that the transaction is not a case of money laundering. Transactions with shell banks<sup>23</sup> are prohibited.

Directive prohibits credit and financial institutions from keeping anonymous accounts or anonymous passbooks. These may be an important tool for money launderers because their owners are hard to identify.

The directive sets reporting obligations. For this purpose, each state shall establish financial intelligence unit (FIU) at national level. Persons covered by the directive shall inform the FIU on suspicious transaction and furnish FIU with all necessary information.

The duty of record keeping by persons covered by the directive remains the same. The directive deals also with supervision and requires that

---

<sup>20</sup> new feature of the directive

<sup>21</sup> A. 7 of the draft directive

<sup>22</sup> natural persons who are or have been entrusted with prominent public functions and immediate family members or persons known to be close associates of such persons

<sup>23</sup> The directive defines shell bank as “a credit institution, or an institution engaged in equivalent activities, incorporated in a jurisdiction in which it has no physical presence, involving meaningful mind and management, and which is unaffiliated with a regulated financial group.”

currency exchange offices, trust and company service providers must be licensed or registered and casinos licensed.

Member states are required to review the effectiveness of adopted measures by means of keeping comprehensive statistics. The statistics shall at minimum cover the number of suspicious transactions made by the FIU, the follow-up given to these reports and initiate on an annual basis the numbers of cases investigated, the number of persons prosecuted, the number of persons convicted for money laundering and amount of property frozen, seized or confiscated (A. 29).

As to enforcement, the directive urges member states to require that persons covered by the directive establish adequate policies of due diligence, record keeping and other measures necessary for prevention of money laundering. The persons shall also train their staff to recognize money laundering and be able to take necessary steps. Persons covered by the directive shall get access to up-to date information on the practices of money launderers and on indications leading to recognition of suspicious transactions.

### ***3.3 Critical approach to the ( third) directive***

The directive however includes also some controversial issues. Majority of problematic parts remains from previous directive<sup>24</sup>. Main concerns are about disclosure requirements, fundamental right to legal advice and concept of due diligence. This part of the paper discusses selected problematic provisions of the directive.

- **Data protection and bank secrecy**

Institutions have to keep records on transactions for at least five years. This is not relevant only for credit and financial institutions but also for other professions who may not have precisely developed data protection system. To combat money laundering, states have to remove bank secrecy provisions in circumstances related to informing on money laundering. This fact could undermine the credibility of credit institutions. Already the first directive was characterized as “death of bank secrecy”<sup>25</sup>. The opinion of the Communities was that money laundering facilitates drug trafficking and therefore undermines human dignity and physical and moral integrity of its victims.

---

<sup>24</sup> The Council of the Bars and Law Societies of Europe (CCBE) considers the second directive as threat for the independence of lawyers and thus illegal. See Euractiv. Money Laundering. Access from: <[www.euractive.com](http://www.euractive.com)>

<sup>25</sup> see Mitsilegas, V. Money Laundering Counter-Measures in the European Union. A New Paradigm of Security Governance versus Fundamental Legal Principles. Kluwer Law International, 2003. ISBN 90-411-2131-5 p. 132

Fight against money laundering was put forward as a moral imperative everybody has to follow<sup>26</sup>.

- **Scope of responsible persons**

Second directive has broadened the scope of persons covered by the directive. The third directive further extended the scope on trust or company service providers. The remaining question is whether the notification duty doesn't mainly in case of legal professionals, accountants and tax advisers undermine the customer – client relationship. Further, the second directive threatens the independence of legal professionals and therefore the fundamental right to legal advice<sup>27</sup>.

Notification duty may be in conflict with the right on fair trial. However, member states are not obliged to apply the directive on legal professionals, auditors, external accountants and tax advisor *with regard to information they receive from their clients in the course of ascertaining the legal position of their client or performing their task of defending or representing their client in or concerning judicial proceedings* (A.20 of the directive).

- **Due diligence**

A risk based approach to due diligence seems to be welcome by the banks. However, European Banking Federation had several remarks to the original draft of the directive. The enhanced due diligence is problematic in case of politically exposed persons. The definition of such persons appears to be very broad and may cause difficulties for banks. Banks are also concerned with the obligation of identifying beneficial owners because they often don't have access to relevant information. As a result of remarks of European Banking Federation, threshold was raised up to 25% so that the banks would be able to comply with the provision<sup>28</sup>.

- **Effectiveness**

Measures taken by responsible institutions are quite costly. Every state established FIU, which traces suspicious transactions. However, there is no report on the effectiveness of measures taken by first and second AML directive. Detailed report on the effectiveness of such measures should have been a starting point before drafting the third directive. The directive

<sup>27</sup> See Euractiv. Money Laundering. Access from: <[www.euractiv.com](http://www.euractiv.com)>

<sup>28</sup> See Brouver de, F. *Toward Third Anti-Money Laundering Directive*. Better Management. Access from: <[www.bettermanagement.com/library.aspx?libraryid=11366](http://www.bettermanagement.com/library.aspx?libraryid=11366)>

however provides for keeping essential statistics on the effectiveness of AML measures by MS.

- **Costs**

Measures taken by financial institutions to prevent money laundering appear to be very costly. The question of costs goes hand in hand with the question of effectiveness. The directive obliges credit and financial institutions as well as other persons covered by the directive not only to inform on suspicious transactions and keep record of relevant data, but also establish AML system of informing and training of employees so that they are aware of AML rules and are able to recognize suspicious transactions and take appropriate steps. All these measures constitute additional costs.

- **Enforcement measures**

The directive suggests better enforcement of AML through providing access to up-to date information on the practices of money launderers. This is very important because knowledge of the recent techniques of criminals helps to better detection and prosecution. But we shall consider this measure from other point of view. The information shall be provided to persons covered by the directive – i.e. also to notaries, independent legal professionals and tax advisers. This is a scope of persons that are logically the first to be capable to give advice to launderers. The directive therefore ensures that advisers to criminals get recent and up-to –date information on money laundering techniques and helps them indirectly develop their activities. From this point of view, the measure seems to be contra - productive.

- **Security**

Practical question that arises when talking about anti money laundering measures is the security of institutions that have duty to inform about suspicious transactions. Not only notaries and legal professionals but also employees of financial institutions can fear of revenge from launderers. Effectiveness of the AML measures can be from this point of view very lowered. Protection of such persons shall be also considered when drafting amendments to AML rules.

- **Corruption<sup>29</sup>**

No matter how effectively the system is thought out, human factor may also play its role. A corrupted employee of a financial institution can allow money laundering. A corrupted employee may therefore ruin the whole system of AML prevention.

- **Adoption by member states**

The question is whether it is appropriate and wise to adopt a new anti-money laundering directive in the situation when about half of member states haven't transposed the directive into their national legislation. The second directive should have been transposed until 15 June 2003. The new text was therefore created in a situation when it was premature to evaluate effects of measures taken by the second directive.

### ***3.4 Future of the Directive***

The directive is not yet finally approved. Regardless of many remarks of bar associations, banking federations and other persons covered by the directive, there are still some points that shall be considered. The text of the directive was regarded as controversial<sup>30</sup>. Quick preparation of the directive in the situation when the second directive wasn't implemented by all member states could make the EU stop and consider the effectiveness of AML measures. Elaborating appropriate AML measures statistics shall be essential for EU before taking any other steps. Though the amount of laundered money can be only estimated, sufficient could be however the statistics demanded by the directive: the number of cases investigated, the number of persons prosecuted, the number of persons convicted for money laundering and amount of property frozen, seized or confiscated.

---

<sup>29</sup> “*Money laundering is the handmaiden of international corruption . . . Those who take bribes must find safe international financial channels through which they can bank their ill-gotten gains. Those who provide the bribes may well assist the bribe takers to establish safe financial channels and launder the cash.*”

## 4. Conclusion

The European Union, mainly after September 11, 2001, tries to combat money laundering and terrorist financing. The fight is important in international context and EU AML rules are in conformity with international AML standards. When adopting the third directive, we shall however consider the effectiveness of AML rules. The remaining questions are measuring of the effectiveness of such measures, costs, scope of responsible persons and possible conflict with human rights.

The question shouldn't be whether we should fight against money laundering or not. The fight is internationally very important – it shows criminals that crime doesn't pay. The question is whether we have internationally found the right balance between effective AML fight and protection of human rights, bank secrecy and economic and professional interests of persons covered by AML rules.

## **Abstract**

*The control of legality and regularity in the use and administration of nonrefundable funds coming from the EU financial assistance programs, accorded to Romania, has as aim:*

- the identification of irregularities, of the imperfect financial administration and of frauds*
- the establishment of eventual prejudices*
- the establishment of the persons guilty of producing the prejudices.*

*The control begins when are clues or remarks from the part of the internal or external audit's structure, or from other institutions named by the law, or also from the part of citizens or mass-media, concerning the imperfect or illegal financial administration of public funds. The recuperation activity consists in executing the administrative function that leads to the disappearance of the debts resulted from fraud and irregularities.*

**Keywords:** *budget debts, financial administration, co-financial funds, fraud, control procedure*

## **1. Fighting fraud and embezzlement**

Fraud against the community financial interests is any deliberate act that consists in using and handling false documents or statements that result in the fraudulent appropriation or incorrect possession of funds and the illegal diminution of the resources of the general community budget. In the actions directed at abolishing fraud against the community financial interests, the Union pays attention to the public property fraud. The principle at the basis of this orientation consists in the fact that while the losses of the victims are relatively limited in cases of fraud in private wealth, the damage caused to the public wealth affects all the tax-payers by diminishing the public funds. Designed to remove the deficiencies and irregularities between the provisions of the criminal law of the member states, the Convention for the protection of the community financial interests (the PIF Convention adopted by the Committee Act of July 26<sup>th</sup> 1995, 95/C 316/03) requires that the member states should make sure that the action defined as fraud against the community financial interests is a crime. In order to include the different types of fraud, two complementary concepts cover the financial process within the Union: income and expenses.

From the perspective of the expenses, by fraud, one understands any deliberate act or omission connected to the use or presentation of false, incorrect or incomplete documents, the concealment of information by breaching a specific obligation that result in the fraudulent appropriation or incorrect possession of funds from the general community budget, or the fraudulent investment of these funds with purposes other than their original destination. From the expenses viewpoint, the effect of the fraudulent appropriation or retention is not necessarily present in the fraudulent investment of funds.

As for the income, by fraud one understands any deliberate action or omission of using or presenting false documents or statements, incorrect or incomplete the concealment of information by breaching a specific obligation and the fraudulent investment of legally obtained benefits that result in the illegal diminution of the resources of the general community budget or its management by or for the European Union.

The adequate protection of the community financial interests must be ensured not only against fraud but also against embezzlement, not necessarily fraudulent.

By irregularity one understands any breach of a community law provision that results in an action or omission of an economic agent, with the purpose of harming the general community budget, by the diminution as well

as the loss of income gained from the resources collected directly or on behalf of the Union, or by unjustified expenses.

One of the instruments of fighting fraud is the internal audit. This procedure is concerned with the protection of the public funds against the losses that may occur due to errors and/or fraud.

The internal audit is conducted by a special division, organised within every public institution and consists of one or more people hired for this purpose or contracted for audit, people who are never involved in the activities they audit.

The internal audit is applied according to the norms issued by the Ministry of Public Finance and is based on the principles of independence and ethics.

Another prophylactic measure against fraud is that of the financial control carried out by the Ministry of Public Finance, in those situations that show evidence of fraud or any other breach of the financial regulations of public institutions. From the perspective of the income, fraud offends the national financial interests by tax evasion.

The influx of financial funds from the budget is monitored by the tax inspection, concerned with the implementation framework, the legality and the concordance of the financial operations, the correctness and the exactness of the obligations of the citizens, the observation of the provisions of the fiscal and bookkeeping regulations as well as their accessories.

The tax inspection is directly and freely enacted by the National Agency of Fiscal Administration (in Romania), on all the citizens, regardless of their organisation, citizens who are compelled to establish, retain and pay the taxes.

Tax evasion leads to the illegal diminution of the budget resources, thus being classified as fraud. For this reason, the legal provisions (Law no 87/1994, reissued in 2003), concerning the control of tax evasion, can be interpreted as support in controlling fraud.

The legal provisions concerning the control of tax evasion establish a series of events that can be classified as crimes: The refuse to hand in to the control authorities the justifying documents and bookkeeping papers, as well as the material goods undergoing taxation and contributions to the public funds, to determine the budget duties;

The incomplete or inadequate drawing up of the primary documents or accepting such documents with the purpose of obstructing the financial-

bookkeeping control, if the deed had as consequence the diminution of the income or taxable sources;

The illegal issue in any manner, or the possession in view of illegally circulating financial and fiscal documents. The circumvention from paying the legal taxes by not registering certain activities that must be legally registered or by conducting unauthorised activities with the purpose of obtaining profit;

The complete or partial circumvention from the fiscal obligations with the purpose of gaining profit, by not declaring the taxable income, hiding the taxable object or source or by the diminution of the income as a result of fictitious operations;

The omission, total or partial, of the bookkeeping or any other legal documents of the developed commercial activities or of the profits made or the recording of unreal operations or expenses with the purpose of not paying or diminishing the tax or contribution;

The organisation and management of double bookkeeping, the change or destruction of bookkeeping documents, memories of the electronic taxation or identification machines or other data recording means with the purpose of diminishing the profits or the taxable sources; The issue, distribution, purchase, filling in or accepting false fiscal documents.

The measures against fraud are also provided in the Customs Code that stipulates as a crime the use of false documents and/or the transportation or presentation of commercial documents with the purpose of reducing the taxes while the customs declarations are carried out.

Similarly, an additional measure for fighting/controlling fraud at the customs is the existence of the anti-fraud service as part of the Customs Surveillance Division.

Moreover, the Bookkeeping Law stipulates that the deliberate registering of inaccurate data as well as the deliberate omission of the bookkeeping records, having as consequence the alteration of income, expenses, financial results as well as the assets and liabilities provided in the balance are defined as intellectual false.

Eventually, beyond the income-expenses approach of the funds, the Criminal Code defines the different kind of activities that can generate fraud. These include especially:

The fraudulent administration, as a deliberate act of causing prejudice to one person by managing and keeping the goods that belong to that particular person;

Deceit, i.e. the use of a mistaken interpretation of reality, the presentation as correct of false information or papers or vice-versa, the presentation of real facts and truths as untrue, to the deliberate end of gaining for oneself or someone else undeserved material benefits. The presentation of false information at the time of the conclusion or implementation of a contract, information whose presence would have prevented the victim from signing or implementing the contract, is also considered fraud;

The abuse against the public interests, as a deliberate act of a civil clerk, during his mandate, that willingly causes or alters the good functioning or causes prejudice to the state, department or institution goods.

Embezzlement, as change of destination of the money or material resources, by violating the legal provisions in the field, causing the bankruptcy of the economic and financial activity or causes prejudice to the state or the institution respectively.

## **2. The European Anti-Fraud Office (OLAF)**

OLAF was founded in 1999 as a subsidiary of the European Committee, as a consequence of the fact that the units and departments for the prevention of fraud proved to be inefficient control authorities.

The OLAF activities concentrate on the discovery and monitoring of customs fraud, the fraudulent appropriation of subsidies and tax evasion, if the community budget is affected, as well as on the fight against corruption and other illegal activities that damage the community financial interests.

The OLAF activities especially involve:

The development of administrative investigations (internal and external) for the fight against fraud, corruption and other illegal activities;

Commission counselling in cooperation with the member states, in the field of prevention of fraud;

The development of other operational activities of the Committee, related to the fight against fraud.

The investigations, administrative inspections and other measures taken by the OLAF employees according to their duties may be:

External, developed in the member states and, according to the cooperation agreements, in third countries;

Internal, developed in the community institutions, departments, offices and agencies.

OLAF has the right to:

Immediate and unannounced access to any information of the institution, department, offices and agencies and their subsidiaries;

Make, get copies and acquire extracts of any document or contents that include additional data;

Require information from the members of the institutions, departments, offices and agencies, in written or verbally;

The OLAF executive can conduct the internal or external investigations, at his own initiative or as a consequence of a request of a member state or a community institution, a department, office or agency.

*The OLAF independence is ensured by:*

*the rules that establish the executive's appointment, activities and the disciplinary sanctions*

For the appointment of the executive, following a public advertisement for applicants and a favourable opinion of the Surveillance Committee, the Committee draws up a list of the applicants qualified for this position. When the Surveillance Committee has issued an opinion on the candidanship of the executive and after consulting the European Parliament and the Council, the Committee can appoint the executive.

The executive does not seek or follow any instructions from any government or institution, department office or institution on the initiation and development of investigations or editing of reports. If the executive feels that a decision made by the Committee threatens his independence, he has the right to take action against this institution in the Court of Justice.

The executive regularly reports to the European Parliament, to the European Council and Court of Auditors, on the findings resulted from the investigations he has conducted;

*the powers granted to the Surveillance Committee*

The Surveillance Committee is made up of five independent individuals (from outside), with the right expertise, and its main role is to support the OLAF independence by regular surveillance of the implementation of its investigative power. It expresses its own opinions or at the request of the OLAF executive, on the OLAF activities, without disturbing the developing investigations.

The OLAF executive regularly informs the Surveillance Committee on:

the OLAF activities, investigations, their results and the measures that have been taken;

the cases when a community institution, office, department or agency did not act according to the OLAF recommendation;

the cases when the information must be transmitted to the judiciary authorities of a member state.

### **3. The single OLAF contact in Romania**

The single contact with OLAF in Romania is the Romanian institution that ensures the cooperation between OLAF and the corresponding authorities in Romania until Romania becomes a member of the European Union.

The coordination of the anti-fraud fight and effective and balanced protection of the financial interests of the European Union in Romania is ensured by the Government Control Body, as unique contact with OLAF.

In this direction the Government Control Body:

coordinates the anti-fraud fight and protects the financial interests of the European Union in Romania, acting with complete functional and decisional autonomy, independent from other public institutions, according to the obligations assumed by Romania;

receives for control, from OLAF or any other interested institution or individual, notes on embezzlement or possible frauds in gaining, developing or using the funds from the assistance programs of the European Union and makes a control note with the result of the investigations. The note is sent to the Prime Minister and to OLAF.

In order to investigate the notes on embezzlement or possible fraud in gaining, developing or using the money from the assistance programs of the European Union, the Government Control Body requires the necessary data from the public authorities and institutions, as well as the public or private companies involved. These institutions and companies are compelled to answer in a complete and adequate manner within 30 days.

In order to ensure the anti-fraud fight and the effective and equivalent protection of the financial interests of the European Union in Romania, all the central and local, public and private institutions appoint one or more contact persons. Those individuals benefit from specific expertise and technical means to adequately answer to the requirement of the Government Control Body.

At the request of OLAF, its representatives may be directly involved in the control developed by the Government Control Body which reacts to the

notifications of OLAF. The OLAF representatives may have legal access to the data and information that lead to the drawing up of the control note.

If there is evidence of criminal elements in the granting or use of the community funds, the control note is transmitted to the competent criminal prevention authority that must take legal action to release the funds, recover the damages, as well as to bring action against the people responsible.

The Government Control Body can benefit from technical assistance and facilities from the European Union, as well as from specific training programs for its personnel.

The control and recovering of the community funds and the additional co finance funds, used inadequately.

#### **4. The object of control and recovery of the budget debts caused by embezzlement and fraud**

The control of the observance of laws and regulations in using and managing the funds resulted from the irredeemable financial assistance provided by the European Committee to Romania, as well as the afferent co-financing funds, is directed at:

- identifying the embezzlement, the faulty financial management and fraud;

- establishing the possible prejudices;

- identifying the people responsible for the prejudices.

Another object of control and recovery of the budget debentures are the unjustified sums paid from the community funds and/or the afferent co-financing, as a result of the embezzlement and/or of fraud, their accessories, i.e. interest, delay penalties and other penalties, as the case may be, as well as the bank expenses.

Co-financing is the financing of a program, project, sub-project, objective and other such steps, partially by budget credits and partially by external source financing.

The budget debts resulted from embezzlement and/or frauds caused by the inadequate use of the community funds and the afferent co-financing funds, are sums to be recovered for the European Committee budget as well as for the budgets that have released those funds, co-financed as follows:

- the state budget;

- the state social insurance budget;

the special funds budget;

the state treasury budget;

the budget of the public autonomous institutions;

the budget of the public institutions, fully or partially financed from the state budget, the state social insurance budget and the special funds budget, as the case may be;

the budget of the funds that came from contracted external funds or guaranteed by the state and whose reimbursement, interest and other costs come from public funds;

the budget of the irredeemable external funds;

the local budgets of the villages, cities, municipalities, sectors of the capital Bucharest, the counties and Bucharest;

the budget of the public institutions, fully or partially financed from local budgets, as the case may be;

the budget of internal and external loans for which the reimbursement, the pay of interests, commissions, expenses and other costs is ensured by the local budgets consisting of: contracted external loans and further loaned to the authorities of the local public administration and/or the economic agents and public services subordinated to them; external loans contracted by the authorities of the local public administration and guaranteed by the state. External and/or internal loans contracted or guaranteed by the authorities of the local public administration.

Irregularity means any deviation from legality, regularity and conformity, as well as any disrespect of the provisions of the financing memorandums, of the agreement memorandums, of the financing agreements on the financial and irredeemable assistance provided to Romania by the European Community – as well as of the provisions of the contracts signed under the terms of these memorandums or agreements, resulting in an action or omission of the economic operator who, by unelectable expenses, prejudices the general budget of the European Community and/or of the internal budgets that have provided or co-financed the funds about to be recovered.

Fraud is any intended action or omission, deeds that result in the allocation or acquiring, or inadequate or incorrect use of the community budget of the European Communities or the budgets administered by them or on their behalf and/or of the afferent co-financing sums.

Fraud is:

the use or presentation of false, inaccurate or incomplete documents or statements, resulting in the unlawful gaining of funds or the illegal diminution of the community resources;

the omission of willingly communicating the data required according to the law, failing to communicate information by breaching a specific obligation respectively, if the deed results in the unlawful gaining of funds or the illegal diminution of the community resources;

the change, without abiding by the legal provisions, of the destination of the funds, the embezzlement of the funds from their initial purposes, respectively;

the change, without abiding by the legal provisions, of the destination of a legally gained use, if the deed results in the illegal diminution of the community resources.

The procedure of recovery of the budget debts resulted from embezzlement and fraud comprises two stages:

the finding – the control activity that establishes and singularizes the obligation of payment in the form of a debenture;

the so-called recovery of the budget debt through the voluntary payment, the deduction from the subsequent expense statements, by forced execution or by other means provided by the law.

The debenture is the document or paper that establishes and singularizes the obligation of payment of the budget debts resulted from embezzlement or fraud, drawn up by the inspection officials or other lawful authorised control structures, as follows:

the document or paper that establishes the obligations of payment of the budget debts resulted from unlawful payments made from the community funds and/or from afferent co-financing funds, as a result of embezzlement and/or fraud, as well as their accessories and the bank costs, issued by the inspection officials or other specialty structures of the Ministry of Public Finance or other institution qualified by the law ;

the final or unalterable court order that establishes the obligation of payment of the budget debts resulted from embezzlement and/or fraud;

other documents issued by appointed officials, documents which assess and singularize, according to the law, the budget debts resulted from embezzlement and/or fraud.

These documents establish the sums unlawfully paid from community funds and/or from afferent co-financing as a result of embezzlement and/or

fraud, their accessories, i.e. interest, delay penalties and other penalties, as the case may be, as well as the banking costs, the breached law as well as the individuals compelled to pay them.

## **5. The competent officials should carry out the control of the recovery of the budget debts resulted from embezzlement or fraud (in Romania)**

Qualified to carry out the control and to manage the recovery of the budget debts resulted from embezzlement and/or fraud, the officials of the central or local public administration and their subsidiaries, as the case may be, as well as other public institutions qualified by the law.

The competence of carrying out the control is granted to:

the inspection and/or control officials or other specialty structures from the Ministry of Public Finance , according to their specific legal framework;

the specialized structures of the local or central public administration authorities, including their territorial subsidiaries, structures that manage the funds from external financial assistance and have ensured national co-financing by specialty departments. The responsibility of establishing the necessary organisational framework for the above-mentioned specialty structures is granted to the manager of that specific entity;

the institutions qualified by the law, like the Government Control Body and the criminal investigation officials, according to their specific legal framework.

The Ministry of Public Finance and the other budget creditors who manage the budget debts of the co-financing budgets are qualified by the law to carry out control, to enforce and to carry out the insuring measures and to apply the forced execution procedure under the circumstances established by law.

## **6. The control procedure. The control report.**

Control is imposed when there are clues or notices from the internal or external audit structures, from other lawful institutions as well as from the citizens or the mass-media, on the faulty or fraudulent financial management of the public funds, including the external irredeemable financial assistance.

The manager of the control structures establishes:

the nominal constitution of the control team;

the length of the control which cannot overcome 30 days;  
the warrant on the control of the confirmation of the notice.

The control team announces the institution undergoing the examination on the starting date of the action, at least five days in advance. The announcement establishes the purpose and length of the control. The control caused by a notice is not announced

The control is carried out totally or by survey with reference to:  
the complexity of the activities and operations undergoing control;  
the value and nature of the goods;  
the frequency of the previous infringements.

The control by survey covers a large number of the operations that will allow the issue of solid conclusions. In the case of finding prejudices, control by census can extend over the entire period during which, according to the law, recovery and indictment measures can be enforced on the guilty parties, by correctly extending the control period, but not more than 90 days.

In order to accomplish the control objectives, the controllers have access to all the data and documents, as well as to all the storing and production locations of the assets during the control of the structure and of the beneficiaries of the public funds financial assistance. The staff of the controlled structure, including the beneficiaries of the public financial assistance, is compelled to bring forward, at the settled time, all the required data and documents and provide all the necessary support for a proper development of the control activity.

For concordance, the control officials can require data, information, as well as copies of the certified documents from the legal or natural persons related to the structure undergoing control, including from the beneficiaries of the public funds financial assistance, and they are compelled to provide this information at the specified date.

The control officials may require the development of specialty expertise from authorised individuals, for the goods, services and executed works, resulted from financial activities and operations undergoing control and only in a case of utter necessity to ground their findings.

The quantum of the prejudice is established from the specific time it was inflicted, and if this time cannot be established, from the time it was found.

The budget debt includes, aside from prejudice, the interest and delay penalties owed at the time when the prejudice was inflicted or found, calculated according to the legal provisions related to collecting budget debts.

When the control has been carried out,, a control report is drawn up with the following information:

the identification data of the control officials and of the responsible individuals of the bookkeeping structure, its headquarters and the locations where control has been developed;

the description of the context in which embezzlement or fraud have appeared, the breached normative acts, the budget debt, separating it for the affected budgets, including European funds as well as the people responsible;

the bank accounts where the budget debts are to be collected;

the full evidence that lead the findings is registered in annexes.

The control report is sent:

to the controlled structure for announcing, signing and completing further observations. The control paper is a debenture;

to the manager of the institution initiating the control, who, if prejudice is found, will require the bookkeeping recording of the budget debt and will enforce the measures of recovery.

The Obligation of payment of the budget debt resulted from embezzlement or fraud can be disputed in a court of law.

## **7. Methods of extinction of the budget debts resulted from embezzlement and/or fraud.**

### Obligation and responsibility of payment

The payer of the budget obligation, i.e. the funds received unlawfully from community funds and/or from afferent co-financing, as a result of embezzlement and/or fraud, as well as their accessories (interest, penalties, bank costs) will be the economic operator as debtor or the individual who, according to the law, represents the operator or who, on behalf of the debtor operator unlawfully profited by the money that came from community funds and/or afferent co-financing funds as a result of embezzlement and/or fraud.

If the budget obligation resulted from embezzlement and/or fraud is not paid by the economic operator, the person who represents him or who profited by the money from the community funds and/or afferent co-financing, as the case may be, under lawful provisions, compelled to pay is:

The institution or the person who assumes the obligation of payment of the debtor by a payment commitment or by any other authentically signed paper, with the insurance of a real warranty at the level of the payment obligation;

Other institutions or individuals under lawful provisions.

The recovery of the budget debts resulted from embezzlement and/or fraud

The recovery action consists in executing the administrative function that leads to the extinction of the debts resulted from embezzlement and/or fraud.

The extinction of the budget debts resulted from embezzlement or fraud is developed in the following ways:

The voluntary payment by the individuals responsible for it;

The deduction from the future expense statements;

Forced execution;

Other means provided by the law.

The payment of the budget debts resulted from embezzlement or fraud, found and established by the inspection officials or any other qualified structure, is made by the debtors in the accounts indicated by the budget creditors, at the dates established by the present legislation concerning the collection of the budget debts.

The debtor's obligations of payment, as well as their accessories due for untimely payment and the bank costs are calculated and paid in Romanian currency at the exchange rate established by the National Bank of Romania the day the payment is made.

The manager of the entity that has initiated control has the payment notification sent to the debtor who is compelled to record the owed sum in the ledgers and, within 15 days from the notification, he should pay the debts or prove the extinguishment of the debt. Otherwise, when the time has expired, the debenture becomes writ of execution and is sent to the competent execution officials.

If the debtor does not willingly pay his obligations on the budget debts resulted from embezzlement or fraud, the qualified officials decide and carry out the insuring measures and develop the forced execution procedure.

Authorised to carry out the ensuring measures and to develop the forced execution procedure are the officials or specialty departments of the

central public authorities or their territorial subsidiaries, of the local administration authorities or other public institutions qualified to manage the budgets that provided the co-financing.

The qualified control officials authorised to find and to establish the debts may impose by a motivated decision in an administrative procedure, the insuring interdiction on the income and/or the insuring distraint of the debtor's goods, measures carried out by the qualified execution officials.

The insuring measures in the form of insuring interdiction and the insuring distraint imposed on the movable or immovable goods owned by the debtor, as well as on his income, are enforced when there is a possibility that he may steal them, hide or spend his patrimony, thus endangering or considerably slowing down the recovery of the debts resulted from embezzlement or fraud.

These measures can also be enforced when the budget debt has not yet been singularized and fallen due.

The enforced insuring measures remain valid during the period of forced execution, without carrying out other formalities. Once the debt has been singularized and fallen due, in case of delay in payment, the insuring measures become execution measures.

A copy of the report of insuring distraint on immovable goods is announced for recording to the cadastral register and the recording prevents the distraint to all those who subsequently gain any rights on the building. The enforcing papers subsequent to the recording become void.

If the value of the debtor's assets does not fully cover the budget debt, the insuring measures can be called in on the goods owned by the debtor together with third parties, for the share he holds.

The enforced insuring measures are removed by a motivated decision, when the reasons for insurance no longer exist or when a guarantee for the debts had been settled.

The forced execution of the budget debts resulted from embezzlement or fraud is developed only on the grounds of a writ execution, according to the law.

A writ execution is:

the paper or document drawn up by the inspection officials or any other lawful control structures, for the budget debts resulted from embezzlement or fraud;

the court decision, for the budget debts resulted from embezzlement or fraud settled in a court of law;

Any type of expenses caused by the carrying out of the insuring measures and the development of the forced execution procedure are deducted from the budgets of the central public administration authorities, the local public administration authorities and other institutions qualified to manage the co-financing budgets that have started the forced execution procedure.

The recovery procedure for the unlawful sums paid from the community funds and/or from the afferent co-financing budgets, as well as their accessories and of the bank costs does not influence in any way the development of the criminal procedure when the embezzlement or fraud is classified as criminal offence.

## **Abstract**

*Our paper is a synthesis of the practical achievements of a research programme financed by the Ministry of Education and Research of Romania, focused on auditing by information-based means the financial statements of different business establishments. It is well-known the fact that since the financial auditor is not an employee of the audited company the financial-accounting information is submitted on various media, which means it is highly unlikely that it could be incorporated in the auditing software. At this level of our research, we suggest a prototype of information-based product that would facilitate the work and exchange of financial-accounting information. In other words, our prototype is based on an on-line dialogue interface with the audited company, which will allow the auditor a quick development of the audit files (both the permanent and current ones) based on electronic evidence. At the same time, we shall make a presentation of certain financial-accounting restrictions considered when developing the marketable version of the information product called FINAUDIT.*

**Keywords:** FINAUDIT, financial statements, financial audit, prototype.

## 1. Introduction

Accounting is, in fact, an information system that quantifies, processes and communicates financial information related to an identifiable economic entity. Each accounting information user needs information which reflects reality that is "real" information, although it refers to an "accounting truth" built by reference to a series of accounting conventions. In order for the user to trust this accounting information, there is needed the intervention of the accounting information quality controllers who thus provide a guarantee for the enforcement of and compliance with accounting principles [4].

## 2. Financial audit and the accountant profession

The checking and certification of the financial statements by authorized bodies before they are made public has become a must. Moreover, the Romanian accounting legislation, drawn up in accordance with the provisions of the 4<sup>th</sup> Guideline of the European Economic Community and with the International Accounting Standards, states that the publication of the annual financial statements should occur after their auditing by authorized bodies called financial auditors. In the countries having a tradition in the market economy, the checking of the financial statements of the economic entities is stipulated by the act of companies of each country, many of these laws dating back from the 1900s.

Etymologically speaking, the term *audit* comes from Latin and means listening or checking. Considering the statement according to which *financial audit consists of an examination performed by a qualified and independent professional accountant, in order to be able to express a justified opinion on the drawing up and presentation of the financial statements in accordance with an identified accounting reference system*, the re-establishment of the trust between the accounting information emitting and the receiving parties is influenced, among other things, by the quality and efficiency of the audit. The independent opinion expressed by the auditor on the financial statements in question must defend all the users of accounting information alike [Berheci, M., 2004].

The reputation of the auditors as regards their skills and independence was highly appreciated throughout the time. Hence, banks, investors and creditors request the opinion of a financial auditor whenever they decide to invest in a company or to give a loan to a company that was audited.

The international standards regulating the audit profession originate from America, since the United States of America are one of the countries

that have had the longest experience in the financial audit field. At international level, IFAC has taken on the task of drawing up the financial audit standards aimed at supporting the development of the accountant profession. International audit standards are the reference grounds for the elaboration of national standards and are meant to improve the quality of the financial information on international markets. It is highly unlikely that international audit standards apply to all the situations an auditor may encounter. Therefore, we may consider that these standards set out the *basic principles* that one must comply with, as procedures vary depending on the circumstances of each case and any professional accountant is free to decide upon.

### **3. Financial audit in information-based society**

#### *a. Definition of the information-based society*

Generally speaking, we may say that the information society may be defined as an information-based society. In a modern meaning, we may speak of an information-based society since the use of computers in economy, after the building of the ENIAC in 1947, that is since the second half of the 50'.

#### *b. Transition towards the globally information-based society*

The following years will bring about essential changes in our every day life. Thus, the use of electronic computer will be extended to all activity fields, due to an increase by almost 100 thousand times of the current performance, until it reaches the performance of the human brain, together with a reduction of its sizes to the shape of a chip. The name of this computer will be system-on-a-chip, and its price will be so small that its package will be more expensive than the system itself. At the same time, the information and communication technologies, together with the discoveries of new materials, shall lead to the so-called Cyberspace, whose spine will be the INTERNET and the virtuality through digitization. Moreover, the federal government of the USA has recently launched a 5 year research program, financed with 400 million dollars for the future development of the INTERNET, that should be 100 faster than the current one and will be called NREN [7]. Finally, the Cyberspace will include the BODY AREA NETWORK (BAN) [3].

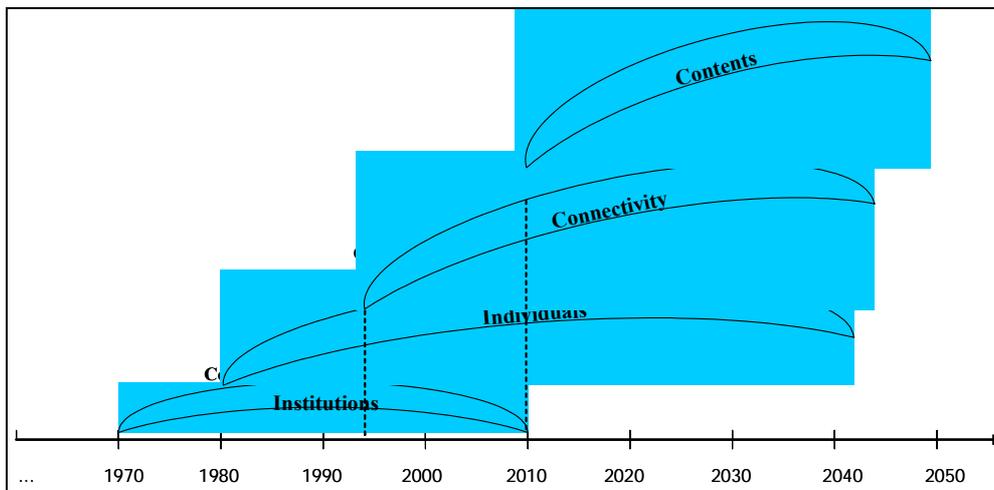

At network level, performance will be amazing. Thus, many types of networks are meant to fulfill people's dreams about a wholly or partially cyber-based world and about an information super-highway.

In other words, the grounds of tomorrow's society will be constituted by information and computer-mediated communications. J.A. O'Brien has

drawn up a globally information-based society transition chart and he reckons that humanity, in order to reach that point, must go through four waves, namely:

- Computerized Enterprises, corresponding to the period 1970-2010;
- Networked KnowledgeWorkers, which started in 1980;
- Global Internetnetworked Society, started around 1992-1993;
- Global Information Society, which will begin after 2010.

**Figure 1. The four waves of information technology**

As it is presented in figure 1, until 2010 we will be crossing a period of time when the first three waves superpose, what means we are in a transition period with its specific risks and advantages. Thus, as we can see, humanity has not even gone through the first stage, but two other have already been started and in 2010 the fourth will start as well. In other words, until 2010, the human society is crossing a continuous transition process towards this information world-wide covering. Therefore, the traces of modernity will become even more obvious as we approach 2010, when the first wave of the simple information technology is completed and the fourth wave is more and more present, namely the “*Globally information society*” wave.

*c. Necessity of total informatization of the financial audit*

Literature in the field of informational technologies shows us the fact that subjects like intelligent company, virtual companies, Internet extension, e-commerce, e-bank, e-\* and the global informatization of the society are trends that mankind cannot avoid. Under these circumstances, companies, with or without their will, must get modernized. At the same time, the professional accountants should understand at least partially their field of competence from the perspective of this evolution, otherwise their opinions will be easily influenced and disregarded. Therefore, professional accountants cannot stay indifferent to these technological trends!

In other words, in the current society based on information, which is more and more based on knowledge, in which the achievements in the field of artificial intelligence are more and more promising, it becomes imperiously necessary that the professional of the financial audit field should be endowed with as many work tools as possible based on the newest information and communication technologies.

By the means of the International Audit Standard no. 400, titled Audit in an environment of computer systems, there are determined a few criteria for the evaluation of the risk in an audited entity that avails of a partial or integrated accounting information system. We consider that it is necessary to resume and materialize the issue of accounting and audit informatization in standards that should take into account the specific technological system of an information-based society.

Recently, INTOSAI<sup>1</sup> Standing Committee on IT Audit centralized in a published report the situation of the use of softwares in the field of financial audit and IT. In table 1 we present this situation (<http://www.intosaiitaudit.org/directory/topic/Audit1.html>).

---

<sup>1</sup> INTOSAI is the professional organization of supreme audit institutions (SAIs) in countries that belong to the United Nations or its specialist agencies.

The previous table shows that there are countries which do not have the practice of using such an information product in the financial audit field or countries which use it by means of applications developed within the organizations, which are, most of the times, unstandardized and hard to generalize.

#### **4. Stage of financial audit computerization in Romania. A few accomplishments**

Romania currently makes shy attempts at employing the IDEA information product used by a part of the National Audit Office of Romania, and to a smaller extent by the private audit offices. On the other hand, international audit offices use information products meant for audit activities in companies whose partially integrated business computing and accounting programs are audited. This limitation of the use of financial audit information programs is justified by:

1. a developing financial audit market;
2. rather aged financial auditors;
3. considerable IT investments required;
4. lack of an integrated information system of the company which is the beneficiary of the audit activity;
5. high price of softwares.

As concerns the coverage of the financial audit market, one should note that our research shows that about 95% of the financial auditors active on the market do not use an computerized solution for auditing the financial statements of their clients, while, on the other hand, the latter use MSO Word and Excel on a large scale, when preparing the financial audit files needed for drawing a conclusion. In other words, computers are used as audit file "type writers" and storing and finding devices. The rest of 5% of the financial auditors work with foreign audit companies that provide them with modules ready to use for the partial preparation of the financial audit sections<sup>2</sup>.

All these justify the need for a wider use of information products in this financial audit field.

#### **5. Finaudit – prototype of software for auditing financial information**

##### *a. Research team*

From our research, it results that in Romania there are information models at a conceptual level resulting from doctoral research, that are usually

---

<sup>2</sup> These data result from a survey we performed in December 2003 among professionals in 6 counties in Romania.

made at an industrial level and not by a team, which restricts the area of the future prototype or commercial applications further to the fact that the field to be covered involves knowledge coming from accounting, financial administration, specialized practice, programming, design etc.

These reasons determined us in proposing for financing to CNCSIS of the Ministry of Education and Research of Romania, a research theme that should have as finality the automated modeling of all activities specific to the financial audit, theme that was accepted for financing for a period of three years, starting from 2004. To approach this theme we have made up a complex team of highly skilled members: certified accountants, financial auditors, accountants, PhDs and PhD students in accounting and administration computing, PhD students in accounting and accounting and financial-audit companies, as it results from the table below.

**Table 2. Structure of the research team**

No	Members of the research team	Qualities, scientific titles
1.	Prof. univ. As you can see from the previous table, the research team has specialists in theoretical and practical fields necessary for the development of

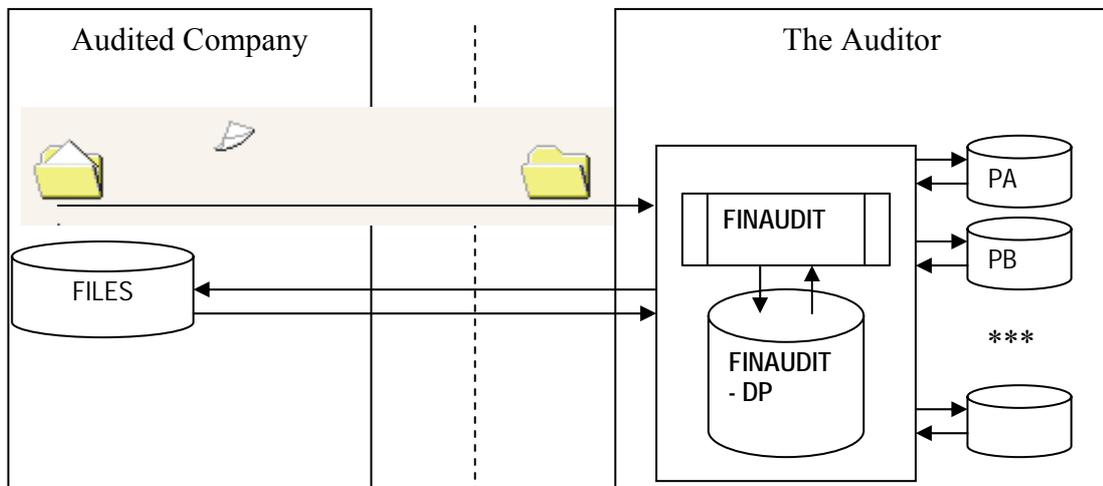

the FINAUDIT application. Moreover, the partners of the trade company provide the link with the market in the financial audit field.

*b. Presentation of the information product FINAUDIT*

An information product for the financial audit must settle two basic components of a financial audit file, that is: the permanent file and the current file of the audited company. At this moment, the FINAUDIT prototype settled from a conceptual viewpoint the permanent file.

From a conceptual viewpoint, FINAUDIT is designed as a *module that meets the demands of the audit company and of the beneficiary company*, it enables various security levels for information updating between both partners. In other words, on the server of the audit company FINAUDIT is installed and the audited company by an authorized agent, shall have the possibility to access the permanent file in order to view and to add information in an electronic format. The auditors of the audit company shall take over the electronic files and shall attach them as enclosures to the specific section of the permanent audit file. Hence, we shall make more efficient the work of collecting the documents necessary for the development of the permanent audit file and we shall contribute to the enhancement of the financial audit quality. In Figure 2 we have the work schemata between the two partners of an audit file.

**Figure 2. Work schemata with the module Permanent file of the information product FINAUDIT**

The stages of using the DP module (permanent file) of FINAUDIT consist in:

1. Installing FINAUDIT with the audit company;
2. Installing the module DP with the audited company (client) and the assignment of a username and of a password;
3. Generation of the database for the client at the audit company;
4. Joint preparation of the work sheets PA, PB ... PF;
5. Viewing data and information on the permanent file at any time by the client;
6. Adding information (enclosure electronic documents) by the client;
7. Auditor's using the new documents as enclosures to the sections PA, PB ...;
8. Printing at request the permanent file.

*The main characteristics of the FINAUDIT product are:*

1. uses WEB technologies for registering and storing information on trade company auditing;
2. the basic technology for the interface of the application is *Windows SharePoint Services* (WSS<sup>4</sup>).
3. users' authentication is made based on the Active Directory that represents the directory service supported originally by Windows 2003 server and Windows SharePoint Services;
4. data persistence is provided by the data support SQL Server 2000;
5. list and list format customizing may be achieved originally from WSS or using a Web page editor, in the case of this application we recommend using FrontPage 2003;
6. the advantage of using Web technologies as application interface is represented by the fact that at the main office of the customer there should not be installed a client-type component, the only requirement being a WSS-compatible browser: Internet Explorer (recommended), Firefox etc;
7. users may be grouped per page-access levels from read-only users to administrators;

---

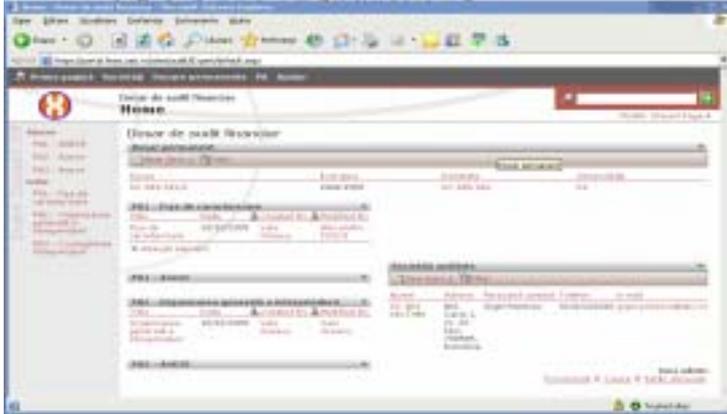

<sup>4</sup> Customizable solution of document management provided by Microsoft Company

8. entry security and data confidentiality may be achieved by determining and grouping the users per work groups and per access levels;
9. to determine a security per correlated levels, the solution is Small Business Server that includes all services necessary for the implementation of the application at the level of the audit company.

In order to use the application FINAUDIT, the following aspects should be known:

- main page: <https://portal.fea.uaic.ro/sites/audit/Expert/default.aspx> (figure 3);

**Figure no. 3. Main page of the application FINAUDIT**

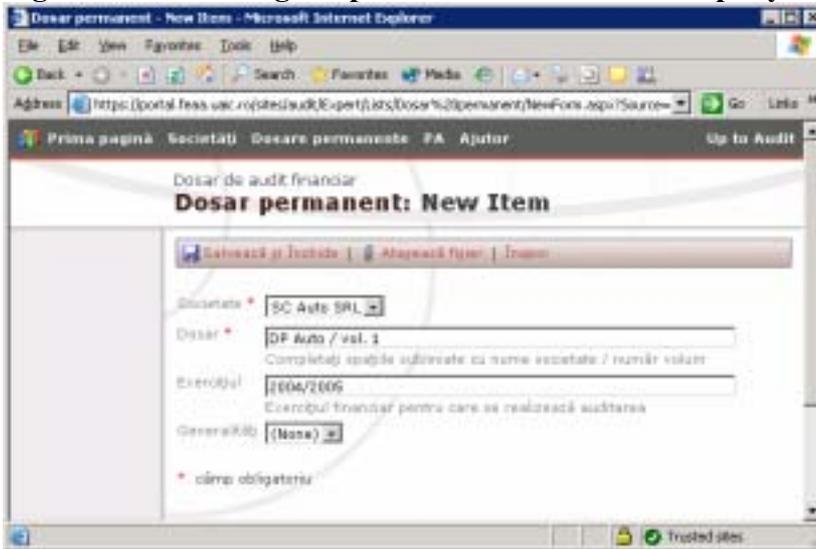

- to add a new company, press the button *New item* of the area audited *Companies*.

**Figure 4. Statement of a new company client**

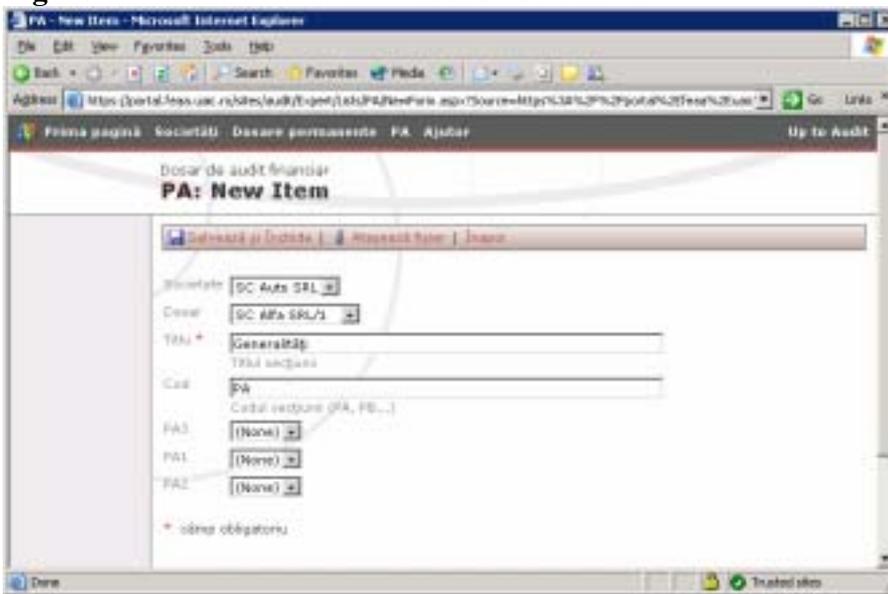

- to add a new permanent File, activate the link *Permanent files* of the top menu and then press the button *New item* of the permanent file page;

**Figure 5. Generating the permanent file for the company**

- to fill in the sheet PA, press the link *PA* and then the button *New item*;

**Figure 6. Definition of the PA section structure**

- to fill in the sheets PA1 and PA2 ... activate the left links of the first page of the application, press the button *New item*. For instance, in figure 7 we present the PA1 form;

**Figure 7. Work modality for the *Sheet of characteristics***

The screenshot shows a web browser window with the address bar displaying a URL. The page title is "PA1 - Fișa de caracterizare: New Item". The form is organized into several sections:

- General Information:** Includes fields for "Fișa de caracterizare", "Subul caracterizării", "Cod", "Cantitate", "Data", "Data de încheiere", "Data de începere", "Data de încheiere la BC", and "Data de începere la BC".
- Technical Specifications:** Includes fields for "Nume produs", "Adresa", "Numele societății producătoare", "TM", "Pai", "Numele recipient", "TM", "Pai", "Numele produs", "Data fabricării", "N. de înregistrare BC", "Data fabricării", "Data înregistrării la BC", and "Local fabricării la BC".
- Product Details:** Includes a dropdown for "Cant. produs", a text field for "Cant. produs", a dropdown for "Unitate de măsură", a text field for "Unitate de măsură", a dropdown for "Cant. produs", a text field for "Cant. produs", a dropdown for "Unitate de măsură", a text field for "Unitate de măsură", and a dropdown for "Cant. produs".
- Calendar:** A calendar widget for November 2009 is displayed, showing the days of the week and the dates. The date 14th is highlighted in yellow.

This is the final shape of PA, after the other sheets have been completed.

**Figure 8. Presentation of the PA sheet**

<small>Created at 10/13/2005 5:05 PM by <u>GEORGESCU C. ILIANA</u> Last modified at 10/13/2005 5:46 PM by <u>Razvanh TUGUI</u></small>			

We mention the fact that the work logic for the PA section is applicable also to the other sections of the permanent file afferent to an audited company (client).

*The main advantages of the FINAUDIT application are:*

- converts into digital format the Audit Files of an audited company;
- involves in the stage of Audit File completion the audited company;
- imposes electronic administration of documents at the level of the audit company;
- the cost of the application is relatively low;
- provides the possibility of audit automated modeling and of obtaining under the requested format for the work sheets the enclosures of the two audit files;
- very low costs of the implementation of the application with the users;
- enhancement of the auditing quality by observing certain information procedures;
- an advantageous role of the ones that implement the product FINAUDIT;

- a work interface close to the logic of financial auditors.

These are some *disadvantages*:

- difficulty in automated modeling of the professional reasoning, hence the necessity of auditor's intervention in the work sheets;
- the continuous harmonization of the auditing activity imposes the permanent updating of the application, if this one was designed as modular;
- great reticence of financial auditors with regards to the new information and communication etc.

## **6. Conclusions**

This study shows the high degree of informatization of the tomorrow's society in which business operators will work, which justifies the necessity to resort to ICT in the activity of financial audit, too. By our research theme, we undertook to make available for Romanian financial auditors a work tool in the logic of the end users, which should enable the construction of the audit files of their customers.

Our research team is on an advanced stage of design of the current file of an audit mission and we succeeded even in obtaining a prototype for the F section - Audit approach.

What do we undertake? We undertake this year to complete the demo version of the FINAUDIT product and to present it to the accounting and financial accounting professionals. During 2006, we want to achieve the commercial version of FINAUDIT. Moreover, we want to continue our studies in the field, with financing from the forecast sales on the Romanian market, on two directions: a. product completion with modules specific to artificial intelligence (expert systems, intelligent agents etc) and b. the conversion of this product on the market of the Republic of Moldova and other countries that undergo the same process of financial-audit harmonization.

## **Abstract**

*This paper try to emphasize the importance of predicting financial situation for any firm's management, necessity of this process and certainly are present some practice modalities of preview a balance sheet, a profit and loss account and a cash-flow statement. Especially we will refer at the statistical method of preview the financial statements based on the data of the last 5 to 10 years of activity.*

**Keywords:** *prediction, financial statements, additional funds needs, managerial finance*

## 1. Introduction

In any activity, the existence of a program that can provide the future coordinates of the activity is very important. In the economic activity, such an objective must be achieved. The enterprises must plan the value of their assets, expenditure, income, results in order to efficiently allocate their funds.

The firms need more assets if they wish to increase their sales, meaning that they have to make new investments. For this, they need funds that in most of the cases are represented by new loans. These loans generate interest. Although a part of funding can be obtained by self-finance, a high growth rate implies external financing even for a very profitable firm. In these circumstances, every firm, in its process of financial prediction, needs to have appropriate solvability, liquidity, profitability rates.

As a conclusion, any accounting management that wants to increase the efficiency of his activity must accept the aid of predicted financial statements. The degree of detail of these financial statements depends upon the period considered.

The prediction of financial statements refers to the following documents:

- the predicted financial position synthesized in the actual predicted balance sheet;
- the predicted financial performances synthesized in the predicted Profit and Loss account;
- the modification of the predicted financial position reflected in the predicted Cash-Flow;
- the predicted efficiency of the activity reflected by the main predicted financial indicators.

Prediction of sales, that is the estimation of net turnover for a certain future period, is the starting point in estimating the future funding needs. The prediction of future sales is done by analyzing the net turnover of the last 5 -10 years, its trend providing the future evolution. This can be very useful. Even so, the hypothesis that the sales will grow in the same rate as in the past not always can be valid and can lead to unrealistic predictions. Because of this, the following information need to be analyzed, such as:

*Establishing the strategic fundamental objective of the firm.*

Every firm acts in a specific economic and competitive environment and, because of this, the future strategic objectives are dictated by this

environment. Practically, a firm can establish a certain objective. The degree in which this objective is accomplished is very much influenced by the governmental policy, by the legislative system and so on.

*The elaboration of a market study.*

Every company produces for the market, and consequently it must know the demand. The market study must offer the producer, information on future evolution of demand and factors with impact in the future. In every day activity this information has a certain degree of probability due to the several natural, political, legislative factors that may appear.

Every good prediction implies a lot of effort. If the prediction is wrong, the consequences can be negatives. .

If the demand is higher than the predicted one, the firm won't be able to satisfy the customers. The consequences can be accumulated orders, delayed delivers and finally lower market share because the clients will choose a firms more competitive and prompt with its deliveries.

On the other hand, if the prediction regarding sales is too optimistic, the company will be in the situation of having more product reserves and unused technology. This will generate low rotation speed for fixed assets, increased costs which will result in general depreciation of the firm's stocks and value. But, if the company has financed its development with bank loans, the problems could be much worse.

Because of these, a correct sales prediction is useful for a firm's long run success.

## **2. Methods of predicting the Balance Sheet and the Profit and Loss Account.**

Next, we will refer to the methods of predicting the Balance Sheet and the Profit and Loss Account because the Cash Flows and the financial indicators result of the predictions concerning the financial position.

In consequence, for the elaboration of the two predicted documents can be used the following methods:

**1. Method "percent from sales"** which can be applied successfully in the hypothesis:

a) The majority of the elements of the financial position presented in the Balance Sheet vary in the same rate with the sales.

b) The current values of the entities assets are optimal for the current values of the sales.

## 2. "Statistical methods"

When the hypothesis used by the "percent from sales" method are not confirmed, another prediction can be used, among which regression methods has the largest applicability. There are numerous situations when the two conditions cannot be fulfilled

### *a) The existence of the "scale savings"*

Various times the entities must have a basic stock even though the turnover at the moment is very low. According as, this turnover increases also increases the value of the stocks but with a lower growing rate so the initial ratio among the value of the stocks and turnover decreases.

### *b) Lumpy assets*

In many industries, the development of an enterprise can be made only buying valuable assets. This is the case of the paper industry where even the smallest cellulose operation unit can be efficient.

In Canada, for example, the firm must have at least 75 millions fixed assets, this meaning at least a complete unit in order to be competitive. This situation influences significantly the ratio fixed assets/turnover for different sales amounts is influenced also the financial needs. The relation between an asset and turnover is in several occasion laniary. In this case, simple laniary regression method is applied for assessing the increase in value of that asset determined by a certain increase of the sales. A mathematical equation can be established based on information from the last five to ten years. In inflation this methods determines consequent transformations in a constant currency in order to obtained pertinent data.

Practically, the application of the regression method for the provisions of the financial statements is the following:

a) The assets from the last 5 to 10 years are analyzed in accordance with the turnover which they generated each year. The relationship between each asset element and turnover over the analyzed period is reflected by the "statistical cloud". The parameters of the regression equation are estimated and subsequently the value of every asset element considered.

b) Based on the prediction of sales, the incomes and the expenditures are assessed and the predicted profit and loss account is elaborated. for the following year.

These stages can lead to a predicted balance sheet without equilibrium between assets and liabilities. In the liabilities will appear a so called "*additional funds needed*" – AFN. This need will generate new loans, from the shareholders or banks and this choice is based on the compared analysis

of the the costs generated by these two and by the existing restrictions. The restrictions regarding supplementary loans are determined according to:

- the maximum level of loans established by the indicator “degree of debt”;
- the loan estimated for the following period;
- the difference represents the loan that the firm can contract.

If the need for funds is not satisfied by contracting new loans then new shares are issued and the assets grow. The equilibration of predicted balance sheet by contracting loans will take into consideration the cost of these new loans (the interest or the dividends).

The need for funds can be determined from the balance sheet equilibrium or with the help of a formula that has some advantages:

- it reveals the relation between the sales growth and the need for finance;
- by the equation  $AFN=0$  we can see the growth rate that can be financed from the firms resources; this growth rate is know as the sustainable growth rate.

The formula for the need for financing is:

$$AFN = \Delta CRA + \Delta FA - \Delta NFL - M * Rap * S1$$

Where:

- AFN represent additional funds needed
- $\Delta CRA = CRA1 - CRA0$  where CRA1 represent estimated current assets presuming that this increase at the same rate with a sales according to the equation:  $CRA1 = a + b * S1$ , where “a” and “b” are the parameters of the regression equation, which where resulted from the statistical analysis of the relationship between CRA and S over the analyzed period; CRA0 represent current assets on the N year (the last year analyzed).
- S1 represent the predicted net turnover;
- $\Delta FA = FA1 - FA0$  where FA1 represent the estimated fixed assets presuming that this grow at the same rate with sales after the equation:  $FA1 = c + d * S1$ , where “c” and “d” are the parameters of the regression equation, which where resulted from the statistical analysis of the relationship between FA and S over the analyzed period. FA0 represent the fixed assets on the N year;

-  $\Delta NFL = NFL1 - NFL0$  where NFL1 represent the estimated nonfinancial liabilities (like note payable, trade account payable, taxes and wages to pay and so on) presuming that this grow at the same rate with the sales after the equation:  $NFL1 = e + f * S1$ , where “e” and “f” are the parameters of the regression equation, which where resulted from the statistical analysis of the relationship between NFL and S over the analyzed period. NFL0 represent the nonfinancial liabilities on the year N;

- M represent the profit rate (Net profit/Net turnover \*100);

- Rap represent acumulated profit ratio;  $Rap = (1 - \text{dividend payout ratio})$ ;

For exemplification we will consider a company  $\alpha$  that has the following predictions:

- the estimated net turnover is 1.500 monetary unit (m.u.) for the year N+1;
- the profit rate (Net profit/Net turnover)\*100 is estimated at 4%;
- from the net profit, 50% is given as dividends;
- general liquidity rate is not to exceed 250%;
- debt degree (total debt/total liabilities)\*100 is not to exceed 50%;
- the production technology isn't used at the maximum capacity;
- the expenses will decrease to 60% of sales;
- assets sales is estimated that will generate 300 m.u.. loss;
- other exploitation expenses are estimated at 98 m.u.;
- profit tax is 16%.

The balance sheet and the profit and loss account at 31.12.year N is:

**Table 1. Simplified Balance sheet at 31.dec.year N (m.u.)**

Fixed assets	300
Current assets	390
Stocks	200
Trade account receivable	170
Liquidities	20
<b>Total assets</b>	<b>690</b>
Trade account payable	100
Taxes and wages to pay	50
Current liabilities	150
Bonds	140
Total liabilities	290
Share capital	200
Reported result	200
Net result	10
Repartition of result	(10)
Total shareholders equity	400
<b>Total liabilities and equity</b>	<b>690</b>

**Table 2. The simplified Profit and Loss Account at 31.dec.year (m.u.)**

Net turnover	1000
Material costs	700
Amortization costs	20
Loss from asset selling	168
Exploitation result	112
Interest costs	100
Current result	12
Gross result	12
Profit tax	2
Net result	10

The assessment of the current assets and nonfinancial liabilities for the year N+1 is made based on the statistical analysis of the connexity between these and turnover in the last five year. From the statistical analysis of the variables mentioned above, can be determined the following conditions:

$$FA = 40 + 0,26 * S$$

$$St = 20 + 0,18 * S$$

$$TAR = 10 + 0,16 * S$$

$$C = 5 + 0,015 * S.$$

$$NFL = 18 + 0,132 * S, \text{ where}$$

- FA represent the fixed assets in the last five years;
- St represent the stocks in the last five years;
- TAR represent the trade accounts receivables in the last five years;
- L represent cash in the last five years;
- NFL represent the nonfinancial liabilities in the last five years.
- S represent the sales in the last five years.

For an estimated turnover for the year N+1 of 1500 m.u., can be obtained the following values of the assets:

- Estimated fixed assets for the year N+1 : FA1= 430 m.u.
- Estimated stocks for the year N1: St1= 290 m.u.
- Estimated trade accounts receivables for the year N+1: TAR1= 260 m.u.
- Estimated cash ( liquidity) for the year N+1: C1 = 27,5 m.u.
- Estimated nonfinancial liabilities for the year N+1: NFL1 = 216 m.u.

Based on the mentioned formula, the *additional funds needed* is:

$$AFN=(430-300)+(290-200)+(260-170)+(27,5-20)+(216-150)- 4\%*50\%*1500 =221,5 \text{ m.u.}$$

The need for financing will be satisfied by new loans but in case of emergency by issue of shares or by increase in equity. For this, must be respected certain restrictions such as:

*a) The restrictions regarding the degree of debt imposed:*

$$\begin{aligned} \text{Maximum of debt allowed} &= 0,5 * \text{Total assets} = \\ &= 0,5 * 1.007,5 = 503,75 \text{ m.u.} \end{aligned}$$

Minus: Loaned capital estimated for year N+1:

$$\text{Current debt} = 216 \text{ m.u}$$

$$\text{Bonds} = 140 \text{ m.u}$$

$$\text{Total} = 356 \text{ m.u}$$

$$\text{Maximum of supplementary loan} = 503,75-356= 147,75 \text{ m.u}$$

*b) The restrictions regarding the general liquidity degree impose:*

$$\text{Maximum of current debt allowed} = \text{Current assets allowed}/2,5 = 577,5/2,5= 231 \text{ m.u.}$$

Minus: Current debt estimated for N+1 = 216 m.u

Maximum of supplementary current debt = Maximum of current debt allowed - Current liabilities already estimated = 231-216 =15 m.u

*c) Need for shareholders equity:*

Total supplementary need for funds = 221,5 m.u

Maximum of allowed supplementary loan = 147,75 m.u

Need for shareholders equity = 221,5-147,75 = 73,75 m.u

*d) The predictions for external financing are:*

Current debt = 15 m.u

Long run debt = 132,75 m.u

Supplementary shareholders equity =73,75 m.u

After satisfying the need for financing and after take into consideration the restrictions mentioned above, the predicted simplified balance sheet for 31 December year N+1 will be the following:

**Table 3. The Simplified provisioned balance sheet for 31.dec.N+1 (m.u.)**

Fixed assets	430
Stocks	290
Trade account receivables	260
Liquidities	27,5
Current assets	577,5
<b>Total assets</b>	<b>1 077,5</b>
Nonfinancial liabilities	216
Current debt	15
Current liabilities	31
Bonds	272,75
Total liabilities	503,75
Share equity	273,75
Reported result	230
Net result	60
Result repartition	(60)
Shareholders equity	503,75
<b>Total liabilities and equity</b>	<b>1 077,5</b>

**Table 4. B. Estimated profit and loss account at 31.dec.N+1 (u.m.)**

Net turnover	1,500
Material costs	900
Amortization costs	30 <sup>1</sup>
Loss from asset give away	300
Other exploitation costs	98
Exploitation result	172
Interest costs	100
Current result	72
Gross result	72
Profit tax	12
Net result	60

<sup>1</sup> Amortization expenses are increased with 10 m.u. by taking into consideration the supplementary purchase of assets.

<sup>2</sup> We didn't took into consideration the implications of the indebtment over the profit and loss account.

Using the estimated balance sheet and the profit and loss account we can determine the predicted cash-flow. Using the indirect method this will be:

**Table 5 The predicted cash-flow for 31.dec.N+1 (m.u.)**

<i>Exploitation activity</i>	
<b>Net result</b>	<b>60</b>
Adjustments:	
<b>* Regarding current assets</b>	<b>-104</b>
- Δ Account receivables	-90
-Δ Stocks	-90
+Δ Nonfinancial liabilities	66
<b>* Regarding nonmonetary exploitation elements</b>	<b>53</b>
+ Amortization costs	53
<b>* Regarding investments</b>	<b>300</b>
+ Loss from fixed assets sale	300
<b>A. Net cash flow from exploitation activity</b>	<b>299</b>
<i>Investing activity</i>	
- Fixed assets bought	-550
+ Fixed assets sold	67
<b>B. Net cash flow from investing activity</b>	<b>-483</b>
<i>Financing activity</i>	
- Contracting loans on short and long term	147,75 (15+132,75)
+ Bonds issued	73,75
- Dividends paid	-30

<b>C. Net cash flow from financing activity</b>	<b>191,5</b>
<b>Net cash-flow (A+B+C)</b>	<b>7,5</b>
Estimated reserve for end of N+1	<b>27,5</b>
Reserve at the beginning of N+1	<b>20</b>

For the estimated cash flow we will take into consideration the following information extracted from the investment budget: new investments in the amount of 550 m.u. will be made a part of the old machinery will be sold at a value of 67 m.u ;the estimated net accounting value (entry value minus costs with cumulated amortization) is 367 m.u.

### **3. Conclusions**

Statistical methods are very good used in the prediction of financial statements especially based on the regression method. In this way the manager benefits of the most elevated methods for the best decisions that he wants to do refering the future of their activity.

telephone: +40 230520263

## **Abstract**

*The financial-accounting audit was legalized in Romania in 1999 and since then there were made important steps of development through CECCAR, as well as through the Ministry of Finances. The financial-accounting audit interposes between the manufactures and the users of accounting information, by high-class professionals, which assume the responsibility of certification that the financial situations are concluded in all the significant aspects and in comply with the national and international standards of accountancy. In a financial audit, the control of objectives is planned in terms of the risk factors and of their relative significance, which changes from a company to another. Through his activity, the auditor must achieve a comprehensive understanding of the accounting systems and of internal control in order to program the audit activity.*

**Keywords:** *financial audit, internal control, financial-accounting*

## 1. Introduction

In an increasingly active business world, the performance of the enterprise is expected by its partners – shareholders, banks, financial analysts, suppliers, creditors, etc. In a first phase, the ensemble of its activities, translated in accounting language, makes the object of thorough examinations, conducted by management controllers or internal auditors who intervene in the area of the enterprise business management; they contribute to the improvement of the enterprise organization and thus to the ability to reach the objectives set by the management of the enterprise.

The effectiveness of the financial and accounting information, synthesized in the financial statements, is subsequently validated by a professional accountant holding the title of auditor. He will not reiterate the examinations already conducted within the enterprise, examinations whose extent varies according to the size of the enterprise.

In the course of an audit of the accounting data, the most important step is to determine whether the recorded information correctly mirrors the economic events that occurred during the accounting activity. As the accounting rules represent the evaluation criteria of the adequate recording of the accounting information, any auditor involved in the activities related to these data, must also have perfect knowledge of these rules. In the context of an audit of the financial statements, the rules applied are often the generally accepted accounting principles.

Aside from a good knowledge of accounting, the auditor must also have experience in collecting and interpreting the audit samples. It is this experience that separates the auditors from bookkeepers. The identification of the adequate audit procedures, the assessment of the number and types of elements to be tested, as well as result evaluation, these are all unique problems that define the activity of an auditor.

The auditors that certify and identify the financial statements and the information provided by the accounting department are called in to fulfill their mission according to “The Code of professional ethics and conduct in the field of financial audit”, without getting influenced by the often contradicting interests of the users of the information. Due to the need external users have of relying on the financial statements, there is a set of strictly defined standards for the audit of these financial statements.

## 2. Manager decision process

In order to underline the need of the auditing, let us take as an example the decision of a bank manager concerning a loan granted to an enterprise. This decision will be based on factors like: the previous financial relations of the bank with the respective enterprise and the financial position of this enterprise, as reflected in its financial statements. If the bank grants the loan, it will request an interest rate widely determined by three factors [1, p. 81]:

1. The interest rate for no risk investments. It is approximately equal to the interest rate the bank could get if it were to invest in state bonds with equation of payments as the loan requested by the enterprise.
2. The economic risk represented by the client. This type of risk reflects the probability that the enterprise may not be able to return the loan due to general or specific economic circumstances linked to the activity of the enterprise like: economic recession, wrong managerial decisions or unpredicted competition in the branch.
3. The informational risk reflects the probability that the information on which the evaluation of the economic risk was based might not be exact. A possible cause for the occurrence of an informational risk is the probability of drawing up inaccurate financial statements.

The audit has no influence on the interest rate for no risk investments or on the economic risk but it may have a significant impact on the informational risk. If the bank manager is content with the minimum informational risk of a client because the latter has hired an auditor for his financial statements, the risk is significantly diminished and the total interest rate applied to the debtor can be alleviated.

As our society becomes more complex, the decision factors are facing an increasing probability of receiving incorrect information. This is explained by several reasons: the wider distance between the information and the users, bias and the personal reasons of the information provider, the large volume of data as well as the existence of certain complex commercial transactions.

The enterprise managers and the users of the financial statements could conclude that the best way to manage the informational risk consists in simply maintaining it on a reasonably high level. A small company could find that it is cheaper to pay higher interest than increase the expenses brought about by the attempts to reduce the informational risk.

For larger enterprises, it is a more practical habit to assume the expenses on the reduction of the informational risk. This measure can be enforced in three ways: the information is checked by the user, the

informational risk is shared between the management and the user, and audited financial statements are provided.

*The user verifies the information.* The user could come to the headquarters of the enterprise that provides the information in order to examine its accounting records and to get information on the effectiveness of the presented situation. Normally, this measure is not a practical one because of its cost. Moreover, it is economically inefficient for each user to verify the information. Nevertheless, certain users conduct their own checks. For example, the IRS conducts important examinations of the enterprises and the natural persons in order to determine whether the tax return mirrors the real taxes or not. Similarly, if an enterprise intends to take over another enterprise, the buyer often makes use of a special audit team to examine and independently assess the key information of the potential purchase.

*The user shares the informational risk with the management.* There are significant juridical precedents that suggest that the management is responsible for providing effective information to the users. If the users rely on incorrect financial statements and, as a consequence, they record financial loss, they have the possibility to sue the management of that enterprise. One of the difficulties of sharing the informational risk with the management consists in the possibility that the users may not recover their losses. If a company is unable to reimburse a loan on grounds of bankruptcy, there is a small chance that the management should dispose of sufficient funds to compensate the information users.

*Providing audited financial statements.* The most frequent way for the users to receive accurate information is conducting an independent audit. Subsequently, the audited information is used in the decision-making process, starting from the premise that the information is reasonably complete, exact and unbiased.

The management usually hires an auditor who will reassure the users that the financial statements are accurate. If the financial statements are eventually proved to be wrong, the auditor can be sued by the users of the information as well as by the management of the enterprise that hired him in the first place. Without a doubt, the auditors have a significant juridical responsibility concerning their line of work.

### **3. Risks of audit**

The control of the objectives, in the case of a financial audit, is planned varying with the *risk factors* and *their relative importance*, which differs for every enterprise. During his activity, the auditor must gain sufficient knowledge of the accounting and internal control systems in order to program the audit activity.

A competent auditor acknowledges the existence of the risks and approaches them in the correct manner. Most of the risks the auditors encounter are very difficult to quantize and require thorough analysis in order to be properly assessed. For example, let's assume that the auditor decides that the branch of the client is going through major technological changes that will affect the audit client as well as the purchaser of his products. This change could have an impact on the moral usage of the client's stocks, on the probability of cashing in the commercial claims and perhaps also on the client's ability to sustain business. An adequate reaction to these risks is of critical importance for conducting high quality auditing.

The risks do not have the same probability of occurring. From this viewpoint one can distinguish potential risks and possible risks.

- Potential risks are those likely to occur if no control is imposed in order to detect and correct the errors that might happen. These risks are common to all the enterprises.
- Possible risks are potential risks the enterprise has no means of reducing.

In an enterprise, the auditor usually encounters the following categories of risk [5, p.61]:

- general risks specific to the enterprise;
- risks related to the nature of the developed operations;
- risks related to the conceiving and functioning of the system.

In an enterprise the auditor encounters general risks specific to the enterprise, risks which are likely to influence all the activities of the enterprise. In order to control the enterprise, the auditor must identify those features that distinguish it from the others. Therefore, the following information must be researched and analyzed:

- the activity of the enterprise and its sector of business, including the existence of special regulations for that sector (supply, sales, finance, price formation, etc.);
- the enterprise structure and organization;
- the general policies of the enterprise: financial, commercial and social;
- the enterprise development prospects;
- the administrative and accounting organization, the existence of a data processing system;
- the accounting policies of the enterprise.

As the auditor is not able to control everything, he must be fully aware of the potential risks that may happen in any patrimonial unit; to

identify them and to focus most of his procedure on them in order to determine whether the errors or the inaccuracies have materialized or not.

**The general risks** can be illustrated as follows: [3, p. 178]

a) *The risks related to the economic situation of the enterprise*, caused by:

- Economic factors like: lack of solvency of certain states, thus reducing the markets of the enterprise;
- Internal factors: the existence of certain economic, juridical and revenue regulation specific to one sector.

The economic situation of the enterprise can generate risks caused by the different reactions of the managers. The reaction of a manager from a profit enterprise differs from that of the manager of an enterprise experiencing difficulties, as they may have scattered and dangerous reactions (ruinous loans, dangerous fiscal operations).

The auditor must be fully aware of the perception managers may have on their situation, in order to anticipate their reactions and to help them assess their real situation. This can be accomplished by direct contact with those managers.

b) *The risks related to the general organization of the enterprise* are caused by:

- The policies chosen by the managers: the financial investment policy can influence the classification of the movable values (sharing or investment securities) that must be correctly recorded in the bookkeeping or development policy of the new products can accelerate the ageing of other products;
- The structure of the enterprise: if it is an enterprise founded with the participation of another enterprise at the setting up of the share capital, it will have certain advantages as opposed to another independent one (easier loans, certain advantages) as well as servitudes (supply and sales under certain required conditions etc.).

c) *The risks related to the management's attitude* concern the position adopted by the management with regard to the quality of information.

A management concerned with the quality of information will permanently aim at the implementation and use of accurate and effective systems. On the other hand, if the management puts too much trust in the qualities of the employees and of the current systems, the problem of the

information system tends to get neglected, a situation which can lead to important errors and irregularities.

***The risks related to the nature of the operations approached*** can be identified by classifying the data being recorded in the ledgers as follows:

- repetitive data – are those that result from the normal activity of the enterprise: sales, purchases, wages, etc; these data are dealt with in a uniform manner, depending on the chosen system;
- punctual data – are complementary to the repetitive data but are more or less regularly emphasized, e.g.: physical stock control, final evaluation, etc. These data carry significant risks if they are not discovered in due time and, therefore, the auditor must get acquainted to the situation in time to organize the necessary examinations;
- exceptional data – resulted from operations or decisions that derive from current activities: reevaluations, merges, restructuring. The enterprise does not have the prerequisite criteria of comparative elements and of experienced staff for such operations, therefore the risk of errors and their recording are of high importance;

The more important is the value (individual or cumulative) of a certain category of operations (repetitive, punctual or exceptional), the more likely are the errors to influence the financial statements.

***The risks related to the conceiving and functioning of the systems***

The auditor must understand the bookkeeping and the internal control system of the entity. This will be of use to the auditor in the planning and programming phase of the commitment (mission) as well as in the phase of collecting and evaluation of the audit samples.

Knowing the organization and functioning manner of the bookkeeping and internal control systems, the auditor applies professional reasoning in order to evaluate the audit risks and to establish the audit procedures necessary to reduce the audit risk to an acceptable level.

In the Audit Standard no. 400 “Risk evaluation and internal control”, it is mentioned that the audit risk stands for the risk the auditor determines for an inadequate audit opinion when the financial statements have significant erroneous information.

The audit risk has three elements: inherent risk, control risk and omission risk. [6]

***Inherent risk*** is “the likelihood that a current balance or a transaction category might contain erroneous information that could be individually significant or when accompanied by erroneous information from another balance or transaction”.

The inherent risk mirrors the vulnerability of the financial statements to the occurrence of errors in the case of lack of internal control. If the

auditor reaches the conclusion that there is a great probability of error, without considering the internal control, then he will conclude that the inherent risk is very likely to occur. Internal control is ignored in determining the inherent risk as it is separately analyzed in the risk model of the audit by control related risk.

The auditor should analyze certain important factors when he estimates the inherent risk as follows: [1, p. 305]:

- the nature of the client's activity;
- factors related to erroneous statements that result from fraudulent financial reports;
- the results of the previous audits;
- whether it is an initial or a repeated engagement;
- the affiliated parts;
- exceptional (unconventional) operations;
- the necessary reasoning for the correct recording of the current balances and operations;
- the vulnerability of the assets to the abduction (circumvention) risk;
- the component of the analyzed population.

The inherent risk for certain accounts is influenced by the nature of the client management activity. For example, the possible existence of morally used (unmarketable) stocks is higher in the case of a producer of electronic goods than in the case of a steel producer. The inherent risk has a high probability of varying from one activity sector to another, especially when it is applied to certain accounts like stocks, client debts, loans and fixed assets. The nature of the clients' activity should have a very low or no impact on accounts like cash means, commercial effects and mortgage loans.

**The control risk** is the risk that an erroneous statement that may appear in the balance of an account or in a category of operations or transactions might not be prevented or detected and corrected in due time by the bookkeeping systems and internal control.

After acquiring the knowledge on the internal control, the auditor conducts an initial evaluation of the control risk. This evaluation states the extent to which the auditor expects the internal control mechanisms to miss the possibility of significant erroneous statements as well as to fail to detect and correct the already existing significant erroneous statements.

The initial evaluation is generally conducted for each audit objective related to the operations and for each type of operations.

The initial evaluation usually starts with the analysis of the control environment. If, in the opinion of the managers, the internal control is of no importance, there is a low possibility that the specific control activities may be accurate. The best solution in this case is to assume that the control risk

specific to all the audit objectives related to operations is of a maximum degree. On the other hand, if the manager has a positive attitude, then the auditor analyses the specific policies and procedures of the secondary elements of the control environment and those belonging to the other four elements of internal control. The control mechanisms of all the five elements are used as grounds for evaluating the risk under its maximum level.

There are two important assessments as to the initial evaluation. First, the auditor is not compelled to conduct the initial evaluation in a formal, detailed manner. In the case of many audits, especially those for small companies, the auditor assumes that the control risk is high, regardless of the real situation. The auditors act as such because they decide that it is more economical to make a thorough audit of the balances in the financial statements than to test the mechanisms of internal control of these balances.

Secondly, even if the auditor thinks the control risk is low, the estimated value of the control risk is limited to the level justified by the gathered evidence.

After conducting the initial evaluation and analyzing if a lower risk is possible, the auditor has the possibility of deciding which of the estimated control risks should be used: either on the already justified level of the initial evaluation or on a lower level. The decision on the level to be used is essentially an economical one, based on a comparison between the costs of testing the relevant control mechanisms and the costs of conducting the substantial tests that will be avoided if the estimated control risk will be diminished.

Different techniques can be used for documentation on the information related to the bookkeeping systems and internal control. The selection of a certain technique is an issue that depends on the professional reasoning of the auditor. The common techniques, used singularly or combined, are represented by narrative descriptions, opinion polls, check lists and diagrams of the information flow. The form and extend of this documentation is influenced by the size and complexity of the entity, as well as by the nature of the bookkeeping and internal control systems of the entity. Generally, the more complex the bookkeeping and internal control systems of the entity and the control procedures of the auditor, the more extended his documentation should be.

Some of the procedures conducted for acquiring the knowledge on the bookkeeping and internal control systems, may not have been specifically planned as control tests but they can provide audit evidence on the efficiency of the development and operation mode of the internal controls relevant for certain assessments and, consequently, function as control tests. For example, in understanding the bookkeeping and internal control systems of the cash

flow, the auditor may have gathered audit evidence about the effectiveness of the bank reconciliation process by investigations and observation.

When the auditor concludes that the procedures conducted in order to understand and bookkeeping and internal control systems also provide audit evidence related to the adequate character of the effective development and operation of the relevant policies and procedures in the case of a private examination of the financial statements, he can use that audit evidence, mentioning that it is sufficient to maintain the control risk evaluation on a higher level.

**The omission risk** is the risk that an essential audit procedure may not detect erroneous information in a current balance or in a category of operations or transactions. The omission risk includes: the risk not associated with the sampling, determined by the quality of the staff conducting the audit and the sampling risk which consists in the possibility of reaching different conclusions based on the samples and not using opinion polls.

The auditor's evaluation of the inherent risks, in addition to the control risks influence the nature, length and extent of the essential procedures that must be conducted. In their turn, these essential procedures influence the level of omitting the risk and consequently, the audit risk level.

An important factor that allows the auditors to assess the importance of the above mentioned risks is the **relative importance** defined as opposed to the value or the nature of an inaccuracy or irregularity encountered in the financial statement which will lead to a biased reasoning of decision of a reasonable person that relies on this information.

By irregularity, one may understand all the actions or omissions that either bend the law or enforced regulations applied to companies; either the accounting principles or procedures; either the statutory provisions; either the decisions of the Annual General Meeting; or the decisions of the Board of Directors.

By inaccuracy one understands the accounting or juridical changes and interpretations of a certain fact, disagreeing with the reality like: calculus errors; recording errors; inaccuracies in the presentation of the annual balance (inaccurate numbers).

When the irregularities or the inaccuracies have been detected by the auditor, he conducts the necessary examinations to assess their nature and importance and to report them to the manager only when these errors relate to the direct object of his mission, when they have a relative, sufficient importance.

The assessment of the relative importance by the auditor is carried out taking into account the significant areas of the audited company:

- ◆ significant systems;
- ◆ significant accounts;

- ◆ significance threshold.

By significant system one understands any system existing in the patrimonial unit that secures the recording and posting of the repetitive information, when their accumulated value is itself significant in relation to the value of the financial statements. [4, p.518]

The significant systems related to the purchases from suppliers, sales to customers, payments to personnel, treasury, production of stocks, are common to all patrimonial units. The identification of the significant systems specific to the patrimonial unit is a very delicate activity of the auditor, as only these systems require his study of the procedures.

The significant accounts [4, p.518] are those accounts whose value or nature makes for an important part of the financial statements, accounts that can hide errors or significant inaccuracies whose relative importance is directly related to the regularity of the bookkeeping, bearing a significant influence on the financial statements.

In practice, the auditor takes into account the following bench-marks in order to determine the significant accounts:

- even if the current production is at a very low level at the end of his mandate, it can represent a significant account to the extent where the values it mediates are high and the operations are complex;
- the provisions, even at a low level, are significant accounts;
- accounts which, by their nature, are risk accounts (regulation accounts or accounts affected by a legislative change);
- accounts which have apparent anomalies as compared to the previous balance or against the functioning of the accounts, are also considered significant accounts.

The significance threshold allows the auditor to assess whether the detected errors or inaccuracies must be straightened or not, being able to decide the right direction.

The elements specific to the significance threshold are the following: [5, p.91]

1. The necessities of the users of annual financial statements

The annual financial statements provide information for different users: shareholders, associates, personnel, creditors, revenue authorities, unions, clients, etc. Varying with the requirements and needs of the users, the auditor will set the significance threshold.

2. The characteristics of the enterprise which can be significant for the significance threshold:

- the business sector – in certain business sectors, the actual result of the exercise is replaced by other indices (for example, in the trade field, the net result is replaced by the gross margin);
  - the size of the enterprise determines the maximum and minimum parameters of the significance threshold;
  - the evolution of the enterprise in time;
  - the social-economic environment in which the enterprise conducts business, including legislation, economic circumstances, political situation, competition, social climate, etc;
3. The features of the significant elements are:
- sensitivity – an element is sensitive if a small change in its nature generates major changes in the assessment of the annual accounts;
  - the approximation degree – an error is more significant if it refers to a job that requires precision and accuracy;
  - the evolution of the element – it can reflect a tendency of increase or decrease of the element for dishonest reasons;
  - the sum of several elements – the sum of several insignificant elements may lead to a significant result.

The auditor must consider the possibility of the erroneous information of low values which may have a significant effect on the financial statements if accumulated. “An error detected in the monthly closing procedure may be a clue for a potential significant erroneous statement, if the error is repeated every month”. [6, p. 92]. Erroneous information must be considered from quantitative and qualitative viewpoint.

In order to emphasize the consequences of the significance threshold, at the end of his mandate, the auditor makes up a list of his findings. If the management of the enterprise accepts the corrections of the auditor, then, he grants the certificate without reservations. If the auditor must specify the nature of his reservations (the annual postings he is referring to), how these postings must be corrected and what the influence of correcting these balance postings is, then he will have reserves in granting the certificate.

The common definition of the significance threshold, as applied in accounting and in the area of expertise of the audit, is:

“An erroneous presentation in the financial statements can be considered as significant if the information on the existence of this erroneous presentation could influence the decision of a reasonable user of the situations concerned.” [1, p.63]

In the practical use of this definition, three significance levels are used to determine the type of opinion expressed.

When there is an erroneous presentation in the financial statements, but this presentation is not likely to influence the decision of a reasonable user, it is considered as insignificant. In this case, an opinion without reservations must be expressed.

The second significance level or threshold exists when an erroneous piece of information in the financial statements could influence the decision of a certain user but the situations as a whole provide a correct image and are, therefore useful. For example, being aware of the existence of erroneous information in the presentation of the fixed assets could affect the decision of a user when he lends money to the company, only if those assets are used as collateral for this loan. An error in the presentation of stocks does not imply that the cash means, the debts – clients and other elements of the financial statements, or even the financial statements as a whole, are inaccurate in a significant percent.

In order to make decisions on the relative importance in the occurrence of one of the conditions that require a deviation from the report without reservations, the auditor must evaluate all the effects on the financial statements. Let us assume that, while making the decision on the adequate type of opinion, an auditor is not in the position of reaching a satisfying conclusion on the accurate presentation of the stocks. Because of the effects an error in the presentation of stocks may have on other accounts and on the total presented in the financial statements, the auditor must evaluate the relative importance of the accumulated effect of the error on the stocks, on the total circulating assets, on the total working capital, the total assets, on the profit tax, debts related to profit tax, the total of the short-term debts, the cost of the sold items, the profit before taxes and the net profit after taxes.

When the auditor reaches the conclusion that an inaccurate presentation is significant but it does not influence the financial statements as a whole, a reserved opinion must be expressed (including the expression “except for”).

The highest significance level is applied when there is a high probability that the users might make erroneous decisions if based on financial statements as a whole. Returning to the previous example, if the stocks stand for the highest balance in the balance sheet, a considerable error will be so significant that the auditor’s report will have to mention that the financial statements as a whole cannot present an accurate image. When this maximum level of relative importance occurs, the auditor must issue either refusal to express an opinion or an unfavorable opinion, varying with the applicable conditions.

In order to determine whether an omission is very significant, the percentage in which that omission may affect the different elements of the financial statements must be analyzed. This index is called “depth of

repercussions”. An error in the classification of a sum between a monetary means account and a client debt account only affects the two accounts involved and consequently, does not have a deep impact, it does not influence other accounts. On the other hand, not recording a considerable sale is an error of wide repercussions as it affects the sales, the client debts, expenses on the profit tax, the payment profit tax and shared profit which, in their turn will influence the circulating assets, the asset total, short-term debts, total of debts, equity capital, the gross margin and the result of the exploitation.

As the effect of an error spreads, the possibility of expressing an unfavorable and not a reserved opinion also grows. For example, let us assume that the auditor decides that a classification error between the monetary means accounts and client debts accounts should lead to a reserved opinion as the relative importance of this error is high; not recording a sale of similar value could lead to an unfavorable opinion because of the deep and multiple repercussions of such an error.

Regardless of the sums involved, a refusal to express an opinion must be issued if the auditor is convinced that he does not have the independence required by the rules of the Professional Conduct Code. This very severe condition reflects the importance independence has for auditors.

In theory, the influence of the significance threshold on the type of opinion expressed is direct. In practice, making a decision on the real significance threshold in a certain situation is related to a difficult reasoning. There are no simple, clearly defined recommendations that allow the auditors to decide whether an element is significant, insignificant or very significant. . The evaluation of the significance threshold also depends whether a situation involves a breach of the generally accepted accounting principles or a restriction of the audit perimeter.

The decision of a user can be influenced by the type of erroneous presentation of the financial statements. The elements mentioned below could have a different impact than that of the majority of errors on the decision of the user and, therefore, on the opinion of the auditor:

- The transactions are illegal or fraudulent;
- An element could have repercussions in a future exercise, though not significant if only the present exercise is analyzed;
- An element has “psychological” repercussions (for example, if we compare the impact of a reduced profit with that of a small loss or the impact of a monetary means account with that of an overdraft).
- An element could be important in the light of the possible consequences resulted from contract duties (for example, the impact of disregarding a restriction on the indebtedness degree could consist in revoking a significant loan).

## 4. Conclusion

The audit report can be refused when the regularity and accuracy of the annual accounts does not present an accurate, clear and complete image of the patrimony, of the financial situation and of the results but it can also be impossible if the auditor thinks that there are not enough elements provided by the enterprise to establish an opinion.

The setting of the significant elements and of the significance threshold is important but it is done at the request of the auditor, because of the numerous factors that must be considered (the experience of the auditor, his professional experience and judgment) and of their relative importance.

As stated in the Audit Standard no 320, the relationship between the significance threshold and the audit risk is reversely balanced. The higher the significance threshold, the lower the audit risk is and the other way around. This relation is reversely balanced when the auditor determines the nature, length and duration of the audit procedures. If the auditor determines that the acceptable significance threshold is low, then the audit risk is high.

The auditor can draw significant conclusions along his financial activity as well as during the different stages of financial statement preparation: evaluation, presentation or examination. In practice, the most significant findings can make direct or indirect reference to a posting in the balance and/or in an exploitation account or a profit and loss account, or even to a piece of information written in the notes of the annual financial statements.

In certain cases, the consequence is yet undetermined as the auditor does not have the necessary information or perhaps the conclusions he had drawn have an influence on the general situation of the enterprise. These conclusions may be of a juridical nature or may refer to the future of the enterprise. It is the auditor who will decide whether his report should mention the facts that do not hold a direct influence on the financial statements undergoing his examination but facts that will have consequences on future examinations.

## **Abstract**

*This paper is aimed at providing specialists with a practical method of assessing the significance threshold when auditing financial statements, as well as of determining the analyzed sample. The novelty of this study resides in the information-based modeling of the section "Audit approach" of the Current audit file together with the determination of the sample size depending on the risk margin corresponding to each category of patrimonial assets. Thus, we reckon that the subjectivity of financial auditors is significantly reduced. Hence, we shall present to you a brief description of the section F – Audit Approach, and a presentation of the possibility to automatize this section by means of the software FARisk.*

**Keywords:** *audit, significance threshold, information-based modeling, FARisk.*

## **1. Introduction**

The company images provided by the accounting division as information should not be credible except for the case when they are validated socially in two ways: by launching normalizing regulations and downstream, by account ratification achieved by accredited and certified professionals.

The phenomenon of harmonising accounting regulations at an international level makes the credibility of accounting questionable both from the perspective of accounting information production and from the perspective of its quality certification. Things became more serious after the financial scandals of 2001 (Enron, Parmalat etc.) that showed that accounting systems and implicitly accountants' organization systems are far from perfect.

## **2. The concept of financial audit and the role of the accounting profession**

The correct operation of economy relied mostly on the confidence in audited financial statements. From the perspective of the accounting doctrine, the financial audit is the examination performed by a competent and independent professional in order to express a motivated opinion on the way in which the financial reports of a company are drafted and presented according to an identified accounting regulation book [6].

The requirements that some companies should have their financial statements audited by a skilled professional, introduced by European directives on accounting, protects the public interest. The safety provided by information comprised in audited financial statements should make all parties interested in the company business confide in such information and use it. For many users, the financial statements are the only information source. The transparency that results from harmonizing the way in which financial-accounting information is drafted and presented, as it is published by entities of various countries, and the enhancement of the credibility of such information, further to the financial audit made by skilled professionals, is a premise for achieving the Unique Market.

The role of the financial audit consists in that it should apply checking methods that should lead to the formulation of an opinion on the drafting of financial statements under all significant aspects, in conformity with a general framework of financial reporting that may comprise: The Informational Accounting/Financial Reporting Standards (IAS/IFRS),

national accounting regulations, another framework of identified financial reporting.

The objective of the mission of auditing the financial statements is to allow the auditor to express an opinion that should determine if they were presented in accordance with the accounting principles and standards. This opinion should be communicated in a written report.

An important moment in the normalization and the harmonization of auditing practices is marked by the emergence in 1983 of the International Standard of Audit ISA 13 "Audit Report on Annual Accounts" [7]. This standard establishes regulations and provides recommendations regarding the form and the contents of the audit report drafted by an independent auditor on the financial statements of an entity [11].

In the process of planning and performing the audit procedures, and in the process of result evaluation and reporting, the auditor should admit that the uncompliance of an entity with the legislation and the regulations in force may significantly affect financial statements. Nevertheless, it is expected that an audit should detect such uncompliances. Uncompliance detection, irrespective of the significance level, requires the consideration of the implications of any misconduct of management or staff and of the potential effect on some other aspects of the audit process [3].

### **3. Significance Threshold in Audit**

The audit of financial statements should enable the auditor to express an opinion according to which the financial statements were drafted under all *significant aspects* in compliance with an identified framework of financial reporting. The evaluation of what is significant is an aspect pertaining to the use of professional reasoning.

Information is significant if its omission or its erroneous declaration may influence the users' economic decisions, made based on financial statements. The significance threshold depends on the size of the issue or of the error, judged under the specific circumstances of the omission of erroneous declaration.

Hence, the significance threshold is rather a limit than a primary qualitative characteristic that information should have in order to be useful [4].

When drawing up the audit plan, the auditor uses an acceptable level of the significance threshold able to detect, from the quantitative viewpoint, significant deviations on time. However, one must consider both the amount (quantity) of these deviations and their nature (quality). The auditor must

consider the significance threshold both at the global level of financial statements and at the level of the balances of individual accounts, depending on the transaction categories and submitting of accurate information. As regards the assessment by the auditor of the significance threshold, as compared to the specific account balances and transaction categories, these help him decide on certain aspects like those relating to the items that need to be assessed or whether or not to use analytical and evidence-collection procedures. These enable the auditor to choose those audit procedures which, combined, are deemed to reduce the audit risk to an acceptably low level.

There is a reversed relation between the significance threshold and the audit risk level, namely: the higher the significance threshold level, the lower the audit risk and vice versa. In order to be able to draw reasonable conclusions to support the audit opinions, the auditor must collect sufficiently adequate audit evidence. *Audit evidence* is represented by all the information used by the auditor to draw a conclusion that supports the audit opinion and includes all the information in the books that the financial statements were based upon. The books generally include: initial records and their supporting documents, as well as checks and records of electronic fund transfers; invoices; contracts; ledger and inventory register, accounting-related records and other alterations to the financial statements that do not appear in the official books; other records like work documents and spread sheets supporting funds allotment, calculations, reconciliations and information presentations. [5].

The degree of sufficiency is the measure of the amount of audit evidence, while the degree of stability is the measure of the quality of the audit evidence; in other words, their relevance and trustworthiness in providing support for the categories of transactions, account balances, information presentations and corresponding assertions, or for the detection of the deviations from their level.

#### **4. Audit approach - "F" section of the current audit file**

With regards to the audit approach section, according to the Minimal Standards of Audit of Romania harmonized with the International Standards of Audit, we shall have 4 work sub-sections:

1. F0 – Significance threshold;
2. F1 – Checklist of the general inherent risk;
3. F2 – Checklist of the specific inherent risk;
4. F3 – Specific inherent risks and size of samples.

**The significance threshold** represents the level of value from which financial-accounting operations are audited operation by operation, while under this value the statistical sampling is used. Please notice that the level of the significance is determined by the auditor by professional reasoning depending on the degree of knowledge of the latter on the audited company and on the evaluated risk level. Under these circumstances, the determination of the significance threshold gets a subjective and sometimes even risky character.

Practically, the determination of the significance threshold is made starting from the completion and the interpretation of the form F0 – *Significance threshold* of figure 1.

**Figure 1. Determination of the significance threshold – Section F0**

<b>SIGNIFICANCE THRESHOLD</b>								<b>Sect. F0</b>
<b>Client</b>	<b>ABC SA</b>			Drawn up by <b>AT</b>		<i>Initials</i>	<i>Date</i>	<b>15-Jan-05</b>

Ratio	<b>0.50%</b>	1.50%	6	225	165	127.5	111	
<b>The chosen significance threshold is:</b>			<b>2500</b>					
Explanations:								

Section F0 of figure 1 highlights the following aspects:

- it focuses on the financial year 2004 for the company ABC SA;

- three basic ratios are used, total assets, turnover and profit before tax, but depending on the audited company their number may be increased;
- percentage quotas have been used on each category of ratios, to highlight their degree of sensitivity and the indicators of maximal stability.

After the determination of the significance threshold, two types of audit emerge for each category of patrimonial issue, namely:

1. Over the level of the significance threshold, case in which auditors will audit each and every operation;
2. Under the level of the significance threshold, case in which the audit activity is based on **statistical methods/models of risk evaluation and determination of the samples to be audited** per each category of patrimonial issues.

There are two approaches for the risk evaluation and the determination of the sample size per each category of patrimonial issues in order to audit operations under the value of the significance threshold:

1. *The no-risk statistical method of sampling*, case in which the sub-sections F1 are used (Checklist of the general inherent risk) and F2 (Checklist of the specific inherent risk);
2. *The risk-based statistical method of sampling*, case in which are used F1, F2 and F3 (Specific inherent risks and sample size).

We present in tables 1 and 2 sections F1 and F2 necessary for risk evaluation and the determination of the sample size per categories of patrimonial issues in the case of the no-risk statistical method of sampling.

(b.) Do managers tend to engage the company in highly risky businesses?		<b>YES</b>	
(c.) Were there any managers in key positions replaced during the financial year?		<b>NO</b>	
(d.) Are there some requirements concerning the preservation of a certain level of profitability or the accomplishment of certain goals (for instance, meeting some requirements imposed by the creditors)?		<b>YES</b>	
(e.) Has the reported result a personal significance for the managers (for instance, profit-related benefits) ?		<b>NO</b>	
(f.) Is the administrative and managerial control weak?		<b>NO</b>	
(g.) Are there any competitive managerial information systems?		<b>NO</b>	
(h.) Are the managers concretely involved in the daily tasks? (This question is relevant only if there is a risk under item (d) or (e) identified)		<b>NO</b>	
<b>OVERALL ASSESSMENT OF MANAGEMENT RISKS</b>			
		Very low                      Low                      Moderateh                      Hig	
		<b>The risk is LOW</b>	
<b>Explanations</b>			
		<b>YES/NO</b>	
<b>2. Accounting</b>			
(a.) Is the accounting function decentralized?		<b>NO</b>	
(b.) Do the accounting personnel lack the necessary training and skills to perform their assignments?		<b>NO</b>	
(c.) Are there any attitude- or ethics-related issues in the accounting department?		<b>NO</b>	
(d.) Is there a risk of an error resulting from the employees working under pressure?		<b>NO</b>	
<b>OVERALL ASSESSMENT OF ACCOUNTING RISKS</b>			
		Very low                      Low                      Moderateh                      Hig	
		<b>The risk is VERY LOW</b>	
<b>Explanations</b>			
		<b>YES/NO</b>	

<b>3. Operation of the audited company</b>		
(a.) Does the company operate in a highly risky industry?		YES
(b.) Is there any creditor-third party with a significant individual importance?		YES
(c.) Do certain of the members of the Board of Directors who do not held an executive position have a right of action or vote exceeding 25%?		NO
(d.) Is there any prediction of the future sale of the business (or part of it)?		NO
(e.) Has the management of the company been taken over by somebody else in the last 12 months?		YES
(f.) Is the company insolvent?		YES
<b>OVERALL ASSESSMENT OF THE BUSINESS RISKS</b>		
Very low	Low	Hig Moderateh
		<b>The risk is HIGH</b>
<b>Explanations</b>		
		YES/NO
<b>4. Company Audit</b>		
(a.) Is this the first time the company audits this client?		NO
(b.) Did any of the last two years audit reports contain opinions stating significant reserves?		YES
(c.) Would you describe the relations with the client company as being "conflicting" or "deteriorating"?		YES
(d.) Are there any fees- or time-related pressures?		NO
(e.) Is there a significant number of operations which are "difficult to audit"?		YES
<b>OVERALL ASSESSMENT OF AUDIT RISKS</b>		
Very low	Low	Hig Moderateh
		<b>The risk is HIGH</b>
<b>Explanations</b>		

OVERALL ASSESSMENT OF INHERENT RISKS – Synthesis		
Range	Risk	Value
1. Management	LOW	3.5
2. Accounting	VERY LOW	0
3. Business	HIGH	7
4. Audit	HIGH	6.5
<b>Valuation Inherent Risk</b>	<b>LOW</b>	<b>5.8</b> <b>75</b>

**Explanations:** As work modality, the auditor should answer with YES or NO to the questions asked by means of the section F1 - Checklist of the general inherent risk and to appreciate the risk level per each of the 4 levels (management, accounting, business and audit) with one of the qualifying grades *Very low, Low, Medium and High*. Eventually, we take into account a general appreciation that is also the entry into the section F2 – *Checklist of the specific inherent risk* to determine the size of the sample in the case of the application of the no-risk method of sampling.

**Table 2. Checklist of the specific inherent risk  
Sect. F2**

								Initials	Date

Bank accounts and cash office - receipts							50%	48	
Bank accounts – compared with bank statements	YES	YES		YES		YES	70%	48	

							Initials	Date
Client	ABC SA			Drawn up by		AT	15-Jan-05	
Period	1/1/2004	31/12/2004	Checked up by		CR	17-Apr-05		
Creditors					YES	50%	48	
Long-term creditors						50%	43	
Sales						50%	48	
Purchases						50%	48	
Expenses						50%	48	
Wages and benefits						50%	13	
Other audit sections						50%	23	
Trial balance and book entries						50%	12	
Preliminary financial statements and book entries after the end of the financial year	YES					50%	23	

**Explanations:** Questions I1, I2, I3, I4, I5 and I6 should be answered per each category of audited issues. If there is no answer, it means NO and only affirmative answers matter. This is what every questions means:

I1 – System exposed to errors/inadequate system/non-automated manual system;

I2 – Incompetent accountant responsible for this field;

I3 – Complex operations;

I4 – Risk of loss/fund embezzlement/fraud;

I5 – Many professional judgements;

I6 – Unusual operations.

Affirmative answers per each audited issue is taken into account. Depending on the number we get and on the *General inherent risk*, in our case LOW, the *Specific inherent risk* will be evaluated based on table no.3.

**Example:** In the case of *Corporeal fixed assets* we have an affirmative answer (1) and the general inherent risk LOW, which corresponds to a specific inherent risk of 50%.

**Table 3. Table of evaluation of the level of specific inherent risk**

Bumber of specific risks identified	General level or inherent risc (from F1)			
	Very low	Low	Moderate	High
0, 1 or 2 risks	23%	50%	70%	100%
3 or 4 risks	50%	70%	100%	100%
5 or 6 risks	70%	100%	100%	100%

To determine the size of the audited sample, it is necessary to know how many operations are in the Journal for the audited item, which is related to a volume of population of more than 400 or under 400 operations. The value of the specific inherent risk is part of a risk band for a volume of the sample to audit. In our case, the inherent specific risk of 50% leads for a volume of population under 400 operations at a number of 400 operations. As in accounting there are only 23 operations, these will be checked all in all. Similarly, we proceed for the other items.

In the case of the application of the risk-based model of sampling, it is necessary to use the Section F3 – *Specific inherent risks and size of sample*. This form shows how necessary it is to evaluate the *Risk of non-detection non-associated with sampling* (RDNE), based on table 4 and Control Risk (RC), based on table 5.

**Table 4 – RDNE Evaluation**

Analytical examination safety	Values
Non-Existent	100%
Moderate	56%
High	31%

**Table 5 – RC Evaluation**

Control Safety	Values
Significant	13.5%
Moderate	23%
Limited	56%
Non-Existent	100%

Based on the information of tables 2, 4 and 5, the risk band is determined after having performed the product RI\*RDNE\*RC, that in relation to the number of operations per each audited item will lead to the determination of the sample size. In table 5, we present an example of risk band determination and sample size determination by completing the section F3.

**Table 6. Specific inherent risks and sample size Sect. F3**

## 5. Informatization of the activities run in audit approach

At this time, there are various information solutions for auditing financial statements of economic entities. For instance, the best known products are IDEA and ACL for Windows or even for DOS, to which a series of national products are added. Countries like Bulgaria, Italy, Moldova, Romania are not presented as users of such information solutions.

Please find in table 6 a list of users of information solutions in audit at an European level.

**Table 6. Users of audit software**

<b>Country</b>	<b>Soft &amp; OS</b>
Belgium	ACL - Windows 95 / NT
Croatia	EKOFINA - Win 3.1 Effect Dubrounix CBO
Cyprus	IDEA - DOS
Czech Republic	IDEA - Windows
Denmark	Access - Windows NT/2000
Finland	ACL Windows – Windows
Germany	IDEA V1.2 - Windows
Greece	IDEA - Windows
Grenada	IDEA – DOS
Hungary	IDEA, SAS - Windows 98
Iceland	ACL - Windows
Ireland	ACL - Windows
Israel	Excel, Access, IDEA, SPSS, Wizrule - Windows
Malta	IDEA - Windows
Netherlands	IDEA - Windows
Netherlands Antilles	IDEA – Windows
Norway	IDEA/SPSS - Windows
Poland	ACL - Windows
Puerto Rico	IDEA - Windows
Russia	Oracle Discoverer Application Software - Win NT 4.0/Solaris
Slovenia	IDEA - Windows
Spain	Excel – Windows
Sweden	IDEA – Windows
Switzerland	ACL - Windows 2000

U.K.	IDEA - Windows 2000
Ukraine	SQL - Win NT 4.0, 2000

As you can see from the previous table IDEA for Windows and ACL for Windows prevail on the market of such softwares for the audit of financial statements. The prices of such products surpass in the commercial version USD 5 000, which is a problem for the offices of countries in transition. An addition problem is the fact that the interface is in English.

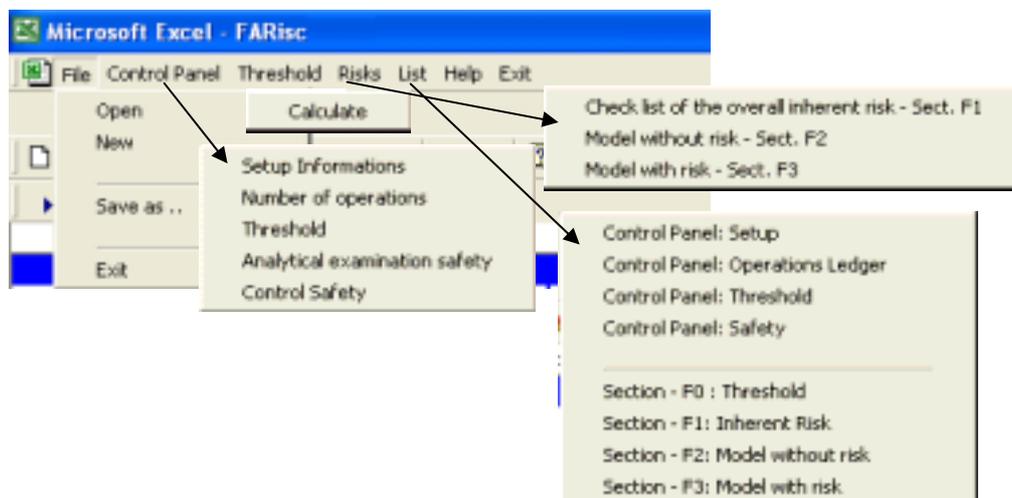

These few reasons made us propose the automated modeling of the activity of financial audit. In this article, we present the module **FARisc** specialised in the section F – Audit approach.

This module is developed under MS Office Excel with VBA support and has a main menu that enables:

1. Files (**Files**);
2. Determination of the work parameters (**Control Panel**);
3. Calculation of the significance threshold (**Threshold**);
4. Determination of risks per various section to audit (**Risks**);
5. Possibility to print audit sheets (F0, F1, F2 and F3) and the data introduced in the control panel (**Lists**).

In figure 2 we are presenting the menu of the application FARisc and the associated options.

**Figure 2. The main menu of the FARisc application**

The advantages of the FARisc are as follows:

1. It is easy to use;
2. It is conceived according to the minimal standards of audit;
3. It may be easily adapted in any language;
4. It is easy to integrate in a general audit application;
5. It is conceived according to the logic of the end user, in our case the financial statement auditor;
6. It makes available for the user the audit sheets under the format demanded by standards;
7. It helps the auditor in risk evaluation by simply using the models;
8. It may be used as work tool by students, accountants and even in the activity of training financial auditors;
9. It is easy to update if the process of international harmonization continues;
10. In the commercial version, its price will be very low.

## **6. Conclusions**

As it is used in specialized offices on a large scale of MS Office Word and Excel for preparing the audit files, the apparition of a module developed in MS Office Excel is an important ace in the activity of covering this market segment.

We consider that the main direction for the close future is the integration of the FARisc module in an integrated product of financial audit and its coupling with administrative and accounting software order to ensure the access to accounting databases and to other databases of the company, for their intelligent exploiting.

We should not disregard the fact that is possible to couple FARisc to intelligernt modules of risk evaluation, in order to eliminate bad practice risks.

e-mail: glaura@uaic.ro

## **Abstract**

*The auditor job is to give his opinion about which of all possible states is the true one. His opinion on the fairness of the financial statements it isn't an absolute guarantee. It is his professional judgment based on the collection and evaluation of sufficient evidence. In this context, to a certain extent, there is a degree of uncertainty in the financial statements auditing. Because of uncertainty it appears the risk that the auditor to give an opinion that does not correspond to the truth. He has to analyze all possibilities and to give the right solution based on his judgment, knowledge and experience. In present in literature there are some models that treat the uncertainty which was adopted for financial statement auditing. One of these models was developed especially for audit, standard model, and it is the most widely used by auditors in their practical work. The rest of them were developed based on mathematical theory and adopted to audit activities. This paper present the most known uncertainty models in financial statement auditing.*

**Keywords:** *audit, uncertainty, financial statement*

## 1. Introduction

Financial audit represents examination activity, for expressing by financial auditors, of an opinion about financial statements according to audit standards, harmonized with international audit standards and adopted by Financial Auditors Organization from Romania. The objective of a financial audit statement is, according to International Audit Standards, the express of an opinion that financial statements were prepared, on all meaningful aspects, in concordance with general identified framework of financial reporting. Therefore the auditor is uncertain about information fairness and truthfulness presented in financial statements and is his task to express his opinion about that. This uncertain determines the existence of a certain risk as auditor's stated opinion not to be the fair one. Within volume and complexity growing of the accountant work, grows the error risk in data processing and implications of these misinform on users are more and more serious. A relevant example in this case represents the negative impact determined in the last years by disorders in producing and supplying of financial information in some banks which lead to a violation of caution principle and influenced the decisions of many legal and individual entities regarding savings assurance deposited in those companies.

Financial audit have to express an independent opinion over financial statements or over other situations and information intended to protect equally all accounting information users, all participants to economic and social life (shareholders, state, employees, banks, clients, suppliers etc). The auditor has to assure information users, by its position, regarding following aspects:

- observance of general accepted accounting principles and of internal procedures settled by company management
- reflection by accounting and by financial statements of trusty, clear and responsible image of patrimony, financial reports and results acquired by company.

Regarding audit objective is obvious that any other mission implies certain risks and their identification is one of the essential's auditor objectives. We have to see that risk evaluation of an entity is denoted by negative impact which may be avoided through protection policy development and by probability which may be avoided through preventive policy development. For precision information check presented in accounting reports is necessary to collect and check data afferent to a small amount of their components which may possible make some situations more credible

then others. In this context audit confront with certain risk mainly connected to impossibility of checking the entire information generated by activity deployment of an organization and the result of audit has a level of uncertainty.

## 2. Uncertainty approaches in financial audit

Considering accountancy of an organization can't be entirely analyzed on the occasion of audit performing we must take into consideration the uncertainty degree which the result implies in terms of a partly control. To frame an image of this we present in the following the models which approach uncertainty: probability theory, upper and lower probability models, belief-function theory and possibility theory and their applicability in financial audit.

### 2.1 Probability Models

From mathematical point of view, probability theory has at its basis probability function. In present are two approaches of it<sup>1</sup>:

- theoretical probability which is computed without experiment effectuation, respectively using only information which is known by physical situation;
- empiric probability determined using an experiment results made by a certain number of times. It is also known as empiric attendance.

Lets be  $\Omega$  a finite number of possible results of an event,  $A$  a finite set of elementary results of event  $A \subseteq \Omega$  and  $\omega$  an elementary event included in  $A$ . Probability  $P$  of  $A$  is given by relation:

$$p: \Omega \rightarrow [0, 1], P(A) = \sum_{\omega \in A} p(\omega) \quad (1)$$

A function  $P$  is a probability function if and only if it has the following properties<sup>2</sup>:

$$a) 0 \leq P(A) \leq 1; \quad (2)$$

$$b) P(\emptyset) = 0; \quad (3)$$

$$c) P(\Omega) = 1; \quad (4)$$

---

<sup>1</sup> Francis, A., Statistica si matematica pentru managementul afacerilor, Editura Tehnica, Bucuresti, 2004, pp. 456

<sup>2</sup> Frank, B., Schulz, W., Tietz, W., Warmuth, E., *Compendiu de matematica*, Editura All Educational, Timisoara, 2001, pp. 235

d)  $P(A \cup A_1) = P(A) + P(A_1)$ , if A and  $A_1$  are incompatible.(5)

In case that events field isn't finite is necessary that:

e)  $P(A_1 \cup A_2 \cup \dots \cup A_n \cup \dots) = P(A_1) + P(A_2) + \dots + P(A_n) + \dots$  if

events  $A_1, A_2, \dots$  are two by two incompatible, respectively if  $A_j \cap A_i = \emptyset$  for  $i \neq j$ . (6)

If  $P(A)=0$  then A is an impossible event and if  $P(A)=1$  then A is a certain event. One of this theory consequence is that  $P(A)+P(\bar{A})=1$ , where  $\bar{A}$  is complement of A referring to  $\Omega$  multitude.

Usage of this probability theory was expanded in audit too, especially in literature. From this perspective there are two approaches: audit risk approach (risk models) and audit modeling approach (decision models). The main difference between these two approaches is their purpose. While risk models are oriented to risk modeling in audit and understanding their components for maintaining it at an acceptable level, decision model is used as one of numerous factors regarding decision adopting more orienting itself to audit activity usage maximization.

### 2.1.1 Risk models

In present there are two models for audit risk approach: Audit Risk Model and Bayesian Risk Model.

#### A. Audit Risk Model

This model was proposed by Audit International Standards and starts from the following formula for audit risk evaluation:

$$AR = IR \times CR \times DR \quad (7)$$

defined according to Audit International Standards by<sup>3</sup>:

- AR – audit risk, respective the risk that auditor to express a wrong audit opinion when there are significant errors in financial reports;
- IR – inherent risk is defined as „the susceptibility of an account balance or class of transactions to misstatement that could be material...assuming that there are no related internal control”;
- CR – control risk is „the risk that misstatements that could occur in an account balance or class of transactions and that could be material...will not prevented or detected on a timely basis by the system of internal control”;

---

<sup>3</sup> *International Standard on Auditing*, <http://www.cafr.ro> [Accessed 12.06.2005]

- DR – detection risk is defined as „the risk that auditors’ substantive procedures will not detect a misstatement that exists in an account balance or class of transactions that could be material...”

This audit risk evaluation model is very simple and intuitive and because is translated as probability is essential to specify that cumulative probability to exist and to get away of control tests and audit is equal with product of marginal probabilities of equation components.<sup>4</sup>

From this equality we get that inherent risk, control risk and undetecting risk are independent which doesn’t correspond with practical reality. This risk evaluation model is mainly used in audit work planning for undetecting risk determination as proportion between the others three components of the equation. Generally, audit risk is considered a constant, respectively 5% and control and inherent risk are often evaluated by auditor on the basis of non-statistical evidences through organization activity analysis, of their relationship with the outside, of accountancy etc. Independent audit risk components treatment is also the most important criticism brought to this model because it don’t exist a rigorous determination between control risk de control and inherent one, those two categories influencing one each other. Some researches have commented other deficiencies of the audit risk model as: it provides an oversimplification of the tasks (Cushing and Loebbecke), it focuses in the likelihood that audit tests will fail to detect material error when it is preset, but does not consider the risk of incorrect rejection (Kinney). With all that, this proposed model by international standards is the most practically used.

### **B. Bayesian risk model**

Bayesian risk model was introduces in literature starting with 1980 by Canadian Institute of Chartered Accountants’ and can be interpreted as a Bayesian version of audit risk model. After that all known models as „Bayesian” in audit dedicated specialty literature are based on Bayes theorem. It handles probability „inverted” provisory probabilities. Is known that provisory probabilities are defined as:  $P(A|B)$  = probability of production of event A if event B is already produced. Bayes theorem treats „inverted” problem: finding probability of production of event A (early) if it will produce (ulterior) event B. Generally formulation is<sup>5</sup>:

H = hypothesis („proposition”, assertion);

---

<sup>4</sup> CARINE VAN DEN ACKER, *Belief-function Theory and its Application to the Modeling of Uncertainty in Financial Statement Auditing*, Katholike Universiteit Leuven, 1996, pp. 71

<sup>5</sup> DINU, O., MIRODOTESCU, B., *Teoria Bayes, Probabilități subiective*, <http://www.upg-ploiesti.ro/sescom/pdf/s07/s07-117-od2.pdf>, [Accessed 15.06.2005]

E = event/evidence;

$$P(H_i | E) = \frac{P(E \cap H_i)}{\sum_j E \cap E_j} = \frac{P(E | H_i) \times P(H_i)}{\sum_j P(E | H_i) \times P(H_i)} = \frac{P(E | H_i) \times P(H_i)}{P(E)} \quad (8)$$

where:

a)  $P(H|E)$  is a subjective probability interpreted as trust degree in H hypothesis, if event E was produced, applicable to systems which contain non-recurring processes.

b)  $P(H|E)=1$  if H hypothesis is true;

c)  $P(H|E)=0$  if H hypothesis is false.

Carine van den Acker proposes the following formulas for Bayes theorem application to define the audit risk and the posterior probability of „error free” by<sup>6</sup>:

$$P(E | A) = \frac{P(A | E) \times P(E)}{P(A)} \quad (9)$$

with:

$P(E)$  - the prior probability of errors;

$P(A|E)$  - the likelihood of accepting financial statements on the basis of evidence, given that they contain errors (this is the risk of incorrect acceptance);

$P(A)$  – the marginal probability of the evidence that implies acceptance;

$P(E|A)$  – the posterior probability of errors, given that financial statements are accepted on the basis of the evidence (the user’s risk of unjustified reliance on accepted financial statements).

$$P(\bar{E} | R) = \frac{P(R | \bar{E}) \times P(\bar{E})}{P(R)} \quad (10)$$

with:

$P(\bar{E})$  - the prior probability of „errors free” financial statements;

---

<sup>6</sup> CARINE VAN DEN ACKER, Read Works, pp. 73

$P(R|\bar{E})$  - the likelihood the rejecting the financial statements on the basis of evidence, given that they are error-free (this is the risk of incorrect rejection);

$P(R)$  – the marginal probability of the evidence that implies rejection;

$P(\bar{E}|R)$  - the posterior probability of errors, given that financial statements are rejected on the basis of the evidence (the user's risk of unjustified neglecting of rejected financial statements).

### 2.1.2 Decision models

Unlike audit risk models which show only how to obtain acceptable level of risk without specifying which is that, decision models get in consideration decisions theory insisting on utility maximizing regarding benefits and loses generated by taking economic decisions in uncertainty conditions. Because of these reason are taking in consideration, in audit risk evaluation, audit procedures cost and efficiency and possible loses happen because wrong decisions. In this models category for audit risk evaluation are included: Bayesian decision models and game theoretic models. In the following is presented only the first model.

Bayesian Decision Models use Bayes theorem for audit risk determining using as parameters economic factors. This was surveyed by many researchers as Kinney (1975), Gwilliam (1987), Steele (1984, 1992). According to this approach trust degree in audit opinion regarding financial statements is determined through trust degree analysis in every elementary component of them and is represented through subjective probabilities.

Those model characteristics may be synthesized hereby:

- financial statements are decomposed in elementary components and is analyzed the credibility of every element. The credibility of financial statements in the whole is determined on the basis of results obtained from the analysis of each elementary component;
- financial statements credibility is continuous updated through new evidences collecting and analyzing for reducing audit risk at an acceptable degree.

For obtaining a specified degree of trust are permanently comparing the relationship between collecting imposed costs of more samples for risk and loses reduction generated in case of wrong opinion. The most important disadvantage of this model usage first comes from difficulty of costs and loses representation through mathematical formulas.

## 2.2 Belief-function Models

Belief-function formalism isn't new. It was tackled along the time by Shafer (1976), Gabbay & Smets (1998), Shafer & Srivastava (1990), Smets (1998, 1990) etc. and it bases on probability theory as Bayesian formalism.

Lets be  $\Theta$  a finite number of results  $\theta$ . Trust degree Bel in a cognitive state A is determined by:

$$Bel(A) = \sum_{b \subseteq A} m(B) \quad (11)$$

A function Bel:  $2^\theta \rightarrow [0, 1]$  is a belief-function, if and only if are accomplished the following conditions<sup>7</sup>:

a)  $Bel(\emptyset) = 0$ ;

b)  $Bel(\Theta) = 1$ ;

(12)

$$\forall A_1, A_2, \dots, A_n \subseteq \Theta$$

c)  $Bel(A_1 \cup A_2 \cup \dots \cup A_n) \geq \sum_i Bel(A_i) - \sum_{i < j} Bel(A_i \cap A_j) + \dots + (-1)^{n-1} Bel(A_{n-1} \cap A_n)$

One of the consequences of these axiom is  $Bel(A) + Bel(\bar{A}) \leq 1$ .

As we see in probability theory formula and in Belief-function theory formula the last one is a generalization form of the first one.

The idea of belief functions was introduced by Dempster in 1967 and implies three connected representations for certainty representation: the basic probability assignment function (bpa or m), the belief function (Bel) and the plausibility function (Pl).

The basic probability assignment is a primitive form of evidence theory. It is also known as m-function, its values m-values and takes values between 0 and 1. Bpa's value for a set of (m(A)) expresses the proportion of all relevant and available evidence that supports the claim that a particular element of X (the universal set) belong to the set A but to no particular subset of A and may be represented as<sup>8</sup>:

<sup>7</sup> CARINE VAN DEN ACKER, Read Works, pp. 2

<sup>8</sup> Sentz, K., *Combination of Evidence in Dempster-Shafer Theory*,

www.sandia.gov/epistemic/Reports/SAND2002-0835.pdf, [Accessed 20.06.2005]

$$\begin{aligned}
& \text{a) } m : P(X) \rightarrow [0,1]; \\
& \text{b) } m(\emptyset) = 0; \\
& \text{c) } \sum_{A \subseteq P(X)} m(A) = 1;
\end{aligned}
\tag{13}$$

where  $P(X)$  is the power set of  $X$ ,  $\emptyset$  is the null set and  $A$  is a set in the power set.

Belief on a set of elements represents the sum of all basic masses ( $B$ ) included in  $A$ :

$$Bel(A) = \sum_{B|B \subseteq A} m(B),
\tag{14}$$

and the plausibility is the sum of all the basic probability assignments of the sets that intersect the set of interest:

$$Pl(A) = \sum_{B|B \cap A \neq \emptyset} m(B).
\tag{15}$$

From these two formulas we obtain the following relation:  $Pl(A) = 1 - Bel(\sim A)$ .

Belief-function models may be used for uncertainty representation resulted from partial ignorance and randomness analysis. The most important studies in this area were realized by Srivastava and Shafer who, on the basis of realized studies made each other a function for risk evaluation at financial statements level, every account level and every audit objective level.

It's argued hereby the usage of belief function in audit achievement<sup>9</sup>:

1. belief function represent ignorance as a separate explicit component of the evaluation, rather than describing it indirectly by assigning some ignorance to each of the possible outcomes;
2. belief function can represent support for an audit objective or account without showing any support against the audit objective or account.

The usage advantages of this model for risk evaluation and representation in audit can be synthesized hereby:

---

<sup>9</sup> Harrison, K., Srivastava, R.P., Plumlee, R.D., *Auditors' Evaluations of Uncertain Audit Evidence: Belief Functions versus Probabilities*, in *Belief Functions in Business Decisions*, Physica-Verlag Heidelberg, New York, 2002, pp. 181

- audit risk evaluation is based on plausibility model and an interpretation of its components with belief function makes it more intuitive;
- components representation with assertive, negative and composite values is more favorable;
- representation on different levels of certainty for information which derive from the same source, respectively data from financial statements and are dedicated to different audit objectives is more suitable. For example, it can make distinction between an objective existence and its evaluation.

### **2.3 Possibility theory**

Possibility theory was first introduced by Professor Lotfi Zadeh in 1978 as an extension of his theory regarding fuzzy sets and fuzzy logic. It's a mathematical theory which works with uncertainty types and represents an alternative to probability theory.

A function  $\Pi$  is a possibility function if and only if is achieved the following condition:

$$\forall A, B \subseteq \Theta : \Pi(A \cup B) = \max(\Pi A, \Pi B) \quad (16)$$

where:

- a)  $\Theta$  is a finite set of possibilities;
- b) A, B are set of elements included in  $\Theta$ .

In case of considering  $\theta$  a set of events and  $p(\theta)$  possibility that  $\theta$  to belong to  $\Theta$  then  $p(\theta) = 0$  means that  $\theta$  is impossible and  $p(\theta)$  means that  $\theta$  is certain. If  $p(\theta') > p(\theta)$  then event  $\theta'$  have bigger chances to be achieved then event  $\theta$ .

Dubois and Prade drew a consequence of possibility axiom according whom:  $\Pi(A) + \Pi(\bar{A}) > 1$ . Starting from those data certainty degree of an event ( $C(A)$ ) is  $1 - \Pi(\bar{A})$  and is given by the relation:

$$\forall A, B \subseteq \Theta : C(A \cup B) = \min(C(A), C(B)) \quad (17)$$

The most important difference between possibility theory, probability theory and belief-function is that first one is ordinal and the other two are numerical.

The most important usage of possibility theory is connected to fuzzy sets, the advantage coming from possibility of using insufficient knowledge, these one being the main motivation for using it in audit risk evaluation. The

disadvantage in this case is that this theory can't be used for randomness representation.

### 2.4 Upper and Lower Probability Models

Upper and Lower Probability is similar with probability theory by difference that some probabilities may be unknown. Let  $\Pi$  be the set of all probability distributions compatible with the available information. Upper and Lower Probability can be interpreted as being the bigger and the smaller frequency which a result A can be obtained with if there are more identical experiments:

$$P: 2^\Omega \rightarrow [0,1], P_{\min}(A) \leq P(A) \leq P_{\max}(A), \forall P \in \Pi, \forall A \subseteq \Omega \quad (18)$$

where  $P_{\min}(A)$  is the minimum number of experiments with result A and  $P_{\max}(A)$  is the maximum number of experiments with result A. In case that A obtaining is conditioned by a certain event B Smets<sup>10</sup> proposed in 1994 the following function based on Bayes theory: let  $\Pi_B$  be the resulting set of conditional probability function:

$$\Pi_B = \{P_B : \forall A \subseteq \Omega P_B(A) = (A|B) = \frac{P(A \cap B)}{P(B)}, P \in \Pi\} \quad (19)$$

And the upper and lower conditional probabilities functions proposed by Smets are the upper and lower limits of these conditional probabilities:

$$P_{\min}(A|B) = \frac{P_{\min}(A \cap B)}{P_{\min}(A \cap B) + P_{\max}(\overline{A \cap B})} \quad (20)$$

$$P_{\max}(A|B) = \frac{P_{\max}(A \cap B)}{P_{\max}(A \cap B) + P_{\min}(\overline{A \cap B})} \quad (21)$$

The main reason which may befriend usage of Upper and Lower Probability Models in audit risk evaluation is the possibility of working with unknown probabilities.

### 3. Conclusion

Evaluation models of uncertainty in financial audit former presented have their peculiarities, have advantages and disadvantages.

---

<sup>10</sup> SMETS, P., *The transferable Belief Model and other Interpretations of Dempster-Shafer's Model*, Université Libre de Bruxelles, [http://www.mat.univie.ac.at/~andrzej/papers/TBM\\_and\\_DST.pdf](http://www.mat.univie.ac.at/~andrzej/papers/TBM_and_DST.pdf), [Accessed 16.05.2005]

Audit risk model presents audit risk as product of inherent risk, control risk and detection risk. It doesn't take into consideration the connection and dependence between these three specified components. Its usage is mainly recommended in audit planning stage for determining sample size of financial information to whose audit activities will be applied to. This model is simple and intuitive but doesn't offer a real value of audit risk, even is preferred by these domain practitioners.

Decision model, proposed by Steele, evaluates audit risk on the basis of elementary components of financial statements. This is a "real" Bayesian model. The main disadvantage of this model is that it doesn't offer the possibility of verifying the completeness of audit risk activity. An important characteristic of this model is the inclusion of audit costs as a component of audit risk evaluation process.

Belief-function model presented by Srivastava proposes evidence representation and risk aggregation. It decomposes the question of fairness of the financial statements in subquestions related to the fairness of each account and further and achievement of objectives and the fairness of transaction. Variables used in this model have two possible values "fair" and "not fair". It's based on "and" relationship. In this context financial statements are fairness if and only if all their components are fair and an account is fair if and only if all its objectives are accomplished. "And" relationship usage between audit risk components makes them less flexible and financial statements decomposition grows very much the process complexity.

All approach models of uncertainty in audit have advantages and disadvantages like I said and I presented before. In practice, the most used is audit risk model because its simplicity, being also the model proposed by Audit International Standards.

The other models based on probability theory, belief-function etc. are more complex and may reflect better the risks situation the auditor may confront with, being preferred by researchers. Another advantage of the last ones is facilitation of process informatization of audit risk evaluation.

## **Abstract**

*We test whether security prices react to an independent, unanticipated and simultaneous change in Moody's bond rating procedure. Moody's eliminated its sovereign ceiling rule on June 7, 2001 allowing a company rating to exceed that of its home country. It placed the long-term foreign currency bonds of 38 companies from 13 different emerging markets, mostly Latin American, on review for an upgrade. We find that the yield spreads of the affected companies fell in a cross-section comparison with control companies on June 8, 2001. However this effect is no longer significant when allowing for a time dimension and not just a limited cross-section comparison on the event date. There is no evidence that companies that a priori would be expected to be more constrained by the sovereign ceiling, react more strongly to the announcement. Finally, there is no stock price reaction, even in a cross-section comparison on the event date.*

**Keywords:** *bond ratings; sovereign ceiling; emerging markets*

## 1. Introduction

The purpose of this paper is to investigate whether security prices react to an independent change in the bond rating procedure. This can be on account of one of two factors. First, ratings may contain pricing-relevant information that investors cannot or find too costly to obtain on their own. Second, some investors (such as institutional investors) may be constrained by statutory requirements. So the removal of the sovereign ceiling may serve to increase the potential pool of investors and in the process affect the market price. The literature on credit ratings (and in particular, that on sovereign credit ratings) has been plagued by the difficulty in accurately testing for rating value and causality. The main problem is the presence of joint endogeneity, whereby ratings are rarely changed independent of market or firm news and events. Therefore it is difficult to ascertain whether a company's (or a sovereign's) bond price reacts because of a rating change or whether a rating change coincides with a fundamental (or at least a market-perceived) change in borrowers' risks. In that case, it would be wrong to attribute the bond price reaction to the rating change when in fact it may be on account of the triggering economic event.

Moody's unanticipated announcement on June 7, 2001 provides an ideal natural experiment to test for the independent information effect of rating changes. On that date, Moody's issued a press release in which it stated that it would no longer apply the sovereign ceiling and it would therefore allow a company rating to exceed that of its home country. Thereby it effectively did away with the premise that companies are always riskier than their governments. It concurrently placed the long-term foreign currency bonds of 38 companies from 13 different emerging markets on review for an upgrade. Prior to that date, Moody's did not issue a rating for a company above that of its home country rating<sup>2</sup>. The companies were mostly in the petroleum, telecommunications, and banking sectors. Of the 38 companies, 28 (or 74%) were Latin American and 29 were in banking & finance. Descriptive statistics on the affected companies are presented in Table 1.

This change in Moody's rating policy was not accompanied by any fundamental change in borrowers' risk nor in general emerging market risk,

---

<sup>2</sup> With the possible exception of a corporate in Panama. In the future, we intend to include in our study the April 1997 decision by Standard & Poor's to upgrade the debt of fourteen Argentinian firms to a rating higher than Argentina's sovereign debt. However it was not interpreted as a wide-spread and permanent change in procedure, especially as it was limited to Argentina.

was not preceded by any announcement<sup>3</sup>, and was carried out simultaneously for all 38 bonds. Therefore to the extent that the sovereign ceiling matters in constraining companies' external financing, we would expect there to be a significant economic effect on the security prices of the affected companies in reaction to the rating policy change.

Rating agencies do not reveal their rating methodology and ratings remain non-transparent. It is extremely rare to find a publicly announced change in procedure or to even instrument for it with a change in a rating committee's members. First, this data is confidential. Second (and directly concerning sovereigns), there has been no material change in sovereign rating procedures in the last 15 years and even since the early 1970s, according to a knowledgeable ratings industry insider. Third, there is a lot of persistence in sovereign rating committee composition and small changes occur continuously but this is also not available.

There is only one paper that we are aware of that has investigated a change in rating procedures. Kliger and Sarig (2000) assessed the information value provided by Moody's refinement of issued ratings on April 26, 1982. They emphasize that the rating changes on that date exclusively reflected rating information. Furthermore, they cite Moody's statements confirming that the change to fine ratings was based on the same information that was behind its previous ratings. Prior to that date, Moody's assigned one of ten "coarse" rating classes to issuers' bonds (such as Baa, Ba and so on). On April 26, 1982, Moody's added rating modifiers ranging from 1 to 3, where a "1" was for the best subrating and "3" for the worst subrating. Using cross-section data on 812 bonds and 386 stocks, they find that debt value increases and equity value falls when Moody's announces better than expected ratings, although firm value is not affected. Therefore they favor an asset-substitution explanation, whereby wealth is transferred from shareholders (the residual claimants) to bondholders when there is "good" bond rating news. More importantly, they therefore conclude that the bond rating information has value to investors.

---

<sup>3</sup> Moody's press release was widely cited and news of it appeared in both The Financial Times and The Wall Street Journal (among others) on June 8, 2001. We carried out a search for Moody's announcement using Lexis-Nexis and all articles mentioned that it was a surprising event and there are no reports prior to June 8, 2001.

*a Source of bond and stock data was Datastream and supplemented with Bloomberg and Reuters*

*b Historical rating data was obtained from Moody's website (<http://www.moody.com>)*

*Note: a rating of Ba1 or below indicates a sub-investment (speculative) grade rating.*

*c Leverage is defined as the ratio of total debt (liabilities) to total assets. The main data source for accounting data was ISI Emerging Markets Database and it was supplemented with Factiva*

We study the reaction of both bond and stock prices to Moody's independent, unanticipated and widespread elimination of the sovereign ceiling rule. We take advantage of the time series and cross-sectional variation in security prices. We find that the yield spreads of the affected companies fell in a cross-section comparison with control companies on June 8, 2001 (as to be expected if ratings have value). However this effect is no longer significant when allowing for a time dimension and not just a cross-section comparison with a limited number of control bonds on the event date. Furthermore, it does not appear that companies that we would a priori expect to be more constrained by the sovereign ceiling, react more strongly to the announcement. Finally, there is no stock price reaction, even in a cross-section comparison on the event date.

That we find little or no security price reaction to Moody's elimination of the sovereign ceiling is a significant result in its own right. The sovereign ceiling rule is important to the extent that rating agencies provide information value in pricing emerging market debt. If the independent elimination of the ceiling rule did not contribute new information, then the rule itself may not have been important. The previous literature has conjectured that rating announcements may have a considerable market effect because many institutional investors are constrained to holding investment-grade instruments (see for example, Kaminsky and Schmukler (2002)). This effect would imply that there should be a significant bond price reaction to Moody's announcement on account of the increase in the potential pool of investors. Previous literature assessing the impact of rating changes on security prices in emerging markets includes Richards and Deddouche (1999). However their study looks at bank rating changes that may have been triggered by bank or market events. Nonetheless, it is interesting that they find that stock prices do not react (for the most part) to the rating change.

A relevant study by Durbin and Ng (1999) find that market participants do not strictly apply the sovereign ceiling. To illustrate their point, they show evidence for several companies with a significantly lower spread than their home country. One of the companies is Telefonica de Argentina, which later was among the 38 companies affected by Moody's announcement. In a comparison of yield spreads on 116 emerging market corporate bonds with those on their home country bonds, they find that a 100 basis-point increase in the spread of the sovereign bond is associated with only a 40 basis-point increase in the spread of the corporate bond and conclude that transfer risk is not 100%. It is interesting that they do not find an increase in the country risk effect on corporate risk during and after the Asian crisis.

## 2. Change in Rating Practice and the Sovereign Ceiling

On Thursday June 7, 2001, Moody's placed the long-term foreign currency bonds of 38 issuers on review for upgrade; effectively eliminating the sovereign ceiling. Moody's issued a press release explaining the factors behind this explicit change in their long-standing policy to reflect "a new reality". Moody's noted that the recent evidence from country defaults ranging from Russia to Ecuador indicated that the foreign currency transfer risk from sovereign to resident companies had declined (for example when the home government can tax firms by imposing foreign exchange controls or by appropriating assets). This contrasts with the across-the-board moratoria placed by countries (such as Mexico and Argentina) during their defaults during the 1970s and 1980s. Further, Moody's cited that the role of the private sector has increased considerably in emerging economies and a private sector default would have significantly more negative consequences on the domestic economy<sup>4</sup>.

These reasons led Moody's to reconsider their sovereign ceiling rule. They listed three main factors that would allow a company rating to exceed that of its sovereign. First is the creditworthiness of the individual borrower. Second is the probability that there would not be a generalized moratorium in the event of a government default. Third are case-by-case circumstances of the borrower in terms of ease of access to foreign exchange. Moody's noted that it would continue to examine other borrowers in the context of its policy change<sup>5</sup>.

The Moody's announcement took the press and market participants by surprise<sup>6</sup>, which is an important precondition for our study. Moody's had also traditionally been viewed as being more conservative than other rating agencies. The Financial Times noted in its June 8, 2001 article that the

---

<sup>4</sup> Nonetheless, the macroeconomic environment in which the firm operates will be affected by the situation of its home country. To the extent that a firm is more responsive to the domestic business cycle, then it should be more affected by sovereign risk, regardless of its size.

<sup>5</sup> However placement on review for upgrade or upgrades after June 7, 2001 are confounded with the standard problem of joint determination with company and/or market news. Therefore only the affected companies on June 7, 2001 can be suitably used to test for the information contribution of the rating procedure change.

<sup>6</sup> In fact, on June 5, 2001, Moody's had confirmed the ratings of 7 Argentinean telecommunications companies (among them Telefonica de Argentina) at B2 with a negative outlook. Furthermore, Vincent Truglia (co-head of Moody's Sovereign Risk Unit) was quoted as saying that "we were not able to talk directly with the individual issuers in light of the sensitivity of the information on the market" (obtained from High Yield Report, June 18 2001).

Moody's announcement may be "controversial because it is so wide-ranging" as it includes purely domestic companies and banks. S&P and Fitch disagreed with Moody's policy relating to banks. On the other hand, Moody's disagreed with S&P's policy of relaxing the sovereign ceiling for dollarized economies. Moody's did not include any Argentinean bank on their review for a possible upgrade<sup>7</sup>.

### 3. Methodology

The central question that we address is whether security prices react to an independent, unanticipated and uncontaminated change in Moody's bond rating procedure. In theory, the paper is in the spirit of an event study. However in practice, we cannot apply standard event study methodology in the presence of perfect clustering on one event date because the covariances between abnormal returns will not necessarily be equal to zero (see Campbell, Lo and MacKinlay (1997) for a good discussion). One way to deal with this problem is to analyze the abnormal returns without aggregating the securities. This is done using a multivariate regression model with dummy variables for the event date among other controls.

We take advantage of the time series and cross-sectional variation in bond and stock prices. The sample of affected companies on June 7, 2001 is arguably small, but from a time series perspective there are many data points available. Therefore the effective sample is quite large. In addition to each bond (or stock) serving as its own control, it is important to control cross-sectionally by including non-affected companies.

We follow the methodology adopted by Kliger and Sarig (2000). They first need to determine a benchmark for the ex ante default risk expectations to assess whether the rating refinement was good, bad or no news for a company. Our study is more simple because the event should have been good news for all the affected companies (for their bonds, more accurately). Therefore while Kliger and Sarig compare the good news relative to the bad news coefficients, it is sufficient for us to compare the affected companies with the controls. They limit their estimation to a cross-section regression of the change in the yield spread using month-end prices of April 1982 compared to March 1982. We begin by estimating the following cross-section on June 8, 2001 using week-end yield spreads. To compute the yield spread for a given bond, we subtract the equal-maturity US Treasury bond yield from the US dollar-denominated company bond<sup>8</sup>. Because it is

---

<sup>7</sup> The Argentinean crisis may have vindicated Moody's opinion.

<sup>8</sup> There are a few cases when the company has issued only bonds in euros, and so we subtract an equal-maturity European government bond. We also intend to adjust for relative duration

uncertain whether the press release was issued during trading hours on June 7, 2001 and to allow for the likely possibility that investors received the news on June 8, we estimate weekly yield spreads as of each Friday (therefore comparing June 8, 2001 to June 1, 2001, etc.)

$$\Delta YS_i = \alpha + \beta I_{Affected} + \gamma X_i + \varepsilon_i, \quad (1)$$

where  $I_{Affected}$  is a dummy for those bonds affected by the announcement when they were placed on review for possible upgrade. We therefore expect  $\beta$  to be negative if Moody's announcement contributed new price-relevant information.  $X$  refers to all other controls. Because of the limited number of affected companies equation 1 can be extended to a panel regression shown below:

$$\Delta YS_{it} = \alpha + \beta(I_{Event,t} \times I_{Affected,i}) + \gamma I_{Event,t} + \delta I_{Affected,i} + \gamma X_{it} + \alpha_i + \varepsilon_{it}, \quad (2)$$

where  $I_{Event}$  takes on the value of 1 on June 7 and June 8, 2001 and 0 otherwise and we again expect  $\beta$  to be negative.

We also study the effect on stock prices using two methods for calculating abnormal returns. The first uses the "mean-adjusted returns" as a benchmark for the expected return. Specifically we calculate the abnormal return of a stock  $i$  as

$$AR1_{it} = R_{it} - R_{i,-[80,10]}, \quad (3)$$

where  $t$  refers to a daily date,  $R_{it} = 100 \times (P_{it} / P_{it-1} - 1)$ , and  $R_{i,-[80,10]}$  is the average return of the stock in the 80 through 10 trading days prior to June 7, 2001<sup>9</sup>. We also calculate the abnormal return using "market-model-adjusted returns":

$$AR2_{it} = R_{it} - (\alpha_i + \beta_i R_{Mj}), \quad (4)$$

where the market model uses the overall domestic stock market index of a company's home country,  $j$ , for the market return. As for the "mean-

---

of the bonds, to account for the coupon structure on the effective maturity of the bond. However, it is worth noting that Durbin and Ng (1999) found no substantially different results when they adjusted for duration.

<sup>9</sup> We follow Kliger and Sarig and use the previous 80 to 10 trading period for the benchmark period. However the results are robust to different estimation periods.

adjusted returns" model, the period of estimation of the market model is over the 80 to 10 trading days prior to the announcement day. We repeat the estimation of equations 1 and 2 but using the abnormal stock return in place of yield spread differences. The coefficient,  $\beta$ , in this case may be of ambiguous sign. If the dominant effect derives from a transfer of wealth from shareholders to bondholders, then abnormal returns for the affected companies should be negative and  $\beta$  should therefore be negative. However, Richards and Deddouche (1999) suggest that the expected reaction of stock prices to positive rating changes should be positive if rating changes reflect improved company operating conditions. Therefore we leave the question to the data to reveal.

### ***3.1 Data***

We first collected daily data on all available long-term foreign currency bond yields and stock prices of the 38 affected companies from Datastream and supplemented with the use of Reuters, Bloomberg, and ISI Emerging Markets. After an exhaustive search, we were only able to obtain data on 23 bonds and 16 stocks. In cases of missing data, we contacted the companies directly through email. Several replied that they are not listed (or were not listed in 2001), which helps to explain the scarcity of stocks. However we should have the full 38 bonds, since the Moody announcement pertained to companies with issued bonds at the time. One explanation is that Datastream and Bloomberg often do not keep data for expired bonds (a point also noted by Durbin and Ng (1999)). A few companies replied<sup>10</sup> that their eurobond was traded very infrequently. Therefore if there is any bias in our sample, it would be towards the more liquid sample. Also to avoid including cases of multiple bonds for one company, we use the most recently issued bond or the most liquid one. All these reasons could imply that we are more likely to find a security price reaction to Moody's announcement. Therefore if we do not find a reaction with our sample, it is also likely to be the case with the full sample. Refer to Table 1 for descriptive statistics on the affected companies.

We also collected historical rating data on each of the bonds from Moody's website and supplemented missing data on expired bonds with the help of a contact at Moody's<sup>11</sup>. Accounting data on the companies in question were collected from the ISI Emerging Markets Database and supplemented with data from Factiva. This data was used to calculate company leverage.

---

<sup>10</sup> For example, Estonia's Hansapank and Lebanon's Byblos Bank.

<sup>11</sup> We acknowledge the help of Mr. Adel Satel at Moody's Cyprus Office.

We collected US Treasury bond yield data and European government bond yield data from Global Financial Database. We also collected country stock price market indices from Global Financial Database. Data on the stripped yield spread of country bonds (JP Morgan's EMBI Global series) was collected from Datastream.

Finally we collected data on control companies that were not placed on review for a possible upgrade on June 7, 2001. Ideally these would be companies chosen from the 13 countries and from the same industries as the affected companies and also rated by Moody's<sup>12</sup>. Although it would be ideal to get data only on similar companies with a Moody's rating, unfortunately there are a number of sectors in various countries where only the affected companies were rated on June 7, 2001 (e.g. the banking sector in Lebanon.)

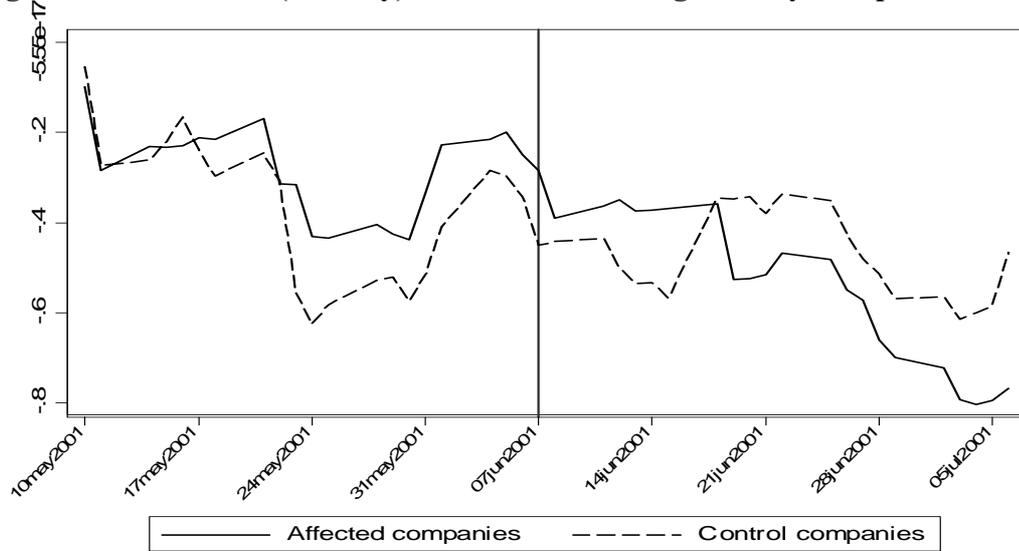

#### **4. Empirical Results**

Before proceeding to the results of the estimations, we present some evidence inspired from the event-study literature. Figure 1 plots the cumulative average difference in yield spread over the -20 to +20 trading day period around the event for the affected and control companies, respectively. This should be interpreted as only illustrative because of perfect clustering. Nonetheless it appears that there was a decline in yield spreads for the affected companies on June 8, 2001. The average yield spread difference on that date was approximately 11 basis points, supporting the anecdotal evidence cited in the press at the time. Formal estimation is necessary to determine if this was an economically significant effect.

---

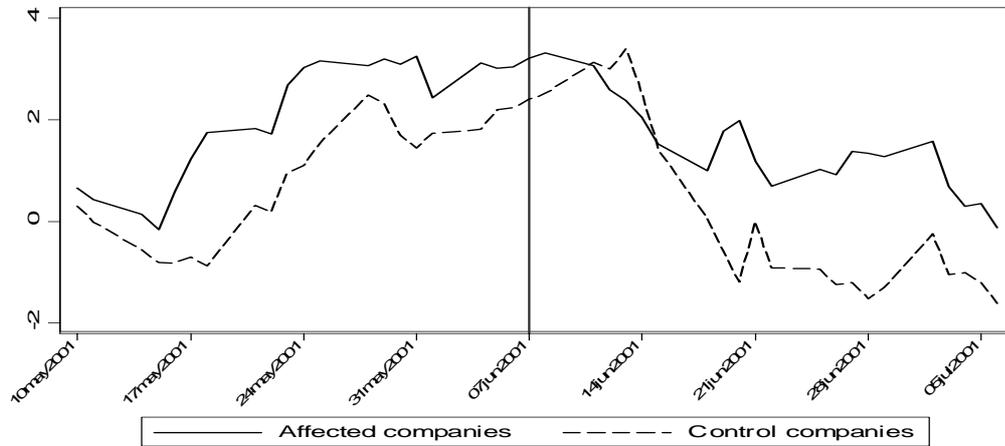

<sup>12</sup> We are currently in the process of improving our control sample, and particularly for bonds. We have so far obtained a maximum sample of 17 control bonds and 31 control stocks.

**Figure 1. Cumulative (one-day) difference in average bond yield spread**

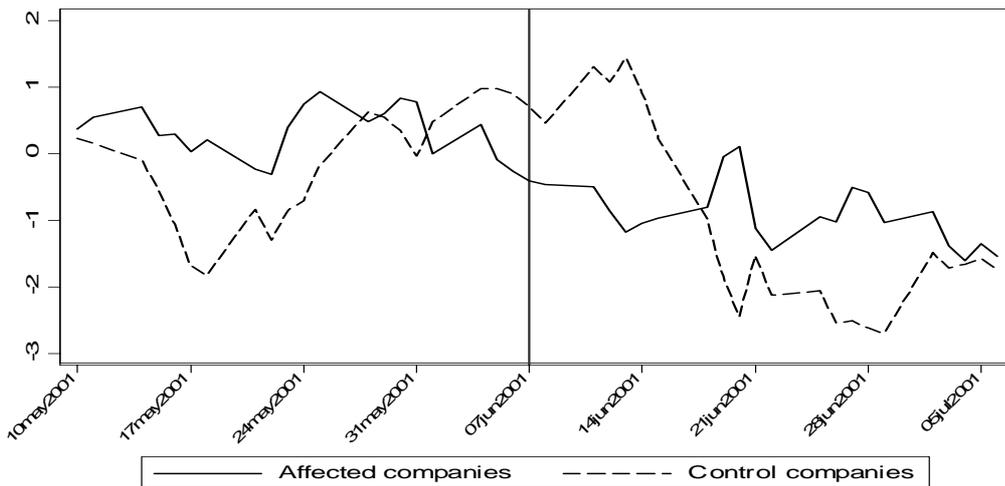

Figures 2 and 3 present the cumulative average abnormal events for stocks using the mean-adjusted and market-model-adjusted abnormal returns. Here the casual evidence is even less clear-cut than for bond spreads. The cumulative average abnormal return appears to be moving with that of the control companies in the immediate window around the event date. That said, Moody's announcement may have been a significant price-relevant event but is simply confounded by other factors that need to be controlled for in the estimations.

**Figure 2. Cumulative abnormal stock market return (using mean-adjusted)**

**Figure 3. Cumulative abnormal stock market return (using market-model adjusted)**

#### 4.1 Bonds

Table 2 presents estimation results for equations 1 and 2, using weekly differences in bond yield spreads as the dependent variable. Column (1) estimates equation 1 on the 31 bonds available on June 8, 2001 and the standard errors are corrected for heteroscedasticity. The estimated  $\beta$ , the

coefficient on the affected dummy is negative and equal to -0.12 (a 12 basis point decline in yield spreads) but is not very statistically significant (only at the 15% level).

When controlling for the company's home country stripped yield spread (using JP Morgan's EMBI Global country index), the estimated  $\beta$  turns more economically significant and is statistically significant at the 10% level (column (2)). Therefore it can be said that Moody's announcement contributed some price-relevant information to the affected companies' bonds<sup>13</sup>.

Columns (5) through (8) present estimation output for equation 2 allowing for the time-series of the 20 trading days prior to the event<sup>14</sup>. The main justification for this is the limited number of affected bonds. Therefore by including each bond's time-series as an additional control, the effective sample becomes quite large. This allows us to test whether Moody's announcement had a significant effect in a time-series dimension and not just in a comparison with a limited number of control bonds on the event date. This is arguably a more relevant comparison because it provides information on the relative importance of the announcement as placed within the context of the previous trading days for a given bond. We include bond fixed effects in all the regressions to account for bond-specific factors. We also cluster the standard errors by bond. Column (5) reports the results of equation 2. The coefficient of interest is the interaction between the event dummy of June 7 and June 8, 2001 with the dummy for those bonds placed on review for an upgrade. The sign continues to be negative, but interestingly, it is no longer significant.

---

<sup>13</sup> The results are slightly more significant when including data for 2 bonds missing on June 8 but using the closest available data and therefore increasing the observations to 33.

<sup>14</sup> The results are robust to allowing for time-series variation around the time of the event from May 10 to July 5, 2001 (+20/-20 trading days).

Column (6) includes sector controls. As shown in Table 1, of the 38 companies affected by the announcement, 29 were in banking & finance, followed by 5 in petroleum, 3 in telecommunications and 1 in beverages. As noted earlier, the immediate press coverage highlighted the controversy over Moody's inclusion of banks in its press release. Suppose that banks were more constrained by the sovereign ceiling than, for example companies in petroleum. This may be because the latter can avoid the sovereign ceiling by

securitizing their future-flow receivables, as discussed by Ketkar and Ratha (2001). Then if Moody's announcement was price-relevant, we would expect banks to have the strongest reaction to the sovereign ceiling elimination. This does not appear to be the case. Included in the regression is the interaction of the event with affected companies and with the sector of the affected company. While all these interactions are negative, none are significant and if anything the strongest effect appears to have been for telecommunications. This may be on account of the fact that banks are more responsive to the business cycle of their home country and also may hold a lot of government bonds. If investors believed that to be important and discounted Moody's opinion on banks, then this would go against finding a strong effect for banks.

Column (7) estimates equation 2 and is similar to column (5) but allows us to test if it matters whether the sovereign ceiling is investment-grade or speculative grade. We therefore include a dummy that indicates that the country ceiling is investment grade as well as the interaction of the event dummy with those companies affected and with whether they are located in an investment grade country. If the sovereign ceiling constrains external financing, then we would expect the bond price reaction of those companies placed on review for an upgrade from speculative-grade countries to be stronger in response to the announcement. In fact, there is no effect. Columns (8) and (9) repeat columns (5) and (7) but allow for an even larger time-series dimension of 3 years around the event date: from June 1998 to June 2004. The coefficient on the interaction between the event and the affected companies continues to be insignificant.

Finally column (3) controls for company leverage. Klinger and Sarig (2000) find that the more leveraged<sup>15</sup> a firm is, the stronger is its bond-price reaction to the new rating information (although they find no significant effect on stock-price reaction). The prior is that bondholders of a high-leveraged company bear more of the firm's risk than bondholders of a low-leveraged company. As a result, the price reaction should be stronger for the bonds of the high-leveraged company if the rating information has value. We find no evidence of this *within* our set of affected companies as we only have collected accounting data on them so far. The coefficient on the constant is

---

<sup>15</sup> where they define leverage as  $[(D^{Book}) / (D^{Book} + E^{Market})]$ , and use the March 31, 1982 total market value of equity for  $E^{Market}$ , and the book value of the debt at the end of the fiscal quarter preceding April 26, 1982. Our sample is more limited and we use book value for both debt and equity for March 31, 2001 if available. If not, we use 12/31/2000. Accounting data are obtained from ISI Emerging Markets and supplemented with information from the Factiva database. We are in the process of extending the sample to the control companies as well. See Table 1 for descriptive statistics.

negative and significant on June 8, 2001 at the 10% level, supporting the results presented in columns (1) and (2). However, within this group of affected companies, those that are more leveraged appear to have had a *weaker* (though only significant at the 20% level) bond price reaction.

Table 3 also reports estimation output for bonds, but using a slightly longer run horizon. The dependent used in Table 2 is the one-week difference in yield spreads. The dependent used in Table 3 is the end-of-

month difference instead. This is the horizon used by Kliger and Sarig (2000) probably because of data constraints. However it is interesting to look at these results as well because they provide insight into whether the Moody announcement had an effect over a slightly longer horizon from end-June 2001 to end-May 2001. It does not appear to have had an effect, even at the cross-sectional level, which was significant when using weekly differences.

#### 4.2 Stocks

Table 4 tests for a stock price reaction of the affected companies to Moody's announcement. As discussed in the methodology section, we use both the (weekly) mean-adjusted abnormal stock return and the (weekly) market-model-adjusted abnormal stock return as dependent variables. There are less stocks available for the affected companies for reasons discussed in the data section. Nonetheless it is worth testing for an effect. In contrast to the case for bonds, there is no stock price reaction. There is a potentially negative but insignificant stock price reaction to the announcement when allowing for the stocks' time-series in columns (4) through (7).

To summarize, bond prices reacted to the independent, unanticipated and uncontaminated change in Moody's bond rating procedure on June 8, 2001 in a comparison with other companies on that date. However this effect is no longer significant when allowing for a time dimension and not just a cross-section comparison against a limited number of control bonds on the event date. Furthermore, it does not appear that companies that we would a priori expect to be more constrained by the sovereign ceiling, react more strongly to the announcement. For example, bond prices for companies from speculative-grade countries do not react more strongly than those from investment-grade countries. In addition, bond prices of affected banks do not react more strongly than those of petroleum and telecommunications companies (which have more easily engaged in structured finance deals and escaped the sovereign ceiling prior to 2001). Leveraged companies do not appear to have a stronger bond price reaction. Finally there is no stock price reaction.

## **5. Conclusions**

Our paper has tested for whether purely independent rating changes contribute price-relevant information to the market. If that prior were true, then we would expect significant security price reaction. The rating change in question is Moody's elimination of the sovereign ceiling rule on June 7, 2001, which was not accompanied by any fundamental change in borrowers' risk nor in general emerging market risk, was fully unanticipated, and was widespread affecting 38 companies in 13 countries. The sovereign ceiling rule is important to the extent that rating agencies contribute value to the pricing of emerging market securities. If the independent elimination of the ceiling rule is found not to contribute new information, then the rule itself may not have been important.

Emerging market bonds have become the main source of emerging market financing. For example, figures from Euromoney's Bondware (and as cited in Durbin and Ng (1999)) show that from 1991 to 1996, the dollar amount of long-term bonds issued in emerging markets jumped from \$12.4 billion to \$93.9 billion. By comparison new equity issues increased from \$5.6 to \$16.4 billion and syndicated loan commitments (the traditional method of financing during the 1980s) increased from \$50.7 to \$79.7 billion.

It is therefore important to distinguish between whether investors perceive company credit risk as "de jure" credit risk and therefore rely on rating agencies or whether they perceive it as a "de facto" company-specific risk and are therefore not sensitive to rating assessments. Ratings may

contribute value on account of possibly two factors. First, ratings may contain pricing-relevant information that investors cannot or find too costly to obtain on their own. Second, some investors (such as institutional investors) may be constrained by statutory requirements. So the removal of the sovereign ceiling may serve to increase the potential pool of investors and in the process affect the market price.

We study the reaction of both bond and stock prices to Moody's elimination of the sovereign ceiling rule. We take advantage of the time series and cross-sectional variation in security prices. We find that the yield spreads of the affected companies fell when compared to control companies in a cross-section on June 8, 2001 (as to be expected if ratings have value). However this effect is no longer significant when allowing for a time dimension and not just a cross-section comparison against a limited number of control bonds on the event date. Furthermore, it does not appear that companies that we would a priori expect to be more constrained by the sovereign ceiling, react more strongly to the announcement. For example, bond prices for companies from speculative-grade countries do not react more strongly than those from investment-grade countries. In addition, bond prices of affected banks do not react more strongly than those of petroleum and telecommunications companies (which have more easily engaged in structured finance deals and escaped the sovereign ceiling prior to 2001). Affected companies that are more leveraged do not appear to have a stronger bond price reaction. Finally, there is no stock price reaction, even in a cross-section comparison on the event date. Although the cross-sectional sample is not large, the effective sample is quite large on account of daily time series for each security. Therefore given that we find no effect most likely means that there is no effect. Our findings are therefore closer to that of a fund manager who is quoted as saying that "I don't care about [the sovereign ceiling]. We don't pay any attention to it. The agencies should rate the companies for their own creditworthiness, not based on the sovereign's creditworthiness."<sup>16</sup> A contrasting view asks "but are you going to open up the floodgates and allow a lot of other companies that should be constrained by their sovereigns into that group?"<sup>17</sup>

How can we reconcile our results with those of Kliger and Sarig (2000) who find that bond rating changes contain pricing-relevant information? Aside from timing and sampling issues, one explanation is that their study examines a new system that provides information in a strictly

---

<sup>16</sup> Rodrigo Briones of Deutsche Morgan Grenfell in New York, quoted in *LatinFinance* May 1997.

<sup>17</sup> Walter Molano, senior managing director at BCP Securities, who focuses on Latin American markets, as quoted in *The Financial Times* June 8, 2001.

finer partition than the coarse system, but both systems are based on the *same* rating procedure (and information). In contrast, Moody's rating procedure itself changed on June 7, 2001. One possibility is therefore that the market was ahead of the rating agencies in discounting transfer risk and generally more sophisticated in assessing individual company risk than that implied by the (former) Moody policy. Therefore the event was no news and just a confirmation. Alternatively, the market may have disagreed with Moody's *change* in rating procedure and investors continued to rely on their own assessments of risk.

## **Abstract**

*With this subject we intend to discuss about the IT impact on the audit process. Even when the client's use of IT leads to a better control of the internal mechanisms, the creation of the economical systems based on such technology supposes the existence of new risks that are not usually found in the traditional systems. The well administrated companies admit the existence of these new risks and react to them by instituting (in the IT system) some new general and applied controls with the aim of reducing the impact of these risks upon the financial market. The auditor must be informed about the risks and he must gain an understanding of the general and applied controls of the client in order to plan (in a better way) the audit. One part of the tests of the control mechanisms that the auditor makes can be executed with the help of computers, this solution allowing the creation of some more efficient audits. The reference to the general and applied controls with the aim of reducing the risk can be modified when the clients use microcomputers, administrative database systems and centers for external IT service instead of using the centralized informational technology system.*

**Keywords:** *audit process, IT, control, technology systems.*

## **1. Introduction**

The use of informational technologies could improve the internal control by adding new control procedures, executed by computer, and by replacing the manual control devices, liable to the risk of human error. Despite the fact that it improves the internal control, the addition to informational technologies could also generate new risks that the client could administrate through setting up new control devices that are specific to environments based on such technologies.

The paper highlights the risks specific to the environments based on informational technologies, identifies the control devices that can be set up in order to administrate those risks and emphasizes the way in which the control devices connected to informational technologies affect the audit process.

Before accepting as being reliable any result generated by computer, the auditors must firmly evaluate the internal control in the cases in which clients have a book-keeping system based on modern technologies. However, too often we trust computer generated data, without testing their accuracy, because auditors forget the fact that a computer does what it is programmed to do. Auditors must understand and test the computerized control devices before concluding that information produced by informational system is reliable.

## **2. How do Informational Technologies Improve the Internal Control?**

Most entities, including small, familial enterprises, are based on informational technologies to register and process the economic operations. As a result of the impressive progresses in this field, even those societies with a relatively simple activity use personal computers with informational programs for their accounting systems that are inefficient and less effective. As they grow and evaluated, enterprises are often improving the informational technologies systems in order to respond to the growing need of information. Nowadays using some complex network environments and some centralized informational technologies functions is wide spread in enterprises.

Among the improvements of internal controls a result of the integration of informational technologies in accounting systems we enumerate:

- **Informational control devices that replace the manual ones.**

The obvious benefits of informational technologies, like the possibility of profitable administration of impressive volumes of complex economic operations, determine organizations to resort to such technologies in the process of financial reference. One of the advantages of informational technologies consists of the possibility of improving the internal control through the incorporation of computer executed control devices in daily activities of operation processing. Replacing manual procedures with programmed control devices, that applies tests and calculates balances for each processed operation, could reduce human errors that could appear in traditional manual environments. A well-checked IT system offers a bigger potential in reducing errors, because computers process information in a consistent and uniform manner. Among the examples of internal control procedures that are executed nowadays by computers and that were in the past the employees business we enumerate: the comparison of the client's and product's code to the systematic files or the comparison of selling operations' sums to the established credit limits.

- **Higher quality information is available.** After the management is convinced of the reliability of the informational technologies data, the use of such information offers an additional potential to the improvement of managerial decisions. First of all, the complex IT environments are, usually, administrated effectively, because complexity requires organization, procedures and efficient documentation. Secondly, IT systems usually offer to management a bigger quantity of quality information that is available faster than in most manual systems.

### **3. The evaluation of risks related to informational technologies**

Though informational technologies could improve the internal control of a company, they could also affect the general control risk of the company. Numerous manual systems related risks are diminished and, in many cases, even eliminated. Still, there appear new risks that are specific to IT environments, and these could lead to substantial loss if ignored. For example, the impossibility to recover important information due to an informational system blockage or to the use of incorrect information based on such technologies could paralyze an organization. These risks increase the

probability of the appearance of significantly erroneous presentations in financial situations, fact which should be taken into consideration by managers and auditors. These are the key-risks, specific to environments based on informational technologies:

- **The addiction to functional abilities of informational equipments and programs;** without an adequate physical protection, informational equipments and programs might not work. Eventually, it is vital to ensure a physical protection of equipments, programs or data against physical degradation that might be the result of inappropriate use, sabotage or certain natural conditions (like fires, high temperatures, humidity or floods);

- **The visibility of the audit track.** As the greatest amount of information is directly introduced in the computer, the use of informational technologies reduces or even often eliminates the explanatory documents and the source book-keeping that allow any organization to remark the itinerary of the accounting information. These documents and accounting evidences are called „audit track”. Due to the loss of audit track, there must be introduced other control devices in order to replace the traditional possibility to compare the resulting information to data written on physical support.

- **The reduction of human factor implication.** Inside numerous environments based on IT, employees who deal with the initial process of operations never see final results. Therefore, they have a smaller possibility to identify the processing errors. Even though these employees see the final result, errors are often difficult to detect, because data is, mostly very synthetic. Also, the employees tend to consider information generated by use of modern technologies as being „correct” as it was produced by computer.

- **Systematic errors versus incidental errors.** As organizations replace manual procedures with procedures based on modern technologies, the risk of some incidental errors decreases. Still, the risk of systematic errors increases as a result of the uniform character of computer executed operations. After a procedure set is programmed in informational applications, the computer processes information in a consistent manner and also in a uniform procedure for all operations, until the moment of modifying the programmed procedures. Unfortunately, the gaps in the applications programming and the modifications brought to those applications affect the reliability of the computer executed operations, having as a result numerous risks. The risk is even bigger if the system is not programmed so as to recognize the unusual operations or the situations in which the audit tracks of the operations are inadequate.

- **Unauthorized permission.** Accounting systems based on informational technologies often allow permission in real time to data in

systematic files and other evidences kept on electronic support. As the access in real time can be made from numerous access points, situate at distance, there appears a risk of making unpermitted, illegal access. If there are no adequate restrictions regarding the access in real time, such as passwords or identification codes of users, through computer there can be made unauthorized activities, having as a result inadequate modifications of informational applications and of systematic files. More over, in this way there can be obtained in illegal manner confidential information.

- **Loss of data.** The majority of fundamental data in an environment base don IT is stocked on centralized electronic files. When data is centralized, the risk of loss or degradation of entire data files with important ramifications grows. It appears an elaboration potential of some erroneous financial situations and, in certain cases; the organization can undertake serious interruptions of activity.

- **The reduction of separating tasks.** As the organizations pass from manual processes to the informatics ones, the computers execute more and ore tasks that were traditionally separated, such as authorizing operations and keeping accounting situations. Eventually, mixing the activities of different parts of organization into one function of international technologies centralizes the responsibilities that were separated in the past. The staff of the informational technologies department, which has access to applications and to systematic files, could embezzle assets if the key tasks are not properly distributed among employees of the informational technologies function.

- **The absence of traditional authorization.** In very modern IT system it is used for certain types of operations to be initiated automatically by computer. Among examples, we enumerate the calculation of interests in the deposit accounts and the initiation of provisioning commands when it is reached a predefined level of stocks. Eventually the adequate authorization depends upon the procedures included in the informational application and upon the accuracy of the systematic files used in taking the authorization decision.

- **Need of experience in IT domain.** Even when companies purchase relatively simple informational systems, which include configured programs, it is essential to exist staff with experience and knowledge necessary for installation, keeping and use of the system. As the use of IT systems spreads inside organizations, most of the times it also grows the need of qualified specialists in informational technologies domain. Numerous companies set up a function or a whole department of specialized staff in IT domain, in which we include programmers, operators, network administrators, data library administrators, employees who introduce data

inside the system, specialists in ensuring the quality and data basis administrators. The reliability of an IT system and of information generated by it often depends upon the ability of the organization to hire staff or consultants with experience and suitable Knowledge in IT domain.

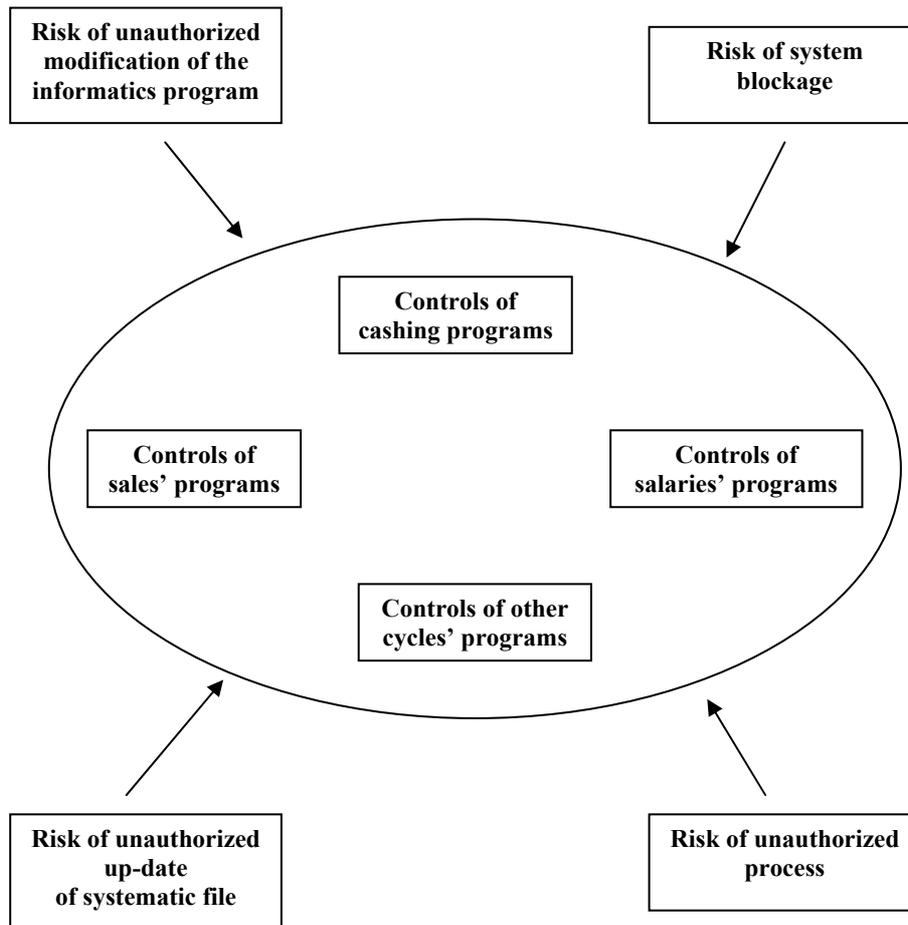

#### **4. Internal Control Devices that are Specific to Informational Technologies**

Frequently, in order to face the numerous risks connected to the growing addiction of informational technologies, organizations set up control devices that are specific for the IT function. Audit standards describe two main categories of control devices concerning systems base don informational technologies, namely: general controls and application controls.

**General control** refer to all the aspects about the IT function, including systems' administration, acquisition and maintenance of informational programs, physical security and electronic (logic) access security to equipments, programs and data associated to them, planification of making back-up copies in case of unpredicted events and conception of control devices integrated in informational equipments.

**Application controls** are practiced over processing individual operation such as the control sales or cashing process. Eventually, application controls are specific to certain informational programs and, usually, do not affect all functions that use informational technologies. Out of this reason, process controls must be evaluated for each segment of the audit (account or category of operations) affected by a informational application, in which the auditor plans to reduce the estimated control risk.. As shown in the next graph, general controls are projected in order to protect all application controls, to ensure their efficiency. Solid general controls reduce those types of risks identified in the box outside the oval containing general controls in this figure (**figure 1.**).

**Figure 1 Connections between general controls and application controls**

Source: *Arens Loebbecke, Auditing.*

More the addiction of informational technologies in the economic environment grows; the administration of the IT function becomes more important. The management must distribute sufficient resources in order to support the technologies.

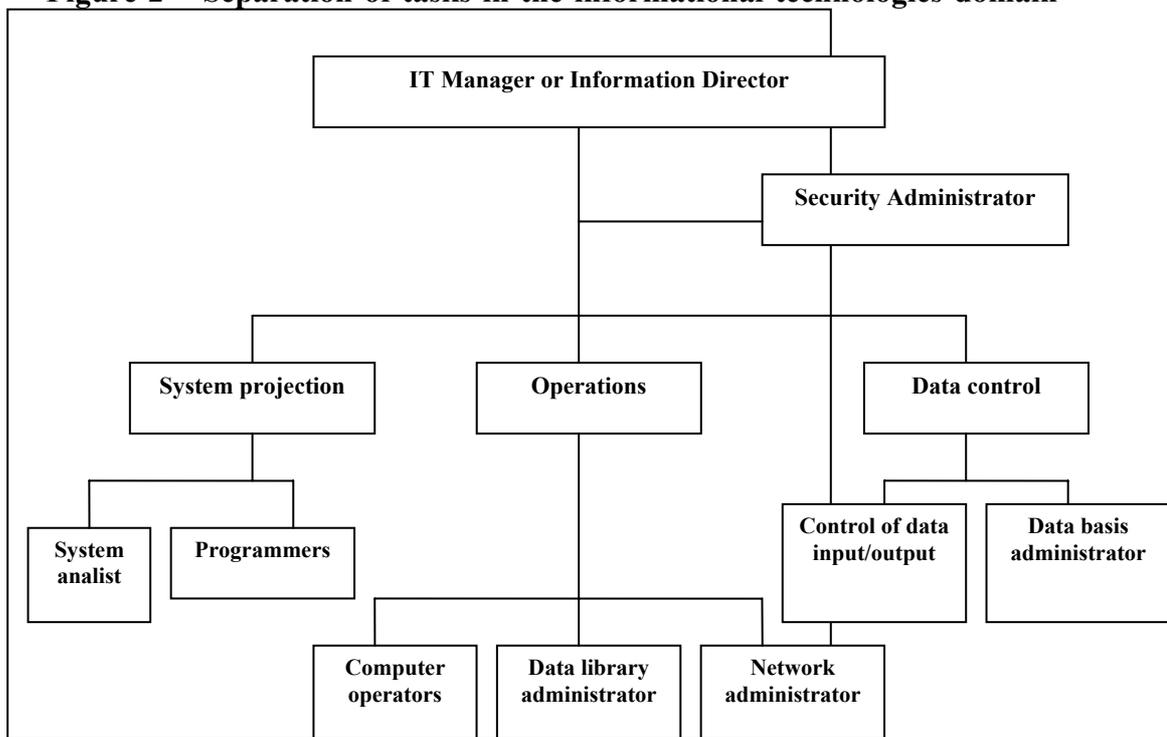

The attitude towards the importance of informational technologies inside an organization is often determined by the position adopted by the board of directors and by the top management. The supervision, the distribution of resources and the implication of this factor in the key-decision regarding informational technologies consists in a powerful clue about the

importance of this function inside the company. In the complex environments, the management often creates internal committees to contribute to the supervision of the technological needs of the entity. Inside less complex organizations, the board of directors could rely on periodical reports concerning informational technologies, elaborated by an Information Director (ID) or by another top manager, in order to maintain the management up to date.

In comparison to such situations, in the case in which functions connected to technologies are exclusively commissioned to employees from lower hierarchical levels or external consultants, it is being transmitted the implicit message that the informational technologies might not be a priority of the company. Often, it results an IT function with insufficient staff, insufficient resources and inadequate control.

To respond to these concerns, the programming, the computerized operations (including security of physical and logical access to equipments, programs of data and over production of result should be separated such as the model in the figure 2.

**Figure 2 – Separation of tasks in the informational technologies domain**

Source: *Arens Loebbecke, Auditing.*

In an ideal situation, responsibilities connected to IT management, system projection, operation execution and data control should separate as it follows:

- **IT Management.** Supervision of informational technologies function generally regards the responsibility of Information Director (ID), or IT Manager. This person is responsible for the supervision of all functions connected to the informational technologies, in order to ensure that activities go in accordance with the strategy plan regarding informational technologies. Besides an ID, a security administrator supervises also the physical access and the logic one to equipments, programs and data files and executes the necessary investigation procedures after detecting some breaches or gaps inside the security system.

- **System projection.** The projection and the modification of IT system are, usually, coordinated by a system analyst who is responsible for the general projection of each system application and who represents the connection person between IT department employees, application programming managers and employees outside IT function, who would be the main users of the system (such as the staff responsible for the evidence of credit-clients). Programmers elaborate sequential diagrams that are special for each application, also elaborate informational instruction, test programs and gather evidence of results on the basis of recommendations given by the system analyst. Programmers should not have access to the introduction of data or to the computerized operations as the well knowledge of a program might be used in personal interests. The access to programs' back-up, that is effectively used for information production and the access to data basis should be limited, so that programmers could not make modifications in the informational applications without a suitable authorization. In exchange, programmers should work only with test back-up of programs and data.

- **Operations.** Daily effectuation of computerized operations concerns PC operators who should fulfill their tasks according to the work schedule elaborated by ID and follow the appearance on their electronic consoles of any messages regarding program working or computer trouble. The librarian is responsible for keeping informational programs, operation files or other evidences or important electronic documents. The librarian controls these programs and evidences by offering them to operators, only in the indicated conditions of the work schedule. He puts to programmers' disposal a test back-up only with the approval of the top management. Inside environments consisted of networks, the network administrator is the one responsible for planning, functioning and keeping of a server network, that makes the connection between users, different applications and data files.

- **Data control.** Employees responsible for the control of data inputs and outputs independently check the quality of the introduced data and the reasonable character of the produced information or extracted from system information. In the case of organizations that use data basis to stock information which is used, in common, by book-keeping and other functions, the administrators of data basis are responsible for the security operation and common data basis access.

Of course, the proportion of task separation depends upon the volume and the complexity of an organization. Inside numerous small companies it is not practical to separate tasks in the manner described above.

The existence of some solid physical controls of computers and the limitation of real-time access to applications and to associated data files reduce the risk of operating some unauthorized modifications inside informational programs and data files. Security plans should be elaborated in a written form and their application should be permanently supervised. It follows a short presentation of a typical physical control and of a real-time access control.

- **Physical controls.** Physical controls of informational equipments starts with the limitation of the access to equipments, programs and safe back-up of data files kept on magnetic bands or disks, CD and disks. Among the examples of limitation modalities of unauthorized use of equipments are: use of electronic locks, installation of systems based on magnetic cards access, use of security video cameras and hiring security staff. For a higher level of security, the physical and logical access is allowed only after reading employee's fingerprints or scanning employee's retinas, which are later compared to an approved data basis. Among other physical controls we enumerate the supervision of conditioned air system and of humidity of equipments. The immediate access to the prevention and fighting against fires system reduces the potential loss caused by fires.

- **Real-time access control.** The adequate use and existence of some identification codes of users and some access passwords to programs and associated data files reduce the probability of operating some unauthorized modifications in the informational applications and data files. Operating systems of most computers offer the possibility to define some identification codes of users and some access passwords. In modern IT systems there can be installed a package of additional programs in order to improve security.

Accidents like interruption of electricity, fires, heat or excessive humidity, floods or even sabotages can cause serious consequences for the companies that use informational technologies. To face this kind of risks,

organizations elaborate plans concerning the creation of some safe back-up and concerning the reaction to unpredicted events. One of the success back-up of informational programs and of data files are made and stocked outside the headquarters of the company. Often, in order to stock this safe back-up there are being used underground strong boxes that are being used underground strong boxes that are resistant to fire and explosions. Moreover, this kind of plans should identify the alternative physical equipments that might be used for processing the company data.

For smaller IT systems, there can be purchased computers and server for replacement, which can be used along with the safe back-up of the informational programs and data files. In the case of more complex systems, organizations install inside the company's premises safe batteries and diesel oil generators to face the temporary interruptions of electricity and they can even sign alternative agreements for providing basic services in case of emergency.

Control devices that are integrated in informational equipments by their producer and that concern detection and raportation of flaws are called personal controls of equipment. Independent auditors are rather interested in the methods used by clients in order to administrate the computer identified errors than in the adequate character of personal control of equipments in the system. No matter what the quality of personal controls of equipments is, the information produced by the system will not be corrected only if the client's organization has foreseen administration measures for the equipment generated errors.

Application controls are projected for each informational application and their target is to help the company respond to the six audit objectives concerning operations that were discussed in the previous chapters. Although, one part of application controls do not affect more than one or very few audit objectives connected to operations, most controls forestall or detect several types of errors. Despite the fact that the control objectives in the introduction, processing and extraction of data domain are identical, the procedures used to realize these objectives are totally different. These three types of application controls will be presented in the following paragraphs.

The control devices created by organizations in order to ensure that all computer processed information is authorized, accurate and complete are called controls of data input. Controls of data input are critical as a large amount of IT system errors result from errors produced when introducing data. Errors in data input process lead to errors in given results, no matter what the quality of information processing is. Typical control devices in manual operated system keep their importance. Among the examples there

can be mentioned: written authorization of operation given by the management, elaboration of explanatory documents for data input and for hiring qualified staff. Other controls are specific to IT systems. Examples are: suitable projection of information input displays, menus with lists of available program options and validation tests for the precision of the introduced data, executed by computer, such as the validation by comparing the client's number to the client's systematic files. Moreover, the immediate error correction procedure and error collection procedure in a separate file that would later be analyzed by the responsible staff permit an early detection and correction of errors produced during the process of data input,

The control devices that forestall and detect errors produced during data processing operations are called controls of data processing. Although solid general controls, especially those connected to the projection and security of systems, offer some of the best control devices to minimize the risk of error appearance, controls of application processing are often integrated in the informational programs in order to prevent, detect and correct the processing errors.

An auditor must know these control devices because he takes all the responsibility of obtaining an internal control agreement, including general and application controls, no matter if the informational technologies use by client is simple or complex. Also, knowledge connected to general controls consolidate the ability of the auditor to rely on efficient application controls in order to reduce the control risk of audit objectives connected to operations.

Most auditors evaluate the efficiency of general controls before evaluating the application controls. In the case in which general controls are inefficient, it appears the probability of producing some significant errors in each informational application in book-keeping, no matter what the application controls' quality is. For example, if the tasks are not properly separated, PC operators being also programmers and having access to programs and informational files, the auditor must be interested in false operation registering or unauthorized data registering and also in emission in accounts such as sales purchases and salaries. In dike manner, if he notices that data files are not adequately protected, the auditor could conclude that there is a significant risk of data loss, because general controls affect each informational application. In this kind of situations, audit tests concerning the confirmation of exhaustivity objective should be spread in certain fields, such as cashing, payments and sales.

On the contrary, if there are solid general controls, the possibility to attribute a higher level of reliability to application controls increases.

Thus, the auditors can test the operational efficiency of some application controls and they can rely the results of these tests in order to reduce the quantity of substantial tests. This use of efficiency of the audit.

Still, there is a challenge in IT environments which refers to the effect of modifications operated in informational programs about the trust that the audit can have concerning control devices. When the client modifies the applications, the auditor must determine whether it is necessary to use additional tests. In the case in which general controls are efficient, the auditor could easily identify the program operated modifications. In environments where general controls are inefficient however, the probability of the appearance of some unidentified modifications increases. As a result, the auditors must foresee the effectuation of periodical tests concerning the operational efficiency of application controls during a whole year when general controls are weak.

Usually, the auditors receive information about general and application controls using the following techniques: questioning the staff and the key-users of informational technologies, examination of system documents, such as sequential diagrams, user books, requests of program modifications, test results, and the analysis of detailed questionnaires completed by the informational technologies department staff. In most cases, it's best to use more methods to understand the internal control, as each of them offers different information. The interview with the informational department manager and with the system analysts offers useful information concerning the operation of the whole informational technologies function, the proportion of the projection process of informational applications and the modifications operated in the key-accounting applications, and also a panoramic view over the planned changes. The analysis of the program modification requests and of system tests results is useful for the identification of programming modifications in informational application. The questionnaires are useful to identify the specific internal control devices.

Of course, the auditors do not correlate the qualities and the flaws of general controls with the specific audit objectives connected to operations. Like the control environment, general controls affect the audit objectives connected to operations in more cycles. In the case in which general controls are inefficient, the possibility of the auditor to rely on application controls in order to diminish the control risk is reduced. On the contrary, when general controls are efficient, the ability of the auditors to rely on application controls in order to reduce the control risk increases.

Auditors identify both manual application controls and computer executed ones, and also the system flaws for each audit objective connected

to operations, using a matrix of the control risk. For example, the computer comparison of staff identification number that were introduced manually to the systematic file data could reduce the control risk regarding the objective of expenses existence for salaries, through the fact it stops making payments to fictitious employees.

Most organizations use informational technologies in order to process operations and they project their systems so that their explanatory documents could be restored in legible form and easily followed in the accounting system until the final resulting data. In such situations, organizations keep most traditional explanatory documents like the clients' purchasing commands, the delivery and the reception dockets, sales invoices and supply invoices. The accounting informational program also generates printed versions of journals and books which allow the auditor to remark the itinerary of the individual operations through all accounting evidences. Moreover, the internal control devices often include a comparison by the client of the computer generated evidences to the explanatory documents.

In this kind of situations, using informational technologies has no significant impact on the audit track. Usually the auditor obtains an agreement of the internal control and makes control devices tests, substantial tests of operations and verifying procedures of account balances. The auditor has also obligation to understand the general and application controls executed by computers, because this kind of knowledge will be useful in identifying the risks that might affect the financial situations. However, usually the auditor doesn't make tests of controls effectuated by computer. This audit method is often called audit around computer as the auditor doesn't use computerized controls in order to reduce the estimated control risk. In exchange, the auditor uses control devices outside the informational technologies to justify the adequate assessment of the control risk.

As the use of informational technologies by organizations spreads, internal control devices are often integrated into applications and became visible only in electronic form. When traditional explanatory documents, such as invoices, provisioning commands, invoice registers and accounting books, such as sales journals, stock evaluation lists and analytic registers of credit-clients, are available only in electronic form and not on paper support, the auditor must change the audit method. This audit method is often called audit by computer.

There are three categories of testing strategies that can be used in the audit by computer: test-data method, parallel simulation method and modulus of integrated audit method.

**Test-Data Method.** Test data method is about processing a set of test-data of the auditor using the computerized system and informational applications of client in order to determine whether the control procedures executed by computer ensure the correct process of test-data. As the auditor is the one who defines the test-data, he can identify the testing elements that should be can accepted or rejected by the client's system.

When using the test-data method, the auditor must take into consideration three fundamental aspects, namely:

1. Test-data should include all relevant conditions that the auditor wants to test. The auditor should project the test-data so that he could test the main computerized control devices that he intends to rely on in order to reduce the control risk. The auditor's test-data should contain realistic elements that might be part of the normal processes made by client, including valid operations and inadequate operations.

2. Informational programs verified by the auditor's test-data should be identical to the ones used by client along the accounting exercise. One of the methods would consist in processing the test-data by surprise, possibly at aleatory moments of the year, though this solution is expensive and takes a lot of time.

3. Another method consist in relying on general controls of the client that were carried out by the responsible employees for the administration of the informational library and system projection, in order to ensure that the tested program is the same used in the current data process.

Test-Data should be eliminated from the client's evidences. If testing informational programs of a client supposes processing test-data in parallel with processing client's real operation, the auditor must eliminate all test-data from the client's systematic files after he finishes testing. It is not allowed to permanently keep some fictions operations in the client's systematic files. To remove the fictitious operations, the auditor must introduce additional data to invert the effect of those operations.

**Paralle Simulation Method.** There are numerous informational applications that help the auditors to evaluate the efficiency of the informational control devices and to obtain proofs concerning available balances of accounts in electronic form. The auditor uses programs that are controlled by him in order to execute operations parallel to the client's application, using the same data files. Who matter if the tests control devices or final balances of accounts, the auditor compares his own output data to data generated by applications used by clients, whit a view to test the efficiency the client's informational programs. The absence of difference in

the resulting data indicates a correct working of the client's programs, while the existence of some deviations indicates potential flaws of the client's system. Since the auditor's applications are projected to effectuate in parallel (to imitate) an operation processed by the client's applications, this testing strategy is called parallel simulation.

Frequently used instruments by auditors to effectuate the tests of parallel simulation are generic applications of audit (GAA), namely informational applications projected to be utilized by auditors. These informational programs can be already-made purchased and are, usually, compatible with Windows system, being easily installed in the office computer or laptop of an auditor.

Generic applications of audit present two advantages. First of all, it is relatively easy to train the audit staff how to use them, even if there are involved persons with no preliminary preparation in the field of informational technologies that are applied in audit. Secondly, generic applications of audit can be applied to a large variety of clients, with a minimum effort of adaptation and personalization.

**Modulus of Integrated Audit Method.** When being used the modulus of integrated audit method, the auditor inserts a modulus of audit in the system applications of the clients in order to extract those operations having characters that the auditor is interested in. For example, the auditor could extract all the purchases that exceed a determined economic value, so that he could examine all the sizable operations that have crossed the cycle of purchase and payment.

Auditors can use either only one method (test-data, parallel simulation or modulus of integrated audit) or a combination of them. Usually, auditors use test-data in order to test the control devices and to make the substantial tests of the operations. Parallel simulation is often used for the substantial tests, such as the fresh calculation of operation sums and the overall of the analytic evidences of account balances included in the systematic files. Auditors use the modulus of integrated auditing method to identify unusual operations in order to effectuate substantial tests.

Microcomputers are widely utilized in most companies, no matter what their sizes are. Usually, they have even in small societies an important role in processing or analyzing accounting data by using accounting programs or tabular calculations that were ready-mode purchased or especially created for the company.

Usually, in small companies general controls are less efficient than in more complex IT environments. Often, there is no qualified staff in

informational technologies or the client relies on the periodical implication of consultants for support in installing and keeping equipments or informational programs. Also, the responsibility connected to IT functions is often attributed to the utilizing departments inside which physical equipments are placed. Still, even in these IT environments, purchase controls of informational programs, physical security, real-time access security and planning of safe back-up are important.

Often, client's auditors who use microcomputers in environments with less sophisticated general controls make the biggest part of their audit "around the computer". These systems often produce sufficient audit tracks which allow the auditor to correlate the explanatory documents of data input with data output.

Still, even in less sophisticated IT environments, there are situations in which the auditor can rely on controlled procedures executed by computer. For example informational program from microcomputers can be installed on the hard disk of the computer so that the client's staff could not modify them. The risk of unauthorized modifications in informational applications is, consequently, diminished. Before making reference to integrated control devices in those applications, the auditor must be convinced of the informational program, namely in what concerns the quality.

A problem that appears in environments based on microcomputer is the access of some unauthorized persons to the systematic files. For example, the utility of comparing the client's sales commands and of credit-clients balances to the systematic files of credit limitation depends upon the accuracy of the established credit limits. Unlike the sophisticated IT environments, often, microcomputers do not contain protection of data files by means of access password. Without such protection, any user could introduce a modification which cancels the utility of a control device. An example is the increase of a client's credit limit which is sufficient to avoid the rejection of the operation by the system. In alike situation, it is critical an adequate separation of the staff's tasks, staff who has access to the systematic files, by the data processing responsibility. Moreover, a periodical check by the owner-administrator of output data connected to operations consolidates the internal control.

Another risk related to the use of microcomputers is the data and program loss due to informational viruses, which can infect other programs or even the whole system. Certain viruses can deteriorate disk files or block a whole network of computers. The existence of some protection programs against viruses, which should permanently scan the system to detect possible viruses improves the internal control.

The spectacular intensification of use of networks connecting equipments as microcomputers, average size computers, extremely powerful computers, data input terminals, servers and printers has changed the IT function in numerous companies. Local Area Networks (LAN) connect equipments from one building or a small group of buildings and are used only for operation inside companies. A typical use of LANs consists in data and program transfers from one computer or terminal to another, using programs for the network system which allow all the equipments to work together. Wide Area Networks(WAN) connect equipments from larger geographical regions, permitting even operation at an international scale.

In environments based on networks, the informational applications and data files used for processing operations are stocked on servers, which are equipments used for data administration. The access to the respective operations from microcomputers or terminals is administrated by the programs for network systems. Often, companies have several servers. In the case of many ample network environments, there are applied most general controls because the support given by informational technologies and the implication of users are centralized. In other companies, the use of a network medium often leads to modifications of control devices, which the auditor must analyze during audit planning. Numerous organizations decentralize the network servers, fact that often increases the control risk as it lacks security and whole supervision of network operations by the management. Also, numerous network environments have no equipments and standardized procedures. Organizations which need fast communications and easy access to data often create network outside the control sphere of the informational technologies function. The responsibility concerning the purchase, maintenance, administration and physical security of equipments and informational programs is frequently incumbent upon the key-groups of users and not upon a centralized IT function, fact which often leads to an absence of adequate control devices. Also, sometimes, network informational programs do not include the necessary options to ensure security, including for task separation (devices which are usually available in centralized environments), because there are numerous users having easy access to data and programs.

When clients have book-keeping applications that work in a network environment, the understanding of the internal control by the auditor should contain accumulation of data regarding the network configuration, including the servers' location, the terminals' and the computers' connection, as well as accumulation of some data concerning the network program used for the system administration. Also, the auditors should be informed about the

control devices for the access and modification of international applications and data files stocked on servers.

Controls are better when data is centralized into an administration system of data basis, by the fact that it eliminates the redundant data files. However, administration systems of data files can also create risks connected to the internal control. For example, there are risks related to the fact that numerous users, among whom we enumerate persons outside the book-keeping department, can access and update data files. Without a suitable administration of data basis and without an access control, the risks of appearing some unauthorized, inaccurate and incomplete data files increase. Also, centralizing data into one single file increases the importance of the insurance of a safe data back-up, which should be proper and regularly created.

Clients' auditors who use administration systems of a data basis should understand planning, organizing, politics and procedures of the clients in order to determine how well these systems are administrated.

To cover a part or all their needs of informational technologies, many clients prefer to resort to independent informational service centre sooner than to set up an internal department of informational technologies. Numerous smaller companies subcontract the administration function of salaries, because this is not enough similar between companies and because there are reliable suppliers of salary administration services. Like in any other subcontract decision, companies determine whether it is worth to subcontract the IT function on the basis of a cost-advantages analysis.

When activities are subcontracted to an informational service centre, the client delivers the input data, and the service centre processes them for a certain price and then delivers the client the convenient output data and the original input data. In the case of salaries, the company presents the service centre the check sheets and the daily rates.

It would be more difficult for the auditor to understand the internal control of the client in such situations, as a large amount of control devices works at the service centre level and the auditor can not start from the hypothesis that these devices are suitable only because it concerns an independent services supplier. Audit standards require the auditor to analyze the need to understand and test the control devices of the service centre in the cases in which applications used by the respective centre involves the process of some significant financial data.

The decision concerning the proportion of understanding and testing the control devices of the service centre used by the client should rely on the

same criteria the auditor takes into consideration when evaluating the internal control devices of a client. The depth of understanding would depend upon the complexity of the system and upon the level in which the auditor intends to reduce the estimated control risk in order to diminish the quantity of substantial audit tests, if the auditor concludes that the active implication at the level of the service centre is the only manner to effectuate the audit, it could be necessary an agreement of the internal control inside the service centre and a testing of the control devices, using test-data and other testing methods.

## 5. Conclusion

In the last few years, it has become more and more frequent the practice through which an independent auditor understands and tests the internal control devices of the service centre, in the interest of all the centre's clients and of their independent auditors. The aim of this independent evaluation consists in offering the service centre's clients a reasonable level of insurance concerning the adequate character of the general and application controls used in the service centre and in eliminating the need of redundant audits made by the auditors of the centre's clients. If the service centre has numerous clients and each one demands an understanding of the centre's internal control by his own independent auditor, the perturbation of activities and the costs supported by the service centre could be substantial. The moment after the independent auditor of the service centre concludes devices, it is being elaborated a special report, indicating the perimeter of the audit proceedings and the auditor's responsibility to decide over the measure in which he is willing to rely on the audit report of the service centre.

## **Abstract**

*This article explores the determinants for off-site surveillance of the short-term and long-term bank rating changes for rated banks in Asia and the differences between them. Application of an ordered logit model reveals that the CAMEL criteria of asset quality and capital adequacy as well as non-financial variables such as asset size and mergers and acquisitions play an important role to influence both the short-term and long-term bank ratings. Notably, it is found that higher capital to loan ratio, greater liquid asset ratio, and lower capital to asset ratio are likely to improve the probability of long-term creditworthiness, while higher impaired loans ratio are less likely to improve the short-term bank ratings. Results of the marginal effect suggest that the dividable scale helps to improve long-term creditworthiness through cross-selling tactics, synergy gains and a better capability for fund raising.*

## 1. Introduction

Numerous studies have documented that the banking system in developed countries had become a highly regulated procedure by the early 1980s. (Johnson and Lindley, 1993; Benink and Llewellyn, 1994; Warf and Cox, 1995) By this point the regulatory environment consisting of controls on interest rates, credit and capital acted as a protection in the banking industry. The existence of restrictive practices and high entry barriers into the banking sector not only provided excess capacity, but also formed monopolistic profits in response to low degrees of competition. Subsequently, the banking system experienced a period of profound crisis due to the rapid process of financial liberalization associated with mismanagement, deregulation, and depressed economies that intensified competition among banks. Consequently, many banks collapsed and faced financial insolvency because the substantial rise in bank lending and eroded credit rationing raised markedly the proportion of nonperforming loans in the early 1990s. A number of studies have examined the effect of bank-specific variables on predicting bank failures. Abrams and Huang (1987), Pantalone and Platt (1987), Randall (1993), Estrella, Park, and Peristiani (2000), and Brewer, et al. (2003) suggested that bank failures are influenced by both financial performance and supervisory assessments associated with CAMEL criteria and other ratings aimed at maintaining bank safety and soundness.

Much previous research has used the probit and logit models to investigate the relationship between the financial performance and the risk of domestic bank failures, rather than a linear cardinal approach. The empirical evidence so far suggests that bank-specific variables such as asset size, nonperforming loans, and capital to asset ratio, together with loans and monetary policies such as regulation Q and Federal Deposit Insurance play important roles in influencing the probability of bank failure.<sup>2</sup> However, little information has been available to policymakers to discuss how to apply the off-site surveillance on a comparison of nations for banks because the differences in the surveillance procedures of nations can affect how the probability of bank risks reflecting their ratings are determined. This study adds to the existing academic evidence but differs by exploring whether and how CAMEL criteria and non-financial factors are related to how bank's off-site surveillance reflects the bank's rating changes.

In this paper we test whether the financial variables followed CAMEL criteria, with non-financial variable including bank size and dummy variables

---

<sup>2</sup> Under the approval of Regulation Q, the Federal Reserve permitted commercial banks to provide the maximum explicit interest rates to be paid on savings and time deposit liabilities (Cebula and Saltz, 1994).

such as financial holding company, mergers and acquisitions, and geographic differences responding to the off-site surveillance of bank rating refinements. This paper uses an ordered logit model with maximum likelihood estimation and the sample is comprised of bank rating changes for 151 banks in Asia during 1996 to 2002. We probe deeper using a comprehensive investigation to determine if there are inherent differences between the long-term and short-term bank rating changes in order better understand off-site surveillance of banks worldwide.

Our results indicate that CAMEL criteria and non-financial variables do exist and influence the rating agencies' behavior for evaluating bank ratings. Generally, we found that a small net loan to total asset ratio, lower expenses to asset ratio, higher return on assets, and larger bank size enhanced the creditworthiness of short-term and long-term bank ratings, which may increase asset quality, management efficiency, extra funds and earnings. It was also be found that mergers and acquisitions lead to lower probability of upgrading bank ratings due to improper managerial performance and financial difficulties of acquired banks. Geographic differences seem to be caused by the vulnerability of the banking sector and sovereign risks that rated banks faced. The results suggest that a higher capital to loan ratio, greater liquid asset ratio, and lower capital to asset ratio are likely to increase the probability of the long-term bank ratings. In addition, the positive coefficient for financial holding company supports the notion that rated banks belonging to a financial holding company may benefit from a better financial environment to improve their portfolio performance and obtain extra funds, leading to improved long-term creditworthiness. In particular, we found evidence to support the view that a higher impaired loans ratio was associated with lowered asset quality and profitability, making rating agencies less likely to upgrade the short-term bank ratings. Overall, the marginal effect results revealed that rated banks may incorporate the dividable scale of the investment-grade and speculative-grade of long-term bank ratings to rebuild creditworthiness by utilizing cross-selling tactics, enhancing synergy gains and assessing extra funds properly.

The remainder of this paper is organized as follows. Section 2 presents a literature review of bank failures. Section 3 presents the empirical model used in this study. Section 3 reports the data and some testable hypotheses. Section 4 presents the empirical results and Section 5 summarizes the findings.

## 2. Literature Review

A considerable volume of empirical studies on bank failures have explained the role of financial performance and supplement supervisory assessments (e.g., Abrams and Huang, 1987; Pantalone and Platt, 1987; Randall, 1993; Estrella, Park, and Peristiani, 2000; and Brewer et al., 2003). In two influential papers Abrams and Huang (1987) and Khorassani (2000) found that a lower probability of failure occurred when banks were larger or were affiliated with holding companies. Abrams and Huang found empirical evidence that U.S. banks which depend heavily on large certificate deposits and loan portfolio have a higher probability of failing. Randall (1993) and Warf and Cox (1995) analyzed U.S. banks that had profound crisis and failed during a period of 1980s -1990s. Their results generally supported Abrams and Huang's findings that an overbuilt commercial real estate market, which had markedly increased the proportion of nonperforming loans at higher risk exposures, was the dominant factor in bank failures. Consistent with these findings, Brenda, Ceyla, and Robert (1997) confirmed that a higher share of nonperforming loans to total loans decreased the survival time for Mexican banks that experienced the Mexican financial crisis during the early 90s. They indicated that banks with smaller size and capital asset ratios seem to be more likely to obtain liquidity support. Likewise, Wheelock and Wilson (1994) also indicated that an increase in ratios of capital to assets reduced the likelihood to failing. In other study, Henebry (1997) used the CAMEL rating system areas of capital, asset quality, earnings and liquidity to test the stability of bank failure prediction. He found that the ratios of primary capital to total assets and of nonperforming loans to total loans both have strong power in predicting bank failure.

Previous studies have identified possible links between capital ratio requirements and the risk of subsequent bank failures.<sup>3</sup> These ratios are especially for the development of early warning systems for predicting the likelihood of bank closings and they play a crucial role in prompt supervisory action for bank regulators. As pointed out by Khorassani (2000), the capital adequacy requirements to assess safety and soundness for the banking industry can be significant predictors of bank failure. Estrella, Park, and Peristiani (2000) evaluated three types of capital ratios, risk-weighted, leverage, and gross revenue ratios. They found that the risk-weighted ratio

---

<sup>3</sup> A comprehensive international approach to capital adequacy was recently developed by the Basel Accord to Banking Supervision in 1988 (Estrella, Park, and Peristiani, 2000). To emphasize capital regulation and promote safety and soundness, the new framework has been expanded to the three pillars-minimum capital requirements, supervisory review, and market discipline (Gunther and Levonian, 2001).

tend to perform relatively in predicting bank failure over long time horizons, while the leverage and gross revenue ratios can play an important role of prediction over the shorter time periods.

To build an effective early warning model of bank failure to identify banks taking excessive risks, Pantalone and Platt (1987) used Logit regression analysis to discriminate between healthy and failure-prone commercial banks in U.S. They reported that adopting a risky management strategy that inadequately diversified away from loans or having insufficient controls to prevent fraud would jeopardize a bank's survival if a major stress in the economy occurred. They also showed that an increase in bank lending has affected bank failures because the rapid process of deregulation has increased the competitive environment among financial institutions. In support of this position, Benink and Llewellyn (1994) provided empirical evidence based on Tobit estimates for pooled banking data of Norway, Sweden and Finland, suggesting that rising credit losses may speed up banking crises due to intensified competition from substantial deregulation.

A number of studies argued that changes in the risk of bank debt may not be the sole cause of bank failures. Johnson and Lindley (1993) and Cebula and Saltz (1994) examined the pattern of the bank failure rate in the U.S. in response to the monetary policy changes over last two decades. They found that regulation Q for the U.S. Federal Reserve policy appeared to play a crucial role in contributing to bank failures.

In addition, Cebula (1993), Wheelock and Wilson (1994), and Laeven (2002) have provided convincing evidence indicating the connection between deposit insurance and bank failure. In this regard, they pointed out that the Federal Deposit Insurance (FDIC) has probably been the most criticized monetary policy related to the proximate cause of the rapid growth of banks and the Savings and Loan (S&L) failures during the 1980s. Cebula (1993) and Wheelock and Wilson (1994) found that banks and S&L institutions that carried FDIC were more risky, and hence had an increased failure rate. They suggested that the regulators may consider an increase in the cost of deposit insurance proportionately with risk in order to discourage the risk taking behavior of banks for lending. However, Laeven (2002) showed that private banks or other financial institutions with the highest cost of deposit insurance tend to take greatest risks.

The comprehensive studied of on-site inspections and examinations by Flannery and Houston (1999) and by Gilber, Meyer, and Vaughan (2002) attempted to assess and control the regulatory risk exposures associated with deposit insurance and lending activities which affected bank's market value. Flannery and Houston (1999) provided a notable result in that surprise

examinations were more likely to have a significantly negative effect on well-capitalized banks.

To evaluate the off-site surveillance at the bank level for scheduling on-site exams, Cole and Gunther (1998), Gunther (2002), and Gilber, Meyer, and Vaughan (2002) used both CAMEL and CAMELS ratings to predict bank failure.<sup>4</sup> Gunther and Levonian (2001) summarized the usefulness of the BOPEC rating as a benchmark for banking organizations' financial safety and soundness.<sup>5</sup> These results indicate that stock price information was useful in predicting financial conditions that affected BOPEC ratings to supplement supervisory assessments. Moreover, Elmer and Fissel (2001) and Brewer et al. (2003) indicated that equity market information can help forecast downgrades in the supervisory ratings and responded unfavorably to bank failures. Among previous studies that used stock returns or prices to examine the supervisory ratings, Gilber, Meyer, and Vaughan (2002) found that the CAMELS downgrade ratings performed slightly better than the SEER (the System for Estimating Examination) Ratings. This indicates that the CAMELS ratings models have a little contribution to off-site surveillance. Gunther (2002) evaluated the potential trade-off between credit enhancement objective of the Community Reinvestment Act (CRA) and the risk-constraining objectives of safety and soundness used in assigning CAMEL ratings.<sup>6</sup> However, the limited evidence revealed that aggressive banking strategies to expand credits and low managing capital were both associated with favorable CRA ratings, but they conflict with safety and soundness ratings so that losses may occur at a high level of risk.

To the best of our knowledge, the current paper extending previous empirical work on bank rating changes is the first attempt to test off-site surveillance among banks across different nations in Asia. While a limited number of studies have examined the impacts of off-site surveillance on the probability of domestic bank failure, these papers have not attempted make

---

<sup>4</sup> To assess supervisory information, both composite CAMEL and CAMELS ratings were obtained from examinations of five/six components aimed at maintaining bank safety and soundness including capital protection (C), asset quality (A), management competence (M), earnings strength (E), liquidity risk exposure (L) and market risk sensitivity (S) (Gilber, Meyer, and Vaughan, 2002).

<sup>5</sup> BOPEC rating was obtained from financial performance of five factors: Bank subsidiaries (B), other (non-bank) subsidiaries (O), the parent company (P), consolidated earnings (E), and consolidated capital (C) (Gunther and Levonian, 2001).

<sup>6</sup> Since July 1990, the Community Reinvestment Act (CRA) has legislated that Federal regulators were to encourage financial institutions to meet local credit needs in a bank's service area (Gunther, 2002). The CRA ratings can be classified to four levels: outstanding, satisfactory, needs to improve, and substantial noncompliance.

an international comparison linking bank ratings in reflecting bank's insolvency associated with leverage risk, credit risk, and liquidity risk.

### 3. Ordered Logit Analysis of Bank Ratings in the Banking Sector

An ordered logit models with the random effects fitted by maximum likelihood are now well established in the economic and financial research literature of bond ratings and credit ratings (e.g., Kamstra, Keenedy and Suan, 2001; Badu and Daniels, 1997; Blume, Lim and McKinlay, 1998; Chen, 2003). It is to be noted that Walker and Duncan (1967) originally developed an ordered logit models for pooled data. Greene (1993) revealed that the standardized logistic probability distribution functions are available to constrain the estimated probabilities for an ordered logit models. In principle, the random effect estimates of both models use maximum likelihood functions and asymptotic standard errors to assess the parameters that were formed to similar statistical characteristics.

To capture the relations between discrete-valued dependent variables and continuous-valued independent variables, we consider the following specification for an ordered logit models with the random effects:

$$\begin{aligned}
 Y_{it}^* &= \beta' x_{it} + \varepsilon_{it} + \varpi_i, & (1) \\
 Y_{it} &= 0, & \text{if } Y_{it}^* \leq z_1, \\
 Y_{it} &= 1, & \text{if } z_2 < Y_{it}^* \leq z_3, \\
 Y_{it} &= 2, & \text{if } z_3 < Y_{it}^* \leq z_4, \\
 & \dots & \\
 Y_{it} &= M, & \text{if } Y_{it}^* > z_M, \\
 \text{Var} [\varepsilon_{it} + \varpi_i] &= \text{Var} [v_{it}] = \sigma_\varepsilon^2 + \sigma_\varpi^2, \\
 \text{Cov} [v_{it}, v_{is}] &= \sigma_\varpi^2, \\
 \text{Corr} [v_{it}, v_{is}] &= \rho = \frac{\sigma_\varpi^2}{\sigma_\varepsilon^2 + \sigma_\varpi^2},
 \end{aligned}$$

where  $Y_{it}^*$  represents an approximation of the unobserved measure of bank ratings and  $Y_{it}$  refers to the observed variable. The values of a matrix of the independent variables  $x_{it}$  can be observed for the bank  $i$  at time  $t$ . Note that  $z$  is the unknown "threshold" parameter which can be defined as the range of the set of observed value,  $Y_{it}$ , to be estimated in combination with a vector of

the estimated coefficient  $\beta'$ . Let  $\varepsilon$  have a standard logistic distribution and its underlying cumulated distribution function can be expressed as  $\frac{\exp(z)}{1 + \exp(z)} = \Lambda(z)$  and  $\varpi_i$  represents the group specific term which is distributed as  $N(0, \sigma^2)$ . We consider  $M$  categories ordered from lowest to highest as  $0 < z_1 < z_2 < \dots < z_M$ . A maximization of the log likelihood function associated with the threshold values  $z$  can be formed as follows:

$$L(\beta, z) = \sum_{i=1}^N \sum_{j=0}^M \log(\text{Prob}(Y_{it} = j | x_{it}, \beta, z)) \cdot \ell(Y_{it} = j) \quad (2)$$

where  $\ell(\cdot)$  is an indicator function which takes on the value 1 if the argument is true, and 0 otherwise. In this study we use an ordered logit to combining the marginal effects in order to obtain the impact of change in the covariates of each independent variable on the cell  $M$  probabilities:

$$\frac{\partial \text{Prob}(\text{cell } M)}{\partial x_i} = [f(z_{M-1} - \beta' x_i) - f(z_M - \beta' x_i)] \cdot \beta, \quad (3)$$

where  $f(\cdot)$  is the appropriate logistic density function,  $\Lambda(z)[1 - \Lambda(z)]$  (Greene, 2002).

We measured the  $\beta$  coefficients to reflect the importance of each of the independent variables on the probability of bank rating changes. The marginal effect was implemented by holding  $\beta$  and the unknown “threshold” parameter  $z$  constant. The effect of an additional unit increase in the independent variable  $x$  shifts the probability of the logistic distribution of bank ratings to the right. Therefore, the unchanged signs of the marginal effects for the probability of bank rating changes at the highest ordered level will be the same compared to the  $\beta$  signs. However, the opposite signs related to  $\beta$  signs for the probability of bank rating changes at the lowest ordered level will occur. To capture a better interpretation of the marginal effect, we need to further examine the signs of the changes in other probability of bank rating changes levels because these signs are indeterminate in either direction (Greene, 1993).

## 4. Data

This study considers the impact of ratings changes from 1996 to 2002 for both short-term and long-term bank ratings to measure a bank's intrinsic safety and soundness. The sample was well dispersed regionally over the cross section of 151 banks in Asia. The regional dispersion is quite important to our analysis due to the differences in the regulations of on-site inspections and examinations to provide supervisors that affected bank's valuation by certain nations (Gunther and Levonian, 2001).

To identify the effects of off-site surveillance, we used the cross-section and time series of bank ratings based on an ordered logit with the random effect model as follows:

$$\begin{aligned}
 RATING_{i,t}^* = & \alpha_1 + \alpha_2 \cdot ADE_{i,t} + \alpha_3 \cdot CAP_{i,t} + \alpha_4 \cdot LOAN_{i,t} + \\
 & \alpha_5 \cdot IMP_{i,t} + \alpha_6 \cdot EXP_{i,t} + \alpha_7 \cdot ROA_{i,t} + \alpha_8 \cdot LIQ_{i,t} + \alpha_9 \cdot SIZE_{i,t} + \\
 & \alpha_{10} \cdot FHC_{i,t} + \alpha_{11} \cdot M \& A_{i,t} + \alpha_{12} \cdot GRE_{i,t} + \alpha_{13} \cdot SOUTH_{i,t} + \varepsilon_{i,t} + \psi_i,
 \end{aligned} \tag{4}$$

where  $RATING_{i,t}^*$  represents some unobserved measure of bank ratings. It was assumed that  $\varepsilon_{i,t}$  and  $\psi_i$  are the white-noise residual and group specific term, respectively. The two dependent variables of the short-term and long-term ratings are a linear cardinal measure of bank ratings, which consist of the following five or six values of the dependent variable of  $RATING_{i,t}^*$ , respectively:

$$ST_{i,t} = \begin{cases} 0 & \text{if } RATING_{i,t}^* \leq C \\ 1 & \text{if } C < RATING_{i,t}^* \leq B \\ 2 & \text{if } B < RATING_{i,t}^* \leq A3 \\ 3 & \text{if } A3 < RATING_{i,t}^* \leq A2 \\ 4 & \text{if } RATING_{i,t}^* > A2 \end{cases} \quad \text{for the short-term}$$

bank ratings; or

$$LT_{i,t} = \begin{cases} 0 & \text{if } RATING_{i,t}^* \leq CCC \\ 1 & \text{if } CCC < RATING_{i,t}^* \leq B \\ 2 & \text{if } B < RATING_{i,t}^* \leq BB \\ 3 & \text{if } BB < RATING_{i,t}^* \leq BBB \\ 4 & \text{if } BBB < RATING_{i,t}^* \leq A \\ 5 & \text{if } RATING_{i,t}^* > A \end{cases} \quad \text{for the long-term}$$

bank ratings.

The independent variables for the short-term and long-term bank ratings model include a set of financial and non-financial ratios to capture the impact of leverage, credit, and liquidity risks that have consistently caused financial insolvency in the banking sector. The short-term bank ratings were defined as having a threshold value ranging from 0 to 4 in order to represent ascending ratings of no rating or C below, B, A3, A2, and A1. Likewise, the threshold values ranging from 0 to 5 symbolize an ascending rating of CCC or below, B, BB, BBB, A, and AA for long-term bank ratings, respectively. This article uses the CAMEL criteria (e.g. capital adequacy, asset quality, management quality, earnings ability, and liquidity) to identify potential financial performance variables for the models. The non-financial ratios include bank size, mergers and acquisitions, financial holding company and geographic difference factors based on previously published articles. Table 1 shows the definition and notation of bank ratings as the dependant variable, and the impacts of other independent variables are described below.

This article uses the ratio of equity capital to total loans (ADE) and capital-asset ratio as a measure of capital adequacy. Persons (1999) examined the behavior of banks in response to the potential of unanticipated losses, pointing out that adequate capital must be maintained at a higher level to reflect unanticipated losses in order to reduce the likelihood of bank risk. Banks with higher ratio are assumed to be in stronger financial condition, which tends to increase probability of higher bank ratings. Moreover, the bank ratings model captures the impact of the ratio of capital to total asset (CAP) which is the most commonly used measure of leverage risk. Khorassani (2000) and Gilbert, Meyer and Vaughan (2002) found that a negative relationship between capital-asset ratio and bank risks. These findings are consistent with our view that lower levels of capital-asset ratio increased leverage risk to render a bank insolvent will enlarge the likelihood of bank ratings downgrades.

**Table 1: List of variables**

<i>Variable</i>	<i>Notation</i>	<i>Definition</i>
<i>Bank Ratings</i>	RATING	The dependent variable: [1] 1. Short-term bank ratings (ST): 0=no effect or below C; 1=B; 2=A3; 3=A2; 4=A1. 2. Long-term bank ratings (LT): 0= no effect or below CCC; 1=B; 2=BB; 3=BBB; 4=A; 5=AA.
<i>Capital to Loan Ratio</i>	ADE	The ratio of equity capital to total loans. Unit=% [1]
<i>Capital to Asset Ratio</i>	CAP	The ratio of capital to total asset. Unit=% [1]
<i>Net Loan to Asset Ratio</i>	LOAN	The net loans to total assets ratio. Unit=% [1]
<i>Impaired Loans Ratio</i>	IMP	The ratio of impaired loans to total loans. Unit=% [1]
<i>Expenses to Asset Ratio</i>	EXP	The ratio of overhead to total assets. Unit=% [1]
<i>Return on Asset</i>	ROA	The ratio of net income to total assets. Unit=% [1]
<i>Liquid Asset Ratio</i>	LIQ	The ratio of liquid assets to total assets. Unit=% [1]
<i>Bank Size</i>	SIZE	Natural log of total assets. Unit= billion \$ [1]
<i>Financial Holding Co.</i>	FHC	A dummy variable for financial holding company. If FHC=1, the bank was a subsidiary company affiliated with a holding company. Otherwise, FHC=0. [2]
<i>Merger and Acquisition</i>	M&A	A dummy variable for mergers and acquisitions. If M&A=1, a rated bank made a major mergers and acquisitions of targeting banks. Otherwise, M&A=0. [2]
<i>Greater China Region</i>	GRE	A dummy variable for Greater China Region. If GRE=1, a country locates in Greater China Region. Otherwise, GRE=0.
<i>Southeast Asia</i>	SOUTH	A dummy variable for Southeast Asia Countries. If SOUTH=1, a country locates in Southeast Asia. Otherwise, SOUTH=0.
<i>Northeast Asia</i>	NORTH	A dummy variable for Northeast Asia Countries. If SOUTH=1, a country locates in Northeast Asia. Otherwise, SOUTH=0.

*Source: Bankscope, Bureau Van Dijk Electronic Publishing Inc., 1995-2002. The Banker, Financial Times, 1995-2002.*

To capture the strength of lending activity for asset quality, this article used the net loans to total assets ratio (LOAN) as a proxy variable to measure asset efficiency. Persons (1999) contended that LOAN has a positive impact on the probability of failure. His findings reflected that the deterioration of asset quality augmented bank risks. A high ratio means poorer asset quality and it should decrease the likelihood of bank ratings. We used the ratio of impaired loans to total loans ratio (IMP) which served as credit risk to control for the lending quality of a bank's assets. We expect that the credit risk measures of IMP have a negative relationship with the bank ratings. If borrowers failed to make promised interest or to repay principal, credit losses increase the likelihood of bank failures and insolvencies caused by reducing net earning, anticipating a larger write-off of bad loans and lost capital. Benink and Llewellyn (1994), Brenda, Ceyla, and Robert (1997), and Khorassani (2000) revealed that the coefficients of the Nonperforming Loan Ratio turn out to be positive and statistically significant related to bank fragility.

This current article uses the ratio of overhead to total assets (EXP) as a proxy variable to measure the quality of management. Persons (1999) also used a similar measure for the quality of management. This ratio helps to determining a managerial efficiency of bank's overall performance that involved qualitative issues related to the risk-taking preferences, regulatory compliance, and internal control to maintain safety and soundness. It is reasonable to expect that a higher ratio reflects lower management quality and higher probability of bank risk that downgraded bank ratings to insolvency.

The next variable is a measure of earnings ability, that is defined as the ratio of net income to total assets (or, return on assets, ROA). Abrams and Huang (1987) and Khorassani (2000) found that a negative relationship may exist between profitability and the bank failure. Brenda, Ceyla and Robert (1997), and Gilbert, Andrew and Vaughan (2002) provided evidence that high levels of profitability enable a bank to increase its additional capital through accumulated retained earnings, thus improving its viability to overcome economic shocks. We expect that higher ROA increases the probability of bank risk for the bank ratings upgrade.

With regard to measuring sufficient liquidity for banks to meet the demand for unexpected deposit withdrawals, we include the ratio of liquid assets to total assets (LIQ) which plays an important role in depository financial institution risk. Brenda, Ceyla and Robert (1997) reported that an increase in liquid assets would allow a bank to deal with unexpected deposit withdrawals and hence reduce the likelihood of failure. Thus, a positive coefficient of LIQ is hypothesized for the bank ratings.

To capture the impact of asset size, Abrams and Huang (1987), Persons (1999), Khorassani (2000), and Gilbert, Meyer and Vaughan (2002) linked a non-financial variable -size variable (SIZE) (natural log of total assets) influenced the probability of bank failure. They suggested that SIZE reduces the probability of failure because larger asset size may influence bank performance by diversifying away risks by means of providing more financial products, accessing extra funds, and expanding geographic regions. Thus, banks with larger asset size should have lower probability of bank rating downgrades.

We included the financial holding company (FHC) as another non-financial variable to examine the bank's capability of fund raisings. FHC was a dummy variable that equals 1 if the bank was a subsidiary company affiliated with a holding company, zero otherwise. Abrams and Huang (1987) and Khorassani (2000) found that a dummy variable for financial holding company was negatively associated with the probability of bank failure. We used FHC as a measure of cross-selling gains to achieve better portfolio performance and to raise addition capital more easily than unaffiliated banks, thus lowering the probability of decreased bank ratings due to reduced credit risk.

We also examine to see if there is any empirical evidence that activities of Mergers and Acquisitions (M&A) in the banking sector affect bank ratings. Healy, Palepu and Ruback (1992), Cebenoyan, Papaioannou and Travlos (1992), and Lyroudi, Lazaridis and Subeniotis (1999) have examined the post-merge performance of acquirers. They found a strong positive relation between increases in shareholder wealth of the targeting firms after merger and abnormal returns around the acquisition announcement date. The results showed that financial markets were likely to expect an improvement of equity revaluations of acquirers. Thus, a dummy variable of M&A would be expected to have a significant positive influence on the probability of upgrading bank ratings due to a financial enhancement caused by gains of synergy.

Geographic differences among regional economies may also partially account for regional variations in bank ratings attributing to geographically diversified cash flow, guaranteed external support, and sound financial regulations. To account for these differences, the analysis included three regional dummy variables to capture the effect of any systematic differences by regions due to the difference in economics, finance and the regulatory environment on bank risks. We specified Northeast Asia (NORTH) as the reference dummy. We employ dummy variables for Southeast Asia (SOUTH) and Greater China Region (GRE) to determine whether geographic

differences in short-term and long-term bank ratings exist relative to NORTH.

Table 2 contains the recent history of Capital Intelligence ratings and Standard & Poor's ratings for the short-term and long-term bank rating changes, respectively.<sup>7</sup> In general, most rated banks in Japan, Hong Kong, Korea, Taiwan and Singapore had a rating of BBB or higher, whereas rated banks in Indonesia, China, Malaysia, Philippine and Thailand were mostly in the range of BBB or lower for the long-term bank rating changes. In addition, many rated banks in China, Hong Kong, Korea, Malaysia, Singapore and Taiwan obtained a rating of A3 or higher, while rated banks in Indonesia, Philippine and Thailand were generally in the range of A3 or lower for short-term bank rating changes. Rated banks in China, Taiwan and Thailand have been upgraded for long-term bank ratings since 1996, and most of them remained in the same category for short-term bank ratings. Some rated banks in Korea and Japan were downgraded to lower levels. Shizuoka Bank in 1996 and Bank of Taiwan in 1999 have received the higher ratings (i.e., A1+ or AA-), while Panin Bank in 1998 and Philippine National Bank in 1996 received lower ratings (i.e., CCC or C) for the short-term and long-term bank ratings.

We compared the definitions for the entire set of credit ratings assigned by Standard and Poor's Rating Service (S&P) and Capital Intelligence Rating Service (CI), as shown in Table 3. Note that the addition of rating modifiers (+ or -) which indicated slightly greater or lesser standing within each category were ignored to simplify rating categories. Generally, S&P and CI rating agencies issued Credit Ratings and Financial Strength Ratings for banks that were expressed in terms of default risk, and periodically assessed and correct ratings to renew the issuer's credit positions.

---

<sup>7</sup> We neglected S&P short-term bank ratings and Capital Intelligence long-term bank ratings due to a variety of missing observations. Thus, 78 rated banks remained in our analysis.

**Table 3: The definitions of standard & Poor’s (S&P) and Capital Intelligence (CI) ratings**

<i>S&amp;P Long-Term</i>	<i>Definitions</i>	<i>CI Short-Term</i>	<i>Definitions</i>
<b>Investment Grade</b>			
<i>AAA</i>	Extremely Strong Capacity to meet its financial commitments.	<i>A1+</i>	Superior credit quality. Highest capacity for timely repayment of short-term financial obligations that is extremely unlikely to be affected by unexpected adversities.
<i>AA</i>	Very strong capacity to meet its financial commitments.	<i>A1</i>	Institutions with a particularly strong credit profile have a "+" affixed to the rating.
<i>A</i>	Strong (satisfactory) capacity to meet its financial commitments but is somewhat more susceptible to the adverse effects of changes in circumstances and economic conditions than debt in higher-rated categories.	<i>A2</i>	Very strong capacity for timely repayment but may be affected slightly by unexpected adversities.
<b>Speculative Grade</b>			
<i>BBB</i>	Adequate capacity to meet its financial commitment, but adverse economic and financial conditions more likely to weaken capacity. Lowest investment-grade rating.	<i>A3</i>	Strong capacity for timely repayment that may be affected by unexpected adversities.
<i>BB</i>	Debt has less near-term vulnerability to default than other speculative issues. However, it faces major ongoing uncertainties and exposure to adverse business, financial, or economic conditions that could lead to inadequate capacity.	<i>B</i>	Adequate capacity for timely repayment that could be seriously affected by unexpected adversities.
<i>B</i>	Greater vulnerability to default but still has the capacity to meet its financial commitments.		
<i>CCC</i>	An obligor is currently vulnerable, and is dependent upon favourable business, financial, and economic conditions to meet its financial commitments.	<i>C</i>	Inadequate capacity for timely repayment if unexpected adversities are encountered in the short term.

*Note: S&P and Capital Intelligence used the addition of a plus or minus sign from “AA” to “CCC” and from “A1” to “C” to indicate relative slightly greater or less standing within similarly rating categories.*

*Source: Bank Rating Guide, Standard & Poor’s Service, 2004, [www2.standardandpoors.com](http://www2.standardandpoors.com) and Capital Intelligence, 2004 [www.ciratings.com](http://www.ciratings.com).*

Rating agencies provide not only an opinion of a bank's inherent financial soundness and risk profile, but also consider the quality of banking regulation and supervision within stability of the financial and legal systems. Rated banks with extremely strong capacity to meet their financial commitments on interest payment and principal in accordance with the terms of the obligation will be rated as AAA for long-term rating. Likewise, agencies assigned a rating of A+ to indicate that rated banks have the highest quality in a timely manner for repayment of short-term financial obligations. Banks with superior credit quality tend to be less impacted by unexpected difficulties. For a comparable assessment purpose, rating agencies classify bank ratings into two major categories, investment-grade rating and speculative-grade rating. The investment-grade rating is restricted to a bank's creditworthiness graded at least BBB for long-term and B for short-term and above by the rating agencies. Banks ranked investment-graded rating are suitable for investment by financial institutions. The speculative-grade rating is designated as BB or below for long-term and graded B or below for short-term ratings, indicating a bank reduced ability to meet financial obligation. Ogden (1987) and Cheung (1996) pointed out that investing in a speculative grade in any form of securities with higher yields or returns was prohibited by many financial institutions to avoid default risks.

## 5. Empirical Results

We began our empirical analysis using LIMDEP software to estimate an ordered logit model of bank rating changes by the maximum likelihood. The empirical results of four alternative models are shown in Table 4. We also compared short-term and long-term bank ratings to evaluate off-site surveillance. The results of short-term bank ratings are in columns (1) and (2), while long-term bank ratings are in columns (3) and (4) with different specifications, respectively. The analysis utilized a Likelihood Ratio (LR) test to examine the group specific heterogeneity, and the test results are presented in Table 4. We find that the values of the LR test statistics are greater than the critical value of  $\chi^2(0.01, 1) = 6.64$ . This suggests that we are able to accept the random effect for better estimation rather than a fixed constant in the logistic function under the null hypothesis. Note that in-sample predictions of correct rating classifications was correctly predicted at 81.52 percent for short-term bank ratings in column (1), comparing other predictions which were below 60 percent in columns (2)~(4). The results of the threshold values, such as B, A3, A2, and A1 for short-term and B revealed that  $B^- \sim B^+$ ,  $BB^- \sim BB^+$ ,  $BBB^- \sim BBB^+$ , and  $A^- \sim A^+$  for long-term bank ratings, are all statistically significant. This finding reveals that categorizing

bank ratings were clearly definable and appropriate for uneven spacing intervals.

*Source: Author's calculation*

The estimated coefficient on the ratio of equity capital to total loans is positive and significant in column (4), similar to the finding of Persons (1999). Higher adequate capital level has great impact on financial performance improvements to lessen unanticipated losses and bank risks that upgraded long-term bank ratings, whereas other types of specifications do not. The coefficient for the ratio of capital to total assets is positive and statistically significant for long-term bank ratings in column (3), indicating that higher levels of capital that lowered leverage risks tended to upgrade bank ratings.

It should be noted that all four of the estimated coefficients of net loans to total asset exhibit the expected signs and are significant. These results are consistent with the earlier findings of Abrams and Huang (1987) and Persons (1999), that rating agencies take a higher net loans to total asset ratio as more accurately reflecting lower asset quality and larger loans default, which significantly contribute to downgrade short-term and long-term bank ratings.

The results strongly suggest that the ratio of impaired loans to total loans ratio (IMP) has a negative and statistically significant impact on the probability of short-term bank ratings in column (1). This implies an inverse relationship between downgrade probability and credit risk due to the deterioration in asset quality and profitability.

The estimated coefficients on the ratio of expenses to assets are negative and statistically significant although they are insignificant in column (2). This indicates that higher operating expenses to total assets makes the rated bank's management inefficient due to overpayment of its personnel and highly leverage that incurred greater risks would indicate poorer financial position and hence downgrade the bank's ratings.

The significant positive coefficients on return on assets (ROA) in columns (1) and (4) provide further evidence that an increase in ROA, which indicates higher earnings ability and relatively lower exposure to default risk, may raise the probability of bank ratings upgrade on off-site surveillance.

As for the effects of liquidity risk of rated banks, the results reveal a positive and statistically significant impact of the ratio of liquid assets to total assets (LIQ) on long-term bank ratings in column (3). We find that higher LIQ improves the long-term bank ratings since there is sufficient liquidity to meet the demand of large withdrawals for long-term certificates deposit but

not in short-term bank ratings. One reason for this may be that rated banks are required to maintain reserve requirements regulated by the central bank to meet their demand deposits.

Generally, bank size carries a positive and significant sign. This is consistent with a priori theory because larger-sized banks may be more successful in raising extra funds and diversifying away risks, thus increasing the probability of better short-term and long-term bank ratings.

The effects of association with a financial holding company (FHC) are somewhat mixed for short-term bank ratings, and this variable did have statistically significant effects on bank ratings. These results echo the finding of Khorassani (2000) that financial holding companies may decide to hasten the bank closure rather than provide subsidies under the pressure of ensuring the survival of other associated banks. On the other hand, ratings agencies may upgrade short-term bank ratings for associated banks of financial holding companies because they may easily hire capable personnel who can raise more capital and improve management quality to reduce bank risks. In addition, this finding also supports our expectation that rated banks that belong to financial holding companies do receive a greater probability of better long-term bank ratings by rating agencies. Financial holding companies provide a better environment for commercial banks to achieve portfolio performance, obtain addition capital and diminish their inherent risks by increasing their cross-selling gains.

Inconsistent with a priori hypothesis, the findings show that mergers and acquisitions (M&A) have a negative and statistically significant effect on short-term and long-term bank ratings. This suggests that rated banks whose growth strategy involves takeovers have a lower probability of upgrading ratings. Wansley, Elayan and Maris (1990) and Goh and Ederington (1993) reported a significant negative reaction in stock returns for downgrading credit quality when a rating agency notes a firm's financial difficulty and lower earnings. Additionally, Ghosh and Lee (2000) and Kohers and Kohers (2001) concluded that acquirers may not obtain an increase in long-term post-merger performance due to a high premium deal, a low book-to-market ratio, a severe agency problem, and disciplinary actions<sup>1</sup> when there was managerial performance of the targeting firms performed improperly.

To control for geographic differences in the responses of short-term and long-term bank ratings across ten countries, Southeast Asia and the Greater China Region are included in the model. Generally, the results seem

---

<sup>1</sup> Palepu (1986) and Cudd and Duggal (2000) pointed out that the acquirers may use disciplinary actions to whip on the inefficient managers of the targeting firms prior to the acquisition in order to benefit the shareholders' wealth.

to indicate that rated banks located on Southeast Asia and the Greater China Region are less likely to obtain creditworthiness on short-term and long-term bank ratings than rated banks in Northeast Asia.

To better evaluate the probability of observing a particular rating, the estimation of the marginal effect for an ordered logit model is also shown in Table 5. The estimated marginal effects for the set of CAMEL variables, including capital to loan Ratio, capital to asset ratio, net loan to asset ratio, expenses to asset ratio, returns on asset, liquid asset ratio and impaired loans ratio are all close to zero. Thus, small changes of these variables may have a negligible impact on the probability of short-term and long-term bank rating changes. The results of other factors such as bank size, financial holding company, and mergers and acquisitions in explaining short-term and long-term bank ratings are unique. This study clearly reveals that a larger bank size reflecting less default risks and easier fund raising may improve the likelihood of better short-term and long-term bank ratings, especially for the investment-grade rating at BBB or above, and it reduces the probability of the speculative-grade rating at BB or below.

Overall, we found that association with a financial holding company increases the likelihood of receiving long-term investment-grade bank ratings of a BBB or above. This result suggests that rated banks belonging to a financial holding company with many subsidiaries seem to have better financial performance, lower inherent risks, more professional workers and greater cross-selling gains. However, association with a financial holding company not only decreases the likelihood of receiving a BB or below for the long-term speculative-grade, but also downgraded the short-term bank ratings. This would imply that certain policies that regulate the financial holding companies may accelerate the bank closure process rather than rebuild the creditworthiness of rated banks. Most importantly, M&A activities will decrease the likelihood of observing a BB or below for the long-term speculative-grade and short-term bank ratings but increase the likelihood of observing a BBB or above for the long-term investment-grade bank ratings. This implies that the dividable scale of the investment-grade and speculative-grade ratings provided useful information for banks to improve their creditworthiness efficiently and strengthened some principles of mergers and acquisitions behavior.

## **6. Conclusion**

This study used an ordered logit model with random effect to examine the proposition that bank rating changes related off-site surveillance for 151 banks' safety and soundness were determined by financial and non-financial

factors during 1996 to 2002. We attempt to emphasize the marginal effect of the mean value change for the financial variables such as capital to loan ratio, capital to asset ratio, loan to asset ratio, impaired loan ratio, expenses to asset ratio, return on assets, and liquid asset ratio. We also examine the marginal effect for non-financial variables such as bank size and dummy variables of financial holding company, mergers and acquisitions, and regional factors on the different probabilities of bank ratings.

Our findings indicate that a rated bank with smaller net loans to total assets ratio, lower expenses to assets ratio, higher return on assets, and larger bank size was more likely to experience improvements in creditworthiness than other banks. This suggests that rated banks associated with short-term and long-term bank ratings act to certify increased asset quality, improved management efficiency, strengthened fund raising and enhanced earnings ability to investors in order to diversify risks. It was found that a mergers and acquisitions strategy has a lower probability of upgrading bank ratings, because a rated bank faced improper managerial performance, financial difficulty and lower earnings of the targeting firms. Geographic differences are also evident among rated banks in Asia. A rated banks located in Southeast Asia and the Greater China Region were weaker than those in Northeast Asia, possibly due to the vulnerability of the banking sector caused by the financial crisis of 1997 and sovereign risks.

The short-term and long-term bank ratings from an international analysis highlight differences in off-site surveillance of rating agencies. One result from this paper is that the benefits from association with a financial holding company are more likely to accrue to rated banks for the long-term bank rating upgrade. As expected, the results indicated that capital to loan ratio, capital to asset ratio and liquid asset ratio all contributed to the changes in long-term bank ratings. This shows that higher adequate capital level, lower leverage risks, and greater liquidity are associated with upgraded creditworthiness of rated banks, possibly due to better financial performance, fewer unanticipated losses, and larger bank reserve to meet demand for unexpected deposit withdrawals. In particular, the impaired loans ratio is negatively related to the probability of short-term bank ratings due to lower asset quality and profitability. A brief analysis of the marginal effect seems to indicate that rated banks were able to incorporate the dividable scale of the investment-grade and speculative-grade of long-term bank ratings. This provided useful off-site surveillance to improve creditworthiness, enhance synergy and strengthened the mergers and acquisitions activities on the basis of a rated bank's inherent risks. In addition, the advantage of financial holding company structures and mergers and acquisitions activities did not take place, whereas a larger bank size can assess fund raising, apparently

upgrading short-term bank ratings. To the best of our knowledge, the impact of bank ratings changes on off-site surveillance in the pre- and post-M&A period for banks has not been thoroughly examined in related literature. This would be significant topic for further study, providing a useful means by which regulators can assess changes of creditworthiness in the banking sector.

**Table 5: Marginal effects of variables on the short-term and long-term bank ratings**

<i>Regressor</i>	<i>Short-Term Bank Rating</i>					<i>Long-Term Bank Rating</i>			
	<i>ST=B</i>	<i>ST=A3</i>	<i>ST=A2</i>	<i>ST=A1</i>	<i>LT=B</i>	<i>LT=BB</i>	<i>LT=BBB</i>	<i>LT=A</i>	<i>LT=AA</i>

## **Abstract**

*Integration of each state into the world economic flows requires certain adjustments in different fields of economic life. One of the fields where coordination and harmony are necessary is the field of financial reporting. The worldwide financial community recognizes the need for one set of accounting standards, with added transparency and comparability. A desire of all who prepare, audit or use financial statements is one set of high quality accounting standards used globally by all private or public entities. Having a single set of standards helps to ensure consistency of accounting and reporting among all countries, which results in better and more efficient financial analyses of entities. This will result in more efficient flows of capital because investors will not have to assign risk premiums to entities operating in countries with inconsistent or low quality accounting standards. Finally, it will reduce costs because accountants, auditors, financial analysts, investors, and regulators will no longer be converting or reconciling financial statements from one set of standards to another. International Financial Reporting Standards makes significant progress toward global recognition. For private sector, IASB issued IAS/IFRS and for public sector IFAC issued IPSAS/IPSFRS.*

**Keywords:** *accounting; international regulations, private sector, public sector*

## **1. Introduction**

It is now over 15 years since the beginning for many countries in the CEE region of the transition from a command economy to a market economy. As transitional economies seek to adapt to, or join, the international community there have been moves to adopt or adapt international accounting standards (IAS) either for a part or all of the country's enterprises. Local accountancy profession have developed either drawing upon institutions pre 1989 or created de novo as in Romania.

In the same time, the importance of private sector in economy increase, a lot of domestic new companies appeared in Romanian business environment, result of privatization process, or, of private sector investment. Now there is a significant number of large private companies which operate in Romania, beside the public entities.

For all type of entities (private or public) the transition to free market economy brings new challenges to accounting field, especially regarding the information quality and financial reporting.

The aim of this research is to analyze the steps made by Romanian accountancy on the way to the European and Global Harmonization both for private and public sector.

The research was carried out on the basis of the available sources and research methods (historical analyses, benchmarking with international references, s.e.)

## **2. A single set of accounting standards: an Esperanto business language**

### ***2.1. The need of a common language***

Accounting, perceived as business language, becomes a socio-economic necessity of the international business community.

The worldwide financial community recognizes the need for one set of accounting standards, with added transparency and comparability. A desire of all who prepare, audit or use financial statements is one set of high quality accounting standards used globally by all private or public entities.[1]

Having a single set of standards helps to ensure consistency of accounting and reporting among all countries, which results in better and more efficient financial analyses of entities. This will result in more efficient flows of capital because investors will not have to assign risk premiums to entities operating in countries with inconsistent or low quality accounting

standards. Finally, it will reduce costs because accountants, auditors, financial analysts, investors, and regulators will no longer be converting or reconciling financial statements from one set of standards to another. International Financial Reporting Standards makes significant progress toward global recognition.

Till now, for private sector International Accounting Standards Board issued IASs/IFRSs and for public sector International Federation of Accountants Committee issued IPSASs/IPSFRSs.

IPSAS are based on the International Accounting Standards (IASs) issued by the International Accounting Standards Board (formerly known as IASC). Some accounting issues in the public sector are not fully addressed in the IASs. Similarly, accounting for a number of complex issues will be addressed in IASs currently under development.

We must recognize the significant benefits of achieving consistent and comparable financial information across jurisdictions and we believe that the use of a single set of standards will play a key role in enabling these benefits to be realized.

The adoption of standards by public and private entities will improve both the quality and comparability of financial information reported by entities around the world.

## ***2.2. About the single set of standards: concepts and aims***

If the international economic community will agree the use of a single set of accounting standards, these will represent a *single set* of high quality, understandable and enforceable standards, *transparent* and *comparable* information, *convergence* of national and international standards, *principles-based* standards.

**Transparency** Financial statements should represent faithfully events and transactions that imply to represent and report volatility when it happens, not when management chooses to report it.

**Comparability** Financial statements should account for like transactions and events in a like way and account for different transactions and events differently.

The aim of the unique set of standards is to contain clear statement of underlying principles, deal with almost all events, transactions and structures that arise in practice, allow entities and their auditors to use professional judgment in applying the principles to other events, transactions and structures.

### ***2.3. The benefits brought by the single set of standards***

The single set of standards offer important and positive implications for organizations and individuals that adopt them, such should be:

- reduces cost of capital and the ease of using one consistent reporting standard from subsidiaries in many different countries - for entities
- offer better information for decision making, leading to broader investment opportunities - for investors, creditors
- offer better information for market participants in a disclosure-based system.

Undeniable, the standards provide higher quality information, more transparency and consistency, so the entities financial statement will be comparable both in time and space. Financial statement will look alike everywhere, in any country. The entities will report their financial statements according the standards by presenting the same thing, without any selection or options to reconsider. We have to underline that the benefits of improved financial information does not only serve to entities' externals. Management itself, working within an entity, should be able to see more clearly the economic reality of the entity's activity, and take better management decisions.

### **3. Romanian accounting system before 1998 – an overview**

Under the communist regime, socialist accounting system was characterized by 'operating' in the absence of the real and effective price mechanisms. The objective of the system was to record immediate effects of the activities of the state enterprises in monetary terms but deriving from the pre-determined prices. As prices were controlled and contrived records generated by the system lacked an economic substance. Driven by the communist ideology, it was intended to render accounting information unusable for guiding economic performance. In effect, accounting was neutralised. Accounting records were much more important than financial statements.

The Romanian accounting system with its German and French roots was overlaid by a version of the Soviet based system. The Chart of Accounts were issued for different economic sectors (industry, agriculture, services) by the Ministry of Finance, together with very well defined sets of rules regarding the registration and processing of data, and financial reporting.

Annual statements included explanatory notes with information regarding completion of the financial plan, difficulties leading to failures in

the fulfillment, and predictions on the completion of the plan. Operating results were less important. Profit or loss statement was included as an appendix to the balance sheet. These statements were not publicly available but directed to the Ministry of Finance and regional statistical offices.

#### **4. Steps made by the Romanian accountancy regulation on the way of harmonization with European and international standards**

##### ***4.1. 1990- 1994 – the beginning of transition to the market economy***

A necessity to transform the socialist accounting system was, in large, determined by structural changes in a functioning of the economy [2]. As the means of production became incorporated in private ownership, the state created new legal frameworks in which economic activity was supposed to be responsive to stimulated market forces.

The transition processes, from the centralized economy to the market based economy represent a set of complex reforms of which the key issue involve privatisation, labour market reform, the development of capital markets, currency convertibility, price liberalisation, macro-economic stabilisation and welfare reform.

A transformation of the socialist accounting system into a market-based system comprises a number of intermediary stages, in which the transition system gradually becomes more compatible with the principles and practices of the market accounting system. Transformation processes need to be supported with specific measures, including the development of an appropriate institutional framework, education of the accounting professionals, legal enforcement, as well as the development of professional best practices.

In 1991 was issued Accounting Law no. 82 and the Regulations for the implementation of Accounting Law GO 704 by which was introduced of market driven accounting principles.

The above mentioned regulations cover the following subjects: entities subject to accountancy regulations, accounting operations, language and currency used for accounting purposes, corporate accounting, accounting ledgers, financial statements.[3]

1. *Entities subject to accountancy regulations* are: regies autonomes; national companies; commercial companies; national research and

development institutions; public institutions; cooperative enterprises; associations and other legal persons;

2. *Accounting operations* consist in chronological and systematic recording, processing, publication of information regarding the financial status and economic filed of the above-mentioned entities, as well as their business relations with shareholders, clients, suppliers, banks, fiscal authorities, other legal and natural persons.

3. *Language and currency used for accounting purposes* The accounts must be kept in Romanian language and expressed in the national currency (ROL). Accounting operations evidencing foreign currency transactions must be kept both in ROL and in foreign currency.

4. *Corporate accounting* Corporate entities must keep and manage accounting records by distinct departments, led by the business director, by the chief accountant or by any other person empowered to do so. These persons must have graduated a certified business school. Accounting records can also be kept by authorized legal persons or individuals who are expert accountants or chartered accountants. For companies where accounting records are not organized in distinct departments, which do not employ qualified staff under with the law or have not accountancy services, the Ministry of Finance establishes externalized turnover thresholds, beyond which authorized or certified accountancy services become applicable. The responsibility for the accounting lies with the director or any other person in charge with the entity's management.

5. *Accounting ledgers* are: *Journal - Ledger* (recording all company operations, payments received or made, as well as amounts used for shareholders/associates' personal expenses when allowed by the Articles of Incorporation, kept in chronological order), *Inventory - Ledger* (recording all real estate and movable assets, commercial and civil debenture and receivables, pursuant to an inventory), *General Ledger* (serving as a summary of the journal - ledger, –offering a synthetic view of the corporate status).

6. *Annual financial statement*. comprise the balance sheet, the profit and loss account accompanied by accounting policies and explanatory notes, and for the large companies are added: capital movements statement, cash flow statement. Data in the financial statement must be consistent with data recorded in accounting books and to the assets and liabilities inventory and any set-off between accounts, as well as between income and expenses in the profit and loss account are prohibited. The annual financial statements must be kept for 50 years.

In 1991 was issued an another important law, the Company Law no. 31/1990, where there are presented some aspects regarding the accounting:

- The financial statements must be discussed, approved and amended by the General Meeting of the Shareholders, whereby the dividends are based on the earned profit;

- The company directors cannot approve the balance sheet and the profit and loss account except if they own at least half of share capital and legal majority cannot be attained without their vote;

- Corporate auditors check: balance sheet; profit and loss account; accounting books and draw up a detailed report regarding the balance sheet and the profits, relied on by the Shareholders' General Meeting when approving the balance sheet.

- The balance sheet, profit and loss account and directors' and auditors' reports must be submitted at least 15 days prior to the Shareholders' General Meeting. Within at most 15 days after the General Meeting, directors must file a copy of the balance sheet with the fiscal authorities and following its endorsement file it with the Register of Commerce.

In this period, an importance was given to the construction of the accounting record. Hence, provisions for proper and authorized documentation, the compilation of the accounting entries, and the maintenance of proper accounting records were introduced. An emphasis was placed upon the evidential nature of the accounting record. The implicit assumption was made that provided the accounting record was properly compiled, the financial statements would be necessarily correct [4], as was the case in the socialist economy context.

Accounting reform also encompassed a re-adoption of the regulation of the pre-communist era, these provisions have been revived by ministerial decrees and other legal documents, as well as existing accounting norms (authorised practices) were amended to form accounting standards.

In Romania, like in other CEE countries, The Ministry of Finance acts as a regulator of accounting. Hence, state, not the profession, has acquired a dominant position in reforming the systems. Now accounting, previously seen as an instrument of direct administrative control over state enterprises, becomes an instrument of indirect control and surveillance over privatised, and in a process of privatisation enterprises.

The Accounting Law promote the use of accrual basis accounting, but only the private sector entities applied fully accrual basis accounting. The public sector entities continued to apply the cash basis accounting so there are important differences between private and public sector accounting. One

of main difference regards the financial statements. When the accrual basis of accounting underlies the preparation of the financial statements, the financial statements will include the statement of financial position, the statement of financial performance, the cash flow statement and the statement of changes in net assets/equity. When the cash basis of accounting underlies the preparation of the financial statements, the primary financial statement is the cash flow statement. For these reason we will present the follow stage of accounting harmonization separately for private sector and for public sector.

## ***4.2. The private sector accounting harmonization process***

### **4.2.1. 1994-1997 pre-harmonization period**

External pressures (primarily from the Western Europe) have caused accounting reforms to be placed upon political agendas. Romania have retained compulsory national charts of accounts, but reformed them by abandoning the old-Soviet style charts for the charts based on the French model [5].

In 1994 a system of accounting, based on the French system and incorporating a revised "chart of accounts" was introduced. The Romanian accounting system is codified and rule driven, being based to a large extent on the French model, with a chart of accounts consisting of some 100 obligatory accounts, each with its account name and number defined by law. For each new activity (see the case of leasing, merger, provisions) the Ministry of Public Finances issued a methodological guideline, with accounts, accounts correspondence and registration flows, obligatory to follow.

This was in part influence by the mutual interest; Romanian accountants were interested in strengthening their influence with French help and French accountants were interested in strengthening economic interests in Romania [6].

The main characteristics of Romanian Accounting System before the harmonisation with IAS and EU regulations are: [7]

- *main user groups* Historically, accounting in Romania was directed towards providing information to two user groups, the Tax Authorities and the Government. This led to the financial statements that were being prepared according to regulations that allowed very little scope for judgmental accounting entries, provided limited disclosure, and as a result were of very limited use to other users (shareholders and management).

-*profit and loss structure* It should be noted that Romanian expense accounts are categorized by nature rather than destination, thus these include

accounts such as "Wages and Salaries", "Depreciation of Fixed Assets", etc., rather than cost of sales, marketing costs, etc. however, with a reasonably good, preferably data-based driven accounting system, it is not too difficult to meet both Romanian statutory reporting needs and management and group reporting requirements. Although the standard chart of accounts includes a couple of dozen of provision accounts, it is very unusual to see any of these used.

- *strong connection between taxation and accounting* While the new system allowed for a degree of judgment in recording accounting entries, in practice those which did not have any tax consequences were rarely made, reflecting the unwillingness of most accountants to record entries other than those that were required to calculate taxable profit.

- *financial year* starts on January 1 and concludes on December 31, with the exception of the first year of activity when it begins on the date of formation. All Romanian companies have to have a December 31 year-end. If a Romanian company is a subsidiary of an international companies group, and the group has a different year-end, the Romanian company must prepare two separate closures, two financial statements, one under Romanian regulations at December 31 and the other one at the group year –end.

- *period basis* Profit and losses are registered in the accounting records on a monthly basis.

- *allocation of profit* The allocation of profit is recorded in different parts of the book accounts, depending on its destination according to the law.

#### **4.2.2. 1997- 2000 first harmonisation period**

As candidate to the European Union membership, Romania undergoes intensive accession programs. One of key conditions for the accession is harmonization of the financial reporting systems (incorporating practice of accounting, audit and taxation) with the European Directives and with the International Accounting Standards (hereafter IAS) framework (the 2002 EU regulation), under condition that the latter are not in opposition with the European Directives (The British Know How Fund, 1999). The application of the IAS is believed to provide the platform for increased foreign investment and foreign trade [8].

So, from 1996, an UK based project was rolled, designed to help Romanian accounting to evolve in a direction closer to the capital-market style of accounting in the Anglo-American context [9].

As a result of this process, IAS has effectively started to be rolled out in Romania, with 197 Companies being required to apply IAS for the first

time in respect of the year ended 31 December 2000. The number of Companies required implementing IAS increased constantly. It should be noted that departures from IAS are still permitted in the new standards, but such departures would normally result in the accompanying audit opinion being qualified.

For these aim was issued the Order no. 94/2001 of the Ministry of Public Finances on accounting regulations harmonized with the 4<sup>th</sup> Directive of the European Communities and with the International Accounting Standards.

Under the terms of Order Nr 94 of January 29, 2001, Romanian Accounting Law is being harmonized with the IV<sup>th</sup> Directive of the European Union and with International Accounting Standards. All quoted companies, state corporations and all companies working in the capital markets must apply the new Romanian Accounting Standards starting with the year 2000. These new standards will progressively become compulsory for other largish companies based on total assets, turnover and number of employees for the previous year, as follows:

<b>Year ending</b>	<b>Turnover (Million Euro)</b>	<b>Total assets (Million Euro)</b>	<b>Employees</b>
December 31, 2002	8	4.0	200
December 31, 2003	7	3.5	150
December 31, 2004	6	3.0	100
December 31, 2005	5	2.5	50

Companies meeting these criteria must be audited, under the provisions of the Government Emergency Ordinance Nr 75 of 1999.

Smaller companies may opt to apply the new rules if they have obtained an approval from the Romanian Ministry of Finance.

Starting with the 2006 year-end, small and medium enterprises (as defined by the existing legislation at that time) only will be left outside the scope of the regs. These enterprises apply the provisions of the republished accounting law 82/1991 and the Regulations 306/2002, wich are the simplified version of Order Nr 94 of January 29, 2001. Where the financial statements are fully complying with Order 94/2001, but do not comply in total with the provisions concerning inflation and/or consolidation, the audit report has to make specific references to that.

Legal persons that do not have to comply yet with the harmonized European accounting rules, the annual financial statements comprise the balance sheet, the profit and loss account accompanied by, if case, accounting

policies and explanatory notes. Legal persons subject to the harmonized European accountancy rules, annual financial statements must comprise the balance sheet, the profit and loss account, capital movements statement, cash flow statement, accounting policies and explanatory notes.

The introduction of MoF Order 94/2001 has seen an increase in the level of disclosure of information in notes and adding additional reporting requirements (including introduction of cash-flow statements and statements of changes in shareholders equity) and an increasing emphasis on provisioning and accruals considerations, although there is still, in some cases, an inclination to limit the differences between accounting and taxation profit.

#### **4.2.2. 2001- 2006 harmonisation period**

MoF Order 94/2001 and subsequent regulations have imposed some non-compliance with International Financial Reporting Standards (IFRS) and is based on the application of International Accounting Standards in effect as of 1 January 2000, being the date when a Romanian authorised translation of International Accounting Standards (as they were then named) were issued. No subsequent Romanian translation of IFRSs has occurred. A number of changes have occurred and are intended in IFRS, as the moves are taken to apply the Standards throughout the European Union and to give them an increasingly prominent position internationally.

Legislation issued in 2004 (MoF 1775/2004) has indicated that the European Union 4th Directive (on financial reporting) and the 7th Directive (on consolidated accounts) is to be applied for financial reporting from 1 January 2006. To follow relevant Directives, implies compliance in full for certain entities with International Financial Reporting Standards. Such compliance would also imply that 31 December 2005 financial statements would be prepared in accordance with International Financial Reporting Standards to provide for 2006 comparatives. This is an area where further clarification is likely to occur for some entities.

MoF Order 94/2001 reporting up to 31 December 2004 has excluded for reporting to the Ministry of Finance and as the basis for the financials to be used for profit distribution purposes hyperinflation accounting (IAS 29) and preparation of consolidated financial statements (IAS 27). The same situation is expected to apply for 31 December 2005 reporting, with reporting for 31 December 2006 to be fully compliant with IFRS for entities in accordance with the EU 4th Directive.

Consolidated financial statements for a company and its subsidiaries, are currently not required by the legislation relating to completion of

statutory financial statements for MoF Order 94/2001 compliant companies. Law 82/1991 (republished in January 2005) requires that the standards in the International Financial Reporting Standards relating to consolidation should be applied commencing with the year ending 31 December 2006.

It has been indicated that the EU 4th Directive will be fully applied for the year ending 31 December 2006 for Romanian entities. This is likely to mean full IFRS application for certain entities. For 2005, MoF 94/2001 reporting is considered to apply international standards that were in force for years commencing on 1 January 2000, with subsequent changes to IFRS not being specifically acquired, although early adoption of IFRSs can occur. For years commencing on or after 1 January 2005, IFRS has had substantial changes that are not considered to be compulsory for MoF 94/2001 reporting, although early adoption of IFRSs are allowed. For banking entities reporting under MoF 1982, IFRS reporting requirements are considered to be followed.

#### ***4.3. The public sector accounting harmonization process***

Until 2000 the accounting system for the public sector applied in Romania was characterized as being an accounting system based on cash .

For Romania, in the context of European integration, the achievement of the public sector accounting reform has become an urgent necessity. The key-element that confirm the need of reform in public sector accounting is the informational gaps of the actual system based on cash accounting.

An example is the extreme case of local governments from villages which are strictly in the limits of pure cash accounting, by the overlapping of the expenses notion with the payment notion, of the income notion with cashing-in, low-training level of the staff, over standardization of activity, low technical endowment or even the lack of it.

The harmonization process of Romanian Budgetary accounting suppose some main adjustments of current system, regarding:

**1. Accrual systems, for inventories, receivables (taxes, social contributions and interests) and payables:** these are necessary for the recognition of expenditures (and receipts) made in financial periods other than those in which the costs were actually incurred.

**2. Recognition of full depreciation of fixed assets:** to ensure full incorporation into the costs of activities of the consumption, use and deterioration of fixed assets. This is often a significant cost component of capital-intensive public sector activities.

3. **Assessment of normal profits as "costs of capital"**: will recognize the return on investment implicit in the use of the funding of fixed and working capital by owners or by other funding sources in addition to loans.

4. **Revaluation of fixed assets to allow for inflation**: will result in recognition of *current* fixed asset values and the related *current costs* of depreciation. It also affects the proper recognition of the return on investment, when expressed as a percentage of the real (opportunity) costs of capital.

In action plan for Governmental Program for the year 2000 and 2001-2004 period for implementing Romania's medium term economic strategy, regarding the fiscal policy area and more exactly enhancing fiscal transparency and improving operational and a locative efficiency of budgetary expenditures, the planned actions were restructuring the budgetary accounting by: improving the budgetary classifications, re-setting economic classification in a privileged position against functional and institutional classifications, supplementing accounting on a cash basis with accounting on an accrual basis.

For comply with ESA 95 methodology, the Ministry of Public Finance promised to introduce the accrual accounting system for public institutions, starting with 2003. In August 2001, the Government Ordinance no. 61/2001 for completing and amending the Accounting Law no. 82/1991 was adopted in order to establish the general implementation framework. One important requirement regard the compulsory use of double entry accounting for all entities.

By the fourth quarter of 2002, the following methodological norms were promised to be prepared: norms regarding the accounting of budget provisions, norms regarding the organization and management of the assets accounting for public institutions, the Accounts' List for public institutions as well as the norms regarding the accounting of the main operations.

In order to take over the communitary aquis chapter 11 Economic and monetary union and chapter 29 Financial and budgetary expenses Romania has started rather shyly than transition process towards accrual accounting, which will require additional capacity and resources. The accounting rules, which will be adopted, will be based on the European Directives no.4 and no.7 and the European accounts system (ESA 95). There are also considered the accounting and information presentation requirements according to International accounting standards for the public sector (IPSAS). Through the position document regarding the negotiation of chapter 11 Romania engaged to report to EC according to ESA 95 requirements European standard

Accounts regarding public accounting and debt. By introducing the new budgetary classification (July 2005) applicable starting with 2006 an important step was achieved in harmonizing the accounting system for the public sector with the European and international regulations.

In order to make the Romanian accounting specialists know the best international accounting practices for the public sector The Chartered accountants Body from Romania translated into Romanian in april 2005 the International accounting Standards for the public sector, issued by the International federation of accountants, January 2005 issue .

With the intention of harmonizing the public sector accounting system with the European and international regulations, in the last 5 year a few reform elements have been introduced which aim at:

-The induction, liquidation, ordering and payment of public institutions expenses (OMFP 1792/2002), the four stages of the budget execution of expenses are carried out by all public institutions no matter their subordination and the way of financing expenses with compulsory pre-observance of procedures. Public institutions are also compelled to organize, lead the record and report the budgetary and legal arrangements starting with 2003.

- The re-evaluation and depreciation of fixed assets that are in the patrimony of public institutions (OG no.81/2003 and OMFP no.1487/2003) are introduced for the first time in the history of public administration in Romania. By introducing re-evaluation it was wished to bring at the current cost or the entrance value actualised in correlation with the utility of goods and their market value and by introducing the depreciation it was wished to reflect the real value of goods and the presentation through financial statements of a real image of the patrimony.

-The organization and leading of budgetary incomes accounting (OMFP no.520/2003), according to the Accounting law, that stipulates the compulsoriness of registering in accounting the rights and obligations of the public institutions when they are acknowledged, in this sense there had been until that moment a major contradiction between the national regulation in accounting and the regulations applicable to public institutions.

-The introduction of a new budgetary classification (OMFP no.1025/2005) applicable starting with 2006 according to ESA 95 requirements concerning accounting and public debt has contributed to making an important step in the harmonization of the public sector accounting with the European and international regulations.

With all the reform elements, the present accounting system in the Romanian public sector has a lot of faults especially concerning the quality of information provided both to managers and third party institutions.

The passage to accrual accounting in the public sector in order to take over the communitary acquis will be applied in Romania the latest in 2007.

If until now the public sector accounting has had a secondary role in comparison with the budget, a limited role in patrimony reflection, the cashed incomes and the expenses, by passing to accrual accounting, the accounting system, through the information that it will provide, will regain its deserved place.

Ministry of Public Finance issued some versions of a project of new budgetary accounting harmonized with international accounting standards but without publishing or disseminating.

This reform of public accounting has impact on all public institutions but especially the communes which are currently using another type of accounting and have a limited number of personnel with multiple responsibilities and limited access at training.

Some international consultancy teams in finallising the new accounting system for public Romanian sector help the Finance Ministry. By PHARE: Twinning Project contracted by the European Union, the consultants are involved in providing advice and consultancy with a view to providing financial management controls necessary to implement accruals accounting within the Romanian government. Another project regards the introduction of consolidated accruals accounting into the government of Romanian.

## **5. Conclusion**

### ***5.1. Regarding the private sector accounting harmonization process***

The evolution of accounting system is envisaged as driven by the political, economic and social conditions within the country. These include in particular a stringent need of attracting foreign direct investment and requirements to harmonise the accounting practices with the EU Directives and the IAS, in order to fulfil the necessary standards for integration with the European and International Organisations (EU, IFAC, OECD).[10]

New romanian accounting legislation and regulations have been largely based on International Financial Reporting Standards (which include International Accounting Standards) in relation to fundamental concepts to be followed and applied for private and public sector.

The Romanian development process implied a proper application of the new adopted accounting rules and principles as well as the setting of a time scale within which these were gradually be phased-in.

Facilitating the development of business reporting and emphasising the importance of transparency, accountability and comparability in disclosure, the national accounting system may influence the speed of sociopolitical transition and economic reforms. It also may have a significant impact upon processes of attracting foreign investment, desperately required in this part of the world.

However, with the explosion in cross-border transactions and placements of debt and equity, there is a great need for transparency and comparability of financial statements between countries. As a result, the financial community worldwide - national standard setting boards and securities regulators, multinational companies, international audit firms, and investors - is committed to the goal of one set of high quality accounting standards.

## ***5.2. Regarding the public sector accounting harmonization process***

The use of accrual accounting in the public sector is a relatively recent phenomenon and the balance between costs and benefits is still the subject of substantial debates both for academics and practitioners. The countries which decide to pass from cash accounting to accrual accounting are warned (*IFAC, 2000*) to analyze very carefully the validity and the benefits expected from this reform taking into account the conditions, the priorities and the local characteristics.

About the new accounting system for public sector there are opinion that emphasize the benefits (*Horobeanu S., Alecu G. 2003*) but also more reserved opinions (*McKendrick 2003, SIGMA 2001*). Thus in some people's opinion (*McKendrick 2003*) as long as the transition towards accrual accounting is valid for developping countries it's possible that this not necessarily good for less developed countries or with a transition economy. And in Sigma's opinion (organization that provides assistance to central European countries which are preparing for UE adhesion) : both the efficiency of the reform in the countries where it was implemented and the viability for the economies in transition remains a debatable subject both for academics and practitioners.

A change in mind is also needed, which implies a redesign of the personal value system. This means to overcome the past reluctance of prepares of financial information to disclose more than was absolutely

necessary, in particular in relation to contingent liabilities (including liabilities to State organizations), related parties identification, and disclosure of certain segmental information.

### ***5.3. Regarding the Romanian accounting harmonization process***

The Romanian accounting system (RAS), being adapted from a system originally designed for a planned economy, is particularly unsuited to decision making in a market economy. Thus poor economic decisions are made and wealth is wasted. But if users were provided with relevant information, scarce capital would be more efficiently invested and more correctly priced, to the very great benefit not only of the enterprises but to everyone. It is very rare for a technical matter of this kind to be so beneficial to society as a whole.

From 1990, it has taken some time for financial reporting in Romania to develop, as for much of the past period it has been directed to the provision of information to the State authorities and has not had as a major focus the provision of information to investors (current and prospective owners), management, financial institutions and other common users of financial reports in an international context. Financial reporting (and accounting in general) in Romania has tended to be more about "form" than about "substance",

The Romanian financial reporting requirements are continuing to undergo change and progression to move toward application of standards comparable with the European Union.

We understand that the reform of accounting system in both private and public sector is influenced by the accounting tradition (pre-communist and communist history and tradition of accounting systems). On the other hand, globalization of markets will also shape this transformation. Romania must find the equilibrium between internal and external influences, between past and future conditions, negotiating a fine balance between local culture and global pressures.

The importance of this development does not lie only in the standardization of the world's accounting system, important through that is. It lies, even more, in the fact that the standards adopted (IAS/IFRS) are aimed at transparency and at reporting economic reality, thereby allowing users of enterprise reports to make the correct economic decisions

We consider that if effectively implemented and supported, the transition accounting system can influence the speed of transition and economic transformation, the country's regional and international integration and facilitate societal changes.

## **Abstract**

*The aim of the paper is to compare collective investment in the V4 countries – Czech Republic, Hungary, Poland and Slovakia – with the selected European countries. The authors compare and evaluate fund assets, structure of collective investment funds and the whole contemporary situation of the collective investment in the East European countries and those European countries where collective investment is most developed, zooming in on the most comparable countries.*

**Keywords:** *collective investment in Europe, fund assets, types of funds, Visegrad Group*

---

<sup>1</sup> Preparation of the paper was supported by the Czech Science Foundation within the project GAČR 402/05/2758: Integration of the financial sector of the new EU member countries into the EMU

## 1. Introduction

In the course of the nineties, collective investment has become a significant investment instrument even in the former socialist countries. The purpose of the article is to compare collective investment practice in the Visegrad Group Four - Czech Republic, Hungary, Poland and Slovakia – and the selected European countries. In the selection of the European countries, account was taken of both the overall volume of the assets invested in the funds - in other words, those countries had been selected where the assets volume is the highest (namely France, Italy and Germany), and similarity of the selected countries with the Visegrad Four countries - the chosen criteria include the country's size and population number (market volume), and the country's economic advancement (Austria, Spain, Portugal, Greece, Belgium and Denmark). The authors make comparison of the assets volume in, and structure of, the funds and making use of such comparisons they endeavour to assess to what extent the collective investment in the V4 countries differs from the figures observed in the selected countries; finally they make preliminary conclusions concerning the prospects of collective investment.

## 2. Overall investment volume in the funds in the Visegrad Treaty countries and selected European countries

The base for comparison consists in investment in domestic so-called UCITS funds - i.e. funds which correspond to mutual funds under FEFSI directive (currently EFAMA<sup>2</sup>). These funds account for the majority of the fund investments in the V4 countries.

**Table 1 Total net assets + total net assets per capita for selected European countries**

<i>Country/Number of Inhabitants (million)</i>	<i>Total Net Assets (EUR million)</i>	<i>Total Net Assets per Capita (EUR million)</i>
<i>Czech Republic/10</i>	3 826	0,383
<i>Hungary/10</i>	4 627	0,463
<i>Poland/38</i>	9 551	0,251
<i>Slovakia/5</i>	1 595	0,319
<i>France/62</i>	1 053 700	16 995,161
<i>Italy/58</i>	374 840	6 462,759

<i>Germany/83</i>	230 665	2 779,096
<i>Belgium/10</i>	97 769	9 776,900
<i>Denmark/5</i>	50 432	10 086,400
<i>Portugal/10</i>	24 122	2 412,200
<i>Austria/8</i>	92 887	11 610,875
<i>Greece/11</i>	31 155	2 832,273
<i>Spain/43</i>	240 553	5 594,256

Source: EFAMA, own calculations

Should we compare overall investments into funds in the V4 countries, the majority of financial facilities is invested in Poland - amounting to EUR 9,551 million. The second place is occupied by Hungary (EUR 4,627 million), third is Czech Republic (EUR 3,826 million) and the last position is taken by Slovak Republic (EUR 1,595 million). If the population number is to be taken into consideration, Poland is on the contrary the country to fall on the tail of the chart since the number of inhabitants is markedly higher than in the other three countries. Comparisons however show that all the V4 countries fall considerably behind the selected European countries (see Table no.1) and the assets volume placed in the funds in the V4 countries account for less than a half a per cent point (0.46) in the overall investment volume of all EFAMA countries, which is rather a poor figure.

**Table 2 Breakdown of chosen nationally domiciled funds (the UCITS market, % of total of EFAMA members)**

<i>Country</i>	<i>%</i>
<i>Czech Republic</i>	0,09
<i>Hungary</i>	0,11
<i>Poland</i>	0,22
<i>Slovakia</i>	0,04
<i>France</i>	23,90
<i>Italy</i>	8,50
<i>Germany</i>	5,20
<i>Belgium</i>	2,20
<i>Denmark</i>	1,15
<i>Portugal</i>	0,55
<i>Austria</i>	2,10
<i>Spain</i>	5,50

Source: EFAMA

Considering the further mentioned countries, the absolute majority of assets is located in the funds in France (EUR 1,053,700), whereas France is

also a country in which per capita assets in funds is the highest. Still regarding the overall assets volume in funds, France is followed by Italy (EUR 374,840 million) and Germany (EUR 230,665 million); considering the high number of inhabitants, the said countries nevertheless outrun countries with markedly lower population, such as Austria, Denmark and Belgium, when it comes to assets volume in the funds per number of inhabitants. It is exactly the similar market size why these countries had been selected for comparison purposes; Belgium has equal number of inhabitants to the Czech Republic or Hungary (10 million), Denmark's population equals to Slovakia's (5 million), Austria has comparable number of inhabitants and concurrently it is one of the most proximate neighbours of the V4 countries. A comparable country for Poland is Spain (43 million inhabitants), this country had been selected also due to its relatively limited economic advancement within the European Union; similarly, Portugal (10 million inhabitants) and Greece (11 million inhabitants) had been selected for comparison with the smaller countries since the Visegrad Treaty countries intend to economically approach the former two countries as soon as possible.

The table clearly demonstrates to what extent the Czech Republic, Hungary, Poland as well as Slovakia fall behind these countries in fund investing; hence, it may be implied that a massive development in collective investment in the V4 countries is to be observed exactly because of this considerable lag. Unless a substantial economic change on the financial markets and potential negative changes (both economic and political) are to be observed in the V4 countries, the future development of collective investment in these countries is supposed to be one of the dominant indicators which shall have impact on their financial markets.

### **3. Economic advancement of selected countries and volume of assets in the funds**

Regarding the fact that development in the Visegrad Four had been substantially affected by their socialist history and hence they are still catching up with the West European countries, a part of this article is devoted to the relation of economic advancement of the country and their inhabitants and the overall volume of assets in the funds. Economic advancement is expressed by two indicators - gross domestic product per capita and average monthly salary, which is recalculated as per the purchasing power parity. The second indicator has been applied due to the fact that it better characterises possibilities of households to deposit free financial means to the funds.

As Table no.3 demonstrates, the indicators under review show a certain degree of correlation. If we first take the V4 countries into account, we can observe that the countries with the least assets in funds per capita Poland and Slovakia have the lowest GDP per capita as well as the lowest average monthly salary. The Czech Republic and Hungary show higher volume of assets in funds per capita and higher GDP as well as the average salary per capita than Poland and Slovakia, while it is apparent that Hungary's inhabitants tend to invest to collective investment funds slightly more than inhabitants of the Czech Republic in spite of the fact that GDP as well as the average salary per capita is a little lower in Hungary than in the Czech Republic.

**Table 3 Total net assets per capita and economic advancement of the country expressed by average monthly salary per PPP and GDP per capita**

<i>Country</i>	<i>Total Net Assets per capita (EUR million)</i>	<i>Average monthly salary per PPP (EUR)</i>	<i>GDP per capita (USD)</i>
<i>Czech Republic</i>	0,383	689	10 316
<i>Hungary</i>	0,463	650	9 900
<i>Poland</i>	0,251	579	6 337
<i>Slovakia</i>	0,319	522	7 624
<i>France</i>	16 995,161	1392	32 433
<i>Italy</i>	6 462,759	1347	29 047
<i>Germany</i>	2 779,096	1351	32 850
<i>Belgium</i>	9 776,900	1355	33 621
<i>Denmark</i>	10 086,400	1136	45 033
<i>Portugal</i>	2 412,200	926	16 125
<i>Austria</i>	11 610,875	1461	35 489
<i>Greece</i>	2 832,273	1037	18 366
<i>Spain</i>	5 594,256	1083	24 070

*Source: EFAMA, World Bank, own calculations*

Once we begin to compare the selected European countries, we find out that there exist three distinct groups of countries. France on its own forms the first group, whereas its volume of assets per capita markedly exceeds other countries, it has come on the second position in the average salary and regarding GDP it has fallen within the group of five countries whose GDP per capita exceeds USD 30 thousand. The second group includes Austria, Denmark, Belgium and Italy, where the high volume of assets in the funds per capita directly relates to the high GDP per capita in all the three

countries (absolutely the highest figure from the countries under review achieved in Denmark) and high average salary in Austria, Belgium as well as Italy, while it is rather lower than the average salary in Denmark<sup>3</sup>. The third group of countries consists of Spain, Greece and Portugal, while the economically most advanced Spain has also the highest volume of assets in the funds per capita. Germany may be deemed an exception which regarding the GDP per capita and the average monthly salary has relatively limited amount of assets located in the funds. This is however caused by the fact that a lot of financial means in Germany is invested into other than mutual funds, too.

Taking a look into the future, the amount of investments into funds is supposed to grow in the Visegrad Group countries also hand in hand with the growing economic advancement.

#### 4. Investments in the individual fund types

**Table 4 UCITS assets by fund type in V4 and selected European countries (% of total, as of 31 March 2005)**

<i>Country/Fund Type</i>	<i>Equity</i>	<i>Money Market</i>	<i>Bond</i>	<i>Balanced</i>
<i>Czech Republic</i>	4,68	57,34	19,76	17,00
<i>Hungary</i>	7,56	41,61	46,75	0,95
<i>Poland</i>	11,62	14,25	38,62	35,44
<i>Slovakia</i>	3,13	55,17	34,23	7,46
<i>France</i>	25,31	34,78	18,72	21,18
<i>Italy</i>	19,67	21,21	39,71	19,40
<i>Germany</i>	42,77	14,60	31,82	6,69
<i>Belgium</i>	56,20	2,31	9,20	22,60
<i>Denmark</i>	32,42	0	66,65	0,93
<i>Portugal</i>	7,55	36,54	42,33	7,73
<i>Austria</i>	14,99	11,02	52,79	6,64
<i>Greece</i>	16,26	46,19	32,06	5,49
<i>Spain</i>	33,80	22,14	28,77	15,29

*Source: EFAMA, own calculations*

It is evident that the structure of funds in all the countries under review is dissimilar and it seems to depend largely on the economic situation and historical development of the collective investment in the particular

<sup>3</sup> This fact is determined by the generally high price level in Denmark.

country. Investments in the individual funds reflect the investors' contemporary preferences which may further develop in time under changed conditions – we are however able to find interesting connections in this table. Concurrently, it is possible to compare this structure of funds with the structure of funds within the whole Europe (all EFAMA members) and the entire world<sup>4</sup> (see the Table no. 5 below).

**Table 5 UCITS assets by fund type (world, Europe, % of total)**

<i>Fund Type</i>	<i>Equity</i>	<i>Money Market</i>	<i>Bond</i>	<i>Balanced</i>
<i>World</i>	45 %	21 %	20 %	9 %
<i>Europe</i>	33 %	19 %	25 %	12 %

*Source: EFAMA*

Concerning the equity funds, the majority of financial means are in the Visegrad Treaty countries invested in Poland, followed by Hungary, Czech Republic and the last position is occupied by Slovakia. In total, all the V4 countries have rather limited amount of financial means located in the equity funds, especially making comparison of investments into these funds on the global scale as well as in Europe, where they are noticeably higher. Considering the countries under review, except for Portugal, investments into equity funds exceed 10% in all countries and over 30% in the four countries. The fact that investors in the V4 countries are so conservative is determined both by their limited experience with long-term investments (less experienced investors tend to prefer shorter-term and hence lower-risk investments) and concurrently by the situation on the world equity markets, which have not recovered yet from the three-year dramatic decline in years 2000-2002. Such a recession obviously affected the equity funds' proceeds and investors in the countries with short history in collective investment are yet to gradually regain the trust in them.

The relative "conservativeness" of investors in the V4 countries is clearly demonstrated with investments into funds on the money market, which take up majority in these three countries. Polish investors appear to be an exception, the share of funds on the money market in the total marked has shown a steady decline since year 2000, when these funds achieved 46% market share, presently only 14% share is observed. Out of the countries under review, the funds on the money market have a majority in Greece (46%) and relatively surprisingly in France (almost 35%).

---

<sup>4</sup> Source of information: EFAMA ([www.efama.org](http://www.efama.org)) and Investment Company Institute ([www.ici.org](http://www.ici.org)).

We may forecast that it is likely that if investments are to shift in the future between the individual funds, it is exactly the funds on the money market whose share in the market in the Czech Republic, Slovakia as well as in Hungary is to shrink.

In Poland, such transfers of investments may affect investors' preferences in their investments into balanced funds – Polish investors have in these funds the most financial means of all the investigated countries, the Poles are the only investors which have over 30% fund investments in these funds<sup>5</sup>. In total terms, the share of the balanced funds in the V4 countries is decreasing (e.g. such investments accounted for 63% of the whole market in the Czech Republic in year 2000, currently this figure amounts to 17%) and the individual funds shall profile as equity or bond funds. Limited interest is observed in balanced funds in Hungary, recently further fall in assets in these funds has been recorded, currently accounting for 1% of the market, while since year 2001 their share has been undulating between 1 and 2% of the market. These funds account for merely 1% also in Denmark. On the contrary, investment in balanced funds higher than the European average (12%) have, besides the mentioned Polish and Czech investors, also investors from the other four countries (Belgium, France, Italy and Spain).

The share of bond funds is considerably higher in Hungary, where it accounts for almost a half of the market, while the same investments accounted for even 74% in year 2001; a gradual fall of this share has been observed since that year. In Poland, the share of bond funds shows a dramatic fall as well, these funds showed the highest share in the market in year 2002 – amounting to 63%. The share of the bond funds amounts to approximately 35% in Slovakia and the bond funds have shown a permanent share of 20%<sup>6</sup> since year 2002 in the Czech Republic. As far as other countries under review are concerned, the bond funds are most popular in Denmark (66.65%) and Austria (52.79%), the same funds gain the least popularity in Belgium (9.2%, minimally 10% less than in other countries under review).

It goes without saying that investment in bond funds are more than in the case of other fund investments affected by the overall economic situation in the particular country, primarily by inflation, setting of interest rates and estimation of proceeds from bond funds in the future. Concurrently, the bond funds are considered as securing investments for investments in equity funds.

---

<sup>5</sup> Polish investors tend to make use of balanced funds in the long-term horizon, primarily for pension savings.

<sup>6</sup> The Czech Republic also reports the lowest inflation rate and interest rates out of the four countries.

Taking this point of view, the European investors are more conservative in their investments than “the world” investors (see Table no.5).

## **5. Conclusion**

The collective investment funds have begun to play a substantial role on the financial markets of the Visegrad Treaty countries, which is projected to gain even more significance in the future.

Unless a considerable change in the situation on the world financial markets is to be observed along with a negative event, which would affect the capital and money markets of the Czech Republic, Slovakia, Hungary and Poland, investors on these markets shall carry on investing into the collective investment funds. It may be presumed that the volume of investments into these funds shall continue to rise in the future since these investments are rather low compared to the selected European countries. Hence, there is a wide room for further growth, primarily in relation to their overall improvement of their economic advancement.

It is also likely that financial means shall be transferred between the individual fund types – investors shall pass from the funds on the money market to bond funds, especially to equity funds, as it is commonplace in the more advanced European countries and in the world.

## **1. Introduction**

Institutional investors are a permanent feature of the financial landscape, and their growth will continue at a similar, and perhaps faster pace. The behavioural characteristics of institutional investors, therefore, will be an increasingly determinant of domestic and international financial market conditions, and the implications for financial market stability warrant serious consideration. The role of banks and institutional investors allowed us characterize phases of financial development: bank-oriented, market-oriented and securitized.

## **2. Characteristics of institutional investors**

Institutional investors may be defined as specialized financial institutions that manage savings collectively on behalf of small investors toward a specific objective in terms of acceptable risk, return maximization, and maturity of claims. Videlicet entity with large amounts to invest, such as investment companies, mutual funds, brokerages, insurance companies, pension funds, investment banks and endowment funds. Institutional investors are covered by fewer protective regulations because it is assumed that they are more knowledgeable and better able to protect themselves. They account for a majority of overall volume. Institutional investors are part of non-bank financial intermediaries.

Non-bank financial intermediaries (NBFIs) comprise a mixed bag of institutions. They included all financial institutions that are not classified as commercial banks. But with the assimilation of building societies and other thrift deposit institutions with commercial banks as institutions that accept deposits and make loans, NBFIs mainly include venture capital companies, leasing and factoring and as well as various types of contractual savings and institutional investors. The common characteristic of these institutions is that they mobilize savings and facilitate the financing of different activities, but do not generally accept deposits from the public at large.

NBFIs play an important dual role in the financial system. They complement the role of commercial banks, filling gaps in their range of services, but they also compete with commercial banks and force them to be more efficient and responsive to the needs of their customers. Most NBFIs are also actively involved in the securities markets and in the mobilization and allocation of long-term financial resources. The state of development of NBFIs is usually a good indicator of the state of development of the financial system as a whole.

## ***2.1 Contractual savings institutions***

As already noted, contractual savings institutions are by far the most important NBFIs. They have the potential to accumulate vast amounts of long-term financial resources and to literally transform the structure and functioning of capital markets. Countries vary considerably in the relative importance of their contractual savings institutions. We can usefully distinguish three levels of development:

- countries where the assets of pension funds and insurance companies correspond to less than 10% of GDP;
- countries where they are over 10% but less than 50%; and
- countries where they exceed 50%, in some cases by a wide margin.

The first group covers most Latin American countries (with the exception of Brazil, Colombia and most notably Chile), all Francophone African countries, and all Eastern European and Asian countries (except the Asian countries listed below).

The second group covers Brazil and Colombia among Latin American countries, such Asian countries as India, Indonesia, Korea, the Philippines and Sri Lanka, all MENA and Anglophone African countries, and all continental European countries (except Scandinavian countries as well as the Netherlands and Switzerland).

The third group covers mainly Anglo-American and Scandinavian countries (i.e. US, Canada, UK, Ireland, Australia, New Zealand, Denmark, Finland, Norway and Sweden) as well as Switzerland and the Netherlands among European countries, Hong Kong, Japan, Malaysia and Singapore among East Asian countries, South Africa and Chile. Contractual savings institutions experienced rapid growth in the 1980s in most countries of the third group. In four of these countries (the Netherlands, Switzerland, South Africa, and the United Kingdom), the total assets of pension funds and insurance companies exceeded 100% of GDP in the early 1990s, growing from less than 50% in 1970. Among East Asian countries, Singapore and Malaysia have long had sizable contractual savings sectors, with resources corresponding to between 50% and 70% of GDP, while in the 1980s, following the radical reform of its social security system, the total assets of contractual savings institutions in Chile expanded from less than 1% in 1980 to 30% in 1990 and 52% in 1993. The main factors explaining the high rate of growth in these countries were expansion of coverage and/or high investment returns, especially in the 1980s.

## ***2.2 Contractual Savings Institutions and the Capital Markets***

Contractual savings institutions can play a very important role in the development of a country's capital market. This depends on the allocation of their assets, which varies considerably from country to country, reflecting both historical traditions and differences in regulation. Real assets, and especially equities, are heavily represented in the portfolios of UK pension funds. This is generally attributed to the equity cult that UK fund managers have developed since the mid-1960s in response to the high rates of inflation experienced by the UK economy between 1960 and 1990. But this pattern is also explained by the absence of legally imposed minimum funding requirements and by the use of pension obligations that are quasi-indexed to inflation. Real assets represent a smaller proportion of pension fund assets in the United States and other Anglo-American countries and even smaller ones in continental European countries.

In continental Europe, pension funds (as well as life insurance companies) place the largest part of their assets in government, corporate and mortgage bonds and in long-term loans. This is partly the result of investment regulations and partly the result of a traditional emphasis on conservative investment policies. Although pension funds and insurance companies are subject to upper limits on their holdings of equities (as well as overseas securities) and although their managers are seeking either increases in these limits or their complete abolition, restricted investments are well below the specified limits. But a gradual shift of asset allocations of Dutch and Swiss pension funds in favour of equity investments is taking place and this has major implications for the size and liquidity of their respective national markets.

In most countries around the world, investments in foreign assets have been constrained by regulations, either foreign exchange controls or unnecessarily tight prudential controls. Following the removal of exchange controls and the relaxation of investment rules, pension funds in several countries have built up substantial holdings of foreign equities and bonds, reaching to well over 20% in Australia, New Zealand and the United Kingdom and around 60% in Hong Kong.

International diversification may increase portfolio returns, especially if pension funds become too big for the local markets, but a more general result is a reduction in investment risk, stemming from the less than perfect covariance of returns in different national markets. Contractual savings institutions in most countries tend to display a strong "home bias", which may be attributed to the nature of their liabilities, the absence of efficient hedging facilities, and their preference for investing in markets and securities

they know better. Nevertheless, international diversification has been growing fast. Most countries, especially those with undiversified economies dominated by a few industries and a few family groups, should allow some foreign investments once a new pension system is well established.

### ***2.3 Growth Factors of institutional investors***

Growth of institutional investors can be described on two sides: supply and demand.

#### **2.3.1 Supply sides factors**

A, Institutional investors can offer the possibility of investing in large-denomination and indivisible assets.

B, Also professional management costs are shared among many investors and are marketly reduced.

C, The direct costs of acquiring the information and knowledge needed to invest is eliminated.

D, Ability to move money around among funds is in attraction so we call it customer services.

E, Institutional investors can also better control the companies than individual investors.

F, Specializing in certain types of asset can offer a wider range of options not only to households but also to other institutional investors.

G, They offer liquidity insurance to customers by allowing redemption of funds to cash without notice.

H, They also offer forms of insurance as a consequence of the pooling of risks.

I, Institutional investors can also decrease transaction and cost of diversification by large amount of trading.

#### **2.3.2 Demand side factors**

The key demand side factors underlying the growth of institutions are demographic developments and their link to saving patterns. The population is aging, owing to a decline in birth rate and rise in life expectancy, saving for retirement is increasingly taking place via institutional investors.

### ***2.4 Impact on Capital Market Efficiency***

The impact of contractual savings institutions on capital market efficiency depends on their size, their investment policies and their

management practices. From a quantitative point of view, there is a certain correlation between the size of contractual savings and the development of equity markets, but the pattern is far from clear. The equity market is very large (in relation to GDP) in the United Kingdom and South Africa where pension funds invest heavily in equities, but it is also very large in Switzerland and Chile, where pension funds invest relatively little in equities. Also, in Malaysia and Singapore, the equity market is very large with high trading volumes even though direct investments by the respective provident funds in equities are either minuscule or nonexistent. Other investors, especially foreign institutional investors, probably account for the large capitalization of the equity markets, and the large volume of trading, in these two countries. Levine and Zervos emphasized the importance of the value of trading as an indicator of market efficiency, low transaction costs and market liquidity. They found that market liquidity is positively and robustly correlated with contemporaneous and future rates of economic growth, capital accumulation, and productivity growth. Recent years have witnessed very big increases in trading volumes in many stock markets around the world as well as growing equity markets, measured in terms of market capitalization in relation to GDP. In countries, such as Malaysia and Singapore, the growing internationalization of portfolio investing must clearly be a major factor in the veritable explosion of trading volumes on their equity markets. From 7% of GDP in 1985 (admittedly a recession year with depressed market prices and activity) trading volume exploded to 250% in Malaysia and 150% in Singapore in 1993 (though trading volumes suffered substantial falls in 1994). In contrast, in European countries, in addition to international investors, domestic institutional investors must also have contributed to the growth of trading volumes. This is especially in those countries where contractual savings institutions are in the process of redefining their investment policies in favour of equity holdings. Swiss trading volume was much higher than those of the US and UK markets in 1993, while the Dutch and Swedish markets reached in 1993 the level of the UK market in 1990.

Contractual savings institutions have the potential to act as catalysts for the modernization of securities markets, the development of efficient trading and settlement systems, the adoption of modern accounting and auditing standards, and the promotion of information disclosure. In the United States, the growing market power of pension funds and insurance companies has undermined the dominance of corporate bond markets by the traditional investment banks, that long after the passing of the Glass-Steagall Act in the 1930s continued to operate effectively as a cartel, with rigid hierarchical structures in syndicated issues. Institutional investors have been a major contributing factor to the advent of competitive bidding for corporate

issues, the abolition of minimum commissions on equity trading and the restructuring of stock exchanges. The hedging needs of US corporate pension funds, operating under strict minimum funding requirements, have been instrumental in stimulating the development of immunization techniques and new products, such as zero-coupon bonds and collateralized mortgage obligations as well as index options and futures. More recently, institutional investors have become more actively involved in monitoring corporate performance and exerting direct and indirect pressure for better and more effective structures of corporate governance.

The role of pension funds and insurance companies in the capital markets has also come under criticism for allegedly causing greater market volatility, adopting a short-termist attitude on investments, and neglecting the financing needs of smaller firms. Because they trade more actively, institutional investors increase the liquidity of markets and lower volatility. However, their proneness to herding behaviour exposes markets to sudden changes of sentiment that may cause abrupt fluctuations in prices. The evidence on short-termism is also somewhat mixed and not particularly strong. Moreover, recent developments underscore the growing involvement of pension funds and insurance companies in corporate governance issues and suggest an increasing concern for the long-term performance of the corporate sector. Nevertheless, fund managers are themselves subject to short-term performance evaluations and are therefore forced to pay close attention to short-term prospects. With regard to financing smaller firms, contractual savings institutions need to rely on other specialist institutions such as banks as well as leasing, factoring and venture capital companies.

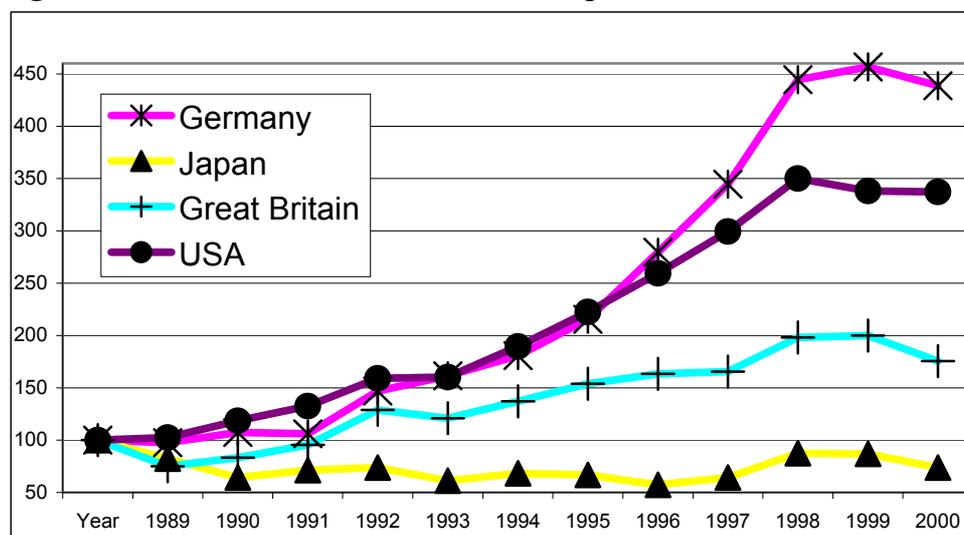

### ***2.5 Mutual funds companies***

Mutual funds investing in equities or bonds have been developed over time as means for offering to small individual investors the benefits of professional fund management and efficient risk diversification. Their number has proliferated in recent years, especially in the financial systems of high income countries. There are now mutual funds specializing by sector or by country or region as well as mutual funds following active investment management policies or passive ones using published indices of various types of securities. The proliferation of specialized mutual funds has allowed their use by pension funds and other institutional investors for their asset allocation, provided a reduced management fee can be negotiated.

Pension funds and other institutional investors clearly lack the specialist skills needed to invest in particular economic sectors or in particular regions or countries. Using well established and successful mutual funds is an economically viable and efficient alternative. Mutual funds, in the

form of venture capital funds, are also established by successful venture capitalists. Such funds have also become an important outlet for the financial resources controlled by pension funds and other institutional investors. Institutional investors often lack the skills for dealing with small firms and new ventures, both in selecting promising projects and in monitoring their performance. Participating in venture capital funds, that may also be listed on the stock exchange and may thus be easy to dispose, is an effective alternative that is gaining popularity around the world. Such funds or investment trusts may also be used for financing infrastructure projects, real estate development, and other forms of private equity. The latter usually offers higher returns than publicly listed and traded equity and is also gaining in popularity among institutional investors in America, Europe and Asia.

### 3. Situation in Slovak Republic

#### 3.1 Banking sector

Banks is still dominated in Slovak Republic at the volume of deposits. Their assets reached volume 1 162 935 mld. Sk at the end of 2004. Development of bank's assets in past few years is shown in the next table.

..

**Table 1 Bank's assets as a % of GDP**

In mil. Sk	1997	1998	2000	2001	2002	2003	2004
Assets	796256	769764	846954	928808	1014014	985445	1162935
As % of GDP	119	113	123	130	135	126	141

Source: NBS

On the other side development of bank's assets were slowly than increase assets of the others Slovak institutional investors. Last five years banks assets contribution gradually descent on total financial sector assets as marketly shown in the next table.

**Table 2 Bank's assets contribution on total financial sector assets as a %**

	1997	1998	1999	2000	2001
Commercial banks	90,0	89,9	89,6	89,2	87,7
Insurance companies	4,9	5,4	5,9	5,7	6,3
Voucher privatization funds	0,7	0,5	0,6	0,0	0,0
Investment companies	0,3	0,3	0,4	0,6	0,8
Voluntary pension funds	0,0	0,1	0,2	0,3	0,5
Leasing companies	4,1	3,7	3,4	4,1	4,7

Source: IMF

We can see the most enlarge insurance companies reducing bank's fraction.

### 3.2 Mutual funds

Mutual funds are significant institutional investors in Slovak Republic. Growth of net cash flow was nobody assuming. Mutual funds became important institutions transferring cash from primary investors to ultimate creditors in that manner. Slovak mutual funds get record in 2003 of net cash flows EFAMA<sup>2</sup> countries. Net cash flow reach amount 138 % on annual basis. Next year was very successful again with 39 % growth. At the end of 2004 was in mutual funds over 30 mld. Sk but begging of 2005 was very amazing. First February week net cash flows attack 2 mld. Sk limit.

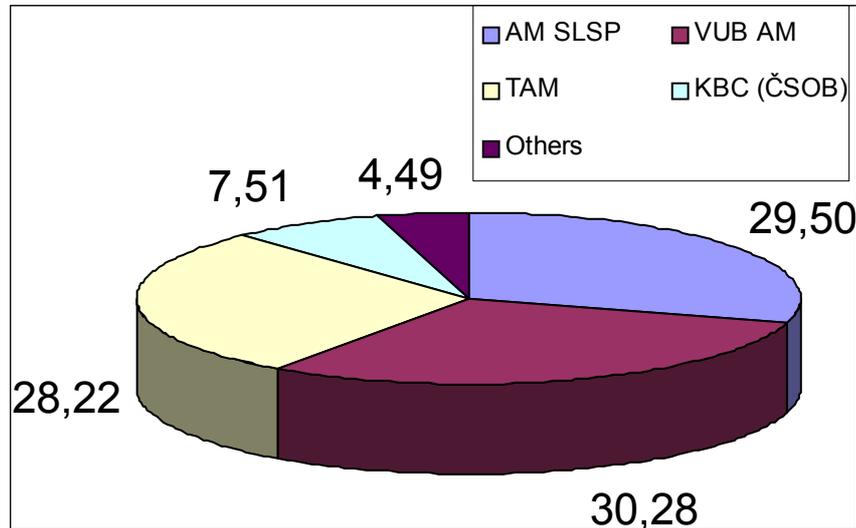

Structure of cash invested to fund follow Europe investment sentiment. Investors mainly prefer not risky type of funds like money-market and bond.

---

<sup>2</sup> Formerly FEFSI

In spite of constantly enlarging supply of new funds administering mainly foreign asset companies this market is relatively little competitive. Market is dominated by four companies established by substantial banks operating in Slovakia. Their market shares are exhibit in the chart.

**Figure 2 Market shares of mutual funds companies in Slovak republic at the end of 2004**

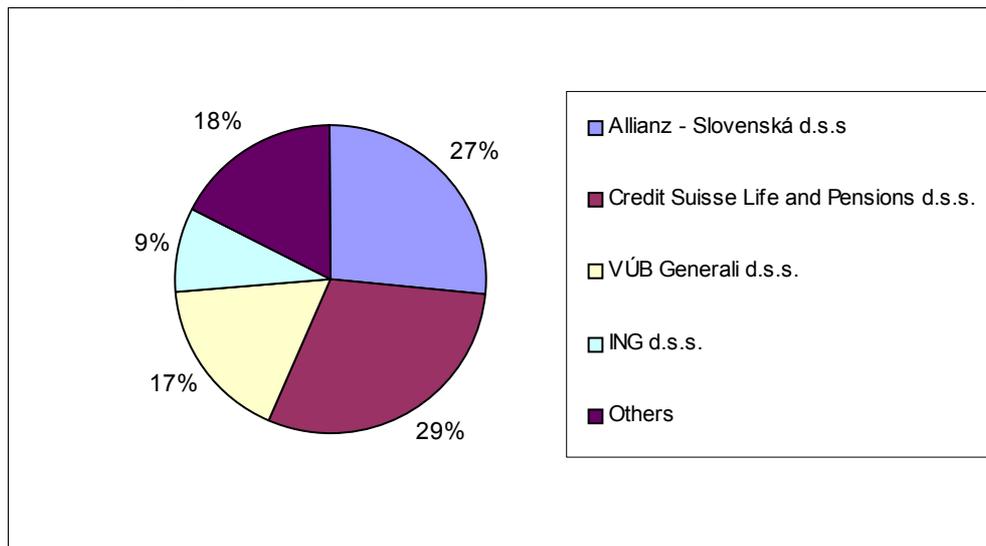

Source: ASS

The three biggest Slovak banks: Všeobecná úverová banka, Slovenská Sporiteľňa a Tatra Banka control near 90 % of all deposits to mutual fund industry. At this point of view we can say that individual investors move the cash from bank time deposits to their mutual fund companies.

### **3.3 Pension funds**

At the beginning of the year 2005 enters into force pension reform enabling to save for working people on retirement in pension funds. Much more people rebound favour about this pension reform than initially expected and now is registered over 1 million people in pension funds. Financial market authority approval eight companies due this reform in which was near 5 mld. Sk at the end of September 2005.

**Figure 3 Market shares of mutual fund companies in Slovak republic at the end of September 2005**

Source: ADSS

As like mutual fund biggest banks or insurance companies operating in Slovakia dominated to the market, exemption Credit Suisse relatively new company, focusing particularly for retired payment. Four companies managed till 80 % of invested capital.

#### **4. Conclusion**

Situation in Slovak Republic is closely to situation in rest of Europe (apart from Great Britain). Ageing of population required change of thinking both on-coming pensioners and governments. Saving for retirement increasingly taking place via insurance companies, mutual funds and newly opened pension funds in Slovak Republic. New act prefer to this by lowering tax. But we can analyze it after few years, but growth of mutual funds can confirm this.

## **Abstract**

*For beginning of a new stage in the development of collective investment in Slovakia it's possible to regard the acceptance of legislature valid from 2000, which has in an imported measure converged to the state usual in the high developed countries. The law made it possible to transform and form new home subjects – trustee companies which manage unit trusts but also entree of foreign subjects of collective investment into the slovak market. The slovak investors have got the possibility to deposit their savings into the standard funds, which activities are high transparent and active regulated. At the beginning of the year 2000, the volume of the assets in the funds of Slovakia doesn't reached a fraction of the assets in banks. The growing of the consciousness in the community about the collective investment and the overall view of subjects activ on the market and decline of the interest for the bank deposits have speeded up the interest for the collective investment through funds.*

**Keywords:** *collective investment, trustee companies, unit trusts, finance investments, yield*

## **1. Introduction**

The most usual way to valorize the finances in Slovakia is still their bearing interest on the current bank deposits. Bank products as current accounts, forward deposits and checkbooks offer a high level of security of the deposited funds, but the yield for such deposits is very low. Nevertheless is this method the most current and that for two reasons: It's altogether the first possibility, which was for the slovak investors at disposal and also the mistrust to other meaner of investing. The reason was the crash of many non bank subjects. Nevertheless straight dealing with securities offers a high yield, however it bears also the risk of loosing. Somewhere between the two a.m. ways of valorizing the finances is the collective investment. Also the open unit trusts offer a very interesting combination of three ground parameters which have to be judged by each investment how the yield, risk and liquidity. The advantage of the unit trusts is, that despite the inspect paradox, that according to the law the trusts can't guarantee a fixed yield. And therefore the client can get higher yields as by current bank productes. The motive of collective investment can be, that the client have to play in the bank that he doesn't loose and the investor in unit trusts play with the goal to win.

The activators of the collective investment in Slovakia have been from the year 2000 mainly consulting firms. Banks also startet their activity and moved the savings of the clients in the trusts. Today we can say, that the move of the savings from the current bank products into the vehicles of collective investment is in Slovakia a trend matter.

The main reason is, that the current bank products reached a negative net yield so the real value of the bank savings is going down. For many years was the reality, that the majority of population has deposited the savings in banks, today each 10th saved crown is invested in unit trusts. That's the proof, that collective investing in unit trusts combine a non risk deposit of money with reaching an overaverage profit.

## **2. Collective investment in Europe**

Collective investment is developing in Europe already over 40 years, but the biggest boom has stated in last six years. The value of the assets rose almost triple. This big increase was connected with an inflating bubble of the prices on the security markets. After the valuations of the security funds multiple exceeded the average valuations nobody want to stay outside. Interesting is the fact, that the crash of this investment bubble has not damaged the assets of the trusts. According to the statements from the European association of national units for trustee companies (FEFSI) the

whole value of assets reached in 20 European countries (EU + Switzerland and Norway) the sum of 4.761 Bi. EUR. The most important segment on the market of collective investment are the open-end unit trusts (UCITS) which bear assets about 3.511 Bi. EUR. In the countries united in FEFSI exist approximately 28.000 unit trusts UCITS, what in literal translation means „enterprises of collective investment into transferable securities“.

European legislature knows also real estate trusts, commodity trusts, hedging trusts which up to now in Slovakia not exist. Even if the unit trusts are developing in each country, on the European market of collective investment are dominant four countries. The most assets of the world fortune in unit trusts are invested in France (8,05 %), Luxembourg (7,61 %), Great Britain (2,67 %) and Germany (1,93 %).

The importance of collective investment grew in the last years significantly. For example if the value of the investment assets in unit trusts in 1995 reached 23 % of the European GDP (15 EU member countries + Poland, Czech Republic, Hungary, Norway and Switzerland), in 2002 the part reached already 52 %. In the USA the part is even 70 %. That reflects the increase of the value of assets shared for one inhabitant from 4.000,- EUR to the present 11.000,- EUR.

The period after 1995 is covering with the stage of investment bubble, when the prices of shares strongly increased. The part of shares in portfolio of European UCITS increased from 25 % to 45 % whereas the part of obligations dropped from 36 % to 24 %. In the years 2001 till 2003 the situation has changed and investors began to buy more less-risk instruments of the capital market. The part of shares in UCITS so dropped to 31 %. That was the proof, that the investors are overall in the world the same. As the share bubble was inflated and the share titles were expensive, European investors bought them. Inverse, after bursting of the bubble, when it's possible to buy shares of good quality cheaper, the part of investments in shares dropped.

Interesting is the difference of the investor-preferences. Whereas the north countries of the EU (Sweden, Belgium, Denmark, Finland) have had a part of shares more as 50 % (Great Britain even 70 %), investors in south and middle Europe have been more carefully with shares. In south Europe was the part of the shares in portfolio 30 – 40 %, in Poland and Austria even only 10 – 15 %.

The average European trust has today assets under administration about 140 Mio. EUR whereas five years ago it was only 90 Mio. EUR. Despite the strong increase the European trusts remain relatively small in comparison with the US trusts. The average size of a US trust has a level

about 875 Mio. EUR. An average trust in USA has a volume of assets like all unit trusts together in Slovakia. Even happened cases when a open unit trust closed for new investments, only to protect the existent investors.

One of leading european countries is Luxembourg, where we can observe a concentration of collective investment despite a small number of population. We can say, that the fund industry, built in this country, was exclusive construed for finance institutions, which distribute funds in the whole world. The first trust was founded in 1959 and today the number of trusts exceeds 1.500. The reasons, why Luxembourg had become the finance center in the area of trust industrie are as follows:

- *taxation*: the luxemburgian trusts are not subject of profit-taxes, taxes from capital yields, there is no taxation of dividend payments and by chance deducted tax. Luxembourg has signed an agreement about avoiding of double taxation with some countries inclusive Slovak republic,
- *favourable legislature area*: The luxembourg law is an ideal area for trusts since 1983. Luxembourg was altogether the first country, which has implemented the regulations of the EU in 1988. Practical it means, that trusts, which are subject of luxemburgian law have a „passport“ and can be distributed in the entire EU,
- *perfect finance infrastructure*: high qualified staff of luxemburgian firms is the guarantee that international investors are interested to register and to provide administration of trusts in Luxembourg.

### **3. Collective investment in Slovakia**

In 2000 passed the legislation the law No.385/1999 about collective investment, which replaced the law No. 248/1992 about investment trusts and companies, which already not corresponded to the changed conditions on the slovak capital market. The law solved complex the problems of collective investment with stress to appropriate regulation and supervision about the subjects of collective investment. At the same time the law solved the problems of investment trusts founded for the first wave of coupon privatisation. According to this law the investment companies, investment trusts and depositories have to be adated to the new legislature till 30.06.2000 and to order a new licence. Already in the first quarter there were first signs that the interest in the population to invest is reviving particularly through the opened unit trusts. The home-trustee companies have reinforced and have got a new profile and there was interest from international trustee companies.

The market for open participate letters in Slovakia exceeded the double in 2000. To it paticipated also relatively a significant decrease of interest rates in banks.

At the beginning of the year 2001 through the collective investment there was collected almost 7 Bi. SKK and in 2002 the trustee companies had under administration together 14,7 Bi. SKK. It's all the strangely that in the given period, ruled on the markets an unfavourable development for the yields of trusts. Regarding the yields in the given period under unfavourable conditions the best results have reached conservative investments: loan trusts and monetary trusts. This situation emerged as consequence of decreasing the interest rates through the central banks meant that the prices of loans soared.

Disastrous development reached the stock unit trusts, because it follows a correction of overvalued stock prices in the technological area and except of that hapened a whole recession of global economy. That caused a 30 % decrease of the fortune-value belonging to the trusts activ in the technological sector. Moreover trusts with investments on the US market have registered a dropp of their value as a consequence of decreasing the stock prices in the USA as consequence of the terrorist attacks, the consequence was the move of funds from stock markets to the loan trusts with a lower risk and a stable yield.

Regulation of collective investment has been amended from the 01.01.2002 through the law No.566/2001 concerning the securities and investment services. The law liberalized the admittance of international trustee companies to the slovak market with the objective to distribute their trusts through security dealers with the permission to grant investment services.

The entire sum allocated in unit trusts amounted to 14,7 Bi. SKK on the market were activ 39 home and 93 international open trusts and 53 closed unit trusts. In 2002 growed the market in dollar expression over 179 %, on the other side the amount invested in unit trusts have been only 5 % of the deposits of the population in banks. The best sell performance reached the currency market trusts because their performance was double higher as by deposits on the current accounts, into the stock trusts has been invested only 1,5 Bi. SKK.

Already in the first six months of 2003 the volume of the administrated fortune was over 50 % higher than in 2002. In the given period has Slovakia in the growth dynamic overtaken all middle european countries because in 2003 the volume of funds administrated through the trustee companies grew about 140 %. By the end of the year the unit trusts registered nearly 37,3 Bi. SKK. To an important measure that was caused also through the decrease of interest rates through the NBS in 2002 with which the term deposits in banks lost the interest by investors. In the category of money and

loan funds the best performance reached the funds, orientated to the slovak crown. The performance of the crown funds was at the level 3-4 % which was caused through a slow down dropp of the crown interest rates. The stock funds have reached a performance about 10 and more percent and the mixed funds 5 -10 %.

The volume of funds invested in unit trusts has increased in 2004 about 30 Bi. SKK. Similar as in 2003 the slovak market of unit trusts reached one of the highest rises in the european countries. Under 17 countries in the european federation which units the national associations of trustees, the Slovakia register the highest percentage increases of funds, invested in unit trusts. The reason is the delayed entrance of that kind of investment in comparison with other members, which have already passed the first boom. Despite this dynamic development Slovakia is still the member country with the with the lowest volume of assets in unit trusts, by conversion to one citizen the Slovakia is on the 15th range. The entire volume of funds invested in unit trusts mounted to the end of the year 2004 already round 70 Bi. SKK.

In comparison with other FEFSI countries in Slovakia are dominant money market funds. In this funds investors placed in 2004 74,6 % of funds, which have benn directed to unit trusts. For comparison in the association reached this part 12 %.

According to statistics of Slovak assciation about trustee companies nearly 75 % of all invested funds have been invested in money funds. Because of multiple decrease of interest rates through the NBS reached these funds an overaveraged value on the level 4-5 %.

Till 17 % of all new investments have been directed to the loan money funds. The drop of key interest rates supported the profits of loan money funds, which reached a valuation in average of 6,4 %. The key factor of this valuation was the decrease of the interest rates through the central bank, because by decrease of interest rates the value of purchased loans is growing and that caused the growth of the unit value.

A good valuation on the level about gross 10 % reached the loan trusts which invested their funds in government loans in middle Europe. Investments in stock trusts reached a part only about 2,6 % which is only 50 % against 2003.

The present valid law No.594/2003 about collective investment has increased the protection of the investors with the obligation of the trustee companies to fulfill the criterions of the capital appropriation in dependence to the fortune under administration of the unit trusts. By the sale of unit trusts is an important factor the width and quality of the distribution net. That

confirms the development of sales for two last years because the sale of unit shares through the branches of strong banks is the biggest competition advantage.

Source: [www.ass.sk](http://www.ass.sk)

The prove is also the reality, that between the three biggest net sellers are the trustee companies of the three biggest banks: Slovak saving bank (AM SLSP), Tatrabank (TAM) and VUB - General saving bank (VUB AM). This three leading companies share one below the other 80 % of the market. The mentioned banks are using a wide net of branches and cross-selling when the bank employees recommending the depositors, who are not satisfied with the traditional deposit products, the diversion of the money into the trusts.

The more demanding the administration of the trust is, the more employees and analyses are required. Because of frequent changes in portfolio the trust manager has to pay higher transaction costs and with it the fee in the trust is higher. The lowest fee have the money funds and the highest fee have the stock funds.

The managers of the trusts ordinary share entrance fees with the distributors, come out fee is a motivations factor, that the share holder doesn't leave the fund. Some trustee companies indicate this fee, but often they remit it, if the share holder persist in the fund a sufficient long time.

The growth dynamics of sales of participation letters has had a big speed also at the beginning of the year 2005. The net sales of open unit trusts in Slovakia have in February reached a value about 1,8 Bi. SKK. That was the second best result in the history. The entire net sales in the present year already exceeded the limit of 10 Bi. SKK. In comparison with the same period in 2004 the sales have increased quadruple and exceeded already one third of net sales of the whole last year.

Probably in the current year it will not be possible that the crown loan funds can repeat the success from the last year, the expected yielding is at the level 3,5-4 %. Money crown funds may reach a valuation between 2,5 and 3 %.

Measures of the NBS against a strong increase of the crown caused a decrease of interest for government securities and the consequence is a reduction of the yields for crown loan funds.

According to the some analytics, in the current year we can expect a more favourable development by the international stocks and by international loans, mainly by multinational european and japanese firms which have to be able to overcome the expected low growth of the economics in this areas. On the other side is to take into the consideration the move of the slovak crown rate against international currencies.

In this year it's assumed a partial increase of the part of investments to the mixed and stock funds how far will continue the growth on the global stock markets. Higher valuation is expected in case of european firms because they state a higher measure of undervaluation.

Slovakia belongs also in the fund branch to developing countries with a big potential. The collective investment started in the last period a trend of a steep developing segment of capital market. This trend will continue and that's obvious from the increase of the volume of administrated fortune in trusts of collective investment. The volume of administrated fortune by the end of the first six months of the year 2003 was 1,55 times bigger then to the end of the year 2002 and 2,1 times bigger in comparison with the same period in 2002. In 2002 the assets in unit trusts in Slovakia increased round 179 % which was in the given year the biggest increase in the world. Even if we are according the volume only a grain in the sea of sand, in the dynamik-coefficient of growth we clear also henceforth overtake other middle european countries. In 2003 no one of these countries had an increase of fortune about 98 % under administration of the trustee companies. The sector of collective investment again confirmed, that it is already some years the most dynamic part of the home finance market. In 2004 the averaged entire deposits to the open unit trusts were weekly in average 500 Mio. SKK.

**Table 2 Structure of net sales OPF in SR (in Mio. SKK, 02.18.2005)**

	<b>2004</b>	<b>2005</b>

	<b>30 262,4</b>	<b>10 612,7</b>

Source: *www.ass.sk*

Net sales of funds in Slovakia had in the first quarter 2005 the following structure: 38,2 % loan funds, 3,1 % stock funds, 2,4 % mixed funds and 56,3 % money market funds. The average investment shows the differences of the slovak investors to the relevant averages in Europe, America or the world. Slovaks are extremely careful and conservative, when they over 50 % of their investments entrusted to money market funds. The stock funds in Slovakia extremely lag behind. If we look at the dates from the end of 2003 in Europe, America or in the whole world, the importance of money market funds sank eventual stagnated. Against that in Slovakia grewed the importance already about 7 %.

On all sophisticated markets of finance investments are valid the same basic rules. The first is about risk and yield. Simplified it can be interpreted: The bigger the yield, the bigger the risk. The money market funds are the most conservative manner of investing, follow the loan funds and to the most risky investments are belonging the stock funds. The second basic rule is the longer investment horizon is at disposal, the higher risk the investor can allow to undergo. This rule can't be generalised because exist investors who don't want, can't or don't accept whichever fall of value of their fortune also when only temporary. The last rule is, that the historic yields are not a guarantee and not a determination factor for yields in the future.

#### **4. Conclusion**

The slovak capital market has a specific character and also the slovak investor has an other position in connection to this rules. He is influenced through a lot of specific factors from which probably sourced his extremely conservativity and difference opposite the more sophisticated markets. The market with slovak stocks is weak and investor in Slovakia who will take more risky investments is forced to take international investments in stocks and automatically undertakes also the currency risk. Except the moves of

share prices which can influence his yield, the move of the exchange rate of the slovak crown against EURO, USD or against other currencies can also influence his yield. The strengthening of the crown drops the profits, which can the investors gain from the stock funds. Maybe therefore the slovak investors avoid the stock markets.

The next of the factors which can influence the investors in Slovakia are historically interesting yields of crown money market funds and loan funds caused through high starting point interest rates and their gradual decreasing. Thanks to that the conservative funds also reached above the average yields. By high yields in the past the investors didn't like to undertake an additional risk in connection for instance with stock funds. In Slovakia high yields definitely not exist and in this direction the market get a standard quality. The interest rates are low and if we deduct the administration fees, the yields by loan or stock funds are more attractive as yields, which we can suspect from the money market funds. The mentioned fact may lead to more popularity of more risky funds and to a progressing approximation the structure of slovak investments to sophisticated markets.

The structure of the slovak investments was influenced through demanding of separate kinds of investments. The easiest, at least complicated and most secure is the investment in the money market fund. But that doesn't mean, that this is for the investor most suitable and most advantageous. But that's a certain tax for the inexperience.

The structure of the trust market in Slovakia has changed in the last two months radical. Market in the year meantime comparison grows, but the investors move their money from the low yielded money market funds into other types of assets. In the last year into the money funds have been directed 75 % of investments, from August of the present year there appear withdrawals from this funds.

At present the biggest increase of investments is recorded by loan funds, but a surprising big share represent investments in stock- and roof funds. In September of the present year 1/4 of entire investments have been directed into stock funds and into the roof funds even 1/3 of entire investments. Last year investors placed into the roof funds ca. 100 Mio. SKK during the last three months of this year almost 2,4 Bi. SKK.

The most important reason of this trend is a weaker performance of crown money funds, but it's also the fact, that the clients are better informed and have got some experiences from the money funds.

## **Abstract**

*Paging through professional financial publications or regular press nowadays we see analysts split over their opinions and recommendations regarding investments in different types of funds marked by varying degrees of risk and return. However, both analyses and experience from collective investments overseas, especially in the U.S., give evidence that, in the long run, index funds replicating the market portfolio yield approximately the same return as the best-performing and most profitable risk equity funds or hedge funds, which often focus on a specific market segment. Latest trends in the fund industry around the world show an increasing number of investors turning their attention to index funds, which limit the risk to investors by diversification.*

**Keywords:** *Index funds, market portfolio, exchange traded funds, innovation ETF*

## 1. Introduction

Index funds are based on Markowitz's market portfolio theory, which says that a market portfolio represents a risk weighted average return of the entire market assuming the existence of a risk-free asset. This important conclusion has led to the construction of index funds in the early 1970s, initially open to institutional investors only. The first index portfolio was set up in 1971 by the bank Wells Fargo, followed in 1976 by the introduction of the first public index fund by the investment company Vanguard and its renowned manager J. C. Bogle. This facilitated access to capital market investments to the lay public as well.

Index funds are a special type of equity mutual funds whose portfolio contains all shares included in a relevant market index, both in terms of structure and value. In other words, an index fund is a perfect copy of its benchmark index. This sort of funds combine the best virtues of open-end mutual funds (UCITS) and investment funds (Open End Investment Companies – OEICs, or investment trusts). Dividends earned on individual constituent equities are reinvested into portfolio equities, while respecting their share based on weights in the index. This ensures that the fund and the benchmark index perform along the same lines.

An index fund may sometimes fall short of the returns posted by the index it mirrors. It is due to a so-called tracking error, which gauges the deviation from the index performance. Where does the deviation come from? It is mostly from various broker fees and the funds' operating expenses or other technical factors.

### *1.1 What are the advantages of index funds?*

- The biggest asset of index funds is their passive management and, consequently, low operating costs. The only operations carried out by fund managers are those required to preserve the appropriate portfolio structure. This means they only purchase securities which are added to the index, or sell those which drop out.
- Index funds have small staff, and since there is no need to analyse securities, there are no analyst bills.
- Empirical and statistical data shows that index funds actually outperform a number of actively managed funds.
- Since their costs are low, customers pay minimum or no fees (e.g. the Vanguard 500 index funds charges a mere 0.18%).

Index funds are distinguished by the type of index they track. Many target or copy a broad market – market-wide indices (Wilshire 5000 Index, S & P 500, and the like). Some funds mirror the dynamics of a particular sector, industry (DJ U.S. Financial Sector Index), or international indices (MSCI Europe Index).

## **2. Exchange traded funds**

This form of investments, known to investors as exchange traded funds (ETF), experienced a boom in the 1990s. Their securities became tradable in secondary markets as well. The first exchange traded funds appeared and received their name in 1993 on the AMEX market (American Stock Exchange). It was mainly in the 1990s that they attracted growing interest from investors, yet the trend has continued after 2000. Investments in ETFs totalled USD 87 billion in 2002, but exceeded the USD 187 billion mark by 2004.

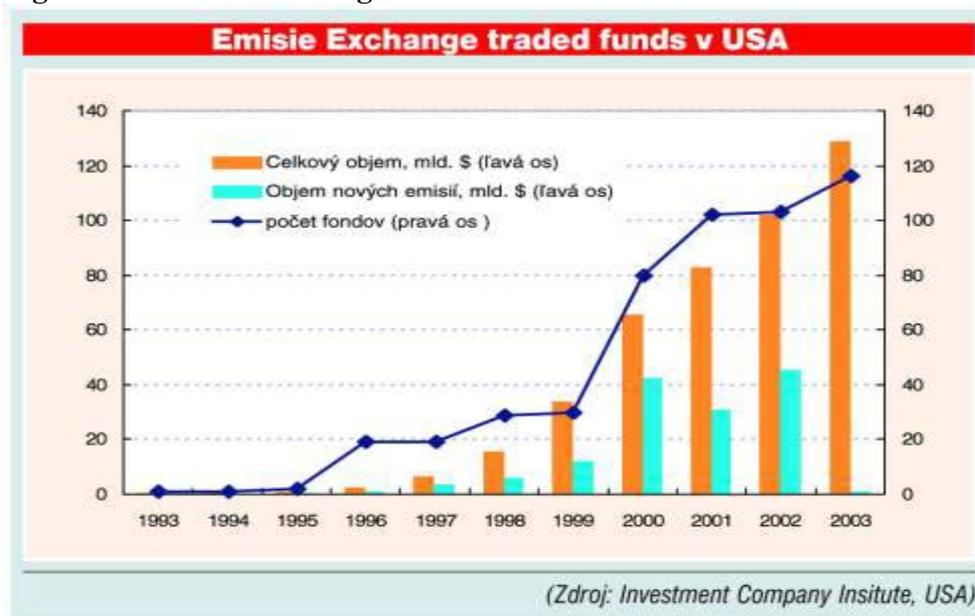

Exchange traded funds are open-ended. They have general meetings, a board of directors, executive officers (unlike classic mutual funds) and an obligation to audit their assets every year. Apart from that, there is another essential difference between classic open-end mutual funds and ETFs. Since open-end mutual funds have their asset management costs to cover, their buy and sell rates are different. The spread (premium) pays for management and trading fees. An ETF issues no unit certificates, but rather regular shares which an investor is free to buy or sell at any time.

ETFs are valued much in the way shares are rated at a stock exchange on a trading day. Their price is derived from the value of the benchmark index, or its components. Gaps, if any, between the index value and the fund price resulting from the interaction of supply and demand are offset by arbitration. The value of individual ETFs does not precisely reflect that of the benchmark index. It is determined as a percentage of the benchmark index value. For a fund replicating, for instance, the NASDAQ 100, whose value is set to  $\frac{1}{4}$  of index, if the index scores 1,200 points, the ETF will be worth USD 30 per share.

An investor may thus take long or short positions, or buy on margin from a broker. Daytrading allows institutional investors in particular to conduct arbitration operations. The very composition of ETF makes it possible. Investors take advantage of the difference between the price of ETF securities and their net asset value (NAV). Stock brokers handling arbitration transactions seek out and buy cheaper ETF shares and trade them for more expensive securities included in ETF portfolios. As the demand for ETF

securities rises, their price begins to grow and near the NAV. As soon as the price of ETF securities exceeds the NAV, the arbitrators carry out a counter operation. However, these operations are only affordable to institutional investors, as they require a large number of securities. That is the reason why the greatest interest in exchange traded funds also comes from hedge funds, which among other things deal in arbitration and other speculative trade. The development of ETFs is illustrated in the chart below.

**Figure 1 Issues of exchange trade funds in the U.S.**

Total volume in USD billion (left axis)  
 New issues in USD billion (left axis)  
 Number of funds (right axis)  
 Source: Investment Company Institute, U.S.

ETFs offer investors a wide variety of investment opportunities. As with index funds, investors can invest in the whole market, a single sector, in bonds, international equities, etc.

Among the first ETFs emerging in 1992 were SPDRs (Standard & Poor's Depository Receipts) which tracked the S&P 500 index. Traded on AMEX since 1993, they still rank among the most popular exchange traded funds today. SPDR issue deposit certificates the value of which mirrors that of equities pooled in the S&P 500 index. Investors are paid a regular quarterly dividend. Unlike early index funds, SPDRs have a lifespan till 31 December 2099. SPDRs currently copy sector indices as well, allowing

investors to diversify their portfolios in certain economic sectors. They also played a special role in the technological sector investment spree in the late 1990s.

Also enjoying great popularity among investors are EFTs based on the Dow Jones Industrial Average and NASDAQ 100 family. Known as DIAMONDS and QQQs, they entered AMEX in the late 1990s. AMEX is considered the “cradle” of exchange traded funds today. In mid-2004 it listed 139 ETFs (out of 159 registered in the U.S. at that time).

The table below gives an overview of the biggest exchange traded funds and their basic characteristics.

**Table 1 Exchange traded funds**

<b>Title</b>	<b>S&amp;P Depository Receipts Trust Series 1</b>	<b>DIAMONDS Trust Series 1</b>	<b>NASDAQ 100 Index Tracking Stock</b>
Acronym	SPY	DIA	QQQ
Slang name	Spiders	Diamonds	Cubes
Index	S&P 500	DJIA	NASDAQ 100
Price/index ratio	1/10	1/100	1/40
Trading launch	29/1/1993	20/1/1998	10/3/1999
Assets (as at 26/7/2004)	USD 41.07 billion	USD 7.55 billion	USD 23.08 billion
Daily trading volume*	USD 43 million	USD 6.7 million	USD 106 million

\* 3-month average as at 26/7/2004.

The market is still dominated by Spiders and Cubes, which make up 80% of total trading volume in exchange traded funds.

In 2002 practically all indices were already occupied by ETFs. Many analysts were sceptical about the future of these funds, in particular those linked to equity indices.<sup>1</sup> In response to that, new ETFs emerged, this time referring to indices of fixed-income securities. Branded as bond exchange traded funds, they were rolled out in the U.S. market on 26 July 2002 by Barclay’s Global Investor. Their indices follow price trends in corporate and government bonds. They are traded similarly as ETFs tied to equity indices. Trademarked iShares<sup>2</sup>, the Barclay’s Global Investor ETF brought larger trading opportunities for those seeking short-term profits. The new iShares allowed investors to focus on the yield curve, taking both long and short

<sup>1</sup> Jim Shirley (a well-known Lipper analyst) says that “the emergence of too many new exchange traded funds investing in equities may have a negative impact.”

<sup>2</sup> The company uses the same trademark for its equity ETFs.

positions in bonds with different returns and maturities responding to interest rate movements.

Bonds index funds are a risk-hedging tool appealing to conservative investors above all. There are only 10 bond index funds in the U.S. at present. To some extent, this appears to be related to the tightening of the Fed's monetary policy. The most popular bond fund among investors is Lehman 20+ Year Treasury (TLT).

Since 2000 ETFs have gone through some innovation in equity indexed funds. The index fund pioneer Vanguard introduced what it called VIPER ETFs – Vanguard Index Participation Equity Receipts. VIPERs can be traded like any other stock. But rather than a stand-alone ETF, they are a distinct class of shares in Vanguard index funds. The company did not stop there and went on to launch Extended Market VIPERs, later followed by Total Stock Market VIPERs. In January 2004, it unveiled a VIPER fund based on sector indices and indices clustering large-capitalisation firms. In doing so, the company broke away from traditional indices such as S&P, Russell and Barra, and switched to Morgan Stanley Capital International (MSCI) indices. ETFs based on MSCI indices emerging since 1996 cover a larger number of world regions and sectors.

Barclay's followed suit with its new iShares MSCI EAFE Index ETF which replicates an international equity index. Another application is the iShares MSCI Japan Index ETF.

Holding company depositary receipts (HOLDS) are a specific ETF category. Introduced in 1998 by Merrill Lynch, they are known for the Semiconductor HOLDRs Trust securities. Each portfolio is a package of 20 equities, their number decreasing whenever a merger or acquisition happens. The structure of depositary receipts implies that the holder owns all shares included in the package. Bank of New York acts as the holder's agent and can be approached by investors to trade HOLDRs for shares featured in the portfolio (in lots of hundreds). Investors may also choose to sell unprofitable shares and keep the most profitable ones.

ETF took some time before arriving in Europe in April 2000, when they started trading on the London and Frankfurt stock exchanges. In London, ETFs are set up mostly by Barclay's and investment banks Merrill Lynch and Bloomberg. The London Stock Exchange created a special trading platform for ETFs called extraMARK.

The major indices currently tracked by exchange traded funds are listed in the following table:

**Table 2 Market indices and ETF**

Market-wide indices	Dow Jones U.S. Total Market, Russell 3000
Large-capitalisation (Large-Cap) indices	Dow Jones Industrial Average, Russell 1000, S&P 500
Medium-capitalisation (Mid-Cap) indices	Russell Mid-Cap, S&P Mid-Cap 400
Low-capitalisation (Small-Cap) indices	Russell 2000, S&P Small-Cap 600
Sector indices (technological, internet, Multi-Cap)	Nasdaq 100, Nasdaq Composite
Fixed-income instrument indices	Lohman Aggregate Bond, Goldman Sachs \$ Inves Top Corporate Bond
International indices	MSCI EAFE, S&P Europe 350
Emerging market indices	MSCI Emerging Markets
Specialised indices	Intellidex Indexes, S&P 500 Equal Weighted Index

**Large-Cap ETFs** track indices pooling companies with high market capitalisation (over USD 4 billion) such as General Electric, Microsoft, IBM, Johnson and Johnson, 3M Co, Boeing Co, Procter and Gamble and the like. These ETFs are marked by relatively lower volatility compared to others and have also paid higher returns in recent years.

**Mid-CAP ETFs** cover the market segment comprising firms with market capitalisation of USD 1-4 billion. They are typical for seeking value growth. They already fall into the higher-risk category, and their portfolios feature corporations such as Washington Post, Coach Inc, XTO Energy Inc, Tyson Foods, or JeBlue Airways Corp.

**Small-CAP ETFs** monitor the performance of firms with market value of up to USD 1 billion. Since they primarily seek rising equity value, they entail higher volatility. Notwithstanding that, in the past few years we have seen these funds perform better than those mentioned above. They list companies such as IDEX Corp, First Midwest Bancorp Inc, Valeant Pharmaceuticals, Human Genome Sciences Inc, etc.

### 3. Innovation in the ETF market

In the past five years, the number of exchange traded funds shot up and, apart from bond ETFs and many other innovations, ETFs have been looking for ways to other segments as well. Specialised ETFs are set up, with assets linked to commodity prices.

In 2003 the first gold-backed securities had their market debut, introduced by the Gold Bullion Securities fund under the label GOLD. The Gold Bullion Securities shares represent 1/10 of troy ounce of gold. Their

issue was supported by the World Gold Council and the Australia-based Gold Bullion Ltd. In December 2003 they entered the London Stock Exchange under the acronym GBS. In the same year, the World Gold Council asked the SEC for permission to trade them on the U.S. market as GLD. The first license for a “gold fund” was granted to Barclay’s Global Investors, whose iShares COMEX Gold Trust trade on AMEX as IAU. One indisputable quality of this sort of funds is the high credibility enjoyed by their financial intermediaries (e.g. Barclay’s is regarded the top player in index trading).

The successful takeoff of gold ETFs set the example for other funds in other countries. Today they relate not only to gold, but to oil as well.

The interest in stock exchange operations in the U.S. has been largely fuelled by the regulation policy. The SEC discarded restrictions to the volume of investments in ETFs imposed by the Investment Company Act, whereby a fund was not allowed to invest more than 5% of its assets in a single firm.

Another change in the world of ETFs is a move to actively managed ETFs which, rather than tracking an index, would modify their portfolios depending on market situation. Such funds, however, require active management and would therefore lose their competitive edge in the form of low fees. ETFs using leverage can borrow funds.

In 2002 the European Central Bank allowed mutual funds to invest a part of their assets in exchange traded funds. Certain limitations remain in Europe, as EU legislation does not allow mutual funds to borrow in the market.

Forecasts envision the assets managed by ETFs to swell to one billion dollars by 2007, posing serious competition to mutual funds. As a result, mutual funds will likely be forced to cut their management fees.

### ***3.1 Advantages of ETFs***

In a nutshell, the advantages of exchange traded funds can be described as follows:

1. The prices of securities in capital markets develop according to the “random walk” theory, meaning that an investor cannot earn returns above market average in the long run. This implies that at a given point his return can be higher or lower than the market average. ETFs always pay the long-term market average.
2. Unlike other mutual funds, they let investors trade throughout the stock exchange trading day, using short selling, margin trading as

well derivatives. It is this high flexibility that has contributed to ETFs being used not only for long-term investments, but for daytrading as well.

3. ETFs cost less. So from the investor's perspective, they are also attractive for low fees. There is no initial fee. The only fee charged is for asset management, withheld from dividend payouts, which usually does not exceed 0.5% of assets annually. As opposed to ETFs, non-index funds often charge investors not only higher initial fees, but also management fees and exit fees. Since these fees are included in reported returns, the investor's actual net (real) gain may be much lower. ETFs usually ask no initial or exit fees.
4. Unlike non-index funds, index funds hardly trade, only if they need to realign their portfolios. An ETF buys or sells securities only if a new security is added or one removed from the benchmark index to reflect the new index composition. This results in low portfolio turnover as a ratio of total transactions to total assets held by the fund. ETFs can thus avoid the high costs involved in trading, such as all kinds of broker fees, analyses, etc.
5. The low portfolio turnover also implies tax savings. While high turnover rates in non-index funds often generate considerable capital gains, which is subject to taxation, ETF can save on taxes with their lower turnover.

### ***3.2 Disadvantages of ETFs***

1. Each purchase and sale involves broker fees which reduce return. This is in particular true for daytrading, where the investor needs to trade a large bulk of securities to cover fees when price movements and gains are small. That is why daytrading involves the application of margin systems, where the investor pays down only a margin (a fraction of the original price) and takes advantage of the leverage effect to earn higher gains.
2. Disadvantages can also be seen for investors using the dollar cost averaging technique, investing certain sums at regular intervals to eliminate and average rate fluctuations. The broker fees incurred naturally reduce the bottom line.
3. As normal index funds, ETFs also encounter tracking errors, meaning that they not always mirror the net value of assets held. In case of a more substantial tracking error, arbitrators intervene by purchase or sale, as necessary.
4. Professionals start to appreciate ETFs in particular for the flexibility they offer in portfolio diversification. As a consequence of ongoing

globalisation and rapid technological progress in financial market trading, risk diversification is becoming increasingly problematic.

This problem is a part the research program VEGA “Europa as the international financial centre” 2005-2008.

## **Abstract**

*The process of European financial integration is one of structural reforms, which were defined in the Lisbon strategy in 2000. Financial integration became a prime objective of the economic policies of the European Union. It is generally accepted that financial integration fosters financial development, which in turn creates potential for higher economic growth. There are many researches studying quantitative and qualitative indicators of financial integration process. Most of the studies concern with estimation of benefits or state and evolution of financial integration. One of many aspects of financial integration process is monitoring and measuring of achieved level on the financial market segments. Paper is focused on selected questions of European financial integration, deals with financial development, definition and benefits of financial integration and presents methods of measuring and monitoring achieved degree of integration process.*

**Keywords:** *European Union; financial markets; integration; measuring; monetary union*

## **1. Introduction**

The paper is focused on the selected issues of financial integration as one of primary objectives of the European Union today. The aim of the paper is to explain the need for monitoring of financial integration in the European Union and present various indicators of financial integration. In the first chapter the financial integration of the European Union is assumed in the context of globalisation and its international financial integration is expressed. Then, the impacts of financial integration are described and the main steps of European authorities to foster the creation of single European financial market are introduced. The crucial part of the paper is chapter four that deals with measuring of financial integration in the European Union. The main and frequently used approaches to measuring the integration and the most common indicators are explained there.

## **2. Globalisation and the financial integration**

European financial integration process calls for many changes in the structure and operation of the financial services sector across the EU member states. Barriers to trade in financial services and financial assets have been gradually eliminated in the whole world and interaction among national economic systems is becoming still greater. It is generally accepted that the financial integration can have a positive influence on economical development, namely for many reasons.

Many studies are engaged in examination of evidence that the financial integration supports economic growth<sup>1</sup>, in particular through financial innovations and investments. Financial integration would further reduce volatility and help to stabilise fluctuations in consumption relative to income. The mentioned effects of financial integration are generally accepted, but in fact it is difficult to establish a strong relationship between financial integration and growth; there is also little evidence that financial markets would be more stabilised<sup>2</sup>. It is needed to realize that there are also negative effects of financial integration, for example: financial crises become more frequent; volatility of financial markets is increased; the extent of financial integration by measures of financial liberalisation is unequal; the rate of financial integration (measured by gross capital flows) is also uneven, net capital flows from poor to rich countries; financial integration can make

countries exposed to external shocks (that reduce growth and consumption smoothing benefits).

Based on experience, we can state that enhanced financial integration has resulted in higher growth and greater convergence among economies in general. Liberalisation of capital movements, financial services, deregulation and further opening of markets to trade and investment are one of major forces contributed importantly to the globalisation process. On the other hand, one of important features of globalisation is the high integration of financial markets.

## ***2.1 Indicators of international financial integration in the European Union***

As mentioned in the previous chapter, the degree of financial integration is increasing. Foreign assets and liabilities in advanced countries have grown rapidly relative to GDP in recent years. Similarly, the portfolio equity and foreign direct investment categories have grown in importance relative to international debt stocks. Is it possible to distinguish between European integration and international integration in Europe? We can describe the broad trends in international financial integration of the European Union on the basis of countries' portfolios of external assets and liabilities – the so-called international investment position<sup>3</sup>.

Summary volume-based measure of international financial integration (Lane, Milesi-Ferretti, 2003) is:

$$IFIGDP_{it} = \frac{(FA_{it} + FL_{it})}{GDP_{it}}, \quad (1)$$

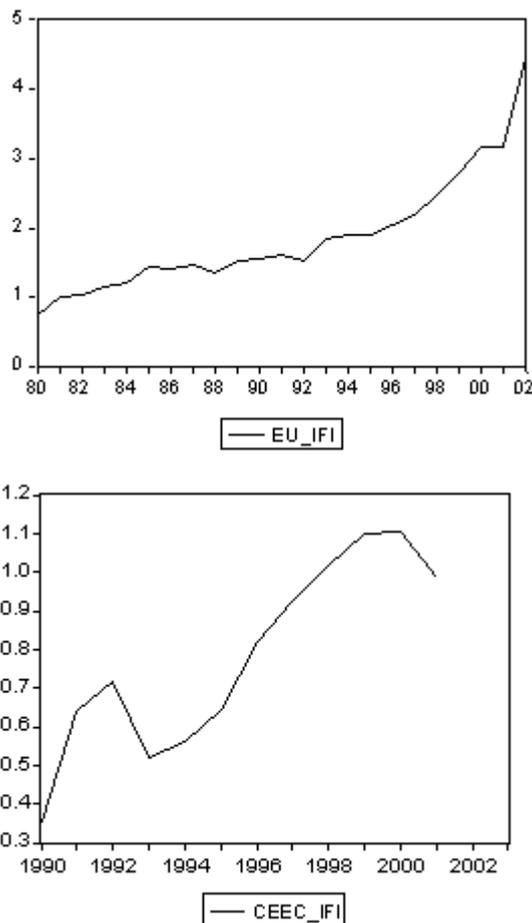

where  $IFIGDP_{it}$  expresses the international financial integration for country  $i$  at time  $t$ ;  $FA$  refers to the stocks of aggregate foreign assets and  $FL$  represents the stocks of aggregate foreign liabilities<sup>4</sup>. The European Union is characterised by an increasing trend (see Figure 1) for the whole period of observation. In case of new member states, the indicator increased four times over 1990s. The figures of these countries are much lower than in EU-15 member states.

---

<sup>3</sup> LANE, P. R. and MILESI-FERRETI, G.M. International Financial Integration. IMF Staff Papers. Vol. 50, Special Issue. International Monetary Fund, 2003.

<sup>4</sup> External assets and liabilities characterize the international investment position – summarize total holdings by domestic residents of financial claims on the rest of the world and non-resident' claims on the domestic economy. External liabilities are divided into four main categories (foreign direct investment, portfolio investment – equity and debt securities, financial derivatives and other instruments – monetary authorities, general government, banks, etc.), assets are represented the same categories plus official reserves (Volz, 2004).

### **3. Integration of financial markets in the European Union**

Process of financial integration in the European Union has been proceeding very intensively in recent years. We can assume that the introduction of euro should speed up the integration process - main reasons are the elimination of the exchange risk and obstacles to the free flow of financial assets and services. The European Commission DG Internal Market

has asked for quantification the macroeconomic benefits of full integration of European financial markets. Based on the study of London Economics (2002)<sup>5</sup>, the process of European financial integration will have significant impacts on the functioning of financial markets.

The study identified number of major expected impacts:

- increased competition among exchanges/market places,
- increased competition among financial intermediaries,
- lower costs due to economies of scale,
- banks and other more traditional sources of corporate finance face tougher competition from financial markets,
- improved price transparency,
- increased market depth and lower liquidity risk,
- larger markets for high risk capital such as venture capital.

More open and effective European financial market could be favourable for both investors and the corporate sector. Investors will benefit from higher risk-adjusted returns on savings, through enhanced opportunities for portfolio diversification and more liquid and competitive capital markets. The corporate sector will benefit from generally easier access to financing capital. Competition in the financial intermediation sector will offer corporations a wider range of financial products at attractive prices.

The economy-wide improved allocation of financial resources to investment projects should impact positively on the equilibrium level of GDP and potentially also on GDP growth. The study deals with macroeconomic impacts on the economic growth process and estimates that the level of EU-wide real GDP should be raised by 1.1% in the long-run, total business investment should be almost 6.0% higher, private consumption should be up by 0.8% and total employment should be 0.5% higher. Results not only of the study mentioned above can be considered just as indicative of the potential benefits of European financial integration that underscore the validity of European policy on financial integration.

Responsible institutions and authorities pay to the process of financial integration in the EU member states great attention. Various measures,

<sup>5</sup>Quantification of the Macro-Economic Impact of Integration of EU Financial Markets. Final Report to European Commission-DG for the Internal Market. London Economics, 2002. Access from: <[http://europa.eu.int/comm/internal\\_market/securities/overview\\_en.htm](http://europa.eu.int/comm/internal_market/securities/overview_en.htm)>

strategies and documents were gradually adopted to foster the creation of single European financial market. We can point out namely the Lisbon strategy, Financial Services Action Plan, Lamfalussy process and Green Paper on Financial Services Policy for the years 2005-2010.

### ***3.1 Framework for integrated financial markets in the European Union***

One of structural reforms defined in 2000 by the *Lisbon strategy* is the process of European financial integration. The next document called *Financial Services Action Plan* (2000, FSAP) proposed concrete policy objectives and specific measures for improving the single market in financial services. Broadly, the action planned is in the areas of wholesale market, retail market and strengthening prudential structures. Main topics<sup>6</sup> are:

- establishing a common legal framework for integrated securities and derivatives markets;
- removing the outstanding barriers to raising capital on an EU-wide basis;
- moving towards a single set of financial statements for listed companies;
- creating a coherent legal framework for supplementary pension funds;
- providing the necessary legal certainty to underpin cross-border securities trading;
- creating a secure and transparent environment for cross-border restructuring;
- information and transparency;
- balanced application of consumer protection rules;
- electronic commerce, insurance intermediaries, cross-border retail payments;
- moves to bring banking , insurance and securities prudential legislation up to the highest standards;
- prudential supervision of financial conglomerates, etc.

The most actual document is the *Green Paper on Financial Services Policy* (2005-2010). The material seeks ideas on the future of European financial service policy and concurs in FSAP.

The overall objective<sup>7</sup> over next 5 years is

- to consolidate progress towards an integrated, open, competitive and economically efficient European financial market and to remove the remaining significant barriers;
- to foster a market where financial services and capital can circulate freely at the lowest possible cost through the EU;
- to implement, enforce and continuously evaluate the existing legislative framework.

As Jean-Claude Trichet, President of the ECB, said<sup>8</sup>: “*However, although the public authorities can, and must, provide an adequate framework conducive to financial integration, financial integration is ultimately a process driven by market forces and decisions taken by the private sector.*”

### **3.2 Need for monitoring of financial integration in Europe**

What the definition of financial integration? We can use the explanation of the European Commission<sup>9</sup> that considers financial integration as a process, driven by market forces, in which separate national financial markets gradually enter into competition with each other and eventually become one financial market, characterised by converging prices, product supply and converging efficiency/profitability among the financial services providers.

Seeing that the financial integration is one of objectives of the European Union, the need for regular monitoring is necessary to map out the state of advance in the creation of a single European market in financial services. As mentioned above, the choices involved in the integration process should be market-driven. However, lack of integration may indicate the existence of market barriers, which effectively prevent the realisation of an efficiently functioning European financial market.

A question arises in achieved level of financial integration assessment. Is it possible to measure financial integration? There are methods using different approaches that are based on two main types of indicators - volume and price indicators. The indicators provide complementary information and help to identify and diagnose market obstructions. It is essentially important that measuring approaches and methodologies of

integration are in evolution. The basic and currently used methodology in measuring financial integration is described in the next part of the paper.

#### 4. Measuring financial integration in the European Union

Financial markets are integrated when the law of one price holds. It implies that assets with the same risk should have the same expected return, regardless of the domicile of the issuer and of the assets holder. Based on the definition, financial market integration can be measured by comparing the returns of assets that are issued in different countries and generate identical cash flows. The mentioned way of testing the degree of financial integration assesses the price convergence of financial assets. The methods are called as the “**price-based**”, “arbitrage” or “law-of-one-price” tests. We should consider that while using the price-based methods, it is usually difficult to identify comparable assets. Generally, when given identical assets command different returns, financial markets are apparently not integrated. The causes for the status are persisting legal barriers such as capital controls, tax codes, accounting and auditing differences, different bankruptcy law, different quality of judicial enforcement; we have to mention also potential economic barriers<sup>10</sup>.

The second approach represents so-called “**quantity-based**” tests and the measurements of financial integration are then based on asset quantities. We can mention also tests based on flow measurements (international capital flows) or stock measurements that identify the amount of cross-border holdings of debt or equity. Generally, in a system with no financial barriers, the domicile of assets issuers and holders should play a decreasing role over time<sup>11</sup>.

As described above, the crucial issue for measuring financial integration is identification of assets generating identical cash flows. In case of no identical assets we can wrongly conclude that financial markets are segmented even when they are integrated and vice versa. Moreover, any measurement of financial market integration must refer to specific assets and specific market, because we need to compare assets issued in different

---

<sup>10</sup> For instance situations of asymmetric information induce investors to evaluate differently assets that are otherwise identical. (Adam et al., 2002)

<sup>11</sup> For more see for example:

BAELE, L. et al. Measuring Financial Integration in the Euro Area. (ECB, 2004).

KIEHLBORN, T. and MIETZNER, M. EU Financial Integration: Is There a „Core Europe“ ? (2005)

PAGANO, M. Measuring financial integration.

PUNGULESCU, C. Measuring Financial Integration in the European Monetary Union: An Application for the East European Accession Countries. (2003).

countries. Even if the price-based method is often used in various studies, in terms of mentioned above, we have always to note data under consideration.

An important implication of financial integration is that asset prices should only react to common news<sup>12</sup>. Then we can speak about “**news-based**” measurements in this case. Local shocks are diversified away by investing in assets from different regions on the assumption that there are no barriers to international investment. Expected returns on assets from different countries but with the same risk characteristics should depend on common rather than local news. This is possible to measure by the proportion of assets price changes that is explained by common factors. We can find researches devoted to specifying explicitly the relevant local and common information variables<sup>13</sup>.

#### ***4.1 Indicators of financial market segments in the European Union***

Based on literature, we can mention a classification of existing indicators of financial integration into four broad categories<sup>14</sup>:

- a. indicators of credit and bond market integration;
- b. indicators of stock market integration;
- c. indicators of integration based on economic decisions of households and firms;
- d. indicators of institutional differences that may induce financial market segmentation.

Several studies consider the effects of financial market integration on households’ choices (for example the portfolio choice between home and foreign assets); we can analyse its effects also on companies’ choices (such as mergers with foreign companies or acquisitions of foreign subsidiaries). Further measurements of integration are based on broad market characteristics (e.g. the size of equity, bond and bank markets, or the cross-border penetration of commercial banks and other financial institutions).

Indicators for measuring of financial integration mentioned above are in detail described in next chapters. The presented survey is processed on the basis of the Adam et al. study (2002).

<sup>13</sup> See e.g. Barr and Priestly (2002)

<sup>14</sup> ADAM et al. Analyse, Compare, and Apply Alternative Indicators and Monitoring Methodologies to Measure the Evolution of Capital Market Integration in the European Union. (2002).

### 4.1.1 Credit and bond market integration

Indicators of credit market integration can be classified into two categories:

- return-based (price-based) measurements and
- quantity-based measurements.

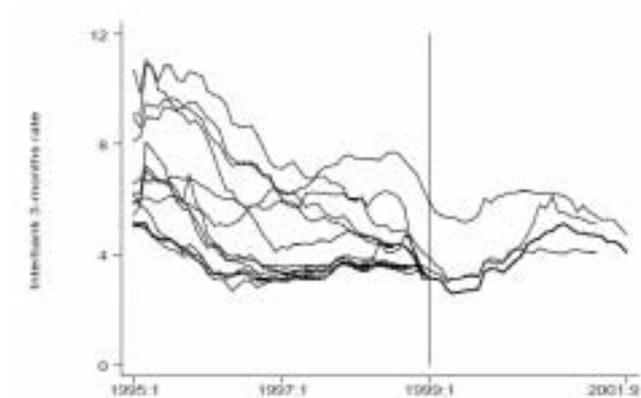

The most common measurement of credit market integration is the assessing of *interest rate differentials*. In case of elimination of transaction costs or any other type of market segmentation, net-of-tax interest rates for assets of the same maturity and the same credit risk class should be identical. In principle, this measurement may be computed for interest rates on public debt, on corporate debt, mortgage debt, and consumer credit. The determination and assessment of differentials between the interest rates charged by banks in different EU countries could be also one of possible ways of measuring the degree of integration<sup>15</sup>.

The Figure 2 plots the level of the inter-bank rate in all EU member states. Before 1999, the highest spread occurs in Greece, Italy and Portugal. After the launch of the Euro, the 11 Euro-zone inter-bank rates converge to the common Euribor rate (the spread is therefore zero). The spread on the 10-years benchmarked bond yield is plotted in Figure 3. Contrary to the inter-bank rate, the 10-years benchmark bond yield spreads don't fall in each country. Generally, the data indicate that convergence has taken place in this market as well, but to a smaller extent than in the inter-bank market.

---

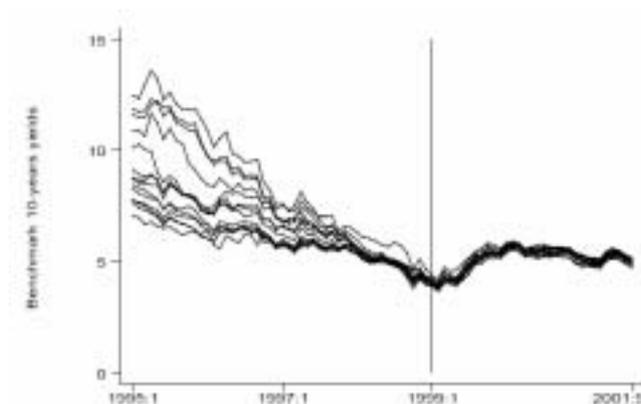

<sup>15</sup> A number of authors have used such measurements, e.g. Stigler and Sherwin (1985), Bodehorn (1995), Jackson (1992), Heitfield (1999), Centeno and Mello (1999), Kleimeir and Sander (2000), De Bandt and Davis (1999).

**Figure 2: Inter-bank 3-months rate in EU-15 (January 1995 to September 2001)**

The effect of regulatory changes on banking competition<sup>16</sup> is also evident in declining *price differentials for the same banking services* (credit

---

<sup>16</sup> An important step in the removal of barriers to cross-border banking competition in Europe was the adoption of the Second Banking Directive (1989) that is based on the principle of a single passport.

cards, loan and deposit rates, corporate loan rates, current cheque accounts, personal equity transaction costs, cross-border transfers of fund). A study of De Bandt and Davis (1999) finds that the level of competition in chosen EU countries (compared to the U.S.) is quite low. The case of loan to enterprises rates in the EU is expressed in the Figure 4. Even though the corporate loans rates are considerably less volatile than other interest rates, the broad picture is similar to that of the 10-years benchmark.

**Figure 4: Interest rates on corporate loans in EU-15 (January 1995 to September 2001)**

Source: Adam et al. (2002). Access from: [http://europa.eu.int/comm/internal\\_market/en/update/economicreform/020128\\_cap\\_mark\\_int\\_tables\\_en.pdf](http://europa.eu.int/comm/internal_market/en/update/economicreform/020128_cap_mark_int_tables_en.pdf)

We can also assume the degree of *cross-border banking activity*. The more financial markets are integrated the more cross-banking activity can be observed. A cause of increased cross-border transactions is especially the elimination of barriers to international capital-flows.

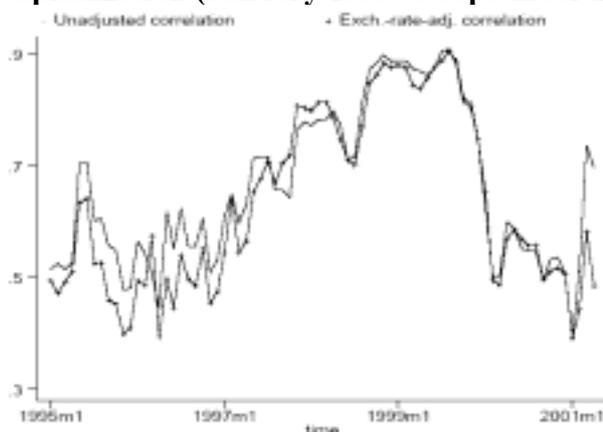

#### 4.1.2 Stock market integration

The indicators can be again divided into two categories: *returned-based* and *quantity-based* measurements. The question is how stock market integration affects stock market returns. It is supposed that stock market returns should be more correlated in the single and integrated capital market. Is it possible to measure the phenomenon under the consideration, that markets are hit by the same shocks (oil shock, monetary policy shock etc.)? That is actual namely in the European Union, where the ongoing integration process of goods and labour markets can speed up the transmission of shocks between countries. Measurements based on ex-post data are not suitable for

this purposes from these reasons and therefore new asset-pricing models (CAPM) based on ex-ante returns have been derived.

Tests of capital market integration are based on estimating if the evolution of the risk premium on domestic stocks is sensitive to the country-specific risk in relation to the covariance with an EU-wide portfolio<sup>17</sup>.

**Figure 5: Stock market returns correlation, weighted by stock market capitalization (January 1995 to September 2001)**

Source: Adam et al. (2002). Access from:

[http://europa.eu.int/comm/internal\\_market/en/update/economicreform/020128\\_cap\\_mark\\_int\\_tables\\_en.pdf](http://europa.eu.int/comm/internal_market/en/update/economicreform/020128_cap_mark_int_tables_en.pdf)

Based on Figure 5, the average stock return correlation appears to be quite unstable in the European Union over time.

The second way of measuring the capital market integration is based on quantities such as the size of capital flows or the composition of portfolios (stock measurements). The widely studied indicator is the share of domestic stocks in household portfolios compared to the share of these stocks in the world market portfolio<sup>18</sup>.

#### 4.1.3 Indicators based on household decisions

This way of measuring deals with effects of financial integration on the relationship between private savings and corporate investment and the relationship between private consumption and income. It is assumed that the saving decisions of domestic households should have no effect on the

---

<sup>17</sup> A number of authors have used such measurements, e.g. Bekaert and Harvey (1995), Hardouvelis, Malliaropoulos and Priestley (1999), Sentana (2000), Chen and Knez (1995), Ayuso and Blanco (1999).

<sup>18</sup> More in Tesar and Werner (1992), Lewis (1999), Ayuso and Blanco (1999).

investment decision of domestic firms, when international capital markets are well functioning (firms can borrow on international debt markets).

Classic tests are based on the *saving-investment correlation*. We can assume that under perfect capital mobility and unchanged investment opportunities the following statement is accepted: an increase in the saving rate in one region would cause an increase in investment in all regions. Large correlations between national saving and investment have been achieved in many studies (e.g. Feldstein and Horioka, 1980). One of disadvantages of this approach is an inability to identify financial markets insufficiently integrated.

The next used indicator is based on idea that integrated financial markets allow for *international risk sharing*. The question then arises if financial markets afford full risk sharing to consumers located in different jurisdictions<sup>19</sup>. The further possible way is a finding of capability of distinguishing the contribution of different financial markets and of public tax-transfer mechanism.

#### **4.1.4 Indicators based on corporate policy**

An increasing financial integration supports the consolidation of banks and companies across geographic borders. Then we can monitor and compare both the development of *mergers and acquisitions* (M&A), namely M&A activities in the banking and securities industry, and the share of bank branches controlled by foreign banks<sup>20</sup>.

Mergers can be defined as the combination of two organisations (with comparable size) into one legal entity. Acquisitions are transactions where one firm purchases a controlling stake of another one, without necessarily combining the involved firm's assets. In terms of numbers, mergers and acquisitions among domestic credit institutions represent about 80% of total consolidation activity in the EU in each year since 1992. The only clear pickup in cross-border mergers and acquisitions is evident in the run up to the creation of the single market in 1992, when the share of domestic mergers fell to about 60%. However, cross-border mergers and acquisitions have never come close to exceeding domestic mergers and acquisitions<sup>21</sup>.

---

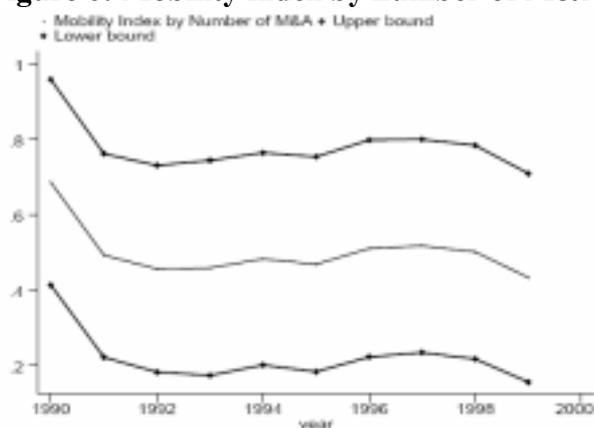

<sup>19</sup> A number of authors have used such measures, e.g. Cochrane (1991) and Mace (1991), Obstfeld (1994), Wincoop (1994), Townsend (1994), etc.

<sup>20</sup> M&A activities in Europe have taken place mainly within national boundaries rather than across them, the state is more favourable within the frame of insurance (Adam et al., 2002).

<sup>21</sup> See: WALKNER, CH., RAES, J.-P. (2005) Access from:  
<[http://europa.eu.int/comm/economy\\_finance/publications/economic\\_papers/2005/ecp226en.pdf](http://europa.eu.int/comm/economy_finance/publications/economic_papers/2005/ecp226en.pdf)>

The negative trend in the European Union is evident in the Figure 6 that represents cross-border mergers and acquisitions expressed by the mobility index based on the relative number of cross-border M&A<sup>22</sup>.

**Figure 6: Mobility index by number of M&A (1990-1999)**

Zdroj: ADAM et al. (2002). Access from:

<[http://europa.eu.int/comm/internal\\_market/en/update/economicreform/020128\\_cap\\_mark\\_int\\_tables\\_en.pdf](http://europa.eu.int/comm/internal_market/en/update/economicreform/020128_cap_mark_int_tables_en.pdf)>

The integration of financial markets substantially affects also the corporate financing decisions of firms. Firms in such environment can issue a wider range of financial instruments at the same standard terms, risk of the instruments then corresponds to each firm's debt or stock irrespective of their nationality. It comes to this, that we can measure the achieved level of financial integration also by the development of *international issues* (debt or equity finance) of European companies relative to their investment or their total debt or stock issuance<sup>23</sup>.

The previous text pointed out that the level of financial integration can be measured by different indicators as the case may be on the segments of financial market. But there are some special factors that should be taken into consideration:

*Data quality and availability* – it is the crucial factor. Both price-based and return-based indicators have clear advantages over quantity-based indicators. E.g. security price and return data are available at higher-frequency (monthly or even daily frequency) and are more accurate than the data on financial flows and stocks (quarterly or even longer frequency); in the

<sup>22</sup> You can find the calculation and definition of the index in the study of Adam et al. (2002).

<sup>23</sup> The large development of international issues has been noted since the launch of European monetary union (particularly by reason of currency risk elimination).

case of household or firm decisions, the choice is between micro and macroeconomic data sources. The bigger problem is certainly to devise the effects of legal institutions on financial markets.

*Price and return data* – computing return-based indicators requires sophisticated estimated procedures in comparison with quantity-based indicators that are generally easier to implement (data are available with sufficient international comparability).

*Indicators based on economic decisions and on legal institutions* – household and corporate decisions indicators can be quite easily benchmarked (the lack of correlation between investment and saving signals that capital is perfectly mobile across countries). However, empirically estimated full-risk sharing doesn't have to mean the perfect financial integration, because risk-sharing can be achieved through other channels. As for differences in legal institutions, they don't tell us if financial markets are segmented or integrated. They can refer to reasons why the markets may be segmented (e.g. institutional characteristics can help us understand reasons of interest rate differentials of identical instruments in two countries).

*Convergence criteria* – the process of financial integration can be assessed through the indicators then summarise the convergence or divergence over time of financial variables. The below mentioned equation is used to determine if the integration occurs and how its degree changes over time (Adam et al., 2002).

$$\Delta i_{ct} = \alpha_c + \beta i_{ct-1} + \sum_{l=1}^L \gamma_l \Delta i_{ct-l} + \varepsilon_{ct} \quad (2)$$

where  $c$  is country,  $t$  is time,  $\Delta i$  is the change in the interest rate, and  $\alpha_c$  is the country dummies. The error term on the right-hand side of the equation denotes exogenous shocks that force interest rate differentials between considered countries. A negative  $\beta$  signals convergence (if  $\beta = 0$  there is no convergence); the magnitude of  $\beta$  denotes the speed of convergence.

#### ***4.2 Degrees of integration in EU financial markets: some empirical results***

We can find many economic studies, namely in recent years; that focus on questions of measuring of financial integration. Such studies pursue the examination if financial integration occurs across the EU member states and frequently focus on European monetary union. As mentioned in the chapter three, financial integration could have positive macroeconomic

impacts on the economic growth process. The process of financial integration (in terms of integration of financial services, creation of single European capital and money markets) is one of priorities of the European Union, as indicated in above mentioned Lisbon strategy, Financial Services Action Plan and next strategies and documents. Many steps have been implemented till this time, primarily in a creation of conditions for further development (especially legislation area). These actions claim for efforts of EU responsible institutions and authorities of individual member states. Then we can conclude that the measuring of achieved degree of financial integration is one of possible ways to monitor the progress of the integration and the effectiveness of adopted measures.

The research of Thomas Kiehlborn and Mark Mietzner (2005) focuses on identifying groups of financially integrated countries from macro-level view in their study. They calculate cross-sectional dispersions by applying an inter-temporal cluster analysis to eight euro area countries for the period 1995-2002<sup>24</sup>. Their results show that euro countries were divided into two stable groups of financially more closely integrated countries in the pre-EMU period. However, this situation has changed remarkably with the introduction of the euro. EMU has led to a shake-up both in the number and composition of groups. The findings suggest as well that financial integration in Europe takes place in waves and degrees of integration differ notably in separate financial markets (see Table 1). The research encourages policymakers to move forward courageously in the post-FSAP era, and provides comfort that the substantial difference between the current and potentially new euro states can be overcome. The analysis could be extended to the new EU member countries, to the global level, and to additional indicators.

#### 4.2.1 Integration of financial markets in the European monetary union

Integration of financial markets is an important presumption for the smooth functioning of European monetary union. The main reason is that it can function as an insurance mechanism facilitating adjustment to asymmetric shocks. The introduction of euro has eliminated one of the most significant obstacles to the complete integration of financial markets but there still remain important differences in legal systems.

European Central Bank strongly supports the Commission's policy of the European financial integration. ECB plays an important role in fostering financial integration and takes adequate steps to support the process. The introduction of the euro played an important catalyzing role for the financial integration process. The time since the introduction is still too short but we can consider the euro is one of factors contributing to the financial integration. We can assume that a well integrated financial system increases the efficiency of the euro area economy (by reducing the cost of capital and improving the allocation of financial resources). ECB began to publish an overall assessment, based on a series of indicators, of the degree of financial integration in the most important segments of the euro area financial markets, ranging from retail loans to wholesale equity trading. These indicators will be regularly updated and published twice a year. The report will be produced on an annual basis with the aim of monitoring the progress of financial integration in the euro area. In these reports, the range of indicators will be extended over time, in line with improvements in the availability of statistics

and advances in research and general economic analysis.<sup>25</sup> The latest report suggests that the degree of integration varies greatly depending on the market segment, analogous to the rest of the Union<sup>26</sup>.

Degree of integration in the European monetary union differs quite between the market segments – is almost perfect in the money market, very well advanced in the government bond market, fairly high in the corporate bond market, and least advanced in the equity market; there still exist obstacles to cross-border securitisation in Europe. Integration of banking market is fairly well advanced in wholesale and capital market-related activities, but in retail market<sup>27</sup>, it is clearly lagging behind (Trichet, 2005).

#### 4.2.2 Financial integration of new EU member states

The financial structure of new member states differs significantly from many reasons, namely with respect to different political and economical development. Financial systems also vary in terms of integration with the euro-area financial system. However, it could be expected that the progress of the financial development will result in progressive convergence with the overall financial structure of other EU member states.

Generally, separate financial market segments in new member states are commonly much smaller than in original EU countries. Banking systems represent a special case because they are contrary to other EU member states characterized by high degrees of foreign ownership (see Table 2) that generally involves a powerful driving force for further financial integration.

**Table 2: Share of foreign ownership in the new member states**

2003	CY	CZ	EE	HU	LT	LV	MT	PL	SI	SK	NMS	EU-15
<i>As a % of total assets</i>	12.3	96	97.5	82.3	95.6	46.3	67.6	67.8	36	96.3	70	24

*Source: Financial Integration Monitor (2005). Background document*

Based on Convergence report (2004), the evidence suggests that financial integration between new member states and the euro area is quite advanced<sup>28</sup>. Over time, the process of financial integration is associated with

<sup>25</sup> See <<http://www.ecb.int/press/key/date/2005/html/sp050930.en.html>>

<sup>26</sup> See <<http://www.ecb.int/pub/pdf/other/indicatorsfinancialintegration200509en.pdf>> for the „Integration of the Financial Integration in the Euro Area“ (2005) report

<sup>27</sup> In 2002, more than 90% of the loans granted by banks in Euro-area went to domestic residents (DeGrauwe, 2003).

<sup>28</sup> See Convergence report (2004).

an increase in domestic financial deepening and the removal of barriers to capital mobility.

## **5. Conclusion**

The European Union pays to the integration of financial markets across EU member states increasing attention. The financial integration could positively affect the economic growth in the long-run, based on several researches. This is one of many reasons why to foster the process of integration from the side of European authorities. It is appropriate to consider that the process of integration is taking place in the framework of the globalisation of the international financial system, major technological advances, improvements in the cross-border regulatory environment, the introduction of the euro, and a diminishing effect of so-called natural barriers such as language and culture. The European Union has to create the conditions for further development that is above all related to the elimination of barriers of free movement of financial services.

One of many aspects of financial integration is monitoring of achieved degree of the integration process. Different methods are used to evaluate the level of integration of individual financial segments. Main approaches are price-based, quantity-based and news-based measurement s. Empirical results indicate that the achieved level of integration differs due to financial market segments. The highest degree is characterized for the wholesale money market, whereas the lowest for the retail credit market. We can say this holds almost for all EU member states, both the euro-area and new member states. The level of integration in national financial segments evidently differs but we can expect a positive development. However, the integration of financial markets across the EU member states is an ongoing process and became one of principle objectives of the European Union for the next years.

## **Abstract**

*This paper analyses the impact of the Euro on the international monetary system, and especially the effects of the Euro on the function and role of the International Monetary Fund. The use of the Euro in international transactions and the fact that it was adopted by countries which are not members of the European Union, can turn this currency into an international one. The relationship between the European Union and the International Monetary Fund is a delicate problem that must be clarified by each country which is a member of the International Monetary Fund, because on that level, each country is being represented and all transactions taking place within the International Monetary Fund are being conducted in the currency of each member state. I will try to show the international role of the Euro, the relationship between the Euro and the International Monetary Fund and the role of the Euro within the framework of the International Monetary System.*

**Keywords:** *Euro; International Monetary System; International Monetary Fund; international money.*

## **1. Introduction**

Ever since the 1<sup>st</sup> of January, 1999, the Euro has become the national currency of 11 European countries, which were joined by Greece, on the 1<sup>st</sup> of January, 2001. Without any doubt, the Euro will become the national currency of the other 13 EU-member states, which joined the EU later on, and in the future, it is very likely that the Euro become the national currency of thirty European countries. One thing is certain: essential matters have become reality. On one hand, we consider that it was essential to start the process of introducing the single currency, a process which was successfully finished in 2002, when the single European currency literally entered the pockets of the European Union founding member states citizens, a fact which represents a world premiere; on the other hand, the first 11 member states of the European Union are large, important countries, the states which are about to adopt the new currency being smaller-sized ones<sup>1</sup>. Due to these aspects, we believe that we can proceed, in order to look at the impact of the single currency on the international monetary system.

The international monetary system has been defined within the conference from Bretton Woods. But from that moment on until now, the system underwent a lot of changes, with the passing of time a huge market emerged, the national currencies of different states being negotiated on it. The incurring changes were so radical, that today, one is no longer talking about reforming the International Monetary System, but about rebuilding – as if it had been destroyed – the international financial architecture. The question which arises is: did architecture replace the system, respectively, did finances replace the currency? A fact that can be easily understood is difficult to contest.

## **2. The international role of the single European currency (Euro)**

The international role of the Euro depends on its use within international transactions, which can be the following ones:

- Transactions of the 25 countries with third states, transactions of Euro-zone residents with non-residents. For instance, France is paying in Euro for the oil, a Spanish tourist travels to Argentina with Euros in his pockets.

---

<sup>1</sup> The 12 EU member states own approximately 24% of the IMF amount holdings.

- Transactions between third states, transactions between non-Euro zone residents. For instance, Norway and Sweden are trading in Euros, Canada issues Euro-bonds in Switzerland.

The Euro will become an international currency, if it is being largely used for such transactions. It can be used as a unit of account when invoicing exchanges of goods and services and when expressing (labelling) financial assets. Finally, it can be used as a reserve currency, respectively reserve hard currency, on one hand, by Central Banks which are using the Euro in order to intervene on the financial market, on the other hand by private agents. Without any doubt, we can affirm, that the Euro is fulfilling today all the traditional monetary functions of the coin.

The reason mostly referred to is the *economic power of the Euro-zone*, from this point of view, the Euro-zone being on the same economic level with the USA. The GDP (Gross Domestic Product) of the Euro-zone is very close to that of the United States of America, representing 87% from the GDP of the USA, while the populace living in the Euro-zone is higher than the American one. But what we consider to be very important is the fact that the Euro-zone is very open towards world economy. The exports and imports of the member states represent, on the average, 24% from their GDP, while the imports and exports of the United States represent 12% from the GDP of the United States. Euro-zone member states hold 30% of world trade, twice as much as the USA. This percentage, we can affirm, lost some of its significance once the Euro was introduced. And this due to the fact that nearly half of the world trade of the Euro-zone member states is being conducted between them, that is, in the bosom of the European Union. This means, that invoices are being issued in Euros, while payments are being made in Euros, which means that at least part of the invoices are being paid in the national currency. The question is: are we still talking, in this case, about world trade? Despite this fact, the world trade share of the European Union stays at the same level with the one of the United States.

But there are also other factors supporting the international role of the single European currency. One of them is *tourism*, which represents an important factor of income for many EU-countries, a fact favouring the use of the Euro by non-residents. It also represents an important expense for countries residents often travel abroad from: thus, the use of the Euro by non-residents is being facilitated. An other factor can be considered *corruption* as well as the circulation of *laundered money*, due to the fact that high-value banknote owners, like, for instance, the banknote of 500 Euro, will, in fact, stay anonymous.

A second reason is the *banking structure of the Euro-zone*. Thus, international payment systems were harmonized, each country implementing a real time gross settlement system (RTGSS), a system known under the name of TARGET, guaranteed by the Central European Bank. The goal of this system was to ease higher-value transactions and especially transactions connected to monetary policy. Transactions that took place between non-residents or with non-residents can be found, naturally, treated and compensated, together with those that took place between residents. Even more, the system of compensation, initiated by the ECU's Banking Association, remained in effect, and the banks situated outside the Euro-zone, like Switzerland, Russia or Japan, take part or are associated to this system. (Lelart, 2001. page 5)

The ability of the Euro-zone's banking systems to cope with the international role of the currency can be seen if looking at the importance of international operations. Regarding the engagements of non-residents' banks, placed in the zone examined by the Bank of International Settlements, the participation of the banks from the Euro-zone was, on the 30<sup>th</sup> of June 2000, of 34%, that of the banks from the United Kingdom of 21%, that of American banks of 11% and that of Japanese banks of 5.4% (BIS 2000, pages 2 and 4).

These percentages underwent no essential variations during the last three years, but the payments of European banks in what foreign currencies are concerned, fell from 35% to 26%, once the Euro was introduced, while payments in national currency increased from 32% to 48.5%. This evolution is normal, since, for instance, French banks' DM payments became payments in Euros. But the percentage of 48.5% is extremely significant: foreign payments of European banks are by far larger than payments in dollars of the American banks (30%).

A third reason is connected to "*developed financial markets*", like those in Paris, Frankfurt or Milan, without even talking about the city of London. During recent years, we saw that agreements were signed between large European financial markets, agreements leading to the emergence and development of a European financial mega-market, which is going to "stretch" the European financial area, born at the beginning of the 80es, when capital flows were liberalized. We can say that the Euro had the chance to become and it became a placement currency, since non-residents got accustomed to invest more in the Euro-zone countries, as well as in the United States – which must finance their current account deficit – than in Japan (IMF; 2000).

**Table 1 Direct and portfolio investments by area in which they were realised (billions USD)**

	<i>Euro-zone</i>	<i>USA</i>	<i>Japan</i>
<i>Direct investments</i>	1.082	2.194	0.046
<i>Portfolio investments</i>	3.321	3.443	1.165
<i>Total</i>	4.403	5.637	1.211

*Source: IMF report, 2000*

Euro-bonds can be issued by Euro-zone countries, countries which have to borrow more and more amounts of money in national currency (Euro), since this became their common currency, but bonds can be also issued by others who borrowed amounts of money in a certain currency and now have to borrow more and more Euros. By the end of 1998, circulating international bonds were labelled (BIS, 1999, pages 70 – 71)<sup>2</sup>:

**Table 2. Bonds and notes by currency in which they are issued**

	<i>In European currencies</i>	<i>In US dollars</i>	<i>In yens</i>
<i>Long-term bonds</i>	27.8%	45.2%	11.7%
<i>Short-term bonds</i>	18.5%	57.3%	2.5%

On the 30<sup>th</sup> of September 2000, long-term, Euro-labelled bonds amounted to 28%, while short-term, Euro-labelled bonds amounted to 31%.

In 2004, at the end of the year, circulating international bonds and note were labelled 48.37% in euro, 34.94% in USD and 3.11% in JPY. We can say that the euro labelled bonds had a real success.

One last reason is a reason of political nature and it refers to the ***credibility of the European Monetary Union***. Here, we must have in view the irreversible character of the Union, no state which agreed upon its creation being able to leave it easily, the Union being about to be continuously enlarged. We are talking about the existence of a single monetary law (one should not forget the Resolution of the European Council from the 3<sup>rd</sup> of May, 1998, which ensured the continuity of existing contracts

---

<sup>2</sup> Bonds issued in European currencies also include ECU bonds.

at the moment of the introduction of the Euro and the preparations of the switch to the single European currency). Last, but not least, it refers to the status of the European Central Bank, which is an independent bank and which, in its mission, resolved, as it is being several times reiterated in its statute and in its founding treaty, to ensure the stability of the single currency exchange rate and to maintain a low level of inflation. And we have to admit to the fact that, in the last year, this proved to be a very difficult thing to manage. We can add that the Euro became the national currency of 12 countries, other thirteen countries trying to cope with the criteria necessary in order to be able to adopt it. From the outside, we consider that the transition to the Euro was a soft one, without encountering major difficulties.

**We consider that all these factors did nothing else than to turn the single European currency into an international one.** The following examples are supporting this statement:

- *bond issuing*: net bond issuing in European currencies and then in Euros quickly increased, their number being even higher than that of USD bonds, but they slowed down in 2000.

**Tabel 3. Net issuance of international bonds and notes by currency (in billion USD)**

<i>Year</i>	<i>euro</i>	<i>In %</i>	<i>USD</i>	<i>In %</i>	<i>Total</i>
<i>1998</i>	224	24.00%	411	59.00%	467.7
<i>1999</i>	571	46.99%	545	44.85%	1215.1
<i>2000</i>	472.1	37.97%	613.3	49.32%	1243.5
<i>2001</i>	597.3	44.30%	652.6	48.40%	1348.3
<i>2002</i>	522.7	51.71%	419.1	41.46%	1010.8
<i>2003</i>	832.9	28.86%	461.6	15.99%	2885.2
<i>2004</i>	923.2	27.96%	372.3	11.27%	3300.7

This evolution may seem to be a surprising one, but it can be explained, first, by the attractiveness of a new currency, and then, by the debtors' preference of resorting to a hard currency, when the exchange rate of the currency plummeted. But after the year 2000 the net issuance in euro grow up quickly, in 2004 the net issuance in euro being bigger than the net issuance in USD.

- *holdings of the Central Banks*: The currency structure of the reserves of the Central Banks is as follows<sup>3</sup>:

**Table 4. The currency structure of reserves of Central Banks**

<i>Year</i>	<i>1999</i>	<i>2000</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>
<i>USD</i>	66,2%	68.2%	68.3%	64.8%	63.8%	65.9%
<i>EUR</i>	12.5%	12.7%	13%	14.6%	19.7%	24.9%

*Source: imf reports 2000 – 2005, statistical appendix*

As we can notice, the American dollar continues to rank first within the reserves of the Central Banks. But ever since the introduction of the single currency and until the end of the year 2004, we have to notice that, in fact, the amount of the single currency within the foreign currency reserves of the banks has doubled. In 1999, we could not compare the holdings in ECU of the Central Banks, from previous years, which were connected to the functioning of the European Monetary System, with the holdings in Euro from the end of the same year. Even more, holdings in USD could not be compared with the holdings in European currency of the 11 states, because the latter ones were reduced, as a result of the fact that the 11 states, later 12, compensated the holdings of national currencies from the foreign currency reserves between them. Central Banks outside the Euro-zone will hold more Euros, since this one replaced the DEM or the FRF, for instance. In 1999, it was difficult to estimate the extent to which the Euro will replace the dollar. Today, we can say that, although it did not dethrone the dollar, it doubled in what foreign currency reserves of Central Banks are concerned. What we cannot see in the Table 4 is the fact that in the meantime in which the euro doubled the weight in foreign currency reserves of the Central Banks and the dollar kept its position the share of Japanese yen in total foreign exchange reserves declined from 7% in 1997 to 4% at the end of 2004. During the past decade the share of pound sterling has been in the 2%/3% range.

Using the Euro as a reserve currency also depends upon the number of countries outside of the Euro-zone, which will tie their own national currency to the Euro. The countries from the Franc-zone did this and we believe that others will follow. Other countries left their national currency floating along with the Euro: Poland, Turkey, Chile... There is no doubt that there will be more and more countries which will do this, and the Euro will become not only a reserve currency, but also a currency of intervention on foreign currency markets.

---

<sup>3</sup> Data retrieved from IMF reports 2000 – 2005, [www.imf.org](http://www.imf.org)

Obviously, there are also other factors which will influence and do influence the international use of the single European currency. On short term, the preference for the Euro depended and continues to depend upon the evolution of its exchange rate referred to the USD, upon the economic situation between Europe and the USA, upon the evolution of the interest rate in Europe and the USA. We believe that the replacement of the dollar by the Euro will incur at a slower or faster pace and will take effect more or less constantly. On long term, due to the fact that the Euro can be owned by non EU-residents, it will have to get out of its zone, to be more precise, it will be transferred into the rest of the world, by dint of international transactions of the EU-zone member states. This means that these countries will import more than they export – which is the opposite of what is happening today, or that they loan more than they borrow – which, in fact, is happening in an alert way. Even more, can foreign Euro holdings increase by dint of transactions conducted by the banks outside the Euro-zone, for instance in London, Montreal, Singapore or Hong Kong? The question we did not find the answer to is “which would be the place of the Euro in the bosom of Euro foreign currencies?”<sup>4</sup>

Another problem is that of the dimension of the Euro-zone, which, as we could notice, keeps enlarging, which was, in fact, to be expected. If, in 1998, it included 11 countries, from 2000, the number increased to 12 countries, and in 2004, the number of these countries was 2,2 times higher than at the beginning, the number of member countries amounting to 25. For the year 2007, Bulgaria is about to join the European Union, and we hope that Romania will join as well. Practically, what could be foreseen in 1998, in what the enlargement of the EU is concerned, became true.

### **3. The Euro and the International Monetary Fund**

The statute of the IMF is based upon the idea that each country can dispose of its own currency. Thus, this institution is “*country based*” and not “*currency based*”. The countries are members of the IMF, but the IMF is using their currencies. But what happens with the Euro: 12 countries, 15 countries, 25 countries, one currency?

---

<sup>4</sup> These transactions do not really affect the amount of international currency, but lead to an increase of international liquidity. The same will apply both for the Euro and for the dollar.

### ***3.1 The structure of the IMF***

Each country which becomes a member of the IMF, must pay the so-called assigned quota, which stands for the size of the subscription each country makes with the IMF. The help the country can obtain and ask from the IMF depends upon this assigned quota, as well as the number of votes the country in question disposes of. Initially, the volume of imports and exports of the respective country and the level of foreign currency reserves used to be the criteria which determined the assigned quota of the IMF member countries. The emergence of the European Monetary Union did not change, at least so far, anything about this fact for the member countries. Assigned quotas are being revised every 5 years, the last revision (the twelfth since the founding of the IMF) took place on the 31<sup>st</sup> of January 2003, when it was decided that the assigned quota remain unchanged. The question is whether, for the EU-zone, the trade conducted in Euro between the member states can any longer be considered as international trade? Given the fact that, during the last revision, the level of assigned quota did not change, we tend to believe that, from the IMF's point of view, the answer is a positive one. Anyway, it remains a problem which needs a direct answer.

Moreover, the level of the foreign currency reserves in the case of the countries which adopted the Euro diminished, or the structure of the foreign currency reserves was, at least, modified, if they were not reduced. Anyway, in a first phase, the level of the foreign currency reserves was reduced once the Euro was introduced, the single currency emerging instead of the national currencies, a currency we can no longer consider a foreign currency, but a national one.

In the future, according to Quota Formula Review Group (which was established in 1999), the GDP is likely to become the prime variable in quota calculations for industrial countries, while the role of reserves and foreign trade would decline.<sup>5</sup>

I was saying that, based on the assigned quota, the number of votes of each country is being determined. In early 2002, the aggregate voting power of the 15 members of the EU was of 29.9%, well above the voting power of the USA (17.2%) and Japan (18%). The enlargement of the EU (2004) increased the EU's aggregate voting power by 2.8%, to 32.8%. But due to the structure of the board of administration, these votes are not being owned by a single person. It is, in fact, normal for the number of votes which should stand for the Euro-zone to be so high, compared to the USA and Japan, since the assigned quota for EU member states represent 30,4% of the volume of

---

<sup>5</sup> Leo Van Houtven, *Governance of the IMF*, Pamphlet Series, no. 53, IMF, Washington D.C., August, 2002, ISBN – 1-58906-130-6, pp. 9

the IMF assigned quota, while in the case of the United States, we are talking about 17.4%, or, in the case of Japan, of 6,23%.<sup>6</sup>

The board of administration of the IMF consists of 24 administrators. Eight countries, out of which five are the ones who own the highest assigned quota, appoint each an administrator to exert their right to vote. The other countries are grouped according to geographical, linguistic or other criteria, totalling 16 groups, each of them appointing an administrator. Even if administrators are being chosen from the ranks of EU member countries, those representing a group of countries will dispose of the number of votes of the respective group, which means that they are going to vote according to the interests of that group. Basically, we cannot say that, within the framework of the IMF, the representatives of EU countries have the last word, but their votes weigh a lot in the scales.

At the present moment, it is more and more problematical to establish whether the criteria, based upon which the IMF establishes the assigned quota, is still actual. Thus, on the 4<sup>th</sup> of November, 2005, the IMF is hosting a round table meeting on the topic of the governance of the IMF and the role of the executive board. One of the subjects to be debated is related to the way the quota system can be reformed in, in order to ensure fair representation to all member states and guarantee to the IMF the legitimacy that is essential for its effectiveness.

### ***3.2 The role of the IMF***

The role of the IMF is, first of all, to **ensure financial assistance to the member states**, which are being temporarily confronted with a deficit of the external balance of payments. The emergence of the European Monetary Union has two consequences. The first one refers to this help the IMF is granting to its members. Approximately 30 years have already passed, with no industrialized country “shooting” at the IMF. But it is possible for the EU countries to be exposed to asymmetrical shocks, which could deteriorate the external situation of these countries to such an extent, that they be compelled to resort to the help of the IMF. The second consequence refers to the way this help can be granted in. The IMF cannot impose to any of these countries an increase of the rate of interest or the depreciation of its national currency, since both the monetary and the foreign currency are decided on EU level and not on the level of the country in question. There is nothing left, except

---

<sup>6</sup> These figures were determined based upon the data published in the report of the IMF for the year 2005, appendix VII

for the economic policy, on which level the IMF could intervene with certain stipulations.

Given the international role of the single European currency, we can imagine that one day, the member countries of the EU could like to wish the stabilization of the exchange rate of their national currency in relation to the USD or to the JPY, and that, in order to do this, they would have to resort to the IMF. As the EU is not an IMF-member, the EU, and, at the same time, IMF member states, should be the ones to request this help. The question is with whom the IMF is going to negotiate the conditions: with the Council of Europe, in what the economic policies are concerned? But the Council of Europe is an organism with informative character; with the European Central Bank, in what monetary policies are concerned? But the bank is an independent body; with the Council of Ministers, in what the foreign currency in relation to non-communitarian models are concerned? But the Council of Europe has never made arrangements in this sense, except for extreme situations. These are questions the answers are still being looked for to.

The IMF has also the role of ensuring the **supervision of currency exchange evolution**, due to the fact of the floating exchange rate system. According to article IV of the IMF statute, each country, which is a member of the IMF “has the obligation to collaborate with the IMF...in order to promote a stable system of the currencies exchange rates...the IMF will exert a rigorous supervision on the foreign currency policy of the member countries...Each country will provide the IMF with the information, which is necessary to enable this supervision, on demand of the IMF, and will consult the latter one”. The emergence of the European Monetary Union had important consequences upon this mission of the IMF. Due to the fact that the monetary policy is unique within the Euro-zone and due to the fact that economic policies of the member states have an impact upon other countries, the IMF has decided to intensify discussions with European institutions. The consultations taking place with each state are being doubled by the discussions with the European Central Bank, with the Council of Ministers and the Economic and Financial Committee. The envisaged modalities include semestral meetings between the IMF services and the EU institutions which are responsible for the common policies within the Euro-zone, a yearly report of the IMF services, debates of the monetary and foreign currency policy on Council of Ministers level. These relations are being facilitated by the decision of the Council of Europe in Vienna, regarding the representation of the EU in the Board of Administration of the IMF, as well as due to the fact that the IMF has given the European Central Bank the statute of an observer. The Bank is invited to delegate a representative to take part in the

reunions of the Board of Administration of the IMF, whenever the agenda reads problems referring to “the supervision of the communitarian monetary and foreign currency policies, the supervision of the Euro-zone countries economical policies, the role of the single European currency in the international monetary system...”, as well as within the reunions when the agenda reads “problems considered by both institutions to be of common interest, in order to comply with their mandate”<sup>7</sup>.

### ***3.3 The transactions of the IMF***

Given the fact that the IMF is “country based”, it conducts most of its operations using the currencies of the member states, deposited into the accounts of their Central Banks. Since the 1<sup>st</sup> of January 1999, its holdings in what the currencies of the 11 European currencies are concerned – and since the 1<sup>st</sup> of January, 2001, its holdings in Greek drachms- were converted into Euros, kept in the 12 Central Banks. Each trimester, the Fund chooses the currencies it will dispense or receive. This is the budget of the IMF operations. It withholds the currencies of the countries whose position is, or seems to be good, solid, because of their good balance of external payment, and due to the fact that they have enough reserves. Every time it conducts an operation, the IMF uses the chosen currency, in order to have proportional quantities for the reserves of each country. This procedure was altered a little, as a result of the emergence of the Euro.

- *A choice does not exist any more*: the Euro is, in a normal and natural way, permanently being withheld in the budget, even if the 12 member state do not always have a solid position...Anyway, we cannot imagine that, at a certain moment, all the members of the Euro-zone would record simultaneous deficits...
- *The amount of money used*: The reserves have become less important, on one hand, due to the introduction of floating currency exchange rates and on the other hand due to the fact that the reserves of the 12 countries were affected by the introduction of the Euro. Because of this, the IMF decided that, in the future, it will consider the assigned quota of each country. To put it in other words, this assigned quota will increase in importance.

---

<sup>7</sup> IMF, 1999, pp. 187

- And, of course, without this being an effective change, *the IMF must impute Euro-operations to one or other member country*. Given the fact that the holdings in the national currency of a country of the IMF determine the position of that country in regard to the IMF, which allows the evaluation of its receivables and debts the country has with the IMF, they will be the basis of the remuneration the country will get or of the commission it will have to pay.<sup>8</sup>

To put it in other words, whenever the IMF dispenses or receives Euro, it must know whether it is dealing with French, Spanish or Greek Euros...

At the same time, the IMF conducts a part of the transactions in SDR, ever since the first allotment, which took place in 1970. The introduction of the single European currency had a minor impact upon these transactions, given the fact that the appointment procedure, by which the IMF was appointing the partner which was to get the SDR a country wanted to use, in exchange for the currency it needed, fell in disgrace. Moreover, for the time being, the European Central Bank is not recognized as a “desired holder” of SDR, thus, it cannot conduct transactions with SDR on its own behalf. The Euro can be traded for SDR, because it is recognized as a “freely usable currency”. Like the DEM and the FRF used to be.

The impact rather refers to the value of one SDR, which is determined based upon a currency basket. Before the 31<sup>st</sup> of December, 1998, the basket contained five currencies (USD, GBP, JPY, DEM and FRF), after the 31<sup>st</sup> of December, 1998, four currencies remained, due to the fact that the DEM and the FRF were replaced by the Euro. As in the case of the assigned quota, the composition of the new SDR is updated every five years. The importance of each currency of the basket is determined based on the exports of each country and of the holdings of the Central Banks in each of these currencies. In the case of the new basket, where only four currencies remained, the importance of each currency has been updated, and the amount of currency which influences the value of an SDR has been recalculated.

---

<sup>8</sup> The difference between the assigned quota of a country and the holdings of the IMF in the national currency of that country represent the Reserve Position of that country, which is initially equal with that part of the assigned quota which is paid in gold or other reserve assets, here USD or SDR, these being those 25% of the assigned quota. The difference between the holdings of the IMF in the national currency of a country and the assigned quota of that country stands for the Credit Access, that is the debt position to the IMF.

**Table 5. Old and New Composition of SDR Basket**

Currency	Initial importance (%)	Initial amount of currency	Amount of currency after the introduction of the Euro	New importance (%)	New basket of currencies
USD	39	0.5821	0.5821	45	0.577
EURO–DEM	21	0.446	0.3519	29	0.426
EURO – FRF	11	0.813			
JPY	18	27.2	27.2	15	21
GBP	11	0.105	0.105	11	0.0984
	100			100	

The basket is also relevant in order to establish the interest rate of the SDR, which can be considered as an efficacy for collecting countries, respectively of cost for paying countries. This rate of interest represents, at the same time, the remuneration received by countries which have a credit position with regard to the IMF and it is also the basis of determining the commission debtor countries must pay to the IMF. It is equal to the weighted average interest of certain short-term credit instruments, labelled in the four currencies. This rate of interest was not altered, once the Euro was introduced. But since in its determination, different credit instruments from corresponding markets are being taken into consideration – three-month treasury bonds in Paris, three-month interbank deposits in Frankfurt, - there still has to be a distinction, in the new basket, between the interest rate of the Euro in Paris and the interest rate in Frankfurt... The Euro-zone has one single currency, but it is not a single country and it is not a single financial market.

#### **4. Conclusion**

The emergence of the single European currency has strongly influenced the international monetary system. It has all the attributes of a hard currency and, as we could see in recent years, it has the power to compete with the American dollar and the Japanese yen. The countries which

adopted the Euro are completely integrated in what international finances are concerned and they are holding an important position within the framework of world trade. Today, the place of the single European currency is very well specified within the international monetary system, but it is hard to establish to what extent it succeeded in stabilizing this system. On the other hand, there are more and more voices speaking about an international financial architecture to the disadvantage of the notion of international financial system. Moreover, the Euro continues to be a young currency, which has to confirm its value. Starting with 2001, we noticed a continuous enlargement of the Euro-zone, an enlargement which is far from being over, a fact which creates a certain state of uncertainty concerning the evolution in its own rows, given the changes it generates for each new member state. The relationship between the European Union and the IMF must be well defined and clarified, the external representation of the European Union must also be clarified. It is hard to forecast the future exchange rate between the dollar and the Euro, given the floating exchange courses we had to notice in recent years. One thing is certain: the emergence of the single European currency opened a new page in the history of the international monetary system.

## **Abstract**

*The article analyses the state of the economic convergence in 11 member states of the European Union and that in the Czech Republic, Estonia, Cypre Lettland, Latvia, Hungaria, Malta, Poland, Slovenia, Slovakia and Sweden. It have used uniform starting points, which affect the price development, the deficit of the common budget, national debt, the development of the currency rate, long term interest rates and other factors. The articles show actual reference values of the price stability, stability of state in public finance, stability of the exchange rates and of the long term interst rates.*

**Keywords:** *economic convergence, reference value, price development, fiscal development, exchange rates, long term interest rates, surplus, deficit common administration, brutt debt,*

## **1. Introduction**

The last convergence report of the ECB analyses the state of the economic convergence in 11 member states of the European Union and that in the Czech Republic, Estonia, Cyprus, Latvia, Lithuania, Hungary, Malta, Poland, Slovenia, Slovakia and Sweden. By this analysis the bank used uniform starting points, which affect the price development, the deficit of the common budget, national debt, the development of the rate of currency, long term interest rates and other factors, like the results of integration of the markets, the situation and development on the current accounts on the balance of payments, development of the unitary labor costs and other price indices. The judgement of the maintenance of convergence have to be emphasised.

The single criterions have to be used in accordance to the exact stated manner:

1. It's inevitable to safeguard, that membership of the Euro-zone can get only member of the EU which have reached economic conditions leading to maintenance of price stability and keep the Euro-zone viable,
2. the convergence kriterions form a whole and strong system and therefore it's inevitable to fulfil all
3. convergence kriterions on the basis of current statements
4. application of the convergence criterions have to be uniform, transparent and simple.
5. The fulfilment of the convergencies will be judged not only at a fixed time but also on a preserved ground. For this reason the judgement of the single countries is directed at the maintenance of the convergence and the single statements will be judged retrospective for the period of the past 8 years. Further the forecast view has to be applicated in a suitable measure.

## **2. Price development**

The criterion of the price stability which means, that the member country maintains a long term price stability and an average rate of inflation announced in the run of the year before the observation doesn't exceed more as 1,5 % of the rate of inflation in max. 3 member states, which reached in the area of price stability the best results. The rate of inflation will be calculated like an increase of the last accessible 12 month average. For this reason, for the evaluation of the ECB - convergence one took the period from september 2003 till august 2004.

For the judgement of the reference value of inflation in 2004 has been applicated a non weithed arithmetic average of the rate of inflation in 3

following EU countries Finland (0,7 %), Denmark (1 %) and Sweden (1,3 %). The average rate of inflation so can reach the value of 0,9 % and with the addition of the a.m. 1,5 % has been stated the reference value about 2,4 %. The inflation will be measured on the basis of HICP ( harmonized index of custom prices ) which have been formed for the purposes of valuation of the convergence in the area of price stability.

### **3. Fiscal development**

To maintain the criterion of stability of state in the public finance resources means that "in the time of statement the decision of the EU council about existence of an excessive deficit doesn't refer to the member country".

By existence of an excessive deficit the European Union will prepare a message about nonfulfilment of the budget discipline requirements and that particularly:

- a) if the relation of the planned or the real deficit to the GDP (gross domestic product) exceed the reference value of 3 % except the cases:
  - if this relation essential dropped or it permanent goes down and reach a level which comes closer to the reference value
  - or if the exceeding over the reference value is only exceptionally or transitional and if this relation is moving near the reference value
- b) if the relation of the national debt to the GDP exceed the reference value stated on the level about 60 % of GDP except the cases when this relation adequate decreases and with a suitable speed comes closer to the reference value.

The report prepared through the European Commission have also to supervise, if the national debt exceeds the government spending for the investment and also for other relevant factors incl. middle periodic economic and budgeted situation of the member country. For the purposes of convergence the ECB expresses its opinion too, which examine the main indicators for the development of the budget finances but unlike the commission the ECB haven't a formal task. The task for the ECB is only to state if the government really reached an excessive deficit.

### **4. Development of the exchange rates**

By exchange rates is required to pursuit the floating band determined through the mechanism of exchange rates of the European Currency System, min. during 2 years before the pursuit without devaluation opposite of the

currency of each other member country. Through it the ECB pursuit, if the country take part in the mechanism ERM II during the period of min. 2 years before the pursuit without causing considerable pressures to the currency mainly without devaluation of the currency against the EURO.

The valuation of stability of the exchange rate against the EURO is aligned to the fact, if the exchange rate is moving near the central parity ERM II, how is to pay attention to factors which can lead to devaluation of the currency. The width of the floating band in the mechanism ERM II has with it no influence on valuation of the criteria of the stability of the exchange rate.

The question of absence of „significant tension“ have to be valued as follows:

- relevant to the deviation of the exchange rates from the central parities against the EURO in the mechanism ERM II,
- relevant to the differentials of the short term interest rates in the Euro-zone and their development relevant to the task, which played the exchange interventions.

Except the development of the nominal currency rates against the EURO have to be valued also the maintenance of the actual currency rates in connection with the development of real and effective currency rates from the current capital- and finance accounts of the balance of payments from the part of the country trade with the Euro-zone on the whole foreign trade and from the clean international investment position of the country in long-term horizon.

## **5. Development of long term interest rates**

The convergence criterion of the interest rates requires a „constant convergence, reached through the member country and his participation in the mechanism of exchange rates and which reflects in long term levels of the interest rate“. This criterion requires, that in the course of one year before the pursuit, the average long term nominal interest rate of the member country not exceed more than round 2 percent the interest rate of these three countries, which reached in the area of price stability the best results. The interest rates have to be valued on the basis of long term government obligations or comparable securities how is to consider the different definitions in single member countries.

The average long term nominal interest rate have to be calculated according to ECB in the course of one year before the pursuit and expressed the interest rate, which was calculated as arithmetic average in the last 12

months, for which are accessible the statements of the index HICP. For the needs of valuation in the convergence message have been used long term interest rates from Finland (4,2 %), Denmark (4,4 %), and Sweden (4,7 %). Afterwards the average rate have reached the level 4,4 % and additional 2 % we will get the reference value about 6,4 %.

## 6. Valuation of the state of economic convergence

All 11 countries valuated in the last convergence message the ECB have in connection to the third stage HMU a valued exception but not a particular status. According to the agreement the countries are obliged to take the EURO with the consequence, that they are obliged to try to fulfil all convergence criterions. The state of fulfilment of the indicators of the economic convergence is described in the following table No. 1.

**Table 1 Indicators of economic convergence in 2004**

Member country	Inflation (HICP)	Long term interest rates	Surplus + Deficit-common adm.	Brutt debt of the common adm.
Česká republika	1,8	4,7	-5,0	37,9
Estónsko	2,0	.	0,3	4,8
Cyprus	2,1	5,2	-5,2	72,6
Lotyšsko	4,9	5,0	-2,0	14,7
Litva	-0,2	4,7	-2,6	21,4
Maďarsko	6,5	8,1	-5,5	59,9
Malta	2,6	4,7	-5,2	73,8
Poľsko	2,5	6,9	-5,6	47,2
Slovinsko	4,1	5,2	-2,3	30,8
Slovensko	8,4	5,1	-3,9	44,5
Švédsko	1,3	4,7	0,6	51,6
<b>Referenčná hodnota</b>	2,4 %	6,4 %	-3 %	60 %

*Source: Report of Convergence, ECB, Eurostat and European Commission.*

### 6.1 Reference value

During of the last two years the inflation have reached in the countries, which are not members of the euro-zone a relative low level. It lowered from the level of 10 % in the year 1997 to the level of approximately 2 % in the middle of the year 2002, where remained till the beginning of the

year 2004. Later increase of the inflation has been caused mainly through some factors connected with the entry into the EU, how the increase of the indirect taxes and regulated prices, strong increase of the domestic demand and the increasing energy prices. Advanced increasing of prices as consequence of increasing of the demand and wages can be expected in the near future. Some central banks have reacted to this development through increasing of interest rates.

The table No. 1 shows, that 5 from 11 valuated countries – Czech republic, Estonia, Cyprus, Lithuania and Sweden – have reached an average value of inflation rate HICP under the limit of the reference value. Inflation in Poland and Malta have only moderate exceeded the reference value. In other countries the inflation considerable exceeded the reference value: Slovenia 4,1 %, Latvia 4,9 %, Hungaria 6,5 % and Slovakia 8,4 %.

We suppose, that in the majority of countries the inflation will decline, mainly in the countries with a high level of inflation in 2004. This assumption based on the expectation of weakly consequence from the increasing of indirect taxes and regulated prices. In the new member countries the inflation can be more volatile as consequence of always significant part of food on the total living costs, and price increase in energy- and raw material sector. New member countries need a strict controlling of the domestic price pressures, which are connected without others with the income costs, the fiscal policy, the reform of product market, the labor and the processing of catch up the high developed member countries.

The fiscal policy has moved very slowly, how the majority of countries just only have to reach the level which can be regarded in wider degree to maintain in the middle term horizon. In this area it's necessary to reach an important progress and so to make it possible to guarantee a sustainable agreement with the fiscal criterion in sense of the requirements through the pact of stability and growth and to fulfil the middle term objective of the budget position which comes closer to the balanced budget or to a budget with surplus.

In the position of an excessive deficit are at the present 6 countries – Czech Republic, Cyprus, Hungary, Malta, Poland and Slovakia. The reference value of the national debt in connection to the GDP exceed only two countries (Cyprus 70,9 % and Malta 71,1 % but in more countries, which joined the EU on 01.05.2004 the national debt is strong growing, because some of them have important structural problems as consequence of state guarantees and pension protection.

All member countries which show in the present a deficit, need a considerable consolidation and have to be interested to reach a permanent

fulfilment of the fiscal criteria and the medium term objective of the budget position, so a balanced or a budget with surplus according to the pact of stability and growth.

After the period of significant decrease of the long term interest rates the yields from the long term obligations began to grow, the differences in some countries in comparison with the Euro-zone increased, which was connected with fiscal problems and inflation pressures. The consequence was the need of an enduring convergence.

By development of the exchange rates no one of the new member countries was member in the ERM II during at least two years before the valuation. Estonia, Latvia and Slovenia have joined the ERM on 28. June 2004. Estonia and Latvia have kept after joining to ERM II as unilateral obligation its currency rates. At the present in Estonia soared a significant deficit on the current capital account of the balance of payments, which have reached a level about 12,7 % which led to increasing of its pure foreign commitments. In Latvia also soared the deficit of the connected current and capital account and reached a level about 6,5 % of the GDP. In both countries was the agreement about participation in the ERM II with the obligation to realise healthy fiscal policy as condition of maintaining macroeconomic stability and keeping of the convergence process. The monetary policy of Slovenia after joining the ERM II was orientated to keep a relative stable currency rate against EURO and to balance the decreasing off the tolar value against EURO. The tolar maintained closer to the central parity.

The majority of currencies, which remained outside the mechanism ERM II against EURO has eased off. The development of the rate of the slovak crown against EURO have been characterized through an initiate period of whole stability till to the third quarter of 2003 and afterwards the rate of the crown has increased in stages. The NBS has regarded the increasing of the crown for too fast and the reaction was the decrease of the key interest rates and intervention on the foreign currency markets. The volatility of the slovak crown against EURO was during the reference period too high and the level of the spread for short term interest rates against euro-zone was significant.

The development of the exchange rates during the last two years was in the single valued countries significant different. In some countries the exchange rates have stated a significant stability, but in other countries have occurred significant fluctuations caused through an uncertainty in the area of fiscal consolidation a high deficit of the current account of the balance of payments, an increasing of private credits and through an increasing of home

demand.

## 7. State of economic convergence in the Slovak Republic

**Table 2 Development of the inflation rate, debt and the deficit of common administration.**

Years	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005
HICP	5,8	6,0	6,7	10,4	12,2	7,2	3,5	8,5	7,6-8,4	4,5
Debt CA	30,3	33,3	34,0	47,2	49,9	48,7	43,3	42,6	44,0	44,2
Exchange debt CA	11,2	5,9	3,8	15,7	7,2	2,6	-1,5	3,0		
Deficit -	-7,4	-6,2	-3,8	-7,1	-12,3	-6,0	-5,7	-3,7	-3,3	-3,8

*Source: Report of Convergence, ECB, 2004*

From the table No. 2 follows, that the inflation in the Slovak Republic exceeds the reference value and in the year 2004 have reached a level of 8,4 %. The inflation grew from the initial value of 5,8 % in 1996 to 12,2 % in 2000 and in the following years dropped to 3,5 % and in the year 2003 again grew to the level of 8,5 %.

The assumption for the decrease of the inflation in 2005 is, to finish the corrections on the regulated prices (28 % share on the commodities HIPC), the indirect taxes and to slow the increase of the wages. The risks of inflation increasing follow mainly from possible secondary influences of high rate of inflation in the last period, from the development of the wages and from the fiscal imbalance.

The deficit of common administration durable exceeded the reference value, but now it tends to decrease. The relationship of the national debt to the GDP was under the reference value, announced an increasing trend but the increase of the national debt was in other years slower ( in the year 2002 even a decrease of 1,5 %) and in 2003 soared about 3 %. If we review the period from 1996 to 2003 we can see that the relationship of the national debt to the GDP soared about 12,3 %. Until 2007 we expect, that the relationship of the deficit to the GDP will go down to the level of 2 % and the relationship of national debt will moderate soar to 45,5 %. In the future a new fiscal consolidation will be necessary with it the Slovakia can fulfil the middle term requirement of the pact of stability and growth, which can be a balanced or a surplus budget.

The slovak crown is not connected to the ERM II and the central parity REM II is not determined. The development of the currency rate will be pursued on the basis of the own reference value ( 41,8 SKK/EUR correspond to 100 %). The development of the currency rate against EURO announced a considerable volatility measured with annualised standard deviations from the daily percent alteration. From october 2002 till september 2004 the max. above deviation from the double central parity against EURO reached the level about 4,7 % and the max. below deviation 0,7 %. The average % deviation of the double SKK currency rate against EURO for the period 1999 till september 2004 reached 20,3 %.

**Table 3 Key pressure indicators on the currency rate of the slovak crown**

	December 2002	March 2003	Jun 2003	September 2003	December 2003	March 2004	Jun 2004
Volatility exchange rate	5,4	5,4	3,7	3,8	2,7	3,1	2,9
Diferent between short term exchang rates	3,8	3,5	3,8	4,2	3,8	3,7	2,8

*Source: Annual Report National Bank of Slovakia, 2003, 2004*

The average level of long term interest rates was in the last two years under the reference value of the criterion of interest rates and has now the value 5,1 %.

## **Abstract**

*Prior to its EU entry, the Czech Republic accepted the obligation to exert maximum efforts in order to fulfill conditions in the possible shortest time, on whose basis it will be able to accept the common European currency – the Euro. During the proper examination of the readiness of the Czech Republic for fulfilling this criterion one has to take into account both prerequisites, which are necessary for the integration of the Czech Republic into the Euro-zone, and the dispositions of the Czech economy to maintain positive effects arising from this membership. Since such a complex analysis concerning the preparedness of the Czech Republic for accepting the Euro would be rather extensive, we paid our attention merely to the examination of the extent, to which the Czech economy meets Maastricht nominal convergence criteria. Based on the analysis, we come to a conclusion that the Czech economy will not be able to meet this obligation in the following three years, mainly due to high deficits of public finances. In the last part, based on our estimates we claim that the Czech Republic could become a member state of the Euro-zone as early as in 2010.*

**Keywords:** *exchange rate stability criterion; government debt criterion; government deficit criterion; long term interest rate criterion; price stability criterion*

---

<sup>1</sup> This article arose thanks to the support of the Grant agency of the Czech Republic within the project GA402/05/2758: „The integration of the financial sector of the new EU member states into EMU“.

## 1. Maastricht nominal convergence criteria

Although the Czech Republic became a member country of the European Union on May 1<sup>st</sup> 2004, one cannot name this momentous day as a moment, at which the process of the European integration was definitely concluded. Prior to the EC entry, the Czech Republic, likewise the remaining nine new member states, pledged that following its entry it would exert maximum efforts in order to comply with the conditions in the possible shortest time too, on which basis it would be able to accept the common currency – the Euro. If we are to evaluate the preparedness of the Czech economy for fulfilling this objective, then we have to take into account both the prerequisites, which are inevitable for the integration of the Czech Republic into the Euro-zone (Maastricht nominal convergence criteria) and its dispositions for maintaining positive effects resulting from this membership (compatibility of the Czech economy with the economies of the Euro-zone). Since such a complex analysis concerning the preparedness of the Czech Republic for accepting the Euro would be rather extensive, we will pay our attention in this article merely to the examination of the extent, to which the Czech economy fulfils Maastricht nominal convergence criteria (hereafter also MNCC).

Event though the professional public is well acquainted with the substance of MNCC, at the beginning it appears to us as appropriate to mention that one standardly distinguishes between monetary nominal convergence criteria, which determine the maximum permissible level of the growth rate of the consumer prices, long term interest rates, and the movement of the exchange rate around its central parity and between fiscal nominal convergence criteria, which determine the maximum permissible level of government deficit and government debt. It is evident from the above stated that while monetary criteria in the case of the Czech Republic are primarily affected by the monetary policy of the Czech National Bank, the level of the fulfillment of fiscal criteria is mainly influenced by the fiscal policy of the Czech Government. At the same time, we would like to remind that the main reason for accepting these criteria was an effort of the EU member states in 1992 to prevent from the fact so that countries, whose economic instability would endanger the stability of the newly arising common European currency, would enter the future Economic and Monetary Union (hereafter EMU).

## 2. Monetary Maastricht nominal convergence criteria

### 2.1. Price stability criterion

According to the Protocol of Convergence Criteria (hereafter also “Protocol”), whose version proceeds from Article 121 of the Treaty on the Establishment of the European Community (hereafter also “Treaty”), the member country complies with price stability criteria if ... *in the long term, it shows a sustainable price stability and the average inflation rate, which is measured in the course of one year prior to the examination carried out, does not exceed more than 1.5 percentage point of the inflation rate of three member states at the most, which have achieved the best results in the area of the monetary stability.* (ECB) Based on that definition, the European Central Bank determines then the reference value of the inflation criterion as ... *the non-weighted arithmetic average of the inflation rate in three countries, which have reached the lowest inflation rate, provided that this rate is in accordance with the requirements of the price stability.* (ECB) The own inflation in individual countries is measured by means of the current average of the harmonized index of the consumer prices for over twelve months in comparison with the previous average of twelve months (HICP 12:12).

**Table 1 – The price stability criterion for the Czech Republic in the years 1999-2007 (HICP; average of the last twelve months against the average of the previous twelve months; %)**

Indicator	1999	2000	2001	2002	2003	2004	2005 <sup>p</sup>	2006 <sup>p</sup>	2007 <sup>p</sup>
Inflation rate	1.80	3.90	4.50	1.40	0.10	2.60	2.56	1.99	1.24
Criterion I	2.07	2.67	3.13	2.90	2.70	2.17	2.09	1.97	1.25
Criterion II	2.07	2.67	3.13	2.90	2.70	2.17	2.09	1.97	2.01
Criterion III	3.00	3.37	2.77	3.43	3.63	3.37	3.17	3.12	3.22
Criterion I	yes	no	no	yes	yes	no	no	no	yes
Criterion II	yes	no	no	yes	yes	no	no	no	yes
Criterion III	yes	no	no	yes	yes	yes	yes	yes	yes

Source: Eurostat and one's own calculation

Note: Data concerning the development of the inflation rate and of the price stability criteria for the years 2005-2007 are the author's own estimates based on the analysis of the respective time series by means of the model ARIMA. They years, for which data was estimated, are marked with a symbol P.

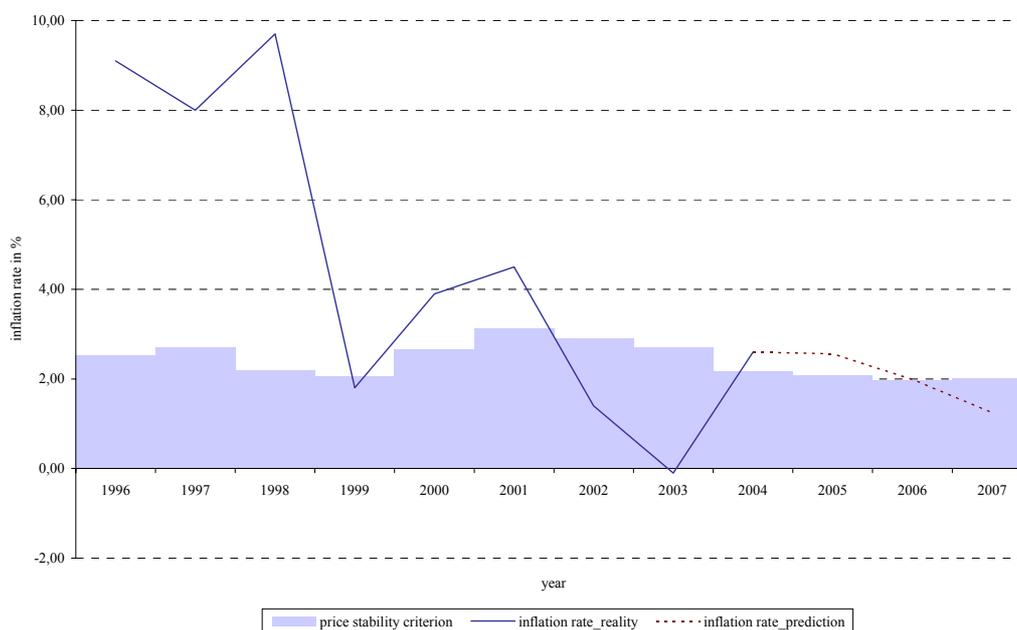

As it is apparent from the above stated, the reference value of the inflation rate is not unequivocally determined within the Protocol, in consequence of which this criterion is a target for member countries of the Economic and Monetary Union, and it is constantly changeable. Moreover, it is necessary to state that the relatively vague definition of this criterion has enabled the economists to interpret the “lowest inflation rate, which is in accordance with the requirements of the price stability” in several possible ways. If we proceed from these opinions, then we can determine the reference value of the inflation rate as an arithmetic average of the inflation rate, which has been reached:

- In three countries of the European Union with the lowest inflation rate (see criterion I in table 1),
- In three countries of the European Union with the lowest inflation rate, at the same time the countries are not included in this group, where this rate has achieved negative values (see criterion II in table 1)

Or in three countries of the European Union, which meet the requirement of the price stability best with the low inflation rate at present time (see criterion III in table 1).

It proceeds from the data showed in table 1 that if we did not take into account only the low inflation rate when determining the reference value but also the ability of the country to meet the requirement for the price stability (criterion III), then the Czech Republic would do well as for fulfilling the corresponding convergence criterion with a considerable large reserve as early as in 2002. If we proceed from another our prediction of the development of the inflation rate for the years 2005-2007, one can assume then that by fulfilling this criterion the Czech economy should not have any problems in the future either. Furthermore, it is necessary to note that this reference value corresponds to the inflation target as well, which the Czech National Bank determined with the national index of the consumer prices for this period (the target was set at the level of 3%).

**Figure 1 – The inflation rate measured by HICP (12:12) and by the price stability criterion (criterion II) in the Czech Republic in the years 1996-2007**

*Source: Eurostat and one's own calculation*

We will arrive at somewhat different conclusions than if we consider as relevant, similarly like the Ministry of Finance of the Czech Republic, the criterion, which takes into account the average inflation rate of three countries with the lowest positive inflation (criterion II). As it is obvious from table 1, in that case, according to our projection, the Czech Republic would be able to fulfill the inflation criterion for accepting the Euro only in 2007, moreover, in 2006 it would relatively and more noticeably come closer to its reference value.

In the case of the price stability criterion, we have to say that even though the Czech Republic has maintained the standard of the low inflation economy since 1999, one cannot rule out the Czech Republic might have certain problems as for fulfilling this criterion in the coming years. The estimate of the potential product<sup>2</sup> leads us primarily to this conclusion, from which arises that the Czech economy has been in the expansion production

<sup>2</sup> We have estimated the value of the potential product by means of Hodrick-Prescott's filter, which we have applied to the time series containing the annual seasonally cleaned data concerning the development of gross national product in the stable prices of the year 1995.

gap since 2003, and at the same time the value of GAP rose by 2,69 p. p. in the years 2003-2004. Should this development continue, one can relatively expect significant inflation pressures in the Czech Republic, which could be the cause of not fulfilling this criterion.

## 2.2 Long term interest rate criterion

It is evident from Article 4 of the Protocol of Convergence Criteria that a member country of the Economic and Monetary Union fulfils the long term interest rate criterion only if ... *in the course of one year, prior to the examination, the average long term interest rate of the member state did not exceed 2 percentage points of the interest rate of three member states at the most, which have reached the best results in the area of the price stability.* (ECB) In that case, the European Central Bank determines the reference value of this criterion as ...*the non-weighted arithmetic average of the long term interest rates in three countries, which have attained the lowest inflation rate.* (ECB) In this case, interest rates from the long term government bonds or comparable securities are considered as corresponding and at the same time, the European Central Bank, for calculating the long term interest rate, considers as relevant the proceeds up to the date of maturity of ten year government bonds on the secondary market.

Shall we in this case also consider the three countries with the lowest inflation rate as the countries, which have achieved the lowest positive inflation in the given period, subsequently we come to a conclusion that in the case of this criterion, the Czech Republic had no problems fulfilling it in the past, simultaneously, the same development, according to our prediction, we are expecting in the coming years. In the case of this convergence criterion, we can determine trust or distrust of the financial markets in stabilizing the Czech Republic finances as a risk factor. Should the trust be violated in the coming three years, then we can rather expect the long interest rates considerably to grow in that period.

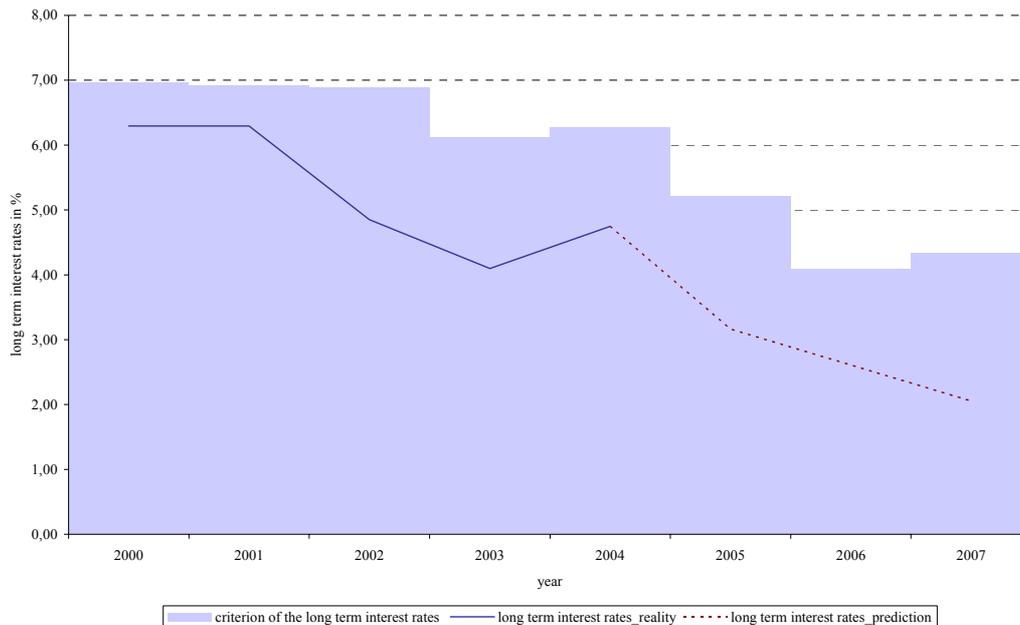

**Table 2 – The criterion of the long term interest rates for the Czech Republic in the years 1999-2007 (10 year interest rates from the government bonds on the secondary market; the average over the last twelve months; %)**

### 2.3 Exchange rate stability criterion

Only that member state fulfills the exchange rate stability criterion, which according to the Protocol of Convergence Criteria ... *has observed the fluctuation range stipulated by the mechanism of the exchange rates of the European Monetary System at least for the last two years, and the exchange rate has not been exposed to hard pressures...*, simultaneously what is applicable is that in that given period it should not have ... *devalued the bilateral average rate of its own currency at its own suggestion against the currency of any other member state.* (ECB) It unequivocally follows from this definition that the respective country is able to comply with the exchange rate stability criterion only if:

- It has been in the last two years, prior to the examination carried out, a participator of the European mechanism of exchange rates, which has been the ERM II mechanism since January, 1999,
- Its exchange rate follows the nominal fluctuation range, i.e. if it moves within this mechanism near its central parity
- And the development of the exchange rate interventions and short term interest differentials against the Euro-zone do not lead to distinct tensions or strong pressures on this exchange rate.

**Table 3 – The exchange rate stability criterion for the Czech Republic in the years 1999-2007 (CZK/EUR, CZK/ECU; December of the given year; fluctuation range  $\pm 15\%$  from central parity)**

<i>Indicator</i>	<i>1999</i>	<i>2000</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>	<i>2005<sup>P</sup></i>	<i>2006<sup>P</sup></i>	<i>2007<sup>P</sup></i>
<i>Exchange rate</i>	36,66	36,66	36,66	36,66	36,66	36,66	36,66	36,66	36,66
<i>Depreciation (-15%)</i>	27,09	27,09	27,09	27,09	27,09	27,09	27,09	27,09	27,09
<i>Depreciation (-2,25%)</i>	32,59	32,59	32,59	32,59	32,59	32,59	32,59	32,59	32,59
<i>Depreciation (+15%)</i>	28,03	28,03	28,03	28,03	28,03	28,03	28,03	28,03	28,03

*Source: Eurostat and one's own calculation*

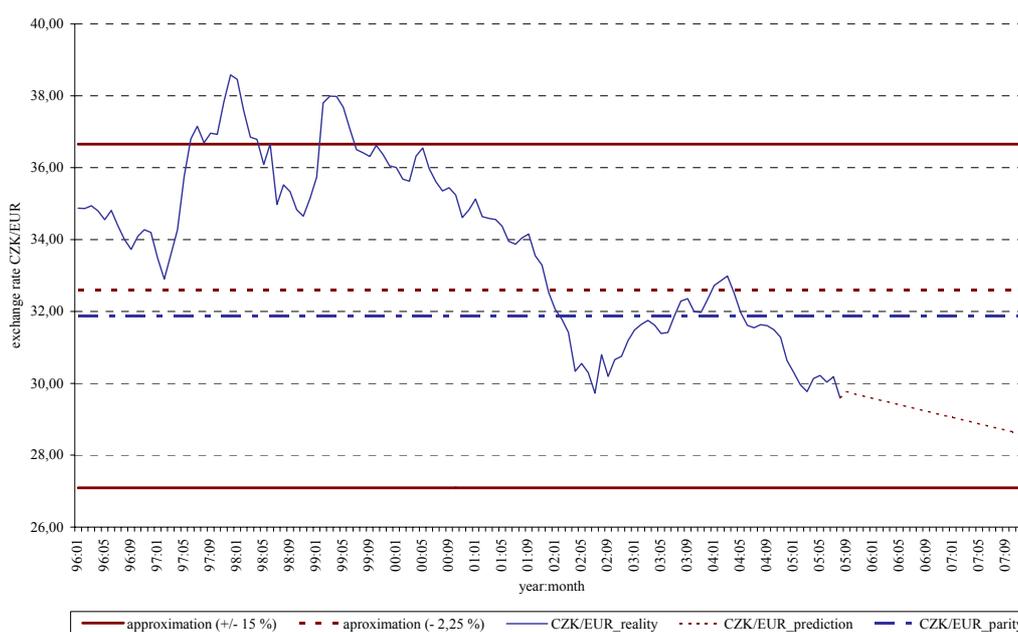

*Note: Data concerning the development of the exchange rate and the development of the exchange rate stability criterion for the years 2005-2007 are the author's own estimates based on the analysis of the respective time series by means of the model ARIMA. They years, for which data was estimated, are marked with a symbol P.*

We consider the determination of the “normal fluctuation range” as the main methodological problem of the exchange rate stability criterion, which can be defined in this case by one of the three following manners:

- The first possibility is to determine the normal fluctuation range in a way, as it was intended at the time of drawing up the Treaty on the Establishment of the European Community, i.e. as a range determined by the variance of  $\pm 2,25\%$  from the bilateral central parity, and exceptionally, this variance can reach up to  $\pm 6,00\%$ ,
- The second possibility is to proceed from the decision, which the Council EMI accepted in August, 1993 and on which basis, the fluctuation range was extended to  $\pm 15,0\%$

- And the last, the third possibility is to accede to a compromise solution, which is referred to by some economists of ČSOB and within which the fluctuation range is determined as a asymmetric range, in which a bigger space for depreciation is given for the currency of the candidate country (appreciation variance is set to +15%) and simultaneously there is a smaller space for depreciation, when the respective variance reaches only - 2,25%.

**Figure 3 – The nominal exchange rate CZK/EUR (ECU) and the exchange rate stability criterion in the Czech Republic in the years 1996-2007**

Source: Eurostat and one's own calculation

Note: The central parity was estimated by the author by means of the average monthly exchange rate of CZK against Euro for the period of 1996-2007.

If we proceed from the above given, it is apparent that in the case of the Czech Republic, formally, we are not able to assess the level of fulfilling the exchange rate stability criterion at present. The main reason for this argument is the non-participation of the Czech Republic in the ERM II mechanism and thus there is the non-existence of the officially determined central parity of the exchange rate of CZK/EUR. Still, if we wanted to partially assess the chances of the Czech economy for fulfilling this criterion, then we could use for these purposes for instance the central parity stimulated

by means of the average of the exchange rates of CZK/EUR for the years 2003-2004. As it obvious from figure 3, since the beginning of the year 2002 the fluctuation of the currency exchange rate of CZK against Euro has been, apart from the first quarter 2004, smaller than the hypothetical asymmetric range [+15 %; -2,25 %], and at present, the significant variances of this exchange rate are taking place from its central parity. If we follow strictly the above stated conditions in this situation, then we can state that the Czech economy could have certain problems regarding its fulfilling the exchange rate stability criterion in the future. It all depends on the fact how the European Commission will view this criterion as well as the European Central Bank.

### **3. Fiscal Maastricht nominal convergence criteria**

#### ***3.1 Government deficit criterion***

The Treaty on the Establishment of the European Union in Article 121 requires member states to strive for ... *a long term sustainable state of public finances apparent from the state of public budgets, which do show an excessive deficit ...*, and simultaneously, as an excessive deficit is considered such an deficit, according to which ... *a ratio of the planned and actual deficit of public finances to the gross domestic product exceeds the reference value (stipulated in the Protocol regarding the excessive deficit procedure of 3 % GDP)....* (ECB) A certain exception of fulfilling this criterion can be made to such member states, where:

- The ratio of the deficit of public finances to GDP markedly and continuously decreased in the past, and in consequence of this fact it reached the maximum, which was close to its reference value at the given moment,
- Or in the case where the exceeding of the reference value took place entirely exceptionally, and at the same time temporarily. In that case, it is assumed that the actual value will be close to the reference value of the given criterion.

The government deficit is then monitored in particular countries by means of the pure loan of the government institution sector, whose value is calculated on the basis of the methodology of the system of national accounts ESA 95.

Speaking of the government deficit criterion one mustn't forget the meeting of the European Council of Finance Ministers (ECOFIN), which took place in March, this year, and in which the representatives of ECOFIN agreed to some partial amendments of the "Stability and Growth Pact", which

significantly affected the conditions, under which a member state is able to fulfill this criterion. According to these conclusions:

- ECOFIN and the European Committee, following the implementation of the compulsory fund system by the member state, can take into account net costs connected with this reform when assessing the development of the government deficit. This consideration will be then applicable in the first five years following the introduction of the reform and will have a regressive character, i.e. 100% of net costs could be taken into account in the first year, and the volume will be gradually decreasing to 80, 60, 40 and 20 % in the coming four years,
- The member states are bound to observe the middle term target, what means the maintaining of almost balanced or surplus state budget and further a share of periodically cleaned government indebtedness in GDP can reach -1% in the long term period in countries with low indebtedness and high potential growth, whereas in countries with high indebtedness and low potential growth, the state budget must be balanced or surplus,
- The Euro-zone member states and ERM II ought to base their predictions concerning the development in the area of public budgets on the same assumptions as the European Committee.

**Table 4 – The government deficit criterion for the Czech Republic in the years 1999-2007 (pure loans of the government institution sector in the methodology ESA 95; December of the given year; %)**

<i>Indicator</i>	<i>1999</i>	<i>2000</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>	<i>2005<sup>p</sup></i>	<i>2006<sup>p</sup></i>	<i>2007<sup>p</sup></i>
<i>Deficit / GDP</i>	- 3.65	- 3.65	- 5.92	- 6.75	- 11.65	- 3.02	- 4.15	- 2.39	- 2.10
<i>Criterion</i>	- 3.00	- 3.00	- 3.00	- 3.00	- -3.00	- 3.00	- 3.00	- 3.00	- 3.00
<i>Criterion</i>	<i>no</i>	<i>no</i>	<i>no</i>	<i>no</i>	<i>no</i>	<i>no</i>	<i>no</i>	<i>yes</i>	<i>yes</i>

*Source: One's own calculation based on data of CSO*

*Note: Data concerning the development of the share of the government deficit in GDP for the years 2005-2007 are the author's own estimates based on the analysis of the respective time series by means of the model ARIMA. They years, for which data was estimated, are marked with a symbol P.*

As it obvious from data depicted in figure 4, the Czech Republic has not been able successfully to fulfill this government deficit criterion since 1998 up to now. In this connection, one has to state that the Czech Republic

will be in all likelihood confronted with these problems in the following three years, furthermore our conclusion confirms the obligation of the Czech Government to lower public finance deficit in the years 2005-2007 from a forecast figure of -4,7 % in 2005 to the final figure of -3,3 % in 2007. It is apparent from the given that the first year, when the Czech economy ought to be able to fulfill the government deficit criterion should be in 2008. As it obvious from the above stated our prognosis of the development of government deficit can be referred to as very optimistic in this case.

**Figure 4 – The share of pure loans of government institutions (methodology ESA 95) in GDP and the government deficit criterion for the Czech Republic in the years 1996-2007**

Source: OECD and ones' own calculation

### 3.2 Government debt criterion

Article 104 of the Treaty on the Establishment of the European Union refers to the fact that ... *an EU member state does not meet the requirements of budget discipline ... if ... a ratio of public indebtedness to gross domestic product exceeds the recommended limit (stipulated in the excessive deficit procedure of the Protocol as 60% of GDP) ...* (ECB) Similarly, as in the case of government deficit, an exception of the government debt criterion can be made to a respective member state only at the moment, when this ratio of public indebtedness to GDP is sufficiently decreasing and at a satisfactory

pace it is nearing the determined reference value. As government debt is considered total gross debt of the government institution sector, which is in this case calculated on the basis of the methodology of national accounts ESA 95.

If we proceed from data depicted in table 5, then it is apparent that the government debt criterion was and in all probability will be the only criterion, with which the Czech Republic will not have any more serious problems in the future.

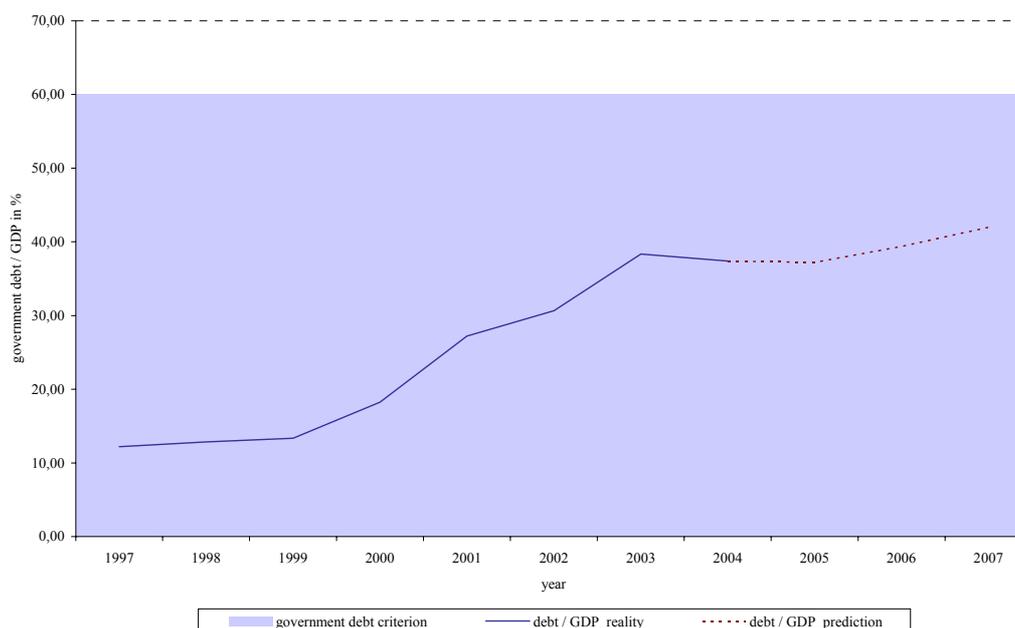

**Table 5 – The government debt criterion for the Czech Republic in the years 1999-2007 (total gross debt of the government institution sector in the methodology ESA 95; December of the given year; %)**

<i>Indicator</i>	<i>1999</i>	<i>2000</i>	<i>2001</i>	<i>2002</i>	<i>2003</i>	<i>2004</i>	<i>2005<sup>p</sup></i>	<i>2006<sup>p</sup></i>	<i>2007<sup>p</sup></i>
<i>Debt / GDP</i>	13.35	18.24	27.21	30.66	38.34	37.39	37.19	39.38	41.97
<i>Criterion</i>	60.00	60.00	60.00	60.00	60.00	60.00	60.00	60.00	60.00
<i>Criterion</i>	<i>yes</i>	<i>yes</i>	<i>yes</i>	<i>yes</i>	<i>yes</i>	<i>yes</i>	<i>yes</i>	<i>yes</i>	<i>yes</i>

Source: OECD and one's own calculation

#### 4. Conclusion

As we have already stated at the beginning of this paper, the Czech Republic, prior to its EU entry, accepted an obligation to exert maximum efforts in order to fulfill conditions in the possibly shortest time, on whose basis it will be possible to accept the common European currency – the Euro. If we are to state whether the Czech Republic is capable of meeting the obligation, then we have to state that in all probability it will not, mainly due to the inability to fulfill the public deficit criterion in the long run. If we proceed from the assumption that the Czech economy could be able to fulfill this criterion as early as in 2008, then we could expect that in the same year, the Czech Republic would enter the exchange rate mechanism ERM II, what would mean that the Czech Republic would become a member state of the Euro-zone not earlier than in 2010.

## **Abstract**

*Generally speaking, Portugal is considered to be a good example of the European integration. The 20-year-old membership in the EU clearly shows an impact of this institution on the stability of democracy in the country, especially during a period of transition – after the fall of non-democratic regime and during the negotiation about the entering EU as well. With the help of structural and cohesive funds the country was directed to the successful economic development. In comparison with the period after so called “the Carnation revolution” in 1974 the image of the country changed. Portuguese political leaders gradually understood that the success of the country’s membership is based in its active approach and participation in the process of the European integration. As a country on the geographical and economic periphery it tried to be in the centre of everything, they took an active part in all significant integration activities, including EMU, the Schengen area, an enlargement of the EU etc. The aim of this article is to point at the Portuguese experience from this process and to present Portugal as a good example for new EU countries, especially for those ones that belong to a group of small or middle-sized countries with many historical, political and economic parallels in their development. It also concerns the Czech Republic and Slovak Republic.*

**Keywords:** Portugal, EMU, Experience, periphery, new EU countries

## **1. Introduction**

Portugal has been a full member of the European Economic Community since 1 January 1986, after the signature of the Accession Treaty, on 12 June 1985. Both Portugal and Spain – and the latter signed the Accession Treaty and joined the European Economic Community on precisely the same date – became members of what was then known as the „Europe of the 12“. The two Iberian Countries had managed to free themselves successfully in the mid-seventies of the dictatorship that had oppressed them for several decades, and with equal success had managed to establish democratic, pluralist regimes. Nineteen years after Portugal joined what was at the time the European Economic Community it is clear that this choice was one of the most important decisions taken by Portuguese political leaders in this century. Joining the European project therefore reflected a solid determination to ensure that the country would return to its historical and cultural origins and to its undeniable European vocation. The desire to consolidate Portugal’s democracy was a major factor in the country’s accession to the European Community. After the accession, there followed a period during which a virtually exclusive priority was given to economic and social development. Initially, the viewpoint was eminently national – an approach shared by the other “cohesion countries”, notably Spain. The challenge of identifying Portugal’s priorities is also a consequence of European economic and monetary integration.

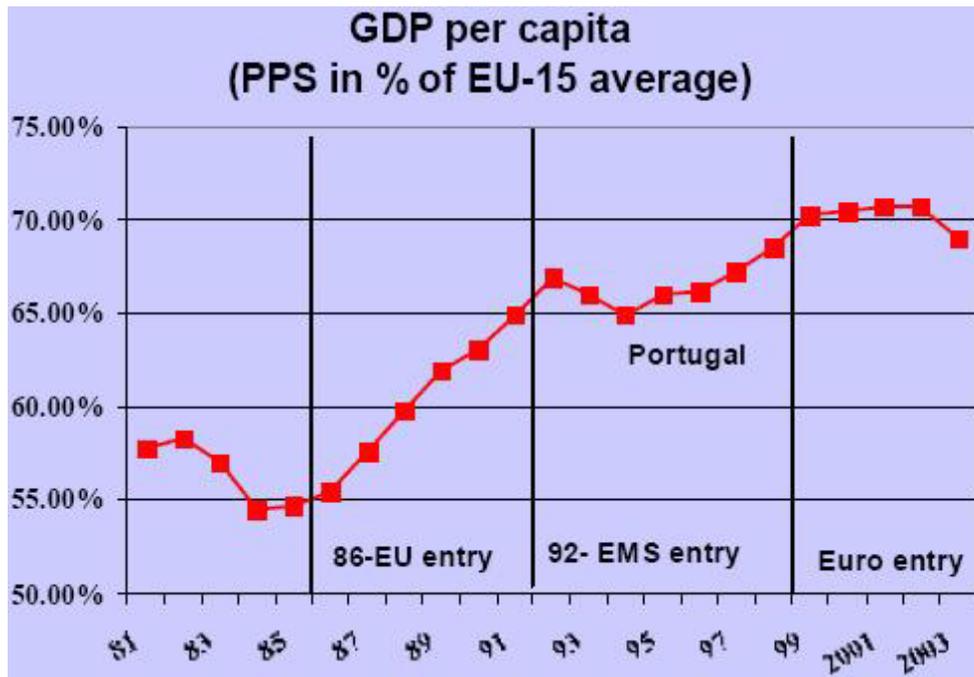

## **2. Portugal’s Transition to Economic and Monetary Union**

### ***2.1 Exchange Rate Mechanism participation***

The Portuguese case is a good illustration of both the benefits and the risks associated with monetary integration. To properly assess its case, however, we should consider the long period of membership since 1986. In this time span we can certainly be seen as a success story, which is also true if we start the analysis in 1992 when Portugal joined the Exchange Rate Mechanism (ERM).

As in most other EU countries, perhaps even more so in the case of Portugal, the challenge of Economic and Monetary Union (EMU) has worked as a mechanism for economic stabilisation and as a pre-condition for structural reform and long-term development.

**Figure 1 GDP per capita**

Source: Banco de Portugal

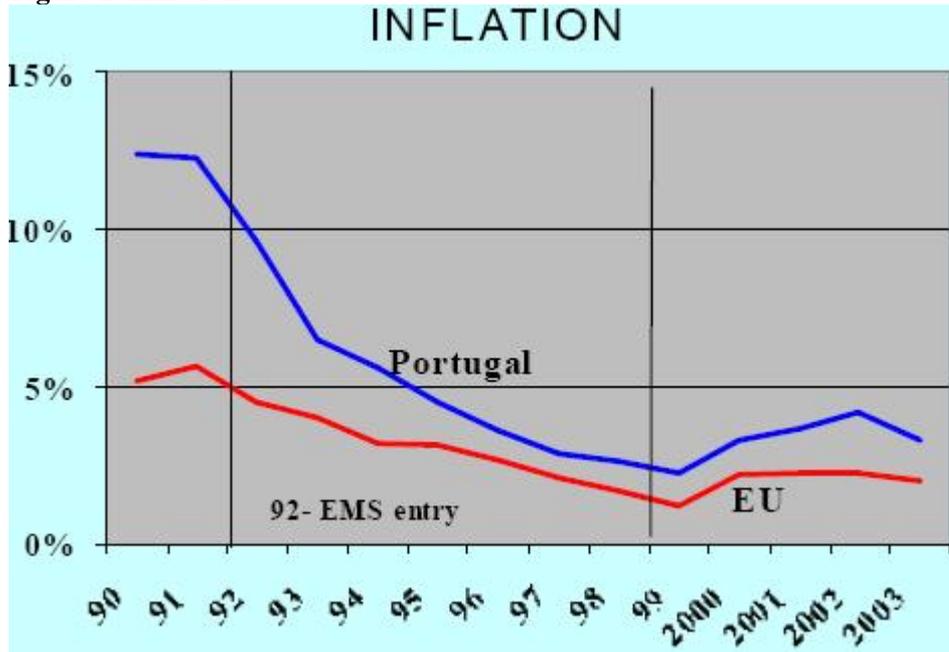

The Portuguese experience has some lessons of interests both for the case of ERM participation and of euro adoption. According to Vitor Constancio, President of the Portuguese Central Bank (Banco de Portugal) „ERM is both a test of the capacity of countries to participate in a monetary union and a useful mechanism to steer economies to comply with the Maastricht criteria“<sup>1</sup>. V. Constancio can understand the reluctance of some new member States in accepting the need to go through ERM participation before joining the euro. Small countries with fixed exchange rate regimes can understandably envisage staying in the ERM for a short a period of time as possible. For countries with flexible exchange rate regimes, including those shadowing ERM, participation in the ERM can be useful as the  $\pm 15\%$  band allows exchange rate flexibility to help stabilization and absorb inflationary pressures. At the same time, ERM acts as a disciplinary framework as adequate domestic policies are essential to ensure compliance with the commitment to exchange rate stability. But the ERM is also a flexible framework as realignments are possible and should be used if necessary. This

<sup>1</sup> Constancio, V.: European monetary integration and the Portuguese case. (presented at the Third ECB Central Banking Conference, Frankfurt, 21 and 22 October 2004). In: Detken, C., Gaspar, V., Noblet, G. (editors): „The new EU Member States: convergence and stability“, ECB 2005, p.2.

means that the initial central rate should not be seen as the future conversion rate. Also, with the wide bands, the ERM - although giving priority to exchange rate stability - still allows room for an independent monetary policy to target inflation, in what is a workable hybrid system.

The Portuguese experience illustrates many of the points just mentioned about the Exchange Rate Mechanism. Portugal initiated an exchange-ratebased stabilization program in 1990 and entered the ERM in April of 1992. Inflation reduction was consistently achieved throughout the decade.

**Figure 2 Inflation**

*Source: Banco de Portugal*

Entry into the ERM was helpful notwithstanding the initial turmoil in the system. Portugal was victims of contagion and the escudo was under attack after September 1992, when Portugal did not follow a realignment of central rates by other countries. This led to a significant speculative episode that was nevertheless successfully resisted. The policy response consisted in a determined and simultaneous use of interventions in forex markets and interest rate moves. Active episodes of intervention (interventions or interest rate moves above 2.5 standard deviations of the period) were 4.4 % of total days of the period and were successful 91% of the time. Successful in the sense that after an intervention the exchange rate appreciated (Frankel criterion 3) or depreciated less than before (Humpage criterion 4). During

the period of turmoil in the system Portugal changed the escudo's central parity three times (Nov 1992, -6%, March 1993, -6.5%, May 1995, -3.5%) without ever having reached the band limits. These realignments helped to offset the initial high appreciation of the currency. Also, they did not harm the disinflation process, which continued to be based on a tight monetary policy and a nominal exchange rate that did not completely offset inflation differentials. As it is stressed in an IMF working paper 5 on exchange-rate-based stabilizations in Greece, Ireland, Italy and Portugal, there was no relation in all these countries between fiscal policy and disinflation. Credibility of the disinflation process was more related with a general sustainability assessment than with the speed of deficit reduction. All these points prove the flexibility of the ERM and the advantage in not seeing the initial central rate as the future conversion rate.

Portugal stayed in the ERM for six years with exchange rate stability after 1993, as domestic policies gradually gave credibility to the objective of participating in the Monetary Union. The disinflation proceeded smoothly, without excessive demand pressures or inflation surges. This development has been influenced by very high interest rates in the first few years and by the European recession of the early 90's that also led to a recession in Portugal in 1993. So, during this period, Portugal did not suffer the Exchange Rate Based Stabilization syndrome of high growth, high capital inflows, high real appreciation, and high Current Account deficits, common features in other experiences. That came later as euro adoption approached and during the first two years of monetary union membership.

In different experiences where inflationary pressures become intense, a contradiction may appear between the Maastricht criteria of exchange rate stability 6 and of inflation performance. This may explain why some countries would like to stay only a very short period in the ERM. That is more understandable for countries with hard pegs as pressures for higher inflation could not be offset by allowing the currency to appreciate within the band. For countries with flexible exchange rate regimes, the possibility of allowing exchange rate moves within the wide bands may be useful, provided they will not stay long without achieving, with credibility, a situation approaching compliance with the Maastricht criteria. That is why they should carefully consider the timing of joining the ERM. It would be preferable if they were to join when already well advanced on the path to compliance with the criteria. In practice, of course, the concrete situation of each country has to be properly assessed.

The first condition for successful preparation of the way for entry into the euro area is the correct use of participation in the ERM as a disciplinary

framework and as a flexible way to manage the pressures associated with the convergence process.

## ***2.2 Monetary Union participation***

In spite of being many times referred to Portugal as a success in terms of European integration, namely with regard to EMU, the political merits of the Portuguese experience are in general over-estimated. In fact, until 1992, the ambiguous Portuguese response to the need for institutional reform and European integration was mirrored by complete discretion regarding the future course of exchange rate policy and the timing of monetary reform. It was only with the Country's first presidency of the European Council in 1992 that Portugal's attitude towards European monetary integration changed and the escudo joined the ERM. According to Francisco Torres „joining a monetary union that is based on institutions that deliver price stability is probably the best way to implement a solid strategy of sustained economic development. The reason is that this option also precludes many of transition costs (the output losses of a disinflation strategy) of such a regime changed. Fixed exchange rates, unlike other policy targets, are easily observable by the private sector but also easily implemented by the authorities“<sup>2</sup>.

The discussion about Portugal's participation in EMU evolved significantly since the objective was put forward in the Delors plan. Initially, the idea of a monetary union in Europe was well received by the public in general as a long-term European goal, although there was some scepticism as to Portugal's capacity to participate. The Portuguese economy was presented to the public, by the government, opposition and social partners, as a peripheral country that was still catching up making a long transition period for monetary and financial liberalisation necessary while concentrating on how to cope with the more immediate challenge of the International Market Portuguese public opinion and polity became used to what was until then the norm, namely that Portugal would be granted yet another transitional period.

Negotiators (the monetary authorities and the administration in general, supported by reactive political parties, resist to any substantial changes, to any increased sharing of national sovereignty, until the important decisions are taken at the top political level. Negotiators and reactive politicians adapt then quickly to the new rules. That was the case of EMS membership and of all the intergovernmental conferences.

---

□ Torres, F.: Lessons from Portugal's Long Transition to Economic and Monetary Union. In: Portugal. A European Story. Principia 2000, p.101

The tendencies for higher inflation and possible overheating will continue to exist in a Monetary Union and can even become stronger and unavoidable. There is a sort of EMU shock as countries undergo a true change of economic regime. The main features of this change of regime with the adoption of the euro are, in Vitor Constantio's opinion, the following:<sup>3</sup>

- a) Increased substitutability of financial assets
- b) Consolidated reduction in the cost of capital
- c) Increase in wealth and reduced liquidity constraints.
- d) Different meaning of the current account and primacy of credit risk<sup>3</sup>.

All these aspects are a direct result of monetary and financial integration that equalizes monetary rates, reduces risk premium as national currencies disappear and promotes integration of capital markets. This facilitates debt financing and equity issuance with an overall reduction in the cost of capital. Member countries no longer suffer from what Eichengreen and Hausman 7 called «original sin», i.e. the difficulty of long term domestic financing at fixed rates or of issuing external debt in their own currency. As a result, the current account deficit is financed in their own currency and ceases to be a macro-monetary problem to become just the result of the budget constraints of all resident economic agents.

For countries coming from an economic regime of higher inflation all these features create the conditions for demand/credit booms and possible overheating that may emerge through the following two channels:

- a) The drop in interest rates increases wealth, reduces liquidity constraints and favours consumption intertemporal smoothing, which decreases savings in the present period.
- b) The reduction of the cost of capital and the prospects of higher growth as a result of goods markets integration (the so-called Rose effect 9), lead to investment growth.

The two types of mechanisms just mentioned are two of the more important channels of transmission of the positive effects of euro membership. Nevertheless, they create risk, thus confirming that there can always be too much of a good thing.

The most important instruments to deal with these problems are the anti-cyclical use of fiscal policy; sensible wage policy; and good prudential supervision of the financial sector.

The Portuguese case is a good one to illustrate some of the developments just mentioned. In fact, the drop in interest rates was

---

<sup>3</sup> See Constantio, p.8

significant after 1995 and by then membership of Monetary Union seemed more assured.

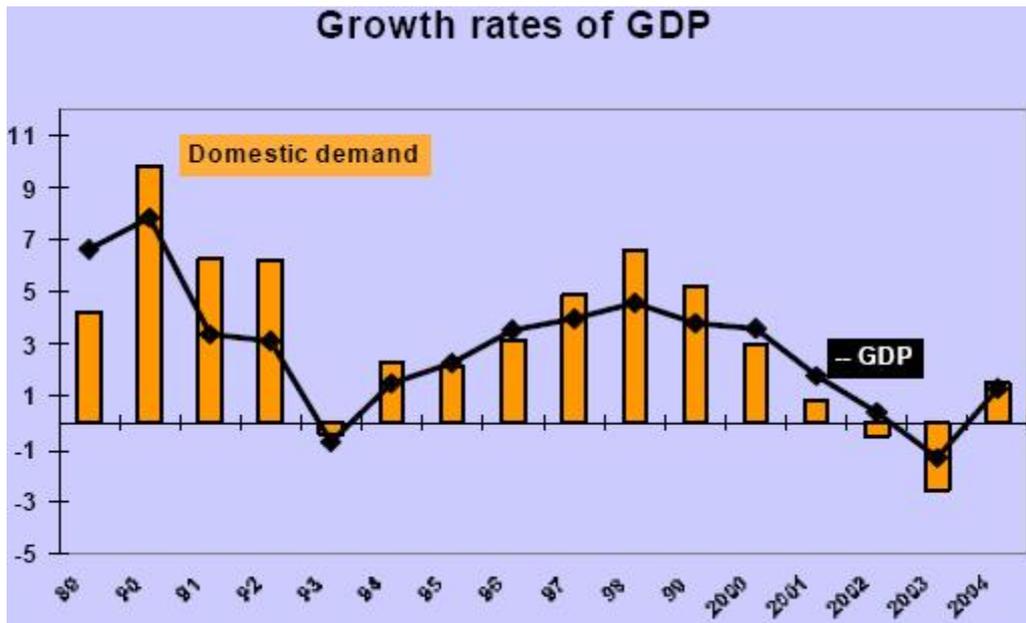

There was, of course, an explosion of debt in both households and companies, which was possible because total interest rate charges increased only marginally for households and actually decreased for firms throughout the decade. Total financial charges (interest and principal) for families stand now at 14% of disposable income, as indebtedness was overwhelmingly related to housing in the form of long-term credits with low annual amortization.

However, the current account of a member of a monetary union has a totally different meaning from the case of a country that has its Portuguese currency. In a monetary union, the financing of a member country current account is carried out in the common currency with reduced liquidity constraints. The balance of payments is no longer an autonomous macro monetary restriction, it is the result of the borrowing requirements of domestic agents conditioned by their own budget constraints. Rational agents' behaviour will reflect these constraints and microeconomic credit risk analysis as it is performed by the financial sector is now the important mechanism of control. The consequence of all these factors is a gradual decline in the Horioka/Feldstein effect within the euro area. In fact, investment can become less correlated with domestic savings as a result of in-depth monetary and financial integration. After 2000, the external deficit started to decrease and it is important to underline that this evolution resulted from the spontaneous change of behaviour of indebted private agents, proving that the two mentioned self-correcting mechanisms were playing their role.

The private sector as a whole had in 1995 a positive financial balance of 5.7% of GDP but this changed to a deficit of 5.8% in 2000, whereas the public sector reduced its excess of investment over saving. Since 2000 private agents have started to reduce investment and increase savings, reaching a balanced position last year. What happened was clearly a market-driven adjustment by the private sector. The initial surge of expenditure was as unavoidable as the correction was spontaneous and equally rational.

More recently, however, Portugal has suffered a marked slowdown in growth and in 2001 Portugal breached the 3% budget deficit limit imposed by the Treaty (Figure 4). The slowdown, which attained recession level with -1.3% growth last year, was very much influenced by the international economic slowdown, but stemmed also from the adjustment of economic agents after a period of high growth fuelled by a credit boom. This type of see-saw development is the result of a practically unavoidable adjustment to a new intertemporal equilibrium associated with monetary unification.

**Figure 3 Growth rates of GDP**

Source: Banco de Portugal

Nevertheless, the recent economic evolution also stemmed from some mistakes of their own. It can be said that the macroeconomics of a successful monetary integration is about economic agents adopting new rules regarding fiscal policy and wage behaviour. Fiscal policy needs to play a countercyclical role to act as a shock absorber. Wage behaviour should take as a reference wage cost developments in the euro area as a whole and should deviate from these only if there is a productivity growth differential. A different performance can lead to dangerous losses of competitiveness and can feed a divergent inflation process. In a Monetary Union, however, no country may for a long period have an inflation rate very much different from the average. Only inflation differentials that are justified by equilibrium movements of the real exchange rate are sustainable. In view of the recessionary nature of the adjustment, when price and cost inflation diverges, a sensible wage behaviour is essential to minimize future unemployment.

These new realities of life in a monetary union are only with difficulty taken on board by economic agents used to other regulation mechanisms for decades. As a consequence, Portuguese fiscal policy has been mostly procyclical and the relative unit labour costs have increased more than the euro area average. Portugal has aggravated, therefore, the risks of boom and bust behaviour. This is a considerable risk which, at an initial stage, confronts all

countries coming from a relatively high inflation regime to join a low inflation monetary union.

Regarding the more recent developments of the Portuguese economy, it should be stressed that the drop in domestic demand associated with the self-correcting adjustment of the private sector contributed to the recession Portugal has last year. Another important factor was the big decrease of external demand directed to the Portuguese economy. This fell from an average of 9% (1995-2000) to 1.4% in 2001 and 0.8% in 2002. Fiscal policy didn't help either as after breaching the 3% limit in 2001 we had subsequently to adopt a pro-cyclical stance.

### **3. The role of fiscal policy**

Portugal misused fiscal policy twice in the decade. The first time at the moment of entering the ERM, which may have contributed to some contagion effects at the time of ERM turmoil in 1992. The second time after 1996, when the savings from the decrease in public debt interest charges were used to increase current expenditures. In fact, twice in the decade Portugal had significant increases in current primary expenditures, basically the wage bill.

The reduction in interest payments generated an unjustified optimism about what the State could spend. The consequence was a pro-cyclical fiscal policy, which, when the economic deceleration came in 2001, led suddenly to a deficit above 4%. To correct this excess, policy had to continue to be pro-cyclical, this time in the restrictive direction. The lesson to draw from this is that a country within the euro area must always keep a margin of safety in fiscal policy to be able to face an economic slowdown without the risk of breaching the 3% limit. Another point worth mentioning refers to the limits of fiscal policy in the context of the initial stages of monetary union participation. As Portuguese case illustrates, the budget stance did not create a demand boom and it would be asking too much of fiscal policy to think that it could have been able to significantly offset the explosion of private expenditure. Fiscal policy should undoubtedly, have been countercyclical in terms that would have allowed us to avoid breaching the Stability Pact. Nevertheless, it is also important to note that a reasonable policy could not have smoothed the cycle very significantly. The reason is that the budget multipliers of very open economies like ours are in general fairly small.

Simulations using the Banco de Portugal model show that to bring the 2001 budget deficit 2 percentage points lower, through a policy of slowing down primary expenditures since 1998, the cost in terms of GDP growth would have been 3.5% in accumulated terms, i.e. around 20% of the growth

achieved in that period. In such a scenario, the current account deficit would have been reduced only from 8 to 6% of GDP.

It should be underlined that fiscal policy, in spite of its limitations, is essential to counter the more negative effects of a demand/credit boom and partially smooth the cycle. In particular, the Portuguese experience shows the importance of some other points. Countries should maintain at all times an anti-cyclical fiscal policy. A prudent approach requires that real budget consolidation with a deficit well below 3% should be achieved before adopting the euro. On the other hand, the structural deficit should never exceed the level compatible with the full play of the automatic stabilizers without breaching the 3% limit. Finally, countries should introduce structural reforms early on to contain future budget pressures, and should adopt efficient institutional procedures for the preparation and implementation of the budget. These should include, for instance, multi-year expenditure commitments approved by Parliament. Also, in view of the need to invest in infrastructure and the limitations of the Stability Pact, which does not allow the use of debt over the cycle to finance those expenditures, adequate rules for Public Private Partnerships and project finance should be introduced to ensure real transfer of risk, transparent accounting of multi-year commitments and limits to future expenditures.

#### **4. Conclusion**

Portugal is generally considered to be a European integration success story. Over the last 19 years democracy has become consolidated, the sense that Portugal was marginal in Europe is being overcome. The benchmark argument for Portugal to join a monetary union was based on institutions delivering price stability – a means to implement a solid strategy of sustained economic development.

There are several causes for the initial effect of acceleration of growth or even for real overheating. The first one stems from the decrease, and possible temporary misalignment, of interest rates and the credit boom that follows from that. The second reason is associated with large capital inflows that add to demand pressures and may be caused either by Foreign Direct Investment or short-term capital movements related with interest rates convergence plays. Finally, the third group of causes is related with more direct pressures on prices coming from several possible factors.

All the preceding points justify some general conclusions about the appropriate policy responses for countries acceding to the European Union and the euro. The list is very simple and contains very well known points:

1. Adequate use of the ERM should be ensured with flexibility but also with a sense of the primacy of the exchange rate commitment. This implies that monetary policy cannot be conducted according to a regime of pure inflation targeting and this fact must be clear to the markets. Also, the initial central rate should not be seen as being necessarily the future conversion rate into the euro.
2. A permanent anti cyclical fiscal policy has to be applied to be able to absorb shocks coming from fluctuations of external demand or capital inflows. In this perspective, a very solid and cautious budget position should be built before joining the euro.
3. A realistic wage behaviour has to be ensured to avoid excessive real appreciation in terms of relative unit labour costs.
4. An efficient prudential supervision of the financial sector must be guaranteed, taking financial stability risks seriously.

Besides the aspects related with macroeconomic stability, openness of the economy and non-distorted markets, the modern approach underlines the importance of institutions and good governance. Countries should make sure that they are continuously making progress in this respect. In Portuguese case we have made great strides in the past couple of decades. However, having attained a good intermediate position we now face the difficult task of making further progress. In the present world conditions, no country can rest on past achievements. A permanent and determined policy of structural reforms is essential to increase or even just to maintain the rate of potential growth. Combined with the need to achieve a real fiscal consolidation, the effort to increase our growth potential constitutes the main challenge that Portugal now faces. A challenge that we are certainly better positioned to overcome within the demanding framework of the European Monetary Union.

# THE STRATEGIC CONTRIBUTIONS OF TURKEY'S FULL MEMBERSHIP TO EUROPEAN UNION ALONG WITH THEIR FINANCIAL DIMENSIONS

**Ali Akdemir**

**Sefer Şener**

Canakkale Onsekiz Mart University

Biga Faculty of Economics and Administrative Sciences

17200 Biga

ÇANAKKALE / TURKEY

e-mail: aliakdemir@comu.edu.tr, sefersener@comu.edu.tr

## **Abstract**

*In this paper, the contributions of Turkey's full membership to the EU is emphasized in contrast to the usual approach. In EU countries as well as in Turkey, the issue is limited to the subjects of the criteria that Turkey fulfills and the burdens of membership on the union. However originating from EU's structure as well as from Turkey's geographic, economic, demographic characteristics, Turkey has strategic contribution dynamics toward EU. The structural characteristics of EU that distinguish strategic contribution that Turkey will provide can be listed as the low population increase of the EU countries, low growth rate, the limited possibilities of reaching to the world through seaways, high labor cost, the geographic distance to the Middle Asia, Middle East and Balkans. The contribution parameters of Turkey's full memberships to the European Union that originates from the outstanding and superior position of Turkey, the parameters which can be specified as having three distinct seaway routes, high growing rate, widespread entrepreneurship culture, young population, nearness to the Middle East, high labor motivation, the large size of population, the existence appropriate potentials for foreign investment. This paper also focuses on the financial dimension (export, import, foreign direct investment) of Turkey's full membership to EU.*

**Keywords:** *EU, Turkey, full membership, financial dimensions*

# **1 The Strategic Contributions of Turkey's Full Membership That Originate From the Structural Characteristics of the EU.**

## ***1.1 Economic Stagnation and the Low Growth Rate***

Starting from the 1990's, the EU countries have grown at the rate of 1 % at most within the last 15 years. On the other hand, Japan and China have had growth rates exceeding 5%. The economic potential of USA is obviously clear. From the viewpoint of the EU who has assertions to become a super power, this aspect of evaluation is quite thought provoking. Though, probably resulting from the fact that these countries have reached to a high level of economic accumulation which has created a point of no-growth situation that requires new partners to realize a positive growth rate.

## ***1.2 High Labor Cost and Low Labor Motivation***

The labor motivation is low due to the fact that a level of prosperity has been reached. The high costs and low productivity are the expected consequences of powerful labor unions and the well established social security organizations. Specifically, the labor cost in the EU is 20% higher than the ones in the US and in Japan, and the productivity is 10% lower. The unemployment rate is approximately 10 %<sup>1</sup>.

## ***1.3 The Loss of Super Power Status Against USA and Japan***

The EU, described originally by some as the super power project, is losing ground when compared to Japan, China, and USA in terms of economic growth, economic size and consequently political superiority.

## ***1.4 The Competition of the Far East Countries, the Low Level of Entrepreneurship Motivation***

The competition capacity of the EU countries against the products coming from the Far East is quite low due to high labor costs and the low labor motivation. The share of the Far East countries in world exports is increasing while the share of the EU countries decreases.

---

<sup>1</sup> TUSIAD, Going Through A Performance Worldwide, UNICE, Competitive Force Report TUSIAD, t/95, 4 , 178, İstanbul, 1995, p.12

### ***1.5 The High Level of Investment Costs and Tax Rates***

The public expenditures are quite large resulting from social security expenses and social government budget. Thus, naturally these are the causes for rising tax rates<sup>2</sup>.

### ***1.6 Export Restrictions to Formerly Soviet Countries***

The exports realized to former Soviet countries are not increasing as much as the imports from these countries. In this context, for the EU countries to establish a higher export possibility, they have to set up better situated connection points in this geographical area<sup>3</sup>.

## **2 The Strategic Contributions of Turkey's Full Membership That Originate From Turkey's Geographical, Economic, Demographic, Cultural Advantages**

Contrary to the unfavorable aspects of the EU which were summarized above, the advantages that Turkey has that would compensate the adverse circumstances and provide strategic contribution to the EU.

### ***2.1 Turkey Has A High Growth Potential***

Beyond the economic crisis Turkey had faced, it has potential growth rates of 5-10% which were realized during the past years. Within the past year 2004, Turkish Economy has shown a growth rate of more than 9%. With Turkey's full membership to the EU, the incoming EU investments will definitely exhibit further acceleration. The greater growth rate of Turkey will create a mediation to the growth rate of EU.

The present level of Turkey's GNP which is calculated as 200 billion US Dollars is rather a low level for the Capacity of Turkey. However the present level of the actual state of economic size bears a great potential of higher growth in the coming years. On the other hand the developed economies of the EU countries have a much lower level of growth potential.

---

<sup>2</sup> TUSIAD, p.36

<sup>3</sup> "EU Foreign Trade and Formerly Soviet Countries", Spot Magazine, Y.1., S.21, 1995, p.19

## ***2.2 The Low Level of Labor Costs***

When compared to the EU, the labor costs are low and the labor potential seem to be high. For the investments that originate from the EU countries, the low labor cost will provide a high competitive advantage to the EU based companies. Being in the status of a developing country, Turkey has a high labor productivity and motivation rate.

## ***2.3 Development Potential of Tourism***

The tourism income which is presently at 12 billion US Dollars level, can also be expanded. It is obviously clear that with full membership, Turkey's tourism activities will develop to a great extent.

## ***2.4 To Provide Support To EU's Mediterranean Policy***

Though some of the EU countries have Mediterranean link, in commercial area the Mediterranean sea has a very high strategic importance for the EU. As an advantageous Mediterranean country, Turkey will play a prime role building a bridge between the EU and the other Mediterranean countries in commercial and political fields. To create Mediterranean policies at the macro levels, Turkey's full membership will bring certain advantages<sup>4</sup>.

## ***2.5 The Reduction of Destructive Competition of Far East Through Turkish Connection***

Turkey who has similar structural characteristics with Far East countries, has better possibility to compete with these countries compared with the EU countries. Furthermore, the EU companies who invest in Turkey will be in a position to produce in a more competitive structure.

## ***2.6 Geographical and Cultural Proximity To Balkans***

Almost in all the Balkan countries there is a sizable Turkish and Muslim population. These people feel themselves very close to Turkey. The Turkish and Muslim Demographic status in Bulgaria, Albania, Greece, Bosnia-Herzegovina, Macedonia, Romania and Kosovo is important for Turkey as well as for the EU.

---

<sup>4</sup> Saim Kohen. "We Are In Mediterranean", Milliyet, 28 October, p.14

***2.7 The Black Sea Factor and BSEC (Organization of the Black Sea Economic Cooperation); Turkey, Bulgaria, Romania, Moldova, Georgia, Ukraine, Russian Federation Constitute the Black Sea Countries***

Turkey who has the longest shore to the Black Sea also has two strategic straits (the Canakkale and the Bosphorus Straits) which tie the Black Sea to the Mediterranean Sea. When the term the Black Sea basin is mentioned, it does not refer to these 6 countries only. The Black Sea is also the area that opens the Caucasus to the world. Almost all of the North Balkans area takes place in this basin. By means of the Danube River, many Middle and Eastern European Countries reach to the Black Sea and then from here to the Mediterranean. The region is the cross point of Asia-Europe which is also at the critical passage from South to North.

The Organization of the Black Sea Economic Cooperation which was established with the initiatives of Turkey does not include only the countries who have shores to the Black Sea, but also include Albania, Azerbaijan, Armenia and Greece who do not have shores to this sea. Some consider it as an alternative to the EU, however BSEC is an organization which supports the EU initiative.

***2.8 Proximity to the Middle East; Turkey's Neaeness to the Middle East Is Not Only Geographical But Cultural at the Same Time***

When energy factor and intensive destabilization is taken into account, the presence of the EU in the Middle East can not be avoided. Thus with the full membership of Turkey, the EU will be closer to the Middle East in terms of economic, commercial and political aspects.

***2.9 Proximity to Asia; the Middle Asian Republics, Kazakhstan, Uzbekistan, Turkmenistan, Tajikistan, and Kirghizistan are considered and named as Turki Republics. In terms of Cultural Composition, They have major Similarities with Turkey.***

These countries have first of all very important natural gas and oil energy resources and agricultural product potentials that attract attention. For the EU countries to have dependable and stable dialog with the Middle Asian countries, it is clearly obvious that Turkey can play an intermediate role.

***2.10 Proximity to Caucasia; In the Caucasus, Georgia, Azerbaijan, Armenia, Turkey, Russia, and Iran are located.***

Oil has a special position for the region to gain importance. Specifically the Azerbaijan oil resources bring forth the region as very important.

### 3. EU Turkey Financial Relations

Turkey-EU Financial relations can be analyzed in three periods namely “Pre-Customs Union Period”, “Customs Union Period” and “Candidacy period”:

#### 3.1. *Pre-Customs Union Period (1963-1995)*

Prior to the completion of the Customs Union, financial relations between Turkey and the EU have been conducted within the framework of Financial Protocols. During this period financial assistances, which are mainly credits, are composed of grants and credits. Community resources and European Bank of Investment are the main sources of credits.

Statistics of the commitment and use of the financial assistance in this period are as follows

<b>Credits</b>	
Commitment: 927 Million Euro	Use: 927 Million Euro
<i>Grants</i>	
Commitment: 78 Million Euro	Use: 78 Million Euro
<i>Total (*)</i>	
Commitment: 1005 Million	Use: 1005 Million Euro

Source : [www.dtm.gov.tr](http://www.dtm.gov.tr)

\*In this period, the fourth Financial Protocol worth 600 million Euros could not be materialized due to the veto of one member state. .

#### 3.2. *Customs Union Period (1996-1999)*

With the Association Council Decision No.1/95, credits and grants are envisaged for Turkey after the Customs Union, within the framework of sources of EU’s Budget and Mediterranean Programs. Although, the said assistance, which was made trough a unilateral Declaration of the Community, are designed to eliminate the negative effects of the Customs Union on Turkish Economy, they were far from satisfying their target both in terms of quality and quantity.

Statistics of the commitment and use of the financial assistance in this period are as follows:

<b>Credits(*)</b>	
Commitment: 2.062 Million Euro	Use: 557 Million Euro
<b>Grants(**)</b>	
Commitment: 754 Million Euro	Use: 393 Million Euro
<b>Total</b>	
Commitment: 2.816 Million Euro	Use: 950 Million Euro

Source : [www.dtm.gov.tr](http://www.dtm.gov.tr)

(\*) The European Investment Bank credit worth of 750 million Euros envisaged by the additional protocol of Customs Union Decision could not be materialized due to the veto of one member state.

(\*\*)The grant worth 375 million Euros envisaged to support competitiveness of Turkey in the context of the Customs Union Decision was vetoed by one member state.

### **3.3. Candidacy Period (1999-2006)**

With the Helsinki Summit held on 10-11 December 1999 at which Turkey was recognized as a candidate state, Turkey-EU relations entered a new phase. With the candidacy, some noteworthy changes were seen in terms of both quality and the quantity of the financial assistances.

In this context, the regulation, known as “Single Framework” which is prepared to combine the EU’s grants assistances under a single framework, was adopted at the Fisheries Council on 17 December 2001. Single Framework aimed to guarantee the use of assistance exclusively for Accession Partnership priorities. To this end, new structures have been established in Turkey, as done in other candidate states.

New structures, established with regard to usage of assistance provided from EU are as follows:

- The state Minister in Charge of EU Affairs has been designated as the “National Aid Coordinator” to ensure the allocation of the EU grants to the Accession Partnership and National Programme priorities.
- A “Financial Cooperation Committee” has been established to set the priorities, to prepare the annual financing plans and to oversee the allocation of the available resources in line with the priorities. The Committee is composed of the representatives of the Ministry of Foreign Affairs, Ministry of Finance, the State

Planning Organization, and the Undersecretariat for Treasury and General Secretariat for the EU.

- A “National Fund” to which the EU Funds will be transferred was established within the Undersecretariat of Treasury, and the State Minister in charge of the economy has been designated as the National Authorizing Officer who will manage the Fund.
- In addition a “Central Finance and Contracts Unit” was established for the overall budgeting, tendering, contracting, payments, accounting and financial reporting of all procurements through the EU Funds.

Presidency Conclusions of the Copenhagen Summit noted that financial assistances to Turkey will be increased and allocated under the "pre-accession expenditure" of the budget heading. Moreover, Accession Partnership, which is adopted on 19 May 2003 by European Council concluded that 250 million Euro in 2004, 300 million in 2005 and 500 million in 2006 will be allocated to Turkey.

Statistics of the commitment and use of the financial assistance in the candidacy period are as follows:

Title	Amount (m €)	Character	Period
MEDA-II***	889	Grants	2000-2006
EUROMED-II	1.470	EIB loan	2000-2006
European Strategy for Turkey***	150	Grants	2000-2002
Strengthening and Deepening of Customs Union	450	EIB loan	2000-2004
Pre-accession Facility *	8.500	EIB loan	2000-2003
Euro-Med Partnership Facility **	1.000	EIB loan	2001-2006

Source : [www.dtm.gov.tr](http://www.dtm.gov.tr)

\*Credits provided under the Pre-Accession Facility were allocated to Turkey and 12 candidate countries, some of which became EU members very recently.

\*\*Credits provided under the Euro-med partnership Facility were allocated to Turkey and other MEDA countries.

\*\*\*From 2002, financial assistances provided under these titles incorporated into Pre-Accession Strategy for Turkey budget heading of the EU Budget.

## 4. Capital Market Integration

Integration of capital markets in Europe has taken a significant leap forward with the Single Act and the endorsement by the Council of Ministers (in Madrid in May 1989) of economic and monetary union (the Delors Report). These call for removal of virtually all barriers to free trade in financial services and the acceptance of rights of establishment of one member country's financial institutions in any other<sup>5</sup>.

Capital market integration is a natural extension of the economic integration that was set by the Treaty of Rome. With this treaty economic and financial integration went hand in hand with political integration. Capital market liberalization and financial integration make factor and goods mobility available. Capital market restrictions distort product market behaviour. Interest rate ceilings artificially depress savings and raise investment; credit controls interfere with domestic sectoral allocations; capital controls impede efficient allocation of resources internationally; and limitations on the free transfer of ownership undermine productive efficiency<sup>6</sup>. Financial integration also has been promoting cross border banking since 1980.

**Table 1- Liberalization Of Banking Activities In EU Member States**

	Lifting of capital controls	Interest rate deregulation	First Banking Directive	Second Banking Directive
Belgium	1991	1990	1993	1994
Denmark	1982	1988	1980	1991
France	1990	1990	1980	1992
Germany	1967	1981	1978	1992
Greece	1994	1993	1981	1992
Ireland	1985	1993	1989	1992
Italy	1983	1990	1985	1992
Luxembourg	1990	1990	1981	1993
Netherlands	1980	1981	1978	1992
Portugal	1992	1992	1992	1992
Spain	1992	1992	1987	1994
UK	1979	1979	1979	1993

*Source : Financial Integration in Europe and Banking Sector Performance, Claudia M. Buch, Ralph P. Heinrich, Kiel Institute of World Economics, January 2002*

<sup>5</sup> European Financial Integration, Alberto Giovannini, Colin Mayer, Centre for Economic Policy Research, 2005, p.1

<sup>6</sup> European Financial Integration, Alberto Giovannini, Colin Mayer, Centre for Economic Policy Research, 2005, p.1

The first EU Member that lifted the control of capital is Germany in 1967. Interest rate deregulation first made by UK in 1979. Although individual countries had opted to liberalize capital flows earlier on, agreements to abolish capital controls on a European wide level were adopted only in the 1980s

**Table 2 – Openness of Banking System Towards Foreign Competition**

	EU	Euroland	Developed countries	High income	Upper middle income	Lower middle income	Lower income
Limits on foreign bank ownership of domestic banks	0.00	0.00	0.08	0.17	0.44	0.19	0.14
Limits on entry of foreign banks	0.00	0.00	0.04	0.07	0.11	0.24	0.14
Concentration ratio	59.19	56.17	60.92	63.75	66.48	72.35	72.91
Foreign bank ownership	16.29	19.97	24.81	33.57	31.72	33.75	33.59
Government-owned banks	9.98	12.97	10.27	10.28	12.32	28.32	35.36
No entry applications	0.00	0.00	0.04	0.09	0.14	0.13	0.00
Domestic	0.21	0.27	0.24	0.31	0.25	0.30	0.11
Foreign	0.08	0.10	0.08	0.16	0.30	0.43	0.22
Fraction of entry applications denied	3.67	3.23	3.21	7.69	11.99	32.22	49.32
Domestic	5.42	3.37	2.13	7.16	8.33	28.04	79.82
Foreign	1.67	2.22	3.21	6.91	16.85	30.83	37.85

All variables are averages by income level or region, respectively. Limits on foreign bank ownership of domestic banks = maximum fraction of banking system assets that can be held by banks that are 50 percent or more foreign-owned. Bank concentration ratio = fraction of deposits held by the five largest banks. Foreign bank ownership = fraction of banking system's assets that are held by banks which are 50 percent or more foreign-owned. Government-owned banks = fraction of banking system's assets held by banks that are 50 percent or more government-owned. No entry applications = dummy variable which assigns a one if applications for licenses have been received in the past 3 years. Fraction of entry applications denied = fraction of applications denied in the past 5 years.

Source: Barth et al. (2001)

Europe is one of the most open regions worldwide towards foreign competition in banking. Table 2 gives an overview of the prudential regulations affecting foreign financial institutions. In Europe there are virtually no restrictions to the market entry of foreign banks in place, indicating a slightly more liberal regime in comparison to high income countries on average and to less developed countries in particular. EU countries as well as developed countries in general also have a lower share of entry applications being denied in comparison to lower income countries.

As it comes to the point of financial liberalization in Turkey; in 1989, the debt-ridden state moved to systematically and completely deregulate Turkey's financial markets. Together with the ongoing processes of liberalizing commodity markets and integrating with global capital markets, financial liberalization was expected to achieve fiscal and monetary stability,

stimulate business confidence to invest in productive sectors, produce stable growth, encourage privatization and control inflation. However, the new hegemony of the capital markets has gone hand-in-hand with deteriorating macroeconomic performance, a worsening income distribution, the discrediting of politics and its isolation from society<sup>7</sup>.

The foundations of the capital markets in Turkey were laid down during the 1980s but, since then, the development of the capital markets in Turkey has not been entirely satisfactory for a variety of reasons. Macroeconomic and political inconsistencies, the shadow economy, high domestic debt stocks and interest rates obstructed the development of fully fledged capital markets with sufficient depth. The market also suffered from more specific securities problems, such as lack of a corporate and individual investor platform and lack of diversity in the capital market instruments.

On the other hand, the Turkish capital markets are poised to emerge. The high-standard legal framework of the capital markets in Turkey, along with the well-operating institutional structure of the Turkish Capital Markets Board, gives the Turkish capital markets potential for new developments that will lead to an increase in investment in securities. Recent developments, such as the introduction of private pension funds, also bolster the liquidity of the Turkish markets. Lastly, even the mere possibility of Turkey acceding the EU has triggered an influx of foreign capital.

The proposed accession of Turkey to the EU requires harmonization of domestic legislation with the EU legislation in many areas, including capital markets. This harmonization is not only vital for Turkey's accession to the EU, but is also necessary for Turkish capital markets to compete globally in terms of economic development.

While the regulatory authorities in the Turkish capital markets are working on integration to the EU legislation, the EU legislation is leading its way to a harmonized capital market within the EU member states. It is assumed that an integrated capital market throughout the EU will decrease the cost of capital and transaction costs, resulting in market growth and lower unemployment.

Representatives of the Capital Markets Board foresee that the amendments on primary and secondary capital markets legislation for purposes of integration with the EU legislation will be completed by the end of 2005.

The Law on Capital Markets 2499 is the main piece of legislation regulating capital markets in Turkey. In turn, the Capital Markets Board is the independent government authority regulating and monitoring the capital

---

<sup>7</sup> Politics, Society and financial liberalization: Turkey in the 1990's, Ümit Cizre Sakallıoğlu, Erinc Yeldan, Development and Change, Volume 31, Issue 2, p. 481, March 2000

market activities through issuance of regulations and communiqués, which are in line with the Capital Markets Law.

The Ministry of Council's decision dated June 24 2003 sets out the primary steps required to be taken in many areas, including the capital markets, to adopt EU legislation.

According to this decision, harmonization of the capital markets legislation, particularly in the area of financial services, will be among the regulatory authorities' main objectives. Also, the regulatory authorities' supervision powers will be strengthened, making them structurally independent.

Another crucial amendment to the Capital Markets Law will be the abolition of the restrictions imposed on EU-based foreign investors that prevent them from investing in Turkish industries. Allowing public offerings of foreign securities in the Turkish market and loosening the restrictions on foreign financial service providers will facilitate integration of EU legislation into the Turkish finance sector.

The amendments that are envisaged for the Capital Markets Law can be summarized under seven headings. The amendments will relate to: (i) publicly listed companies; (ii) brokerage houses and their activities in the capital markets; (iii) corporate investors; (iv) private pension funds; (v) stock exchanges and other capital markets institutions; (vi) taxation in the capital markets; and (vii) effects of penalties and measures.

#### ***4.1. Publicly listed companies***

As a result of the amendments to the Capital Markets Law, corporate governance principles will be widely applied by publicly listed companies. A Corporate Governance Principles Index will be used, whereby companies will be rated based on their compliance with corporate governance principles, and investors will be able to detect which companies are corporate governance friendly. Mergers and spin-offs in publicly held companies will be governed in compliance with EU legislation. Furthermore, the authority of the board of directors under the authorized share capital system to increase the capital of public companies will be limited to a maximum of five years. The scope of public disclosure in special cases will be extended and the voting rights of those that do not comply with the mandatory tender offer requirements will be suspended by court decision. Currently, persons who acquire 25% of the voting stock of public companies are compelled to launch a mandatory tender offer for the remaining shares. Lastly, the Capital Markets Board will be granted the authority to regulate the purchases of treasury shares, which is prohibited under the existing capital markets legislation.

#### ***4.2. Brokerage houses and their activities in the capital markets***

Individuals will be entitled to be involved in capital markets activities within a framework to be determined by the Capital Markets Board. The activities in the capital markets will be divided into two groups, classified as primary and secondary activities.

#### ***4.3. Corporate investors***

The antitrust drawbacks imposed on corporate investors will be abolished during the integration process.

#### ***4.4. Private pension funds***

The restrictions imposed on the incorporators of private pension funds will be abolished and the conditions for incorporation of pension funds will be simplified. The principles for valuation of capital in kind invested in real estate investment trusts will be re-determined. Portfolio custody principles will be set out and the restrictions regarding securities that are traded by investment funds will be abolished.

#### ***4.5. Stock exchanges and other capital markets institutions***

The Istanbul Stock Exchange and Istanbul Precious Metals Exchange will be reorganized to suit competition grounds that will be established throughout the integration process. The terms and conditions for quotations on the Istanbul stock Exchange will be reviewed and amended as per the terms and conditions of the EU member states. Lastly, the transition from physical shares to registered shares will become effective, which will lead to electronic record keeping of the shares of joint stock companies.

#### ***4.6. Tax in the capital markets***

The tax system will be simplified, with a special focus on the taxation of foreign corporate investors. Government bonds that used to have tax advantages over corporate bonds will become subject to the same taxation principles as corporate bonds.

#### ***4.7. Penalties and measures***

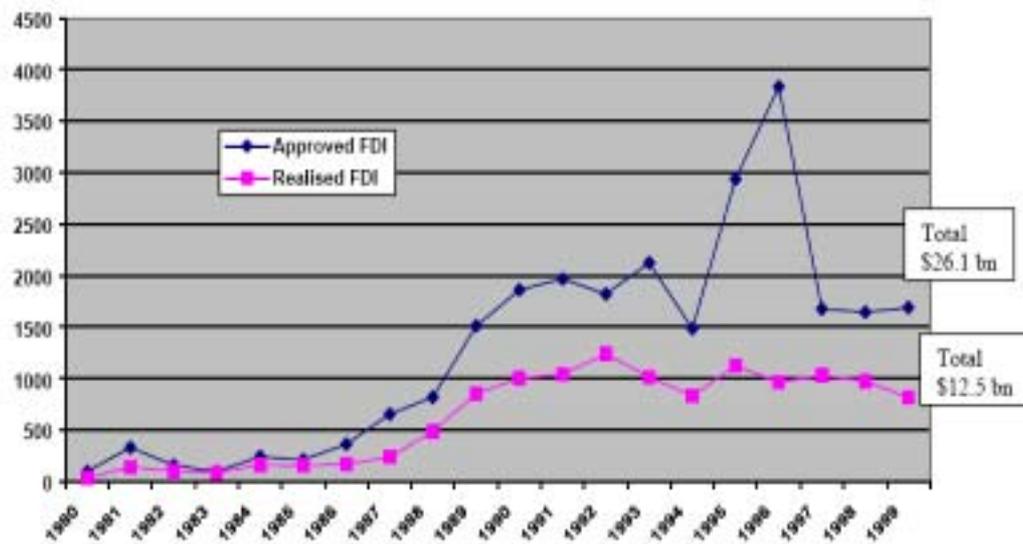

Measures for insider-trading activities will be harmonized with EU legislation. Public prosecutors will only be able to examine defendants and

witnesses in the presence of supervisors from the Capital Markets Board. Those who engage in capital markets activities without obtaining the required permits will become individually subject to bankruptcy proceedings. It has also been stated that monetary penalties will apply to financial crimes. The Capital Markets Board will be granted the authority to request from the courts the deposition of joint stock company directors who infringe the relevant laws and regulations and will be entitled to request that the courts appoint new directors. The Capital Markets Board will further be granted the authority to fine those that fail to fulfil the public disclosure requirements imposed by the Capital Markets Law. And new penalties will be incorporated with respect to joint stock companies that proceed with public offerings without fulfilling the Capital Markets Board's registration requirement.

## 5. Foreign Direct Investment Relationship Between Turkey and European Union

The stock of FDI (foreign direct investment) in Turkey was only \$300 million in 1971, and up until 1980 the average annual inflow of FDI was only \$90 million. But Turkey's FDI inflows significantly when trade regime turned into export oriented economic liberalisation in the mid 1980's (Figure 1)

**Figure 1- Foreign Direct Investment in Turkey 1980-2000, US\$ Million**

Source: [www.treasury.gov.tr](http://www.treasury.gov.tr)

If we look at the main sources of FDI using data we can see that mainly European countries dominate FDI in Turkey (Table 3). France and Germany are the major investors in Turkey in terms of approved investment. In terms of approved investment. In terms of the number of foreign equity companies, Germany is by far the most important source of FDI – accounting for almost 18% of all projects in Turkey.

**Table 3 – Main Sources of FDI in Turkey**

Country	Approved investment, US\$m	Number of foreign equity investment projects
France	5,364.78	243
Germany	3,487.14	897
US	3,028.38	316
Netherlands	2,972.69	316
Switzerland	2,001.55	198
UK	1,825.21	317
Italy	1,598.26	182
Japan	1,284.24	49
Other countries	4497,98	2,506
<b>Total</b>	<b>26,060.4</b>	<b>5,024</b>

Source : [www.treasury.gov.tr](http://www.treasury.gov.tr)

Table 4 shows the breakdown of FDI by sectors and sub sectors. Manufacturing and services dominate FDI in Turkey and there has not been much change in their share of total FDI over time. The table also shows the contribution of foreign capital in the total capital of the foreign equity ventures for each sector. This gives us an accurate indicator of the role of joint ventures in Turkey.

In the 5,024 foreign equity ventures, foreign capital accounted for 56% of the total. Another way of looking at this is that FDI leveraged an additional 44% of domestic investment, which shows the extent of joint ventures between foreign owned and Turkish firms and the spill-over contribution of FDI to Turkey's economy. In fact, up to half of all foreign equity ventures have been joint ventures.

However, government investment agencies across the world only record joint ventures that involve foreign capital, and therefore do not capture new forms of investment that have no cross-border capital flows.

Table 5 compares FDI in Turkey and its key competitor locations, using balance of payments FDI data as provided by UNCTAD. WE can see

that Turkey was the fourth major destination for FDI from 1987-1992, but only the eighth major location from 1993-1999. The key reason for this change in position was sustained growth of FDI in Israel and Central Eastern European Countries. Over this period, Poland attracted nearly six times more FDI than Turkey. When adjusted for GDP, Turkey is by far the worst performing country. Hungary, Czech Republic, Poland, Romania and Bulgaria were the best performing countries. As a proportion GDP, Hungary attracted almost 13 times more FDI than Turkey from 1993-1999.

**Table 4 – Breakdown Of Actual FDI by FDI by Sub-Sector (1980-March 2004)**

Sector	Number of projects with foreign equity	% of total FDI	% of FDI in total capital of projects
<b>Agriculture &amp; Mining</b>	<b>186</b>	<b>1.3%</b>	<b>49%</b>
<b>Manufacturing</b>	<b>1,251</b>	<b>44.4%</b>	<b>50%</b>
of which:			
Food & Beverage	146	5%	50%
Tobacco	10	2.8%	91%

**Figure 2 – Manufacturing FDI Projects (new and expansions) in Europe, January 1997- June 1999**

Source : Ernst & Young, Corporate Location, 2000

If Turkey is to increase its share of FDI projects, it is important to understand Turkey's competitive position relative to first tier locations in the Eastern Europe – Turkey region. At present Turkey is losing projects to Hungary and other countries. For example, Samsung's \$21 million, 500 job

plant in Hungary is actually going to supply the Turkish market. In many cases Turkey is simply not on the investment map. But still foreign direct investment plays a major role in the Turkish economy. Turkey is more dependent on foreign investors than most other countries for technological and innovation activities. However, when compared to its main competitors for inward investment, which we identified to be primarily in Eastern Europe, Turkey has been less successful in attracting FDI relative to the size of its economy and population. A key reason is the minimal level of privatisation – related investment in Turkey.

But if we look at the Table 6 and Table 7 we can understand that in the future Turkey will attract much more foreign direct investment than ever before.

**Table 6 – Engineering and Science Indicators**

Country	Science and engineering students, % of total tertiary students	Patent applications filed by non-residents	R&D expenditure, % of GNP
Russia	50	32,943	0.88

Turkey offers huge opportunities for inward investors, not least because of its large, dynamic economy, quality labour force, and position at the centre of a growing \$1.5 trillion regional economy. The IMF agreement and EU membership promise to remove many of the obstacles to inward investment in Turkey, in particular relating to minimal privatisation, chronic inflation, and obstacles to EU market Access.

## 6. Foreign Trade Relationship Between Turkey and European Union

Beginning from the year 1980, Turkey changed its economic development policy from “import substituting industrialization” to “export led growth” strategy. Economy opened up to world trade, export-promoting incentives were initiated (including tax exemptions, rebates and favorable credit terms), direct import controls have been eliminated, and quantity restrictions have been dismantled. State intervention in the economy was reduced to minimum level. As a result of these efforts, Turkey has increased her share from world markets, from 0,15% in 1980 to 0,6% in the year 2003. Between 1980 and 2004 exports of Turkey has increased from 2,9 billion dollars to 63 billion dollars. Structure of exported goods has also changed much from mainly agricultural products and raw materials to higher value added industrial products. Transformation still continues with increasing exports of transportation vehicles and office equipments.

Western Europe is the most important market for Turkish exports. In particular, European Union (EU) members is a country group that has a major share in it. The share of EU in total exports has always been above 50 percent. Exports to the EU (15) were 7.2 billion dollars in 1990 and mounted to 11 billion dollars increasing by 10.9 percent annually during the period from 1990 and 1995. In 2000, exports to EU (15) reached to 14.5 billion dollars, but its share in total exports fell down to 52.2 percent. Although at the end of 2004 exports to EU (15) has reached to 32.5 billion dollars, it’s share in total exports decreased to 51.6 percent. In the year 2004 EU has enlarged to include 10 new members; but to these ten members Turkey’s exports are not as high yet; these countries have around a total of %3 share in total exports of Turkey.

One of the main developments in the second half of 1990s was the increase in the import of consumption goods. Especially, in 3 years period after 1996, the policy implementation of international liabilities arising from the WTO membership and entering the final stage of customs union with European Union, led the import of consumption goods to grow by 38.8 percent in the period of 1995-2000. Related to the pace of economic recovery and rising income levels the imports of consumer goods increased by 57.8 percent in 2003 and 55 percent in 2004. It can be observed that imports of consumption goods fluctuate more than total imports. During the growth years, positive expectations of consumers determine their consumption demand. In the last 10-15 years, when expectations about the economic condition improve, consumption demand expands.

Between 1995-2002 investment goods imports increased at lower rate compared to total imports, while the trend changed in 2003. In 2003 the rate of increase went slightly above the increase in total imports, but in 2004 capital goods imports enlarged by 53,6 percent while that of total imports was 40,4 percent. The main determinant of this development was the result of the rise of private investments by %54,6 in 2004.

European Countries have an important share in Turkey's imports, largely due to their geographical proximity to Turkey and their level of economic development. Among the country groups of Europe, European Union Members are in the first rank. EU is followed by CIS because of the imports of crude oil and natural gas from that region.

In brief Turkey's foreign trade has developed much in terms of quantity and quality since 1980s. Export performance is spectacular especially in the last two years, thanks to both domestic developments and international developments. Turkey has been implementing new strategies to make this development sustainable and to diversify her exports and imports more on the regional and sectoral basis. Turkey aims to go beyond 500 billion of exports by the year of 2023 and and more than 45% of this is planning to be with EU.

## 7. Conclusion

Up to today, the main approach for Turkey's full membership has been from the viewpoint of the contributions that the EU will provide to Turkey and the criteria that Turkey should fulfill. Whereas the picture also has another face. When the underlying goals of the EU's establishment are analyzed, it is clearly observed that steering of the world politics, economic power domain, creation of a prosperity area and becoming a super power can be seen as the main objectives. However when we look at the present status, to accomplish these goals, Turkey stands as a potentially meaningful power and having economic, demographic advantages within the region who should be perceived as important. It is necessary to think what Turkey expresses for the EU. Turkey who is rehabilitating its democratic, cultural and economic institutions has more to contribute to EU than to receive from. It can be seen very clearly that the regional potential, labor potential, investment potential, tourism and entrepreneurship potential, the factors of the Mediterranean, the Black Sea, the Straits, the proximity to Balkans, to Middle Asia, the Caucasus and the geographic nearness to the Middle East could provide strategic contributions to the strategic goals of the EU.

## **Abstract**

*In this paper we propose an empirical model that considers theoretical facts on the relationship between real exchange rates and the net exports of the economy to supplement the interaction of a number of financial and economic factors with the stock market. We discuss the impact of exchange rate fluctuations on market risk in terms of Value at Risk (VaR). Our empirical findings show that common currency introduction produced increments in VaR whereas European stock returns are more sensitive to changes in competitiveness regarding the EMU rather than national exports. Finally, we show that the synchronisation of variation in competitiveness through the introduction of a single currency has made these changes more decisive in explaining financial market fluctuations.*

**Keywords:** *Euro, Competitiveness, Market Risk, Value-at-Risk, Volatility*

## **1. Introduction**

Over the past decade the world economy faced significant changes in financial markets and international competitiveness. More recently, the growth of trading activity in financial markets coupled with numerous instances of financial instability and a number of widely publicised losses in financial institutions have resulted in a re-analysis of the risks. The most widely advocated approach to have emerged to measure market risk is that of Value-at-Risk (VaR).

Parallel with this development, turbulence in the foreign exchange markets has also undergone significant changes compared with the pre-euro period. This effect was foreseen by various economists (Ghironi and Giavazzi, 1997; Martin, 1997; Benassy et al., 1997; Gros and Thygesen, 1992; Kenen, 1995; Aglietta and Thygesen, 1995; Cohen, 1997). But were these two developments really correlated? And, if so, how exactly could monetary reform be held responsible for higher stock market risk?

One can consider several potential links between exchange rates and stock market. For example, exchange rates may affect a firm's value by means of its impact on the liquidity of a firm's shares. There is a growing literature on the effect of liquidity on firm value. The pioneer work by Amihud and Mendleson (1986) present the first evidence to support the

hypothesis that asset liquidity is priced in equilibrium. Among more recent papers, Datar et al. (1998), Brennan et al. (1998) and Easley et al. (1999) all suggest that asset liquidity affects a firm's value through its impact on the firm's expected return. If the asset liquidity, influenced by exchange rates, determines the firm's value and expected returns, then it is pertinent to study the link between the exchange rate and the market risk, which is the scope of this study.

However, the phenomenon of higher risk is not easily explained in such a straightforward context, as there is no obvious modification in this mechanism ascribable to the introduction of a currency. We consider stock prices and real exchange rates to be intermediated by changes in corporations competitiveness reflected in variations in trade flows directions. In turn, the changes in competitiveness are reflected in company's stock prices and related market risk.

In a multicountry world, movements in one exchange rate can be offset by other factors, such as movements in other exchange rates or interest rates. There are many studies that examine the relationship between exchange rate volatility and international trade.

Asseery and Peel (1991) examine the influence of volatility on multilateral export volumes finding that volatility of exchange rates has significant positive effects on exports. At the same time, Bini-Smaghi (1991) finds strong support for the conventional assumption about volatility effects on trade. Cushman (1983), Kenen and Rodrick (1986), Giovannini (1988), Franke (1991), Pozo (1992), Sercu (1992), Sercu and Vanhulle (1992), Chowdhury (1993) and Kroner and Lastrapes (1993) among others, provide evidence that the level of exchange rate volatility impacts the volume of trade flows. On the contrary, Koray and Lastrapes (1989), Lastrapes and Koray (1990), Gagnon (1993) in their studies on the effect of exchange rate volatility on trade conclude that the relationship between the volatility and trade is weak.

Moreover, it is accepted that if the volume of trade flow is impacted by exchange rate volatility so will the value of firms. But the conclusions of relevant empirical studies are quite different. Amihud (1994) examines a sample of 32 top US exporters and concludes that their stock returns are not affected by changes in the value of the dollar. Bartov and Bodnar (1994) find that the abnormal returns of 208 firms are uncorrelated with changes in the value of the dollar. Griffin and Stulz (2001) noted that changes of weekly exchange rates had negligible impacts on industry stock indices in developed countries. In contrast, Bartov et al. (1996) finds that the return variability of US multinational corporations increases with an increase in exchange rate

volatility. Bodnar and Gentry (1993), studying industry portfolios in the US, Japan and Canada, find that only 30% of them are significantly affected by exchange rate changes. He et al. (1996) examine a large sample of Japanese firms and find that of the 422 exporting companies, 25% are significantly affected by exchange rates fluctuations. Nevertheless, the discussions and arguments indicate that there is a relationship, which seems stronger or weaker in the light of different samples and studies. In our opinion this interrelation between the exchange rate and corporation value is the one most likely to be the link between higher stock market risk and a common currency in the context of structural changes accounted after the euro.

We have constructed a monthly series of market risk as monthly averages of daily VaR (Jorion, 1997) estimated by means of GARCH model (Bollerslev, 1986). GARCH(1,1) was used since it is found to be adequate for many financial time series (Bollerslev, Chou and Kroner, 1992). McNeil and Frey (2000) use GARCH in yet another way to get value at risk. They use GARCH to estimate the volatility, and extreme value theory to get tail probabilities. Ahlstedt (1998) argues that the GARCH models represent a methodological and empirical improvement over other estimates. Therefore, the estimated impact of changes in Euro/USD exchange rates on net exports of EMU countries to the USA is the key regressor of our interest explaining the dynamics of the level of market risk in our empirical model.

Several potential factors of stock market risk are also included in the model in order to make it more specific. In particular, the remaining regressors in the model (referred to below as we further reference them) include proxies for business cycles, domestic market demand as well as bond yields, traded volume of stocks, and foreign reserves variables. Most of these factors are discussed in different contexts of interaction with financial market in financial and economic literature.

The impact of different interest rates on stock returns is studied by a number of researchers (e.g. Gallant and Tauchen, 1997; Peiro, 1996). A similar study by Rapach et al. (2004), among other factors, reveals that relative long-term government bond yields have negative impact on real return from holding stocks. Pavlova and Rigobon (2003) identify interconnections between stock, bond and foreign exchange markets and characterize their joint dynamics as a three-factor model.

Dumas et al. (2003) develop a “dynamic single-index” statistical model capturing the “world” business cycles as well as country-specific fluctuations. They consider current and past production as the information variable that investors use in their investment decision, as a way of predicting their decisions on which stage of the business cycle the economy is currently

running. In our model we use unemployment as a mirror of the business cycle stage. Rapach et al. (2004) also consider change in the unemployment rate as a macroeconomic factor of stock returns.

Cuñado et al. (2004) show that growth in traded volume, the next factor in our empirical model, has a significant impact on stock market volatility in Spain. They, however, conclude that it was not just the acceleration in trading volume that brought about the increased volatility but most likely the intensification of the process of economic development and opening the borders. Thus, to reflect the process of economies development a proxy for domestic market demand (changes in retail trade) is considered as another explaining variable in the model.

An ample part of the foreign exchange reserves is usually invested in international financial markets (mainly in the liquid bond markets) and consistently the changes in the volumes of reserves will somehow be reflected in the financial market volatility. Thus, covering this variable which potentially may impact on general stability of the currency market (Masson and Turtleboom, 1997; Leahy, 1996; Hening, 1997) is also important in our study.

Our empirical research discusses how the set of above mentioned factors explain the market risk dynamics in a sample of EMU countries. The empirical results make it possible to obtain additional findings on how the competitiveness of companies and stock markets interact within the sample of the countries under consideration.

The outline of the remaining sections will be as follows. In Section 2, the changes in market risk before and after the introduction of the euro are discussed. Section 3 presents our empirical model describing the dynamics of stock market risk in competitiveness-exchange rates framework. Section 4 reports the empirical results and section 5 is the conclusion.

## **2. Market Risk Dynamics in pre- and post-Euro Periods**

Financial risk is the prospect of financial loss (or gain) due to unforeseen changes in underlying factors. The changes that euro introduction in 1999 caused in stock markets is the target of particular study. To evaluate the market risk before and after the euro we used the Value at Risk indicator (see e.g. Jorion, P., 2000; Goorbergh and Vlaar, 1999). Value at Risk (VaR) is defined as the maximum potential change in value of a portfolio of financial instruments with a given probability over a certain time horizon, with the assumption that the composition of the theoretical portfolio remains

the same<sup>2</sup>. VaR measures have many applications, such risk management and for regulatory requirements. In particular, the Basel Committee on Banking Supervision (1996) requires financial institutions such as banks and investment firms to meet capital requirements based on VaR estimates. The description of different possible techniques of VaR estimation is beyond the scope of our study. We simply apply just one to monitor the changes in stock market risk in the context of euro introduction.

Estimating volatility is the essence of evaluating of market risk. Among the variance methods of VaR estimation the static models do not take volatility clustering into account. By far the most popular model which captures this phenomenon is the Generalised Autoregressive Conditional Heteroskedasticity (GARCH), introduced by Bollerslev (1986) as an extension of the Autoregressive Conditional Heteroskedasticity (ARCH) model by Engle (1982). The GARCH model defines an innovation  $\eta_{t+1}$ , i.e., some random variable with mean zero conditional on time  $t$  information,  $I_t$ . This time  $t$  information is a set including not only the innovation at time  $t$ ,  $\eta_t \in I_t$ , and all previous innovations, but also any other variable available at time  $t$  as well. In finance theory,  $\eta_{t+1}$  might be the innovation in a portfolio return. In order to capture serial correlation of volatility, or volatility clustering, the GARCH model assumes that the conditional variance of the innovations depends on the latest past squared innovations as is the assumption in the less general ARCH model, possibly augmented by the previous conditional variances. In its most general form, GARCH(p,q), can be written as:

$$\sigma_t^2 = \omega + \sum_{j=1}^p \beta_j \sigma_{t-j}^2 + \sum_{i=1}^q \alpha_i \eta_{t-i+1}^2 \quad (1)$$

$p$  lags are included in the conditional variance, and  $q$  lags are included in the squared innovations. In our study we regard these innovations as deviations from some constant mean portfolio return:

$$r_{t+1} = \mu + \eta_{t+1} \quad (2)$$

expressed  $\eta_{t+1}$  as  $\sigma_t \varepsilon_{t+1}$ , where  $\varepsilon_{t+1}$  is assumed to follow some probability distribution with zero mean and unit variance, such as the standard normal

---

<sup>2</sup> Analytically, the VaR is defined by the top limit of integral of the probability density

function (P) of expected returns (r)  $\alpha = \int_{-\infty}^{E(r)-VaR} P(r) dr$ .

distribution. The parameters are conditioned as  $\omega > 0$ ,  $\beta \geq 0$  and  $\alpha \geq 0$  to ensure positive variances. If the market was volatile in the current period, the next period's variance will be high, and is intensified or offset in accordance with the magnitude of the return deviation this period. Naturally, the impact of these effects hinges on the parameter values. Note that for  $\alpha + \beta < 1$ , the conditional variance exhibits mean reversion, i.e., after a shock it will eventually return to its unconditional mean  $\omega/(1 - \alpha - \beta)$ . In this way, if  $\alpha + \beta = 1$ , this is not the case, we would have persistence.

In order to estimate these parameters by means of likelihood maximisation, one has to make assumptions about the probability distribution of the portfolio return innovations  $\eta_{t+1}$ .

Considering Gaussian innovations

$$\varepsilon_t \stackrel{iid}{\sim} N(0,1), \quad \eta_{t+1} | I_t \sim N(0, \sigma_t^2) \quad (3)$$

leading to a conditional log likelihood of  $\eta_{t+1}$  equal to:

$$\ell_t(\eta_{t+1}) = -\log \sqrt{2\pi} - \frac{1}{2} \log \sigma_t^2 - \frac{\eta_{t+1}^2}{2\sigma_t^2} \quad (4)$$

The log-likelihood for all series is  $\sum_{t=1}^T \ell_t(\eta_{t+1})$ .

The GARCH (1.1) is used to predict the volatility dynamics during VaR estimation period for a sample of 10 EMU member states. The daily VaR estimates, for left tail probability of 1% according to Basel Accord (1996) are reflected in figure 1 in appendix 1 while the average VaR for the pre- and post- euro periods and the corresponding growth in absolute terms is reported in the table 1. The increase in average daily VaR is obvious in EMU major stock markets. Among the countries with significant growth in market risk are the two largest economies of the EMU – Germany and France, only Italy and Austria produced a slight reduction in VaR.

The volatility of exchange rates is of high importance because it affects decisions of market participants. The consequences of exchange rate volatility on trade have long been at the centre of the debate on the optimality of alternative exchange rate regimes.

In fact, the volatility of exchange rates has also grown. For the first four years of the post-euro period the variance of percentage changes in

monthly real exchange rates was 1.191 against 0.745 points of a similar pre-euro period<sup>3</sup>. By the 08/2004 the figure had already reached up to 1.235.

**Table 1: VaR before and after euro and the growth in absolute terms**

Country	Index	Exante	Expost	Growth (% points)
		(%) (1995/01-1998/12)	(%) (1999/01-2004/08)	
Germany	DAX30	-2.97	-3.97	1.00
Belgium	BEL20	-2.16	-2.76	0.60
France	CAC40	-2.94	-3.50	0.56
Ireland	ISEQ40	-2.09	-2.55	0.46
Spain	IBEX35	-2.96	-3.36	0.40
Finland	HEX25	-3.53	-3.88	0.35
Portugal	PSI20	-2.31	-2.45	0.14
Netherlands	AEX24	-2.66	-2.78	0.12
Italy	MIB30	-3.43	-3.19	-0.24
Austria	ATX20	-2.42	-2.18	-0.24

Note: For normal distribution assumption of returns VaR is computed as:  $VaR = -V(e^{\mu + \sigma\phi^{-1}(\alpha)} - 1)$ , where  $V$  represents the initial value of some theoretical portfolio and  $\phi(\cdot)$  is the cumulative distribution function of the standard normal probability distribution.  $\mu$  and  $\sigma$  with GARCH(1.1) are the estimates of the parameters of normal probability distribution function.  
Source: Our own estimates based on Reuters data.

Further, we construct and apply an empirical model to explain how the introduction of euro could impact stock market risk.

### 3. Empirical Model

The starting point is the relationship between financial market risk ( $\phi$ ), estimated on stock price volatility, and a sample of explaining variables – changes in exchange rates ( $\varepsilon$ ), changes in domestic market demand ( $\lambda$ ), traded volume of stocks ( $\nu$ ), bond yields ( $\tau$ ), foreign official reserves ( $\varpi$ ) and the business cycles ( $\rho$ ).

$$\phi = \phi(\Delta\varepsilon, \Delta\lambda, \nu, \tau, \varpi, \rho) \quad (5)$$

We assume that the main link between the stock market risk and exchange rates, which maybe affected by the common currency introduction,

<sup>3</sup> Our own calculations based on monthly series of real exchange rates by ERS, United States Department of Agriculture.

is the change in general competitiveness of the economy, reflected in terms of changes in net exports.

The relationship between real exchange rates and net exports is widely discussed in the financial literature. A number of comparatively older studies (e.g. Ethier, 1973; Cushman, 1986; Peree and Steinherr, 1989) have shown that an increase in exchange rate volatility will have adverse effects on the volume of international trade. More recent studies have demonstrated that increased volatility can have ambiguous or positive effects on trade volume (Viaene and de Vries, 1992; Franke, 1991; Sercu and Vanhulle, 1992). Barkoulas et al. (2002) concludes that under risk aversion, the benefits of international trade are reduced, resulting in a decrease in the volume of international trade. The trade surplus or deficit is reduced as well. However, they note that analysis which considers only the (often indeterminate) effects of exchange rate uncertainty on the volume of trade will not be capable of generating predictions of optimal behaviour.

Our interest in this relationship is limited to the most general ideas on the relationship of net exports with the exchange rates and its volatility by estimating the impact of changes on net export, without any requirement of model modifications or prediction making.

Relating the macroeconomic dependence of import ( $\tau$ ) and export ( $\iota$ ) with the exchange rates, GDP ( $\psi$ ) and GDP of the counterpart ( $\psi'$ ) we have:

$$\xi = (\tau - \iota) = \tau \left( \begin{matrix} - & + \\ \varepsilon, & \psi' \end{matrix} \right) - \iota \left( \begin{matrix} + & + \\ \varepsilon, & \psi \end{matrix} \right) = \xi \left( \begin{matrix} - & - & + \\ \varepsilon, & \psi, & \psi' \end{matrix} \right) \quad (6)$$

Hence, the net export ( $\xi$ ) changes caused by the exchange rate fluctuations from Eq.6 could be expressed as  $\left( \Delta \varepsilon \left( \frac{\partial \xi}{\partial \varepsilon} \right) \right)$ :

Thus, our model describing the dependence of market risk from factors including changes in competitiveness for a single country is:

$$\phi = a_0 + a_1 \left( \frac{\partial \xi}{\partial \varepsilon} \right) \Delta \varepsilon + a_2 \Delta \lambda + a_3 \nu + a_4 \tau + a_5 \varpi + a_6 \rho \quad (7)$$

These particular changes in net exports reflect the changes in competitiveness of the output of the country vs. the output of the trade party. Hence, the proxy for the general competitiveness of EMU countries is the change in the EMU net exports ( $\hat{\xi}$ ) equal to:

$$\Delta \hat{\xi} = \sum_{i=1}^n \left( \Delta \varepsilon_i \frac{\partial \xi_i}{\partial \varepsilon_i} \right) \quad (8)$$

The main assumption is that after introducing the euro the changes in net exports of all the member states reflect the fluctuations of the single currency ( $\hat{\varepsilon}$ ).

$$\Delta \hat{\xi} = \Delta \hat{\varepsilon} \sum_{i=1}^n \frac{\partial \xi_i}{\partial \hat{\varepsilon}} \quad (9)$$

Thus, the changes in net exports of separate countries caused by the exchange rate changes are of the same sign. A single currency has a synchronising effect on general competitiveness changes, so that EMU has a larger  $\Delta \hat{\xi}$  in the case of the euro.

By replacing this term in the equation (7) for the  $i$ -th from the  $n$  countries we obtain:

$$\phi_i = a_0 + a_1 \left( \Delta \hat{\varepsilon} \sum_{i=1}^n \frac{\partial \xi_i}{\partial \hat{\varepsilon}} \right) + a_2 \Delta \lambda_i + a_3 v_i + a_4 \tau_i + a_5 \bar{\omega}_i + a_6 \rho_i \quad (10)$$

From that our proposition is that the exchange rate driven changes of general competitiveness determine the level of financial market risk, which explains the phenomenon of higher value-at-risk in case of a vulnerable euro. These ideas are summarized following two propositions.

**Proposition I.**

In case of a single currency the  $\sum_{i=1}^n \left( \Delta \varepsilon_i \frac{\partial \xi_i}{\partial \varepsilon_i} \right)$  is replaced with

$$\Delta \hat{\varepsilon} \sum_{i=1}^n \frac{\partial \xi_i}{\partial \hat{\varepsilon}}, \quad \text{where} \quad \left| \Delta \hat{\varepsilon} \sum_{i=1}^n \frac{\partial \xi_i}{\partial \hat{\varepsilon}} \right| \geq \left| \sum_{i=1}^n \left( \Delta \varepsilon_i \frac{\partial \xi_i}{\partial \varepsilon_i} \right) \right| \quad \text{because of the}$$

synchronised impact on foreign trade. The currency fluctuations cause greater fluctuation in general competitiveness of EMU production and result in higher volatility and risk in stock markets.

**Proposition II.**

The more significant variable  $\sum_{i=1}^n \left( \Delta \varepsilon_i \frac{\partial \xi_i}{\partial \varepsilon_i} \right)$  (compared with

$$\Delta \varepsilon_{it} \left( \frac{\partial \xi_i}{\partial \varepsilon_i} \right) \text{ national alternative) in}$$

$$\phi_i = a_0 + a_1 \left( \sum_{i=1}^n \left( \Delta \varepsilon_i \frac{\partial \xi_i}{\partial \varepsilon_i} \right) \right) + a_2 \Delta \lambda_i + a_3 \nu_i + a_4 \tau_i + a_5 \varpi_i + a_6 \rho_i$$

equation, the deeper are particular economies integrated, and euro fluctuations are more decisive for particular stock markets.

To test proposition I empirically, it is sufficient to prove the significance of the  $\varepsilon$  in the eq.6. Therefore, when the empirical results support proposition II, together with higher volatility of real exchange rates in the post-euro period, we can fully explain the indicated growth in VaR after the euro.

## 4. Empirical Findings

### 4.1. Changes in competitiveness vs. exchange rates

Before proceeding to the empirical testing of the stated hypothesis explaining the dynamics in the level of market risk we need to obtain estimated changes in net export. We used balanced monthly panel data 1995/01-2004/06 (see table 4 in appendix 2) for 11 EMU member countries (excluding Greece) to build an empirical model where the counterpart of the EMU is the USA. In context of our study the appropriate panel regression model has fixed individual effects ( $b_{i0}$ ) and different slopes (Cornwell and Schmidt, 1984) for log-exchange rates.

$$\xi_{it} = b_{i0} + b_{i1} \ln \varepsilon_{i(t-l)} + b_2 \left( \frac{\psi'}{\psi_i} \right)_{t-l} \quad (11)$$

Heteroskedasticity adjusted estimates of the model are reported in Table 2.

Based on the  $b_{i1}$  vector and the log-returns of the exchange rates with the five month lag, the impact of the exchange rate fluctuations on the net export of the particular countries (the  $\Delta \varepsilon_{it} \left( \frac{\partial \xi_i}{\partial \varepsilon_i} \right)$  series) is estimated. We interpret these estimates as changes of competitiveness of domestic production in the international market (considering US market). Finland and Ireland are removed from the sample of the countries during further analyses because of insufficient observation during the period of study. At the same time because of non robust  $b_{i1}$  coefficient, the Luxembourg is also excluded from the group.

It is normal to assume that the larger the  $\Delta \hat{\xi}_t$  caused by FX changes, the stronger is the position of European companies' shares at the stock markets. Therefore investors can expect the related market risk (VaR) to fall.

## 4.2. Explaining higher stock market risk

### 4.2.1. The choice between two parallel models

Certain proxies are used for the variables in eq. 10 along with estimated proxy of changes of general  $\left( \Delta \hat{\varepsilon}_{(t-5-l)} \sum_{i=1}^n b_{i1} \right)$  and alternatively country individual  $\left( \Delta \varepsilon_{i(t-5-l)} b_{i1} \right)$  competitiveness because of real exchange rate fluctuations. The changes in retail trade volumes are used to proxy the dynamics of domestic market demand ( $\Delta \lambda$ ). We also use the long-term government bond yields, the importance of which already has been discussed ( $\tau$ ). Unemployment rate is included to reflect the particular stage of business cycle ( $\rho$ ). The higher the unemployment, the deeper is the crisis and the higher is market risk.

$$\phi_i = a_0 + a_1 (\Delta \hat{\varepsilon}_{(t-5-l)} b_{i1}) + a_2 \Delta \lambda_{i(t-l)} + a_3 \ln(v_{i(t-l)}) + a_4 \tau_{i(t-l)} + a_5 \ln(\varpi_{i(t-l)}) + a_6 \rho_{i(t-l)} \quad (12)$$

$$\phi_i = a_0 + a_1 \left( \Delta \hat{\varepsilon}_{(t-5-l)} \sum_{i=1}^n b_{i1} \right) + a_2 \Delta \lambda_{i(t-l)} + a_3 \ln(v_{i(t-l)}) + a_4 \tau_{i(t-l)} + a_5 \ln(\varpi_{i(t-l)}) + a_6 \rho_{i(t-l)} \quad (13)$$

We consider two identical models by taking the country individual competitiveness variable in one (1) and the general competitiveness in the other (2) case (see Table 3). Balanced monthly panel data for post euro period (1999/01-2003/12) has been used<sup>4</sup> (see table 5 in appendix 2). The results suggest that replacing the  $\Delta \hat{\varepsilon}_{(t-5-l)} b_{i1}$  in the first model (1) with the

$\Delta \hat{\varepsilon}_{(t-5-l)} \sum_{i=1}^n b_{i1}$  in the second (2) improves the model. If the first variable is significant at a 5% confidence level, the variable of general competitiveness is significant at a level of 1%. The empirical results show that the growth in exchange rates reduces the international competitiveness of particular economies exports, and vice versa, as we know from macroeconomic theory.

We show that the changes in competitiveness in turn cause fluctuations in the level of stock market risk by increasing the risk when the national production loses position on the international markets, and by calming down the stock market when competitiveness grows.

**Table 3: FGLS Estimates of alternative models (eq.12 and eq.13)**

\*\* significant at 1%, \* significant at 5% confidence level.

Hence, the growth in exchange rates results in higher stock market risk. A set of other factors of stock market risk and volatility, already discussed, are also incorporated in the particular model.

While explaining the growth in market risk we made another, a more significant finding, in the context of European integration. Nowadays the situation (risk, volatility, etc.) in particular EMU stock markets is more

affected by the general competitiveness of the sample of European economies. So the contemporary level of European integration already acknowledges the concept of “General Competitiveness of European Economy”. In fact, the introduction of a single currency in EMU was another major step in this direction.

#### **4.2.2. Robustness checks**

This section investigates the robustness of the empirical findings to a number of experiments with the estimated models (see appendix 3 tables 6-7). First, we tried the robustness of model one by one excluding the regressors. Signs and statistical significance are as expected, so that robustness with respect to EMU8 is not lacking. The other regressors are robust as well.

Next, a number of different lag structures were tried. We experiment with different lags for the regressors in the model (0, 3, 6, 9 and 12 month lags were tried one by one), to see how the EMU8 behaves. EMU8 is again robust. Coefficients and statistical significance for the other regressors in most cases also behave in an appropriate manner. However, in the case of change in domestic demand (TRADE), the coefficient keeps the positive sign for 3 and 6 month lag options, while the maximal significance is obtained for 3 month lag. Statistical significance of unemployment (UNEMPLOYMENT) lacks since 3 month lag and registers change in sign in the 6 month lag option. These cases can be interpreted as specific time limitations of the impact of these two factors and, in general, do not affect the robustness of the empirical model.

### **5. Conclusion**

The stock markets of most EMU member states registered higher market risk after euro introduction. First of all, higher volatility of exchange rates affects the stock markets through consequent changes in the stock market value of firms. We show that exchange rates fluctuations affect the stock market risk by causing fluctuations in trade flows of the countries – our proxy for international competitiveness of the national economies.

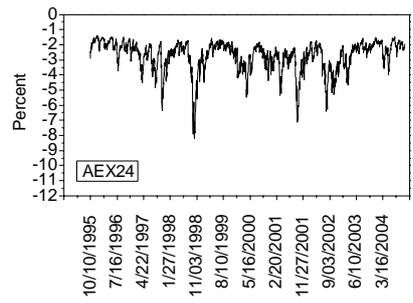

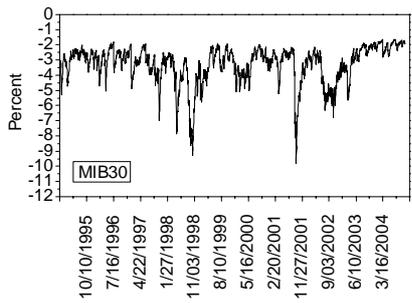

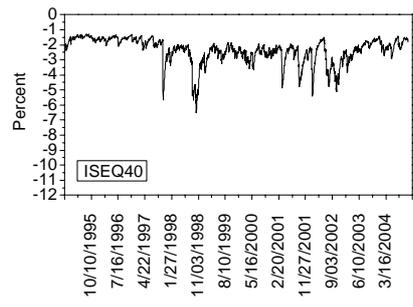

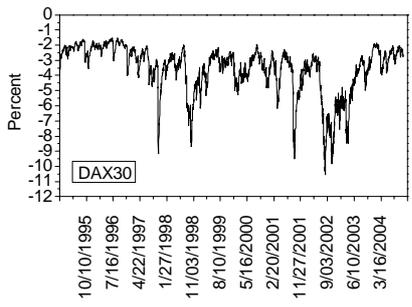

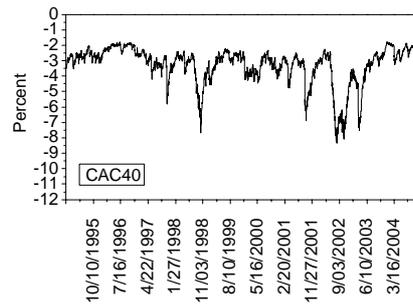

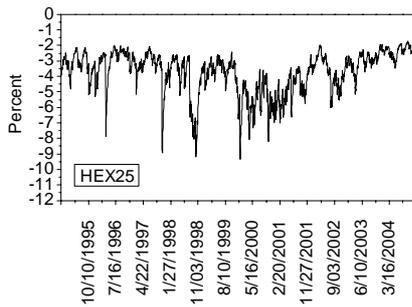

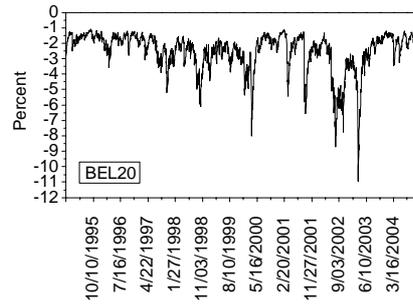

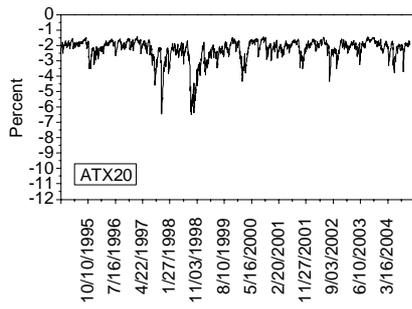

Moreover, an even more interesting fact regarding this is that common currency strengthens the “net volatility” of changes in competitiveness for the entire sample of countries by synchronising the changes of relative prices. Hence, the growth or reduction of Euro/USD exchange rates has a similar (positive or negative) effect on international

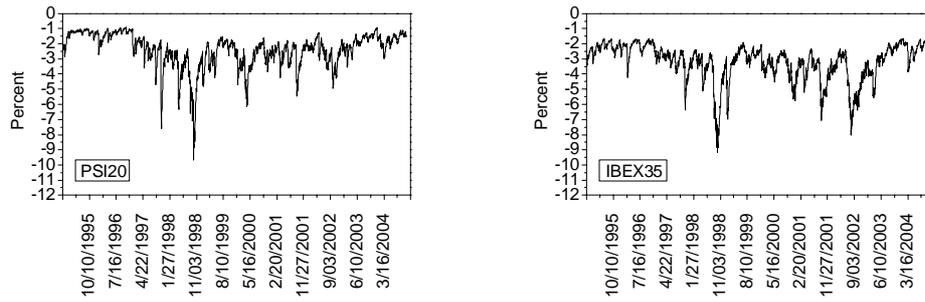

competitiveness of all the economies of the Monetary Union (at least for the observed 8 member states).

The empirical study also shows that due to the deep economic integration of particular European economies at both governmental and corporate levels, the changes in “General competitiveness” are more significant in explaining the stock market risk in separate countries than the changes in competitiveness on national levels. This phenomenon indicates a new stage of European economic integration where a European corporations and brands are represented on the international market of goods and services.

Summarising, the stock markets of most EMU member states registered higher market risk after euro introduction. Our analyses show that the Euro introduction had a triple effect on market risk, as it (1) resulted in higher volatility of exchange rates, (2) increased market risk on the stock markets because of higher synchronised fluctuations in general competitiveness, taking into account that (3) for the sample of countries it becomes more significant in explaining the dynamics of stock prices than the competitiveness changes at the national level.

## Appendix 1. Market risk dynamics

**Figure 1: Value-at-Risk dynamics in EMU major stock markets:  $VaR = -V(e^{\mu + \sigma\phi^{-1}(\alpha)} - 1)$ ,**  
 where  $V$  represents the initial value of some theoretical portfolio and  $\phi(\cdot)$  is the cumulative distribution  
 function of the standard normal probability distribution. GARCH (1.1) model is used for volatility  
 forecasting.

# MEASUREMENT OF FISCAL POLICY FLEXIBILITY (FPF) IN MONETARY UNION MEMBER COUNTRIES

**Paweł Młodkowski**

Department of Economics

Wyższa Szkoła Biznesu – National Louis Univeristy

Nowy Sącz, Poland

e-mail: Pawel.Mlodkowski@wsb-nlu.edu.pl

## **Abstract**

*The paper focuses on fiscal constraints imposed on monetary union member countries and a scope of freedom in conducting fiscal policy at the domestic level. Non-european monetary unions: West African Economic and Monetary Union (WAEMU), Central African Economic and Monetary Community (CAEMC) and East Caribbean Currency Union (ECCU) introduced multilateral surveillance and a variety of fiscal convergence criteria. These constraints for domestic fiscal policies were agreed at the regional level for multiple purposes. Among them the most important are: avoidance of time-inconsistent economic policies and free rider problem mitigation. Despite many other benefits, there are substantial potential costs of employing fiscal convergence criteria. They flow from a decrease in fiscal policy flexibility, which is perceived, by many authors, as crucial for monetary union well-being. The paper offers a methodology for assessment of the fiscal policy flexibility when fiscal convergence criteria or fiscal constraints, in general, are present.*

**Keywords:** *monetary union, fiscal convergence criteria, fiscal policy*

## **1. Introduction**

There is a widely recognized need for fiscal convergence in monetary unions, evidenced by multilateral surveillance introduced in member countries of most of existing monetary unions. There is however a threat that imposing limits and requirements on a domestic fiscal policy will have a negative influence on the member's economy. Therefore the framework for fiscal convergence criteria assessment is needed in order to answer the question about their actual influence. The paper develops such a framework and offers a ratio of fiscal policy flexibility when fiscal convergence criteria are present.

The paper is structured as follows: Section I is a literature review that shows fiscal constraints as crucial factors for a successful, long-lasting monetary union and shows consequences of introducing fiscal convergence criteria for fiscal flexibility. Section II presents experiences of WAEMU, CAEMC and ECCU in fiscal convergence. Section III presents formalization for fiscal constraints. Section VI discusses fiscal policy flexibility idea and measurement methodology. Section V concludes about fiscal policy flexibility main factors.

## **2. Fiscal Policy Flexibility as a factor of a successful monetary union**

It is widely recognized that a monetary union agreement brings many benefits. A recent empirical study by Edwards and Magendzo (2002) shows that independent currency union (ICU) member countries experienced lower rates of inflation and higher GDP growth rates (1970 – 1998) than non-member countries, using currencies of their own. However, these benefits expected to materialize due to a membership in such an agreement, are of a conditional nature. Eichengreen (2001) shows that exploiting all possible advantages offered by a common currency and monetary policy is highly conditional.

Benefits flowing from common currency and monetary policy for member countries depend on the correlation of their business cycles. The more correlated they are, the better common monetary policy is suited for every member. Since there is no country-tailored monetary policy, fiscal authorities are responsible for coordinating and converging economic cycles of members in a monetary union. There is no trade-off between fiscal and monetary policy because the latter is set at the regional level and is not influenced by individual countries. Fiscal policy becomes most important for internal and external balance.

Fiscal policy pursued by every country depends on a wide variety of internal and external factors. Masson and Pattillo (2002) show that it is not clear whether monetary union membership helps or hinders fiscal discipline. Lack of this discipline is responsible for divergence of business cycle phases, which is highly undesired under monetary union agreement. So far, empirical evidence, EMU literature and CFA franc Zone experience suggest the possibility that monetary union membership could create incentives for fiscal profligacy. Governments are tempted to undertake over-expansionary fiscal policy. Worrell (2003) shows that failure to make long-term fiscal and structural commitments implies severe penalty: high interest rates, uncertain climate for investment and low growth potential.

The incentive for fiscal profligacy flows from the possibility of a bailout by the common central bank and the distribution of costs following the imprudent fiscal policies among all member countries. The negative externalities will hit other members. They would rather help “the naughty boy” than let their union to fall apart. This scenario is very costly for every union member. The idea behind fiscal convergence criteria is to prevent such a crisis to emerge.

Hefeker (2003) argues that uncoordinated fiscal policies have negative externalities on the common currency. Another argument is pointed by Debrun et al. (2002). Rulers have an interest to benefit certain groups in the economy and it leads to over-expansionary fiscal policy.

Masson and Pattillo (2002) show also that monetary union is successful only when “the hands of the fiscal authorities are tied by a strong set of fiscal restraint criteria”. These are not to be binding before joining a union but throughout its entire life. This point of view is supported by a theoretical study performed by Chari and Kehoe (1998). They show that the desirability of debt constraints in monetary unions depends critically on the extent of commitment of the common monetary authority. If the common monetary authority cannot commit, there is a free-rider problem in fiscal policy, and debt constraints may be desirable.

Monetary union agreement is not a good vehicle for growth, stability and prosperity, unless fiscal policies are tied by a strong set of fiscal restraint criteria. Beetsma and Uhlig (1999) argue that to avoid negative externalities and spillover effects fiscal policy must be coordinated among member countries. To gain possible benefits, member countries governments should define appropriate fiscal convergence criteria at a regional level and introduce a credible multilateral surveillance. There is however a threat. To meet limits and requirements imposed by fiscal convergence criteria, fiscal authorities lost freedom in conducting domestic fiscal policy.

Lack of fiscal policy flexibility is at the roots of the negative evaluation of all fiscal arrangements. It can be found in Debrun (2000) and inferred from Bean (1992), Buitert et al. (1992) or Dornbush (1997) and Sims (1998). Under common monetary policy, fighting country-specific shocks can only be done using domestic fiscal policy. Otherwise asymmetry between member countries' business cycle may increase. Therefore it is very important to recognize fiscal policy flexibility determinants and offer proxies for decision making purposes in the course of reforming monetary union agreements.

### **3. Experience in fiscal convergence in non-european monetary unions.**

The following review of fiscal constraints in the three monetary unions of low-income countries is an attempt to explain the general ideas on which these criteria are based and also to point out differences which exist in their institutional arrangements.

#### ***3.1 WAEMU – West African Economic and Monetary Union***

The West African Economic and Monetary Union is composed of Benin, Burkina Faso, Cote d'Ivoire, Guinea-Bissau, Mali, Niger, Senegal and Togo.

Following the CFA franc devaluation in 1994 a system of fiscal convergence criteria and multilateral surveillance was introduced. The aim was to assure greater compliance in terms of the economic policies of member countries, with targets at the regional level.

In WAEMU during the first period: 1994 – 1998, the main fiscal convergence criteria (FCC) were the following:

- the public sector wage bill (WAB) could not exceed 50% of tax revenue. In January 1998 this limit was lowered to 40%;
  - at least 20% of tax revenue had to be used to finance domestic fixed investment (DFI) by the public sector;
  - basic fiscal balance (BAB), that is revenue without grants minus expenditure without public investment financed from external sources, had to be no less than 15% of tax revenue;
  - change in arrears (ARR), internal and external, could not be positive.
- In 1999 the WAEMU entered the second phase of fiscal convergence when the Convergence, Stability, Growth and Solidarity Pact (CSGSP)

was signed.<sup>1</sup> New FCC were defined. The aim was to improve macroeconomic stability, speed up economic growth and develop solidarity among member countries.

FCC were divided into two categories - primary and secondary criteria. The first of the primary criteria was aimed at improving and stabilizing public finance in member countries. According to the CSGSP, the basic fiscal balance (BAB) had to be non-negative until 2002. The second primary criterion referred to the public debt (PD) to GDP ratio and limited the ratio of nominal PD to nominal GDP to 70%. The aim of the next primary criterion was to avoid an alternative non-market financing of fiscal deficits. Change in arrears (ARR) had to be non-positive.<sup>2</sup> Yet another primary criterion was the limit for inflation. It had to remain below 3% per annum. The aim was to keep the difference in inflation rates between the WAEMU and France (Euro zone) at the lowest level possible. It was introduced to avoid pressures on the fixed exchange rate commitment.

The four primary FCC presented above were supported by other limits and requirements. Some of them originated from the 1994 set of FCC. Public investment financed from domestic sources (DFI) had to be at least 20% of tax revenue. The public sector wage bill (WAB) could not exceed 35% of tax revenue. Another secondary criterion required tax revenues (TAR) to be at least at 17% of GDP. The last criterion limited the current account deficit (CAD) in the balance of payments to 5% of GDP.<sup>3</sup>

The system of multilateral surveillance and a set of penalties for noncompliance with FCC was defined in paragraph 74 of the WAEMU Treaty. Depending on the degree of noncompliance and level of cooperation, the penalties were as follows: withdrawing financing by the West African Development Bank and suspending budgets financing by BCEAO (the central bank for WAEMU).

The imposed FCC and accompanying multilateral surveillance were successful in consolidating public finance. Dore and Mason (2002) recognized two distinctive periods under this regime. The first was 1994 – 1997. Much of the adjustment took place before 1998. After 1997 fiscal convergence was much slower and divergence appeared. Despite the negative BAB during the years 1994 – 1997, developments were positive. Public expenditure structure was improved and control was gained over current

---

<sup>1</sup> The CSGSP was signed in 1999 and new FCC were binding from 2000. The transition period for adequate adjustments was set at three years. The deadline was December 31, 2002.

<sup>2</sup> This requirement was already present in the previous set of FCC since 1994.

<sup>3</sup> In calculation of this ratio grants received from abroad are excluded.

primary expenditure. The wage bill in the public sector was decreased from 55% to 37,2% in 1998. Only two countries (Niger and Togo) violated this criterion (at 40% of tax revenue). Public investment expenditure rose from 11% in 1994 to 21% in 1998. Arrears (domestic and external) decreased. However, since 1998 those positive trends suffered a steep contraction. Large deficits, slower GDP growth and no control over public expenditure were common in WAEMU member countries. The public sector wage bill increased from 37,2% to 37,9% in 2001. Only three countries (Benin, Mali & Senegal) were in line with this criterion. Public investment rose steadily but differences among members were quite substantial. After 1998 only Burkina Faso and Mali managed to meet this criterion (at 20% of tax revenue). No improvements materialized in terms of tax revenue, which stabilized around 15% of GDP, while the FCC required a ratio of at least 17%.

WAEMU member countries expected a lot from WAEMU Directives. The 2002 deadline for implementation was not met. Countries were adopting them at different paces and with substantial delays. While the directives gave guidance with regard to most important fiscal issues, Mussa (2004) argues that their internal consistency still needs to be enhanced. Otherwise the main goal to harmonize fiscal management within WAEMU will not be attained. Another example of fiscal convergence can be observed in another CFA-franc Zone monetary union – CAEMC.

### ***3.2 CAEMC – Central African Economic and Monetary Community***

The Central African Economic and Monetary Community is composed of: Cameroon, the Central African Republic, Chad, the Republic of the Congo, Equatorial Guinea and Gabon. After devaluation in 1994, the CAEMC underwent an exercise, similar to the WAEMU, which was aimed at intensifying regional integration and to introduce multilateral surveillance. Several macroeconomic convergence criteria were imposed:

- an upper limit for inflation of 3% per annum;
- a public debt limit;
- procedures for foreign exchange reserves accumulation;
- a surplus or zero fiscal balance.

The greatest threat for reaching the criteria was the high dependence of fiscal revenue on crude oil prices and production volumes. Multilateral surveillance in CAEMC was based on a set of quantitative criteria. These were aimed at monitoring for excessive fiscal deficits and observing the economic performance of member countries. In the first phase four ratios were employed:

- foreign exchange reserves (FER) had to cover 20% of money supply,

- basic fiscal balance (BAB) had to be nonnegative,
- change in arrears (ARR) could not be positive,
- changes in public sector wage bill (WAB) could not exceed the growth rate in fiscal revenue.

Some shortages and disadvantages of the above set were noticed. Therefore, on 14<sup>th</sup> of July 2001, the board of the CAEMC Ministers agreed on a new FCC, which were expected to be introduced in January 2002. Since then the following limits constrained fiscal policies of CAEMC member countries.

The first criterion measured the government's ability to finance all current and capital expenditure with domestic resources. Basic fiscal balance had to be positive or zero. The calculation for BAB was as follows: revenue except grants, minus total expenditure. The primary surplus allows for debt repayments and indicates a no debt-trap problem.

The second FCC dealt with the inflation ratio and set the same limit of 3% p.a., as in case of WAEMU. The third FCC limited total public debt (internal and external) to 70% of GDP, starting in 2004.

The last FCC required the change in arrears to be non-positive in the current period. It was aimed at liquidating payment problems, stabilizing economies and national banking sectors and regaining credibility at the international capital markets.

Since 2002, CAEMC countries undertook attempts to meet agreed limits and requirements. After one year of adjustment (in 2003), BAB and PD/GDP criterion was met by four out of six CAEMC members. In 2003 only Republic of Congo experienced increase in arrears and the only country that violated limit for wage bill in public sector increase was Cameroon. Concluding, new set of fiscal convergence criteria was implemented successfully. Most of countries comply with four limits. For those, which violate FCC, substantial fiscal adjustment is required. This is because bringing down public debt from above 250% of GDP to 70% of GDP is not possible in such a short period.

The multilateral surveillance ratios used in the CAEMC were not binding convergence criteria. They served in diagnosing economic and financial condition of member countries. Three kinds of ratios were employed:

- i. general macroeconomic ratios:
  - a. real GDP growth ratio;
  - b. foreign exchange reserve cover of the money supply (at least 20% );
  - c. current account balance to GDP ratio;
- ii. analytical ratios:
  - a. investment ratio (total, public & private), as a % of GDP;
  - b. public sector wage bill as a % of total revenue without external grants;
  - c. changes in competitive position measured by REER;
- iii. indicators of economic policy:
  - a. fiscal policy stance measured by BAB/total revenue, BAB/GDP and OVB/GDP;
  - b. monetary policy stance measured by money and credit supply.

The four FCC binding CAEMC countries were similar to those which were agreed by CFA Franc Zone Convergence Committee, at the super-regional level. Both African monetary unions use the CFA franc as a common currency (names of the currencies are a bit different but both are pegged to the euro at the same ratio). A guarantee by the French Treasury makes this commitment credible. The third non-european currency union that undertook steps toward fiscal convergence between its members is ECCU.

### ***3.3 ECCU – Eastern Caribbean Currency Union***

The Eastern Caribbean Currency Union (ECCU) consists of Anguilla, Antigua and Barbuda, Grenada, Mont Serrate, Dominica, St. Vincent, St. Lucia, St. Kitts and Grenadines. The union's currency is the Caribbean dollar with a fixed parity to USD.

The Eastern Caribbean Currency Union is a special case when considering fiscal convergence criteria. After a substantial worsening in the budgetary situation in member territories during 1990s, the regional central bank undertook an initiative aimed at reverting undesired tendencies.

**Table 1. The actual situation of the six quantitative criteria in 2002.**

ECCB directive	ECCU	Antigua& Barbuda	Dominica	Grenada	St. Kitts & Nevis	St. Lucia	St. Vincent Grenadines
Savings of the central government 4-6% of GDP	-3,8%	-11,8%	-6,8%	1,9%	-3%	-0,9%	1,4%
Overall deficit of central government 3% of GDP	-9,6%	-13,2%	-11%	-8,1%	-13,4%	-7,4%	-3,6%
Public debt 60% of GDP	92,5%	102,3%	105,8%	103,7%	137,2%	56,6%	74,1%
Savings of the public sector 7-8% GDP	-1,4%	-11,8%	-6,8%	2,1%	-3%	7,5%	4,3%
Public sector investment 12% GDP	8,8%	1,5%	5,4%	13,2%	14,4%	10,4%	12,1%
Public sector primary balance	-3,2%	-7,8%	-5,7%	-3,8%	-3,1%	4%	-2,1%

*Source: P. Kufa, A. Pellechio, S. Rizavi (2003): Fiscal Sustainability and Policy Issues in Eastern Caribbean Currency Union, IMF Working Paper, WP/03/162, Washington: International Monetary Fund, p. 9*

The Eastern Caribbean Central Bank is responsible for promoting economic growth in the region under the fixed exchange rate commitment and liberalized balance of payments accounts. To meet this goal and to prevent the monetization of public debt through the financing of fiscal deficits, the ECCB created a set of directives for the public sector. This was aimed at improving the quality of fiscal policy. Quantitative targets were supplemented by structural reforms. It was expected to improve the effectiveness of taxation and the influence of public expenditure on growth.

Introducing directives for public sector was a clear sign that the commitment to abstain from financing fiscal deficits by ECCB was not enough to prevent fiscal profligacy. However, the ECCB directives were not binding and the central bank had no authority to demand compliance with them. ECCB only suggested complying with the following six quantitative criteria:

- savings of the central governments should be at 4 – 6% of GDP annually,
- overall deficit (OVB) should not exceed 3% of GDP,
- public debt (PD) should not exceed 60% of GDP,
- public sector savings, including pensions systems, should reach 7% - 8% of GDP annually,
- public sector investment (PSI) should be at least at 12% of GDP,
- public sector primary balance (BAB) should be nonnegative.

Other general directives are the following:

- liquidation of arrears (ARR),
- public debt repayments due to the creation of amortization funds,
- creating reserve funds for the purpose of mitigating natural disasters .

The ECCB directives were very similar to the FCC implemented in the WAEMU and the CAEMC after devaluation in 1994. In all three monetary unions fiscal convergence criteria were present. The feature that distinguishes them is that, in Africa, FCC are binding while in the Caribbean they are not. In the WAEMU and the CAEMC multilateral surveillance and system of penalties were present. The ECCU case was then only informative because there was no external pressure mechanism for implementing FCC.

**Table 2. Fiscal convergence criteria in monetary unions.**

Source: Author.

Presentation of fiscal convergence in non-european monetary unions bring closer solutions employed to avoid short-sighted and time-inconsistent policies at a domestic level. Utilization of the WAEMU, CAMC and ECCU experience need formalization of fiscal convergence criteria. This is a next step to define fiscal policy flexibility (FPF).

#### **4. Fiscal constraints measurement methodology.**

Six areas are covered by fiscal constraints. The largest set of them was present in WAEMU, and some of them were present in CAEMC and ECCU. The difficulty in presenting general solutions flowed from different definitions of crucial variables. These included revenue, expenditure, basic/primary balance and investment. The methodology will be applicable to all of them after **concerning** the technical differences.

##### **4.1 Criterion I – public debt (PD)**

This criterion is defined as a maximum level of PD/GDP ratio. Nominal value of PD at the end of period “t” is: PD from the previous period (t-1), overall balance in the current period (OVB), net change in arrears (ARR) in period “t”.

$$PD_{it} = PD_{it-1} + OVB_{it} + ARR_{it} \quad \text{for member country } i=1,\dots,n; \text{ and period } t=1,\dots,T \quad (1)$$

In the case of a debt-trap problem, interest payments were captured either in  $OVB_{it}$  or  $ARR_{it}$ . In the first case, financing was based on the market, while in the other, governments used non-market financing.

##### **4.2 Criterion II – overall or basic fiscal balance (OVB, BAB).**

Fiscal balance is one of the most important fiscal policy stance indicators. There are many different ways of calculating a wide variety of fiscal balances. In general, a balance is obtained when expenditure is deducted from revenue. Adjustments made to these two elements lead to a wide pattern of fiscal balances.

In each of the monetary unions covered by this study different fiscal balance was used as an indicator in multilateral surveillance.<sup>4</sup>

Overall fiscal balance may be decomposed in the following way:

---

<sup>4</sup> In CAEMC BAB = revenue (except grants) minus total expenditure. ECCU countries base their multilateral surveillance on two distinctive fiscal balances: overall balance = revenue - expenditure (limit of 3% GDP when deficit appears) and public sector primary balance, which should be non-negative.

$$OVB_{it} = REV_{it} - EXP_{it} \text{ for } i=1, \dots, n; t=1, \dots, T \quad (2)$$

After introducing fiscal constraint, it should satisfy a condition:

$$OVB_{it} = REV_{it} - EXP_{it} \geq 0 \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (3)$$

Using WAEMU's definition of basic fiscal balance as non-grant revenue minus expenditure, excluding foreign-financed investment, one can break down revenue (REV) and expenditure (EXP). This is necessary as other criteria are based on some fractions of those broad categories.

Many concepts are available in the case of the primary basic fiscal balance. A basic fiscal balance in WAEMU, defined as non-grant revenue minus expenditure, excluding foreign-financed investment, serves as one of the primary fiscal constraints. However, for convenience many empirical studies (see for example Dore and Masson (2002), p. 10) used overall fiscal balance in all estimations. This was mainly due to a lack of adequate data for basic fiscal balance.

Overall balance (OVB) is defined above. The concept of basic fiscal balance is based on several exclusions from revenue and expenditure. Let us assume that total revenue (REV) is composed of tax receipts (TAR) and non-tax revenue (NTR).

$$REV_{it} = TAR_{it} + NTR_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (4)$$

Expenditure side of a budget (EXP) is a little more complex and may be divided, at first, into two categories of fiscal payments: current expenditure (CUR) and total public investment expenditure (PIE).

$$EXP_{it} = CUR_{it} + PIE_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (5)$$

Current expenditure (CUR) may be decomposed to wage bill (WAB), interest payments ( $r \times PD_{it-1}$ ) and other expenditure (OTH).

$$CUR_{it} = WAB_{it} + r \times PD_{it-1} + OTH_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (6)$$

Total public investment expenditures (PIE) may be decomposed into two categories: externally financed investment (EFI) and domestically financed investment (DFI). The former is excluded from basic fiscal balance calculation.

$$PIE_{it} = EFI_{it} + DFI_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (7)$$

Summarizing, total public expenditure (EXP) can be written as:

$$EXP_{it} = WAB_{it} + r \times PD_{it-1} + OTH_{it} + EFI_{it} + DFI_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (8)$$

Overall fiscal balance equation takes the following form:

$$OVB_{it} = TAR_{it} + NTR_{it} - WAB_{it} - r \times PD_{it-1} - OTH_{it} - EFI_{it} - DFI_{it} \quad (9)$$

For the purpose of a basic fiscal balance (BAB) calculation, revenue (REV) and expenditure (EXP) must be modified (\* – asterisks denote modified variables):

$$REV_{it}^* = TAR_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (10)$$

Modified revenue covers only tax receipts. In the case of modified expenditure, EFI was excluded.

$$EXP_{it}^* = WAB_{it} + r \times PD_{it-1} + OTH_{it} + DFI_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (11)$$

Basic fiscal balance (BAB) is then given by the difference of modified revenue (REV\*) and expenditure (EXP\*).

$$BAB_{it} = TAR_{it} - (WAB_{it} + r \times PD_{it-1} + OTH_{it} + DFI_{it}) \quad (12a)$$

or

$$BAB_{it} = TAR_{it} - WAB_{it} - r \times PD_{it-1} - OTH_{it} - DFI_{it} \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (12b)$$

According to information from the Bank of France database for CFA franc Zone, on revenue structure in WAEMU and CEMAC, budgetary revenue is composed mainly of TAR and external grants (NTR). In the case of oil exporters in the region, a substantial part of non-tax revenue is from the production of crude oil. Further readings on the topic of natural resources on wealth and fiscal policy in CAEMC countries can be found in Wiegand (2004). The methodology of BAB calculation was then accurate and precise for WAEMU and CAEMC. Furthermore, in WAEMU the difference between OVB and BAB had to be equal to the part of public investment expenditures (PIE) financed from external sources (EFI).

Under fiscal constraints, BAB should have met the following condition

$$BAB_{it} = TAR_{it} - WAB_{it} - r \times PD_{it-1} - OTH_{it} - DFI_{it} \geq 0 \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (13)$$

### 4.3 Criterion III – arrears (ARR)

In this case, two general aims prevailed in the short and the long run. The change in arrears between period “t-1” and “t” could not be positive.

$$\Delta ARR = ARR_{it} - ARR_{it-1} \leq 0 \quad \text{for } i=1, \dots, n; \quad t=1, \dots, T \quad (14)$$

The long-term objective implied reducing arrears to zero.

$$\lim_{t \rightarrow T} ARR_t = 0 \quad (15)$$

Arrears are of a diverse nature. An amount in arrears is understood as the value owed but not yet paid. The question was, from what date was money owed? Arrears emerge when obligations are not met in the period in which they fall due. Government debt is legally binding once goods or services have been delivered. That is the “liquidation phase”. It covers a wide variety of obligations, including these flowing from current expenditure (CUR): WAB, OTH and public debt service ( $r \cdot PD_{it-1}$ ) or repayments.<sup>5</sup>

#### **4.4 Criterion IV – wage bill (WAB)**

The wage bill (WAB) in the public sector belongs to current expenditure (CUR). Remuneration for public sector workers is perceived as a demand-side stimulating instrument and non-productive expenditure with no ability to increase growth. That is why too large burden in the form of WAB is to be avoided for sustainable fiscal policy.

The introduction of fiscal constraint as WAB ratio is aimed at improving the quality of public expenditure when fiscal adjustment is needed. Cuts in wages or public sector employment are politically very unpopular. However, this is sometimes imminent and the only feasible way of arriving at a sustainable and prudent fiscal policy.

$$\frac{WAB_{it}}{TAR} < b \quad \text{for } i=1, \dots, n; \quad t=1, \dots, T \quad (16)$$

When requirements on other expenditures are binding, this constraint points the way for structural changes in expenditure. Once the target level of WAB is set, it is always in connection with a minimum requirement in a category of non-current expenditure. The trade-off effect is expected to

---

<sup>5</sup> The simple fact of placing the order does not commit a government to paying or constitute arrears if the payment is not made. Arrears are incurred when the ordered goods or services have been delivered (liquidation phase), but the order to pay has not been given by a credit manager to a public accountant. In this case “administrative” (or technical) arrears appear. Real arrears appear when an accountant is unable to execute an order to pay because of a lack of cash. Lags between order to pay and payment execution flow from imposed spending procedures. Therefore, even when cash is available for all payments due, they are executed with substantial delays. In this case arrears do not appear.

emerge. Decreasing current expenditure (WAB) serves as a vehicle for increasing public investment. Resources saved in this area are redirected to operations aimed at enhancing growth potential.

**4.5 Criterion V – total public investment expenditure (PIE) and domestically financed investment (DFI)**

This FCC is one of the two criteria aimed at improving the quality of public expenditure. A very common feature of central government spending in low-income countries is the lack of non-current expenditure. This short-term nature is explained by political instability. Governments are rarely formed in democratic elections. Lack of stability implies resources management aimed at gaining all benefits in the current period or as fast as possible without considering nationwide utility function in the long run. Political instability hinders economic growth, also in monetary union member countries. The superior examples are Cote d’Ivoire and Togo in WAEMU, Central African Republic and Republic of Congo in CAEMC or Grenada in ECCU.

The criterion based on PIE/GDP (or DFI/GDP) ratio is of dual nature. First, it serves as a growth potential increasing vehicle.<sup>6</sup> However, it also serves the other aim. When primary FCC is intended to decrease fiscal deficit and arrive at surpluses, adjustment might be made by decreasing investment expenditure (if present). In the short run, this is both feasible and an effective way of meeting FCC. When one evaluates the long-term influence of such a policy, negative impact on growth and growth potential is evident.

“c” – minimum requirement as a percentage of tax revenue

$$\frac{DFI_{it}}{GDP_{it}} \geq c \quad \text{for } i=1,\dots,n; t=1,\dots,T \tag{17a}$$

$$\frac{PIE_{it}}{GDP_{it}} \geq c \quad \text{for } i=1,\dots,n; t=1,\dots,T \tag{17b}$$

The equations (16), (17a) and (17b) should then be interpreted as boundary conditions for basic fiscal balance (BAB) criterion.

In CAEMC investment ratios (total, public, private) are used in multilateral surveillance, but they do not bind governments. They serve only to diagnose economic conditions of member countries. ECCB issued a directive aimed at public investment in the Caribbean. This category is much

---

<sup>6</sup> Private sector is very often unable to undertake sufficient infrastructure investments. High level of sunken costs, long periods of return and non-monetary benefits from enhancing infrastructure leave infrastructure investments for public authorities.

broader because it covers the whole public sector investment (PIE). PIE in ECCU should be at least at 12% of GDP annually.

#### **4.6 Criterion VI – tax receipts (TAR)**

Public revenue can be broken down as shown in (4). The idea embodied in this requirement is not only to improve the quality of domestic tax systems, but to prevent political instability. Ghura and Marcereau (2004) argue that chronic weak revenue performance led to the accumulation of domestic wage and external debt arrears and the degradation of social services in Central Africa in XX<sup>th</sup> century. Substantial arrears and irregular wage payments to civil servants and military personnel led to prolonged labor strikes and army rebellions. Improving tax revenue prevents the occurrence of the aforementioned situations, which are lethal for growth and stability.

Stable and assured tax receipts are highly valued in every country. However, the monetary union's case is different because fiscal policy influences more than just one territory. Automatic stabilizers make tax receipts highly pro-cyclical. Steep contraction in economic activity leads to a decrease in resources available for fiscal policy. Fiscal constraint based on a minimum requirement for tax receipts is aimed at improving a taxation system and making it more resistant to shocks. Receiving a certain amount of GDP in tax revenue completes the goal of sustainable fiscal policy. Tax revenue at the level at least at a certain minimum allows for a better expenditure management in the long run. Information about revenue in the future leads to expenditure tailoring to available resources. In this way, structural deficits may be avoided. Any unexpected deviations from the minimum level might be used for public debt repayments. This criterion may be written in the following way:

$$\frac{TAR_{it}}{GDP_{it}} \geq a \text{ for } i=1, \dots, n; t=1, \dots, T \quad (18)$$

#### **4.7 Criterion VII rate of inflation**

In both African monetary unions covered by this study, a limit is imposed on the rate of inflation. This is also the case in EMU but not in ECCU. The way this limit is set differs in Africa and Europe. For African monetary unions there is an inflation target set at the regional level by the central banks, for each union. It is a numerical value of annual change in general price level. In EMU limit is not fixed but depends on the inflation in member countries with the lowest growth in general price level. This way flexibility is achieved.

#### **4.8 Criterion VIII foreign exchange cover ratio (FER)**

In CAEMC a special convergence criterion is present, aimed at maintaining sufficient level of foreign exchange reserves relative to money supply. This is not a fiscal constrain. It is introduced because of a fixed exchange rate regime in CAEMC. Credibility of this commitment requires high level of backing money supply. On the one hand – French Treasury guarantees convertibility of CFA-franc. On the second hand, BEAC requires foreign exchange reserves for conducting sovereign monetary policy.

#### **4.9 Criterion IX current account deficit (CAD)**

WAEMU countries introduced a new criterion in 2000, limiting current account deficit to 5% of GDP. In calculating this variable, grants received are excluded. This is another indirect fiscal criterion. Current account balance reflects difference between domestic income and absorption.<sup>7</sup>

$$\frac{CAD_{it}}{GDP_{it}} \geq f \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (19)$$

Expansive fiscal policy is very often responsible for current account deficit. This criterion is intended to impose on governments taking into account fiscal policy influence on external stability, under given income and absorption of other sectors.

#### **4.10 Criteria X and XI government (GOS) and public sector, including pensions systems, savings (PUS)**

There is only one monetary union that tries to cover public savings in a regional coordination of fiscal policies.

$$\frac{GOS_{it}}{GDP_{it}} \geq f \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (20a)$$

$$\frac{PUS_{it}}{GDP_{it}} \geq f \quad \text{for } i=1, \dots, n; t=1, \dots, T \quad (20b)$$

In the Caribbean ECCB issued two directives aimed at increasing domestic savings. In this way resources for investment and debt repayments are expected to emerge. However none of the ECCB directives is binding.

---

<sup>7</sup> Lack of direct or portfolio investment inflows – characteristic for low-income countries in Africa – means that there are no sustainable sources of current account deficit financing. To mitigate the problem of foreign exchange reserves depletion, permanent current account deficit should be avoided. Otherwise external instability emerges in the form of devaluation pressures, difficulties for foreign trade and capital flight.

After presentation of fiscal constraints and their interrelations, it becomes possible to show how fiscal policy is constrained at the moment of full implementation and fulfilling commitments flowing from fiscal convergence criteria.

## 5. Fiscal Policy Flexibility (FPF) methodology.

The flexibility of fiscal policy can be defined as a freedom in deciding about spending side of the budget. To measure this freedom one can use a level of independent expenditures. Independent expenditures are defined as the public expenditures that are not constrained directly by any of the fiscal convergence criteria. The higher the value of this indicator, the more flexible the fiscal policy. In this study it is denoted by OTH – other expenditure. Since requirements for revenue and limits on all other expenditure are introduced, little independence is left for governments. The more other expenditure (OTH) is available without breaching fiscal constraints (in UE for example incurring a deficit), the more freedom fiscal policy has. In case of presented non-european monetary unions arriving at nominal levels of fiscal convergence criteria ratios makes fiscal policy vulnerable and not very flexible. There is little freedom in reacting to asymmetric shocks.

Using BAB equation (12b), it is possible to show the level of fiscal policy flexibility when fiscal constraints are met. Satisfying PD limit implies that  $BAB=0$  and  $ARR=0$ , then

$$0 = TAR - WAB - r \times PD - DFI - OTH \quad (21)$$

$$OTH = TAR - WAB - r \times PD - DFI \quad (22)$$

To present the general level of fiscal policy flexibility for comparisons purposes, it is feasible to define it as a percentage of GDP.

$$\frac{OTH}{GDP} = \frac{TAR}{GDP} - \frac{WAB}{GDP} - \frac{r \times PD}{GDP} - \frac{DFI}{GDP} \quad (23)$$

In non-european monetary unions fiscal constraints refer to two categories: GDP and tax revenue (TAR). To employ them all together in equation (23), one should present them with the common denominator. First, it is comfortable to substitute:

$$\frac{TAR}{GDP} \geq A \Rightarrow TAR \geq A \times GDP \quad (\text{GDP is always non-negative}) \quad (24)$$

where “A” is an actual percentage share of public revenue in the form of tax receipts in GDP.

Substituting TAR from (24) to FCC defined in relation to TAR they become:

$$\frac{WAB}{TAR} \leq b \Rightarrow \frac{WAB}{A \times GDP} \leq b \Rightarrow \frac{WAB}{GDP} \leq b \times A \quad (\text{"A" is always non-negative}) \quad (25)$$

b – limit for wage bill in public sector, as TAR percentage

$$\frac{DFI}{TAR} \geq c \Rightarrow \frac{DFI}{A \times GDP} \geq c \Rightarrow \frac{DFI}{GDP} \geq c \times A \quad (\text{"A" is always non-negative}) \quad (26)$$

c – target ratio of public investment, as TAR percentage

$$\frac{PD}{GDP} \leq d \quad (27)$$

d – limit for public debt relative to nominal GDP

Then, fiscal policy flexibility proxy at the moment of compliance with all fiscal constraints, is given by (28) because all “ $\geq$ ” and “ $\leq$ ” become “ $=$ ”.

$$\frac{OTH}{GDP} = A - b \times A - r \times d - c \times A \quad (28)$$

$$\frac{OTH}{GDP} = A(1 - b - c) - r \times d \quad (29)$$

The equation (28) may be used in comparative studies of different fiscal convergence criteria levels. There is, however, one exogenous variable that strongly influences the final score. Interest rate is crucial for fiscal policy flexibility because it influenced directly interest payments which are very often a large part of the public expenditure.

## 6. Conclusions

The main factors of fiscal policy flexibility are: public debt, interest rate and nominal GDP growth rate. All three are beyond any direct influence of fiscal authorities at the domestic level. Public debt is a result, in most cases, of many deficits in the past. Despite debt was created by other policy makers it is required to meet all obligations when they fall due. Emergence of arrears depresses credibility of fiscal authorities as an issuer. Therefore no arrears or refusals to repay “old debts” are possible.

Interest rate depends theoretically on the common monetary policy conducted by the central bank of a union. Under financial account liberalization and fixed exchange rate regime, interest rate depends in fact on the interest rate in a country to currency of which union’s currency is pegged.

In such circumstances interest payments for the debt outstanding can not be influenced by any means by fiscal authorities at the domestic level.

GDP growth rate is very important because it allows for relaxing constraints in nominal terms. However, there is a threat that fiscal authorities would attempt to inflate out the public debt and this way avoid fiscal adjustment to meet convergence criteria. Another way to avoid compliance with fiscal constraints, recognized already in WAEMU, is creative budgetary accounting. A different way of measuring crucial fiscal variables results in business cycle divergence that is most undesired among monetary union member countries.

In the paper a framework for measuring fiscal convergence criteria influence on fiscal policy flexibility is developed. It could be used for evaluating different sets of fiscal convergence criteria, as well as their different levels when considering multilateral surveillance reforms. The methodology would be applicable in the process of creating new monetary unions and designing regional fiscal coordination. It allows for taking into account the current fiscal positions of potential member countries. The limits for fiscal policy should be set at reasonable levels. With too high fiscal adjustments needed – creative budgetary accounting is sometimes employed by member states and fiscal convergence fails. The framework developed in this paper allows also for designing fiscal convergence criteria and their levels according to monetary union well-being in the long run. There is however still the opened question of the optimal set of fiscal constraints to be implemented.

## **Abstract**

*The realization of the aim of structural and regional policy in the European Union is based on the banks participation. It can be reached by offering long term loans, bridge loans, which can be used to span the temporary shortage of the financial sources, occurred due to the time lag between the debtors' payment of the valid expenses to the creditors and receiving finance sources from EK. It can be reached also by the combination of these loans. The existence of the banks in the process of using financial sources from structural and cohesion fund has its own place in case of project preparation, giving in the application for the project, project adoption by supervising institution, and project coordinating and control.*

**Keywords:** *structural funds, cohesion fund, long term loan, banks, pledge*

## 1. Introduction

At first the financing of the environment protection was the domain of green funds. However, later the banks were involved to the financing process so the environmental ranking enters to the valuation of the commercial banks and insurance companies' loan and investment policy. Due to these circumstances in the 1991 from the initiative of UNEP was found UNEP's Financial Services Initiative, and in 1994 the UNEP Statement on Environmental Commitment of the Insurance Industry. At this stage the banks in developed countries in the client analysis consider also its environmental behavior and joint risks. In recent days the bank credibility analysis of client includes also environmental risks.

## 2. The banks and the environmental risks

In the bank analysis the environmental investments are not accounted as a company expense which decreases its competitiveness but in further circumstances this investments ensure the higher competitiveness on global markets. The environmental character of the company is being enlarged by the new dimension - the system of the environmental management. The companies which are applying this system are in the banks consideration asses as the trustworthy companies with the bright management structure. At this stage it is worth to say that in the recent years the insurance companies increased their interest in the environmental risk assessment due to the dramatically rise in the insurance payments for the damages caused by environmental disasters.

In the recent years the pioneering organizations in the financing of the environmental projects are international financial institutions.

The *World Bank* as the first international institution begins with obligatory assessment of the environmental projects. According to this fact it works out the handbook of the environmental assessment procedure.

The *European Bank for Reconstruction and Development* (EBRD) in the establishment process was given the mandate "to provide the complete support to environmentally acceptable activities". These activities should be focused to meet all the national environmental standards and the EU standards. There are mostly the environmental infrastructure projects i.e. building the water pipes and sewages, waste water treatments, disposal places, energy saving implements, and urban transportation systems.

The *European Investment Bank* requires involving environmental aspects to the all phases of bank financed projects i.e. the bank finance only the projects which satisfy all the economical, environmental and technical criteria.

We can assume that in the most prominent banks the environmentally and socially responsible investment behavior is the component of their image. However it is not the main stream of banking. This statement was confirm by the study which was held by UNEP where from 177 of inquired banks only 31% has the environmental oriented products. At least one half of the banks do not monitor and asses the environmental risks. On the question how further, 88% of them answered that they will involve the environmental risk consideration in the next 15 years. Banks assume the consideration will mainly focus on energy and recycling issues.

In the circumstances of the increasing indirect negative financial impact on the financial environment (energy severe, waste) effected in the situation when, in Germany, the environmental management systems spread also in the bank sector. This is inspiring also for Slovak republic.

Only for completeness, the issue of the impact on the environment is also in the consideration of the stock markets. Due to this the Committee for the Stock in the USA calls for the need of higher commitment in the environmental issues especially in the environmental reporting. It emphasis, that the environmental responsibility has the nature, than only by the overall information we can reach the spirit of non misleading and truly informing financial reports. The aim is the early recognizing of threatening environmental loses.

### **3. The bank associations supporting the environmental protection**

The procedure of environmental protection flow in to establishment of the bank associations. For example in 1994 in Bonne there was the foundation of Association for Environmental Management in banks, saving and insurance companies. The aim of this association is to initiate the exchange of the experience and opinions on the environmental issues. This association was the first which had above mentioned aim. The membership in this association can get only the banks, saving and insurance companies. The association regularly held the courses, where the banks and the other institution often discuss about the environmental issues, because their trading

activities are often accompanied by environmental risks and they have to respond by applying the sophisticated strategy.

The American Bankers Association was established in the USA. The members of this association have adopted the philosophy that predicts the prosperity of the banks only in the case of bank servicing markets prosperity. The markets, according to banks opinion, would not be prosperous if they waste and badly manage the sources they existence depends on. Due to the expectation of the Association the 75% of all American banks at the begging of the 1990 considered the environmental risks in the loan granting procedure.

#### **4. Engagement of the Financial Institutions in SR in the financing of the projects supported from EU structural funds**

The gain of the EU financial sources creates the possibility for the Slovak financial institutions to share on financing of the chosen projects. Banks in these circumstances can provide following services:

- Expert advisory and complex services initiating by filling up the application form for the financial contribution, continuing by the preparation of the project that meets the EU requirements and finishing in the fore financing of the project accompanied by the expert advisory
- The client orientation in EU project
- Work out the project financing model
- Draw up the documents fulfilling the requirements of executing bodies – indicative declaration about preparedness for project co financing and binding credit link
- Selecting and adjusting the client needs according to special bank products
  - Bridge loan
  - Investment loan
  - Banker's guarantee

##### ***4.1. Bank credit procedures***

In the credit transaction process related with the project co financing from the EU financial sources there is the possibility to apply standard methodic procedure, which involves credit process and providing the credit transactions.

*Acquisition activity* in the euro financing procedure is performed not only by the employee of the banks but also by the employee of the consultancy and advisory companies cooperating with bank. At this stage it is important for the employees of the bank to find the clients – borrowers and persuade them about the ability of the bank to support their project in terms of co financing and advisory. Successful acquisition is the first step in building relationship with client and developing other common business activities.

*The advisory* is provided to the client by the credit officers in the scope of basic information about EU funds financial recourses drawing possibilities, the operating programs, priorities and regulations, bank procedures according to governing body and also actual information about existing and new appeals announced by governing bodies.

*Banks and documents relating to euro fund financing*

In the initial stage of the euro financing procedure bank issues indicative statement for client that is required by the governing bodies to approve financial recourses for the project. Client asks the bank to issue the statement in writing. The indicative statement is issued by the bank after preparing the initial rating of the client (only financial risk). For preparing the rating the client has to submit standard records (financial statements), in case that bank do not have them.

Indicative statement is for the bank non committal and it declares the banks ability to cooperate in project co financing assuming the fulfillment of the standard conditions for bank stipulated loan terms.

*Binding credit link – the contract on the future contract on loan* – the condition term its opening is approved client project by the governing body and submitting of the acknowledgement to the bank. The binding credit link procedure is similar to loan transaction process.

*The application for opening of the credit link* – the contract of the credit link is the same to standard procedure except information necessary for grant application. With application form the client enclose the grant application and project and other documentation specified in loan repayment assessment ability.

*Open binding credit link proposal – settlement of credit transaction* is processed by credit officer in standard procedure. If the processor in the proposal states also the conditions, according to which the contract with

client can be settled, it is not necessary to hold the other credit transaction approval procedure.

*On the spot check* – prior to processing the application it is necessary for the banks to do on the spot check. Following check are necessary also during the realization of the project at least quarterly. Above mentioned procedure is due to strict rules applied by EU and breaking of these may result in grant withholding during the realization and also after finishing the project.

*Clients own sources* – in case of investment loans, mid term or long term it is necessary to bind the client in order to get client financial participation on the project. Client's participation depends on the assessment of the business plan and it should be in scope from 5% up to 30% in dependence on the duration of his business.

#### *The limits of commitments*

In the loan transaction assessment process it is necessary to define the limits of commitments on clients. These depend on character of financing – i.e. firstly the credit financing of client's project, next refundment of the eligible costs from the EU grants. The bank wants to know if the client is able to repay the loan without getting EU grant contribution. This situation can occur also in the case of vital and high quality project.

#### *Shortening of approval procedure*

There is the great possibility of occurrence the time stress in the EU co financing process between the time for submitting the project and time of getting the necessary documentation from banks (approximately 4 -6 weeks) so it is important to shorten the banks approval procedure. In means it is necessary to shorten the time for performance all the activities defined in the approval procedure from acquisition to the realization of the transaction and signing the contract on condition that the quality of the procedure will be kept.

#### *Contractual documentation*

The signing of the loan contract is under the condition to submit to the bank the governing body confirmation about its amount of the contribution and the whole amount that is necessary to get by client.

#### *Loan drawdown*

The drawing of the loan is performed according to general procedures and after complying with the loan terms. The specific terms in euro financing are:

- To submit the contract with governing body about granting the financial contribution
- opening the separate accounts for contribution from EU and from state budget

#### *Grant drawdown*

The finance contribution will be paid by installments after client will approve the initiating the realization of the project and he starts to spend money. The first payment request has to be given within 4 months from the date of approving the grant. After this the grant is paid in installments, the client has to submit the realization report and grant payment application form supported by documents approving eligible costs (invoice). The application forms are checked by government body and submitted to financing institution – in order to do a payment.

#### *Loan repayment*

Loan is repaid:

- from clients own sources
- form EU grants
- from the State budget.

### **5. The cooperation of the governing body and bank in the Euro funds financing**

The whole preparation, financing and realization process of the projects from the EU funds is build up on stages entered subsequently by client, bank, governing body or mediator and financing institution. The procedure is following:

Client who applies for the EU fund financing sources is obliged to document financial sufficiency for project realization to governing body. Besides own financial sources there are also sources from EU and from state budget. In case of insufficiency of own sources the client has to right to ask the bank for pre financing loan or co financing loan.

- Indicative statement of a bank agreement to co finance the project is a part of the financial grant application if the governing body asks for
- In case of project approval confirmation of the governing body is produced. This enables client to continue in the project realization (selection of suppliers by public procurement). At this stage bank should issue binding credit link.

- After public procurement procedure the client notice to governing body the results of the competition and the costs of the project. The governing body asses the costs of the project and decides about the high of eligible costs and defines the contribution amount to the project. That the confirmation about the high of contribution and the necessary high of own client sources is issued. According to this confirmation bank conclude the credit contract with client (also the pledge contracts).
- After submitting the credit contract to the governing body the contribution contract is signed. This contract is submitted to the bank, bank allows loan drawn (based on fulfillment of all loan drawn conditions).
- The process of the loan drawn and refundation:
  - ⇒ The client begins to draw the loan according to the terms and conditions in the credit contract crediting the suppliers account. He has to have documentation from his suppliers. The purpose of the credit has to be checked consistently. The bank noticek the governing body about the loan drawing and the amounts of draws.
  - ⇒ The client ask the governing body for a payment according to the contract for providing non-recurring financial contribution
  - ⇒ The governing body checks the eligible costs and after costs aproval submits the application to financing institution
  - ⇒ The financing institution performs preliminary financial check of the client payment application, and after application aproval by this institution, the money are transfer to special bank account of the client.
- The project financing procedure is as follows:
  - ⇒ Firstly client has to invest his own financial sources, that can get by credit
  - ⇒ Then the state budget financial sources are drawn
  - ⇒ Finally the EU fund financing
- The close cooperation of the bank with governing body, financial institution and client is in the EU fund co financing process inevitable.

## 6. Conclusion

In the recent years the bank system begins to consider environment protection need as the part of co financing process. The most popular arrangements in environmental protection are use of the environmental management systems (EMAS). The exploitation of the EU fund financial sources expects the close cooperation of the banks and:

- Investors – the money recipient,
- Governing body,
- financing institution.

In this process the bank accompanied the client in all stages: during the preparation, realization and financing of the project. The scope of the services provided involves the expert advisory, preparation of the project, working out the model of project financing, producing the documents about co financing ability, binding credit link. The selection and adjustments to the client needs can differ in individual banks, according to individual needs and bank abilities.

Unsolved problem in the structural and cohesion fund financing procedure is the issue of the pledge. The solution of this problem in the SR is advantageous for the banks.

## **Abstract**

*European Union had been created by states with dissimilar economic level. Differences among particular regions are the backwash of cultural, historical, geographical and other differences affecting various income level in particular regions. EU attends considerable attention on regional a structural policy what is testified by increasing part of funds given to achieving regional policy aims. Regional and structural policy primary aim is elimination differences in economic level and rate of unemployment in particular regions. Terms of Structural funds and Cohesion fund deriving are changing in connection with European Union enlargement. The aim are achieving convergence and increasing competitiveness in EU member states. Filling regional and structural policy aims will depend on volume and timely granting funds which particular regions will receive.*

**Keywords:** *European Regional Development Fund, European Social Fund, Cohesion Fund*

## **1. Introduction**

One of the basic objectives of regional and structural policy of the European Union (the EU) is elimination of economical differences between member states that are inevitably caused by cultural, historical, geographical, and other discrepancies between member states. Also increasing share of the EU budget spent on diminishing the regions differences shows the significance of the regional and structural policy of the EU. The share on total budget for the financing period 2000 – 2006 is more than 30 %. Problem of heterogeneity in the EU always come to question and is important issue whenever enlargement was on and higher form of economic integration came (creation of internal market and then the monetary union).

## **2. Financing the regional and structural policy**

Achieving objectives stated by regional and structural policy requires financial resources that come from structural funds and Cohesion fund and that depends on particular objectives of the regional policy. Concerning structural funds, the greatest amount of resources comes from the European Regional Development Fund (ERDF). This fund was established to promote and finance economical and social cohesion through lowering of regional disparities and through the share on reconstruction and development of various EU regions.

Concerning the amount of financial resources, the European Social Fund (ESF) is the second largest fund in regional policy. Main areas that this fund promotes and finances are promotion of unemployment prevention measures, human resources development, equal opportunities for men and women, development of economic and social cohesion.

The third of the structural funds is the European Agricultural Guidance and Guarantee Fund (EAGGF) that is divided into two main sections. These sections are guidance section and guarantee section. Concerning structural funds, only guidance section is a part of the funds that currently comprises approximately 5 % of financial resources of this fund. These resources finance mainly regional policy objectives in the area of rural promotion.

Finally, the last one among the structural funds is the Financial Instrument for Fisheries Guidance (FIFG) that was created to promote and support the fisheries sector, connected industries and marketing for the fish industry products.

In connection with the monetary union creation was also the Cohesion Fund established (CF). It serves as a promotion instrument for member states that are economically lagging behind. It is also used to finance and promote the projects concerning environment. These projects should help to achieve the goals stated and declared by the EU common policy in this area. The Cohesion Fund also helps to finance the projects in the area of transport infrastructure.

New member countries (candidate countries before) that entered the EU in May 2004, were given financial resources prior to the accession through these instruments:

1. **PHARE** – to promote the strengthening of institutional structure, to promote the participation of candidate countries in the EU programs, regional and social development, industrial reconstruction, and small business.
2. **ISPA** – transport infrastructure development and environmental protection.
3. **SAPARD** – agriculture modernization and rural development.

For the New Member states, 2004-2006 is a transitional period which will allow them to become accustomed to managing Structural Funds in accordance with the current rules. They will receive support from those Funds totaling 21.8 billion euro. The measures will concentrate on a limited number of priorities: infrastructure, human resources and productive investment.

### ***2.1 Regional Policy Objectives in 2000 – 2006***

There are three objectives realized through current budget period:

**Objective 1** – this objective was established to help and promote the regions lagging behind. Their GDP per capita is below 75 % of the EU average. Also the less populated regions (French overseas territories, Madeira, Canaria Islands, Azor Islands) that are below 75 % average are supported. This objective is financed through all of the structural funds – ERDF, ESF, FIG, EAGGF guidance section.

**Objective 2** – this objective is aimed at regions where economic and social changes are prevailing in the industry and service sectors, declining rural territories that are subject to economic difficulties caused by economic activity decreasing. This objective is also concerned with the territories and regions dependent on fishing that undergoes through depression phase. This objective is financed through two of the structural funds – the ERDF and ESF.

**Objective 3** – concerning the support in this objective, the intent is to develop activities focused on human resources mainly through the ESF. This objective is chiefly aimed to support the member states in the area of adapting to and modernization of educational systems, professional training, and employment.

The greatest amount of financial resources is allocated in Objective 1. There is, however, condition that states that no region in member states that profits from the support under the Objective 1 can make use of the other two objectives.

Besides the support from structural funds, there also is a possibility to receive the financial resources through the EU Initiatives. There are 4 Initiatives financed in the period 2000 – 2006:

- **INTERREG** - is an initiative aiming to stimulate interregional cooperation in the EU to achieve balanced and sustainable development in the EU (this initiative is financed under the ERDF).
- **URBAN** – initiative aimed to support the economic and social regeneration of cities and urban districts that undergo the crisis (this initiative is also financed under the ERDF).
- **LEADER** – aimed to rural areas and their development (this initiative is financed by guidance section of the EAGGF).
- **EQUAL** – transnational form of cooperation aimed to fight against all the discrimination forms in the labor market.

## ***2.2 A revised Regional and Structural Policy for 2007-2013***

Financial period for the years 2007 – 2013 will be accompanied by the reform of structural and regional policy. This reform will be focused on changing the rules of structural funds using. Basic principles of the regional policy – perennial programming, partnership, cofinancing, evaluation and complementarity – shall not be changed in the next financial period.

According to proposed changes, the European Commission plans to implement the principle of one fund that should prevent using the financial support from more than one fund for the same operational program. Other changes that should be realized are more frequent and more extensive controls focused on drawing of structural funds resources for big projects and simplification of the programming documents system.

The basic document that will state and define the supportive framework of the EU for years 2007 – 2013 through structural funds and Cohesion Fund is the Community Strategic Guidelines for Cohesion. The very first proposal of certain changes in regional policy was revealed in

February 2004 by the European Commission. Each member state is required to adopt this document to National Strategic Reference Framework that is supposed to join priorities on the EU level with the priorities on national and regional level. Ministers for regional policy from member states agreed in the meeting in May 2005 to priorities of the EU in the area of regional policy. They also agreed to support the strategic guidelines from the EU in case they allow for the varieties of different regional needs and that will be flexible enough for member states to state their own priorities according to particular strategic objectives. Many of the member states required greater emphasis on social aspects while stating priorities through the EU regional policy.

National Development Plan approved by the Commission, should be replaced by new type of programming document – National Strategic Reference Framework. Each member state is required to inform about the NSRF the Commission. NSRF should postulate national strategy according and aimed to achieve the three objectives: convergence, regional competitiveness, and employment.

Simultaneously with the preparation of legislative framework at the EU level began the preparation of national documents at the member states level. These documents will provide the basis for drawing the resources from structural funds and Cohesion fund. Priorities of individual member states will be proposed and stated in the operational programs. The main difference concerning current and future operational programs is that there will be no program amendments in the future operational programs. However, prior to submitting the National Strategic Reference Framework the whole financial framework and allocation of the resources for each member state must be approved.

Concerning the financial period 2007 – 2013, there is € 336.1 billion planned for regional policy. Financial resources assigned to regional policy will be distributed according to fulfillment of three new priority objectives:

- Convergence
- Regional Competitiveness and Employment
- European Territorial Cooperation

The first priority – **Convergence** – will be focused on helping the regions where GDP per capita is less than 75 % of the EU average. This priority is actually identical with current Objective 1. Most of the new member states will be supported under this priority. There is also assumption that interim and specific support of descending form will be provided until 2013 for regions where GDP is over 75 % of the EU average as an outcome of statistical effect caused by the EU enlargement in 2004.

National and regional programs co-financing will be oriented to modernization and diversification of regions economic structures, to protection of environment, to improvement in institutions on labor market and to improvement of education systems. Structural funds that will co-finance these activities are: ERDF, ESF, and CF. Financial support from the Cohesion fund will be provided to those member states where GDP per capita is less than 90 % of the EU average.

From the whole sum of € 336,1 billion, the greatest amount will go to the achievement of this priority - € 264 billion or 78%. The structure for allocation is as follows:

- 67,34 % for regions with GDP per capita less than 75 % of the EU average
- 8,38 % for regions influenced by statistical effect
- 23,8 % for regions that draw resources from Cohesion fund
- 0,42 % for peripheral areas (Azor Islands, Madeira, Canaria Islands, particular French overseas territories)

Concerning the second priority – **Regional Competitiveness and Employment** – it will promote two basic goals outside the territory of the most disadvantaged member states. The first goal includes regional programs as support in economic changes in industrial, urban and rural areas. The second goal is focused, through national programs, on helping the people during their adjustment to economic development according to the priorities of European Employment Strategy. Also the support of employment policies, labor productivity, and social integration are included.

Concerning this priority, only those regions that are not included under the Convergence priority will be eligible for drawing up resources through this priority. Regions that are entitled for the support from current Objective 1 but will not be eligible in 2007 to draw up resources from priority Convergence because of their economic progress, will receive until 2013 specific and interim support through this priority in descending form.

This priority will be financed by ERDF through national development programs and by ESF according to the European Employment Strategy.

From the whole amount of the funds for 2007 – 2013, the sum of € 57,9 billion or 18% is allocated for this priority. The structure is as follows:

- 83,44 % for regions that do not draw finances under current Objective 1
- 16,56 % for regions in transition phase

The third priority of the EU regional policy in period 2007 – 2013 is the **European Territorial Cooperation**. This priority is supposed to follow the current INTERREG Initiative. This priority actually means the continuity of integration policy in the EU territory. This priority is supposed to be achieved by supporting of cross-border and transnational cooperation. Cross-border cooperation includes all the regions that neighbor with outer or inner borders on the land or in the sea. Besides it should also help and support the cross-border cooperation under the European Neighborhood Policy, partnership and pre-accession instruments. All of these should replace the current programs – PHARE, ISPA, SAPARD, TACIS, MEDA, and CARD.

There is a sum of € 13,2 billion for this priority which is 4 % of the total sum of € 336,1 billion allocated for regional and structural policy. The distribution of these resources is as follows:

- 47,73 % for cross-border cooperation, from which 35,61 % is allocated for cross-border cooperation on the EU territory and 12,12 % for the European Neighborhood Policy and Pre-accession Instrument
- 47,73 % for the area of transnational cooperation
- 4,54 % for European cooperation and exchange networks

Responsibility and control while drawing up the money from structural funds and Cohesion fund should be moved from the EU level to national level in member states. Regional policy in the future should be financed only through 3 funds – ERDF, ESF, CF. Commission initiatives URBAN and EQUAL should integrate into the operational programs priorities in member states or regions. Operational programs should be financed only by one fund, either ERDF or ESF. There will be an exception, however, concerning infrastructural programs where ERDF and Cohesion Fund should work together.

### **3. Conclusion**

Expenditures on regional policy in the EU will depend on approved financial framework for period 2007 – 2013. Concerning this financial perspective for the future period there are many controversial issues and different positions from member states. The Commission proposed in 2004 budget expenditures to average at 1,14 % GNP of the EU. Some of the member states (Germany, France, great Britain, Netherlands, Sweden) on the other hand propose freezing the expenditures at 1 % GNP of the EU. This evokes the fears in the Commission that lowering the expenditures will not help to achieve all the goals and priorities that are stated in new regional policy for period 2007 – 2013.

Another problem issue is the agreement in former EU-15 that was adopted before the enlargement in 2004 and that is concerned with the freezing of the expenditures on agriculture. Thus it is probable that in case of expenditures decreasing from the common budget, it will not be on behalf of regional policy. Late political agreement concerning the financial period 2007 – 2013 will probably delay the funds drawing which will affect mainly new member states.

The positive effect for member states from regional policy can be disrupted by the principle according to which no member state can draw up money in one year from all the funds that will amount for more than 4 % of member state GDP. This ceiling can potentially limit mainly the small economies in new member states.

## **Abstract**

*Slovakia became, together with other Central and East European countries, a part of the European Union in May 2004. Now as a full member state with all the rights it is possible to make use of the structural funds created to help poorer regions of the Union. In order for the member states of the European Union to use structural funds it is necessary to create a series of documents. First of all is the National Development Plan which is the basis for receiving the money through the structural funds of the European Union.*

**Keywords:** *NDP, Slovakia, EU, structural funds, regional policy*

## 1. Introduction

One of the principles the European Union (EU) is found on is the principle of equality. Equality among the states, but what is more important, equality among the different regions of the EU. Since the creation of the European Communities in the 50s in the 20<sup>th</sup> century, there are many differences between particular regions of member states of the EU. Before the enlargement that took place in 2004, the poorest regions of the EU were located in Greece, Spain and Portugal. After the enlargement, there are even more regions entitled to receive the support from structural funds. Despite rapid economic growth in new member states, they still face wide regional disparities and inequalities both in income and in wealth. For example, Bratislava, the richest region in Slovakia is 20 % above the EU average. On the other side stand the regions of Prešov and Košice, the poorest regions in Slovakia, with only 39 % of the EU average. Concerning the poorest EU regions, 10 poorest regions are located in new member states. Out of these 10 regions, six are located in Poland, including the EU poorest region - Lubelskie.

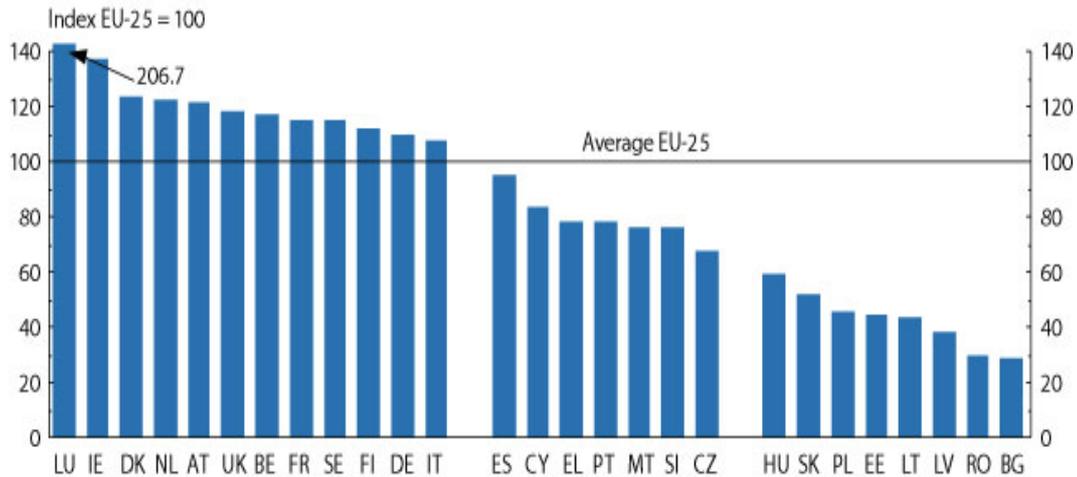

**Table 1 Ten Poorest Regions in the EU**

<i>NUTS 2 Region</i>	<i>GDP p.c. €</i>

Source: [http://europa.eu.int/comm/regional\\_policy/intro/working3\\_en.htm](http://europa.eu.int/comm/regional_policy/intro/working3_en.htm)

The EU helps regions that are behind through the regional policy. Regional policy is based on other principle of the EU – principle of solidarity between the member states. This also includes financial solidarity between prosperous members whose contributions to the budget of the EU go to less prosperous regions of the Union. Prior to the 2004 enlargement transfers between wealthier and poorer regions for the period 2000 – 2006 should account for one third of the EU budget at 213 billion €. Out of 213 billion € 195 billion should be spent by the four structural funds and 18 billion by the Cohesion Fund.

There are four structural funds that help through regional policy to eliminate the regional disparities among the EU regions:

1. European Regional Development Fund
2. European Social Fund
3. Financial Instrument for Fisheries Guidance
4. European Agricultural Guidance and Guarantee Fund.

94 % of structural funding focuses on the following priorities:

- **Objective 1** Helping regions whose development is lagging behind to catch up - 70%
- **Objective 2** Supporting economic and social conversion in industrial, rural, urban or fisheries dependent areas facing structural difficulties - 11.5%
- **Objective 3** Modernizing systems of training and promoting employment. Measures financed by Objective 3 cover the whole Union except for the Objective 1 regions, where measures for training and employment are included in the catch-up programs - 12.3%

There are also four initiatives seeking common solutions to specific problems. They spend the rest of the funding on:

- **Interreg III** Cross-border, transnational and interregional cooperation
- **Urban II** Sustainable development of cities and declining urban areas
- **Leader +** Rural development through local initiatives
- **Equal** Combating inequalities and discrimination in access to the labor market

The structural funds finance multi-annual programs which constitute development strategies drawn up in a partnership with the regions, the member states and the European Commission. The main objectives of the programs are to:

- develop infrastructure, such as transport and energy
- extend telecommunications services
- help firms and provide training workers
- disseminate the tools and know-how of the information society

In addition to the structural funds, there is the Cohesion Fund, which provides direct finance for specific projects relating to environmental and transport infrastructure.

During the pre-accession period ten Central and Eastern European candidate countries received millions euros in EU development aid under these instruments:

- **PHARE** To improve institutions, administrations and public bodies to ensure the correct application of EU law and to assist new investments in the social and economic sectors
- **SAPARD** To support the efforts to join the Common Agricultural Policy

- **ISPA** To finance the construction of large projects in environmental protection and transport.

Currently, the enlarged Union is divided into three main groups:

- 8 new member countries with the lowest income per capita with 20 % of the EU population but only 42 % of the GDP p.c. – Czech Republic, Hungary, Estonia, Latvia, Lithuania, Malta, Poland, Slovakia
- 5 member countries (old and new ones) with 13 % of the EU population and average 71 % of the GDP p.c. – Cyprus, Greece, Portugal, Slovenia, Spain
- 12 remaining old members with 66 % of the EU population and 115 % of the GDP p.c.

## **2. EU Regional Policy**

As mentioned in the introduction, the EU regional policy is policy that promotes solidarity. Regional policy allocates more than one third of the budget of the EU in order to reduce the gaps in development among the European regions and disparities among the citizens. The Union is aimed to three objectives that seek to help the poor regions to catch up with wealthier regions of the EU.

The preamble of the Treaty of Rome, which was signed in 1957, set the basis of what is today known as the EU regional policy: “to strengthen the unity of their economies and to ensure their harmonious development by reducing the differences existing between the various regions and the backwardness of the less favored regions”<sup>1</sup>. One year later, in 1958, two funds were set up – the European Social Fund and the European Agricultural Guidance and Guarantee Fund. In 1975 the European Regional Development Fund was created aimed at redistribution of part of the Communities budget to the poorest regions. The Maastricht Treaty which came into force in 1993 designates cohesion as one of the main objectives of the Union. It also established the Cohesion Fund that promotes projects in the field of transport and environment in the least prosperous member states.

### ***2.1 Structural Funds and Cohesion Fund***

At present, there are four structural funds that enable the EU to grant financial assistance to less developed regions in the member countries:

---

<sup>1</sup> <http://www.bmdf.co.uk/rometreaty.pdf>

1. **European Regional Development Fund (ERDF)** – created to promote economic and social cohesion within the EU through reduction of disparities between regions and social groups

2. **European Social Fund (ESF)** – created as main financial instrument promoting the strategic objectives of the EU employment policy

3. **Financial Instrument for Fisheries Guidance (FIFG)** – created to promote the structural reforms of the fisheries sector

4. **European Agricultural Guidance and Guarantee Fund (Guidance Section) (EAGGF)** – created to promote the structural reforms of the agricultural sector and to promote the development of the rural areas in member states

Concerning the objectives and initiatives under the EU regional policy, each fund is eligible to finance following:

**Table 2 Financing the Objectives and Initiatives**

	<i>Objective 1</i>	<i>Objective 2</i>	<i>Objective 3</i>	<i>Interreg III</i>	<i>Urban II</i>	<i>Leader +</i>	<i>Equal</i>
<b>ERDF</b>	X	X		X	X		
<b>ESF</b>	X	X	X				X
<b>FIFG</b>	X						
<b>EAGGF</b>	X					X	

Source:

[http://www.europa.eu.int/comm/regional\\_policy/funds/prord/sf\\_en.htm](http://www.europa.eu.int/comm/regional_policy/funds/prord/sf_en.htm)

**ERDF** is mainly used to co-finance productive investment leading to the creation or maintenance of jobs, infrastructure, and local development initiatives and business activities of small and medium enterprises. It covers almost all the development areas such as transport, energy, communication technologies, environment, research and innovation, rural development, conversion of industrial sites, tourism, culture, fishing industry, and so on.

**ESF** aims to prevent and combat unemployment and to developing human resources and their integration into labor market. It aims to most endangered social groups – long-term unemployed, young unemployed, persons excluded from the labor market, improving the access of women to labor market. ESF also focuses on improving education and training systems, promoting skilled workforce and boosting human potential in the field of research and development according to the Lisbon Strategy.

**FIFG** seeks to contribute to achieving a sustainable balance between fishery resources and their exploitation. Also it tries to strengthen the fishery sector competitiveness. Main areas of interest include fleet modernization, aquaculture development, marine areas protection, fishing port facilities, processing and marketing of fishery products.

**EAGGF** supports rural development and improvement of agricultural structures. It aims to investment in agricultural holdings, aid for setting up of young farmers, aid for early retirement, compensation for less-favored areas, agri-environmental measures, processing and marketing of agricultural products, development and utilization of forests, encouraging for tourism and craft activities, and so on.

**Cohesion Fund** is a special fund designed to help the least prosperous member countries in the EU. Currently, its funding goes to the 10 new member countries and to 3 old ones – Greece, Portugal, and Spain<sup>2</sup>. The main criterion is that the GNP per capita of particular country is no greater than 90 % of the average of the EU. Cohesion Fund helps member states to reduce economic and social disparities and to stabilize their economies. It was first introduced in 1994. The fund finances up to 85 % of all eligible expenditures of a certain project. Projects must cover two main areas: transport infrastructure and environment.

The EU provided more than 28.21 million € for the Fund. For 2004 - 2006, there is 15.9 million € available, out of which 8.49 million is reserved for new member states.

## ***2.2 Objectives and Initiatives***

All objectives and initiatives of the European Union are financed through the structural funds (see table 2). All of these are financed in both old and new member countries of the EU.

There are three main objectives regional policy works with as mentioned in the introduction.

**Objective 1** is the main priority of the EU cohesion policy. In accordance to the Treaty of Maastricht, the Union promotes harmonious development with special focus on eliminating the gap between various regions of the EU. Currently more than two thirds of structural funding is allocated to this kind of regions where the gross domestic product (GDP) is below the 75 % of the EU average. All regions eligible for funding through Objective 1 have similar economic indicators such as low level of investment, lack of services either for individuals and business, poor

---

<sup>2</sup> Until 2003 also Ireland was eligible.

infrastructure, and unemployment rate higher than the average. Concerning current situation, about 50 regions with 22 % of the European population are covered within period 2005 – 2006. According to the NUTS classification, there are three eligible regions in Slovakia covering 4.7 millions inhabitants: Western Slovakia, Central Slovakia, and Eastern Slovakia. There are two Operational programs that cover the Objective 1 priorities: OP Basic Infrastructure and OP Industry and Services.

**Objective 2** is aimed to revitalize all areas facing structural difficulties – rural, urban, and industrial. Despite the fact, that these regions are close to the Union average, they are faced with various social and economic difficulties that are source of high unemployment. These include decline in traditional activities in rural areas, crisis situation in urban areas, awkward evolution of industrial or service sectors. There is only one region in Slovakia eligible to receive the funds – Bratislava with 3.3 % of the total population in Slovakia.

**Objective 3** is a combination of former Objectives 3 and 4 in the 1994 – 1999 programming period. This objective covers all the territory of the EU which is not covered by Objective 1. It serves as a framework for all measures aimed to promoting human resources in the member states. In the period 2000 – 2006 it focuses on promoting active labor market policies to reduce unemployment, on improving access to the labor market with emphasis on people threatened by social exclusion, on enhancing employment opportunities through lifelong education, and on promoting equality for men and women.

**Interreg III** is an initiative aiming to stimulate interregional cooperation in the EU in the period 2000 – 2006. Interreg III is financed under the ERDF. This is the third phase of this initiative and is focused mainly on strengthening economic and social cohesion in the EU through balanced development of the whole continent. This is carried out by three main strands of Interreg III initiative with total budget of 4.88 billion €:

1. **Interreg III A – cross border cooperation** – aims to the cooperation between adjacent regions through common development strategies

2. **Interreg III B – transnational cooperation** – involves national, regional, and local authorities aim to promote better integration within the EU through formation of large groups of European regions

3. **Interreg III C – interregional cooperation** – aiming to improve effectiveness of regional development policies through large-scale information exchange and sharing of experience

Slovakia is currently involved in Interreg III A - CBC with Austria, Czech Republic, Hungary, and Poland.

**Urban II** is also the initiative of the ERDF for sustainable development in troubled urban districts across the EU for period 2000 – 2006. There are two main objectives of the Urban II initiative: promotion of design and implementation of highly innovative strategies of economic and social regeneration in small and medium towns and declining areas in major conurbations, and reinforcement and sharing of knowledge and experience on regeneration and sustainable urban development in the EU. Urban II is concerned with projects that improve living conditions (creating green areas, renovating buildings), create jobs (in culture, services, and environment), integrate less-favored social classes into education and training systems (Roma minority in Slovakia, though there is no such project in Slovakia financed by Urban II), develop environment friendly public transport, create effective energy management systems and make use of renewable energy sources.

**Leader +** is designed to promote rural actors consider long-term potential of their local region. Leader + has a strong focus on partnership and networks of exchange of experience. The budget for 2000 – 2006 period totals 5.05 billion € of which 2.11 billion is funded by Guidance Section of EAGGF and reminder by public and private contributions. The structure of Leader + is as follows:

1. **Action 1** Support for integrated territorial development strategies of a pilot nature based on a bottom-up approach
2. **Action 2** Support for cooperation between rural territories
3. **Action 3** Networking
4. **Technical Assistance**

Currently, there are 73 programs implemented in EU-15 member countries for 2000 – 2006 period.

**Equal** is, together with all three objectives, financed by the ESF. It is a part of the Union strategy for more and better jobs and also for ensuring that no-one is denied access to these jobs. It began in 2001 as a new way of eliminating discrimination and inequality between those who work and those looking for jobs. The total EU contribution to Equal is 3.27 billion € and is matched by national funding. Responsibility for the implementation of this initiative lies with the national authorities. Currently, there are 101 programs running in Slovakia under Equal.

### 2.3 Financial Support

As it was said, more than one third of the total European budget is devoted to regional development and social and economic cohesion through European structural funds and Cohesion Fund.

For closing period 2000 – 2006, 213 billion € was reserved for all the funds to promote activities and projects in the EU-15. Due to enlargement in 2004, additional 22 billion € was dispatched for the period 2004 – 2006 for new member states. Yet another 22 billion € was spent during pre-accession period. Pre-accession aid continues to flow to two countries that did not become part of the EU during 2004 – Bulgaria and Romania. Total of 257 billion € comprises approximately 37 % of the EU budget for the period 2000 – 2006. Most of the money is being spent through multi-annual programs managed jointly by the European Commission, member states, and regional authorities.

Figure 2 shows the funding of all objectives, initiatives, and Cohesion Fund in financing period 2000 – 2006. There is total 21.7 million € spent on new member countries. The largest amount of money goes to the fulfillment of priorities of objective 1, second largest amount is spent through funding by Cohesion Fund. One can see that there is no funding of the Urban II initiative as well as Leader + initiative.

**Figure 2 Structural Funds Budget for Period 2000 – 2006**

Structural Funds budget		(billion EUR, commitments in 1999 prices)								
	Objective 1	Objective 2	Objective 3	Interreg	URBAN	EQUAL	Leader	Fisheries F.	Cohesion F.	Total
EU-15	137.800	22.040	24.050	4.875	0.700	2.850	2.020	1.106	18.000	<b>213.441</b>
EU+10	13.230	0.120	0.110	0.420	0.000	0.220	0.000	0.003	7.590	<b>21.693</b>
EU-25	151.030	22.160	24.160	5.295	0.700	3.070	2.020	1.109	25.590	<b>235.134</b>

Source: [http://www.europa.eu.int/comm/regional\\_policy/intro/working4\\_en.htm](http://www.europa.eu.int/comm/regional_policy/intro/working4_en.htm)

There is a slight change between the numbers in figure 2 and table 3. It is due to the inflation that is present every year in member states of the EU. Figures in figure 2 are presented in nominal 1999 prices, and figures in table 3 are in 2004 prices.

**Table 3 Aid to New Member States 2004 – 2006 (in million €)**

<i>Country</i>	<i>Objective 1</i>	<i>Objective 2</i>	<i>Objective 3</i>	<i>Interreg III</i>	<i>Equal</i>	<i>Cohesion Fund</i>	<i>Total</i>
<i>Cyprus</i>	0.00	28.02	21.95	4.30	1.81	53.94	113.44
<i>Czech Republic</i>	1454.27	71.30	58.79	68.68	32.10	936.05	2621.19
<i>Estonia</i>	371.36	0.00	0.00	10.60	4.07	309.03	695.06
<i>Hungary</i>	1995.72	0.00	0.00	68.68	30.29	1112.67	3207.36

<i>Slovenia</i>	237.51	0.00	0.00	23.65	6.44	188.71	456.31

Source: <http://www.euractiv.com/Article?tcmuri=tcm:29-12969616&type=Overview>

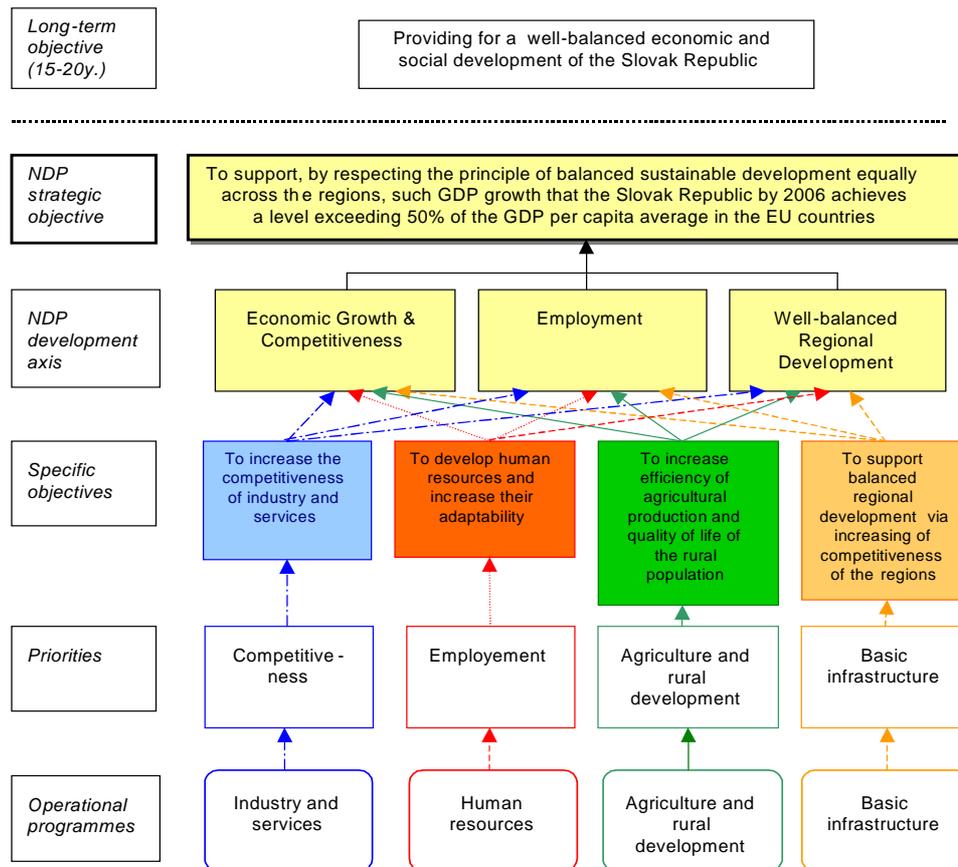

We can see that the greatest proportion of structural funding goes to Poland (12 809.7 million €). Slovakia is entitled to the total amount of 1757.39 million € in 2004 – 2006. The largest proportion of money goes to funding the priorities of objective 1 – 14 959.64 million €. Also there are only three countries eligible to receive funds for fulfillment of the objectives 2 and 3 – Czech Republic, Cyprus, and Slovakia.

### **3. Slovakia and Regional Policy**

Basic programming documents that determine the distribution of structural funds for Slovakia are National Development Plan and Operational Programs. After approval by European Commission, Slovakia in cooperation with European Commission elaborated Community Support framework or CSF. CSF is the basic document, or agreement, concerning the provisions from structural funds of the EU for Slovakia.

The National Development Plan analyses macroeconomic environment, economic, and social situation in Slovakia with emphasis on particular sectors of the Slovak economy. It also comprises the SWOT analysis of Slovakia, as well as main characteristics of individual operational programs. It includes also strategic objective, strategies and priorities necessary for implementation of the NDP. Strategic objective together with priorities of National Development Plan for 2004 – 2006 period are presented in figure 3.

**Figure 3 National Development Plan for 2004 - 2006**

Source: National Development Plan, Amendment

Basic programming documents for Slovakia are: National Development Plan/Community Support Framework, Operational Program Basic Infrastructure, Sectoral Operational Program Industry and Services, Sectoral Operational Program Human Resources and Sectoral Operational Program Agriculture and Rural Development. These documents include the support in Objective 1.

Concerning Objectives 2 and 3 there are separate programming documents of each one of the objectives: for Objective 2 Single Programming Document NUTS II – Bratislava, for Objective 3 Single Programming Document NUTS II – Bratislava. Since priorities of these two objectives are different, there are different managing authorities for these documents in Slovakia. For SPD 2 the managing authority is Ministry of Construction and Regional Development and for SPD 3 is the managing authority Ministry of Labor, Social Affairs, and Family.

There are also strategic documents for the initiatives. For Interreg III there are three Single Programming Documents – Interreg III A, Interreg III B, and Interreg III C. For the Equal initiative there is Single Programming Document SPD Equal.

We can not omit also the Cohesion Fund. There is programming document called Strategy for Cohesion Fund.

According to NUTS<sup>3</sup> classification, Slovakia is divided into statistical units as in table 4:

**Table 4 Territorial Units in Slovakia According to NUTS Classification**

<i>Unit</i>	<i>Number</i>	<i>Territorial Unit</i>
<i>NUTS I</i>	<i>1</i>	<i>Slovakia</i>
<i>NUTS II</i>	<i>4</i>	<i>Bratislava Region West Slovakia Central Slovakia East Slovakia</i>
<i>NUTS III</i>	<i>8</i>	<i>Regions of Slovakia</i>
<i>NUTS IV</i>	<i>79</i>	<i>Districts of Slovakia</i>
<i>NUTS V</i>	<i>2 883</i>	<i>Municipalities of Slovakia</i>

*Source: National Development Plan*

Concerning the Bratislava region, this region is not approved to draw on the aid within Objective 1. Instead, it is eligible for funding of the Objectives 2 and 3 through SPD 2 and SPD 3. The territorial division of units eligible for funding within Objective 1 is presented in figure 4.

### **3.1 Distribution of Structural Funding**

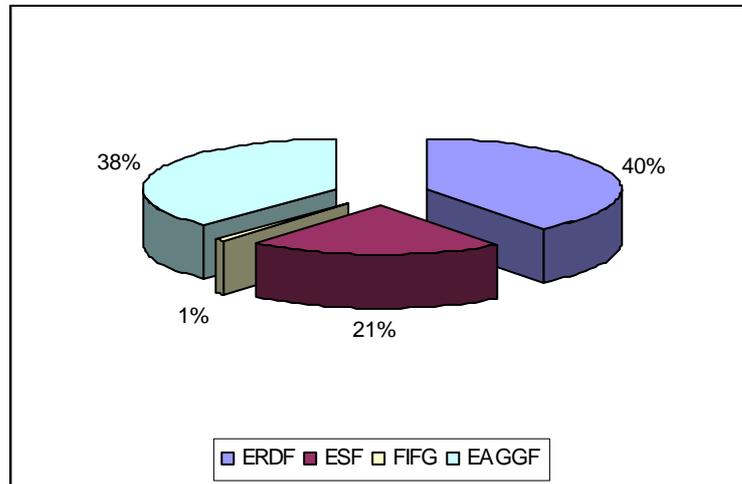

Structural aid in Slovakia in 2004 – 2006 programming period with emphasis on particular objectives, initiatives, and Cohesion Fund is presented in table 3. Total amount of money from structural funding in Slovakia is 1 757.39 million €. Activities undergoing through Cohesion Fund are supported by 570.5 million €. Second largest amount is spent on the Objective 1 – 1 041.04 million €.

Distribution of expenditures by priorities that are set up in National Development Plan is as follows: 40.5 % goes to basic infrastructure, 14.5 %

goes to competitiveness of firms, 27.2 % goes to human resources, and 17.7 % goes to fisheries<sup>4</sup>.

According to the National Development Plan, the distribution of money from particular structural funds is shown in figure 5.

**Figure 5 Proportion of Structural Funds Allocation in Slovakia**

*Source: Authors' Calculation, Data from National Development Plan*

#### **4. Conclusion**

Prior to the accession of Slovakia together with other 9 European countries to the EU, Slovakia benefited in the pre-accession period through pre-accession aid from the EU – PHARE, ISPA, and SAPARD. Since 1<sup>st</sup> of May 2004, the situation has changed. Slovakia is a full member of the EU with all the responsibilities and rights. One of the most important rights is to take advantage of structural funding through which the EU helps poorer regions to catch on with the wealthier ones. This is done through regional policy and its instruments – structural funds. According to the NUTS classification, all of the Slovakia NUTS II regions are eligible for structural funding under the Objective 1 of regional policy except the Bratislava region. However this region is eligible for funding of the Objectives 2 and 3. The total amount of money Slovakia can draw on in the 2004 – 2006 period is

---

<sup>4</sup> [http://europa.eu.int/comm/regional\\_policy/atlas/slovak\\_republic/factsheets/pdf/fact\\_sk\\_en.pdf](http://europa.eu.int/comm/regional_policy/atlas/slovak_republic/factsheets/pdf/fact_sk_en.pdf)

1 757.39 million €. This money should help in the current financing period Slovak regions that are lagging behind to catch up with the rest of the regions of the EU. Or, if not catch up with other regions, at least improve the living standards in our regions and to make them closer to wealthier regions of the EU as it was before. In this, the greatest role plays the regional policy based on the principle of equality among the regions of the EU.

## **Abstract**

*Implementing of the fiscal decentralization in the field of the self-government in the Slovak republic was an important step for the financing the municipalities, for their possibilities of better provision of the local public properties, and also for finishing of the process of the reform of the public finances in accordance to the European Charter of the Local Self-Government. The new method of financing the municipalities and upper-tier territorial units reacts to the changes that were done after passing some competencies from the bodies of the state administration to the territorial self-governments. The fiscal decentralization could be done only in having adequate legal conditions – mainly the new law about the local taxes. After the first year of effect of this law the reality shows that the local taxes has increased severalfold what was not accepted by the tax payers and this calls for the further adjustments of the municipalities financing rules.*

**Keywords:** *Local taxes, local fees, fiscal decentralization*

---

<sup>1</sup> The study was written as a part of the research project conducted within the VEGA scheme 1/0493/03: The Influence of the business environment on the social-economic development of the Prešov self-government region (Vplyv podnikateľského prostredia na sociálno - ekonomický rozvoj Prešovského samosprávneho kraja).

## **1. Introduction**

The reform of public administration belongs to the key system changes that are being realized within the transformation process in the Slovak republic. Its aim is the permanent formation of the modern democratic decentralized state that provides the possibilities for the participation in the public affairs operating to its citizens. The process and the current state of the public administration reform, including its parts – tax reform and the reform of the local taxes have been influenced by different social factors that have markedly influenced the general social development in the country.

Every government that was given a chance by the citizens to realize the necessary changes considered the reform of public administration. None of those governments paid such attention to the reform that it desires. [3] Frequently the political elites, professional groups as well as the representatives of the public administration failed at all its levels. Many of the political nominants leading the individual state offices hobbled the reform process, resp., they acted against the radical reform in the name of political parties they were nominated by. Various domestic and foreign professionals stated that the development in the reform of the public administration until 2002 was not more than a waste of the opportunity. Even despite the fact that many of the partial steps were clear, evident and unforgettable – the reform of the territorial-administration structure, resumption of the territorial self-government at the level of the municipalities and creation of the middle level of the self-government (regional self-government), assignment of the competencies within the frame of the public administration decentralization and the introduction of the tax reform.

## **2. Principles of the fiscal decentralisation and the tax reform**

The year 2002 can be considered as the break-point from the point of reforms in the Slovak republic. In the field of public administration we could see the consecutive shift of the competencies from the bodies of the state government to the municipalities and the upper-tier territorial units. This process was realized according to the law no. 416/2001 of the Code [6] The task of the fiscal decentralization was:

- to strengthen the authority and responsibility of the territorial self-government in decision-making about using the public sources under the self-government bodies – mainly at the local level. It deals mainly with the decision-making about the use of the means gained from the newly introduced local taxes of the municipalities including the

- vehicles taxes at the level of the upper-tier territorial units, but also the shared taxes that are circumvented by the media;
- to contribute to the stabilization of the territorial self-government for longer period of time. Up to that time the financing of the self-government competencies had been every year determined by the law about the state budget for the particular year. Since 2005 the several-years budget is going to be passed and approved. [8] The several-years budget is understood as the medium-term economy tool of the financial policy (of the municipality or upper-tier territorial unit) that in the frame of their activity includes the aims of the territorial development and the local needs of the population for the three budget years;
  - to contribute to more transparent and more rightful disposition of the sources by excluding the subjectivisation in providing the subsidies from the state budget. The financial sources are distributed according to the clear criteria that should be valid and applied to all subjects.

The above mentioned fiscal decentralization deals with the financing of the self- government, original competencies of the municipalities and upper-tier territorial units. Considering the competencies that the municipalities and the upper-tier territorial units perform in the mode of the transferred performance of the state administration, these are still financed by the subsidy from the state budget in the form of the particular chapter of the state budget..

The government of the Slovak republic in its program declaration of 4 November 2002, in the chapter „Economic policy” stated the following aims for the field of taxes:

- to strengthen their own tax incomes of the municipalities,
- to set their own tax incomes of the upper-tier territorial units,
- to make the tax laws more transparent,
- to decrease direct taxes,
- to analyze the possibilities of introducing the direct tax,
- the new system of the horizontal financial compensation,
- to ensure strict, direct, rightful and effective tax collection and to decrease the rate,
- to minimize tax evasion,
- to simplify tax legislation,
- to amend those parts of the tax laws that are the subject of not unified, ambiguous explanation,
- to simplify the vindicatory system in the tax field,
- to consider the possibilities of the unification of the income tax rate,
- the shift of the tax burden from direct toward indirect taxes,

- to reconsider the exercise of the rates of the property taxes,
- to consider the system of the stimulation tax tools for the housing.

The first two aims are directly concerned with the fiscal decentralization and the territorial self-government at the regional level (upper-tier territorial units) and at the local level (municipalities). The rest of the aims are not directly connected with the fiscal decentralization and they deal with the aims of the tax reform. The aims of the above mentioned decentralization had never been elaborated and presented at such level, although the self-governments in the mode of their income base is not less important as it is a part of the same tax reform.

Amongst the most important principles of the tax policy in solving the tax reform belonged the principle of the justice and proportionality; the principle of the neutrality; the principle of exclusion the duplicity of the tax; the principle of simplicity and unambiguity and the principle of effect. Besides the above mentioned general principles of tax policy it is necessary to consider also the following thesis in the formation of the tax system:

- The direct tax of the income should help to fulfill the fiscal aims, and principally it should not be used to fulfill other aims, as e.g. the social policy, structural or regional policy and the economic policy. Introducing the specific tax modes (whatever the reason is) leads towards the increase of the complexity of the tax system, increase of the societal costs to apply it and the increase of the risk of the tax circumvention.
- The tax principles must be realized without regard to the interests, intentions and the aims of the different partial interest groups.
- The unnecessary needs of the state budget will be displayed in the amount of the rates but must not influence the realization of the tax principles.
- The changes in the frame of the tax reform are good to be realized simultaneously if possible and as soon as possible so the tax-payers can experience its advantage sooner and so the new tax system can really function during this electoral period. The first possible term of effect of the new tax laws is 1. 1. 2004. [5]

### **3. Tax reform versus fiscal decentralization**

Enforcement of the fiscal decentralization in the field of the self-government in the Slovak republic was an important step for ensuring the municipality financing, for their possibilities to better provision of the local public goods, but also to round off the process of the reform of the finances

with the European Charter of the Local Self-Government and European Charter of the Regional Self-Government. The new way of financing the municipalities and upper-tier territorial units reacts to the changes that had been realized after transferring some of the competencies from the bodies of the state administration to the local self-governments. The fiscal decentralization could be realized only in the case of ensuring the adequate legal conditions – mainly the new law about the local taxes. The operation of the municipalities in the first year of the validity of this law was as it was expected, i.e. the local taxes and fees were increased several folded what was not accepted with willingness of the tax payers. This evoked the follow-up need to further amendments of the rules of the municipality financing.

Last but one marked reform of the tax system was realized ten years ago under the influence of the serious changes in the economic sphere – shift from the centrally planned economy of the socialistic type towards the market-oriented economy. [2] The tax laws that are valid since 1993 were amended many times, especially with the intention to correct its imperfections. Some changes of the tax laws were also conditioned by the political and other influences based on whose a lot of non-systematic measures penetrated to the tax laws and they gave some groups of the tax payers preferential treatment. The result of this process was a marked complication of the tax law. A lot of exceptions and conditions caused the ambiguity of the laws and consequently it evoked the need to issue further measures or explanations. The next negative phenomenon was that the tax laws were many time suspicious to the tax payers and they lump-sum-“punished” them in advance and most of the tax payers understood it as injustice. Unjust character of some measures in the tax laws at the same time lead to the general tolerance to circumvention and infringement of such “unjust” laws, what is the unwanted tendency of the whole society without dispute. The realization of the process of transferring the competencies from the state administration to self-administration evoked the increased pressure to the deeper and more permanent change of the tax laws. The aim of the recent tax reform was not only the higher level of justice – as it is most often proclaimed aim, but also to ensure the qualified financing of the public goods, that were increased in the process of decentralization. The practical financing lagged behind what was evoking the unwillingness of different subjects of the local and territorial self-government, as well as Združenie miest a obcí Slovenska (Association of the towns and communities) – ZMOS.

In the municipalities’ budgets in their income base there should be one rule valid. The transferred operations of the state administration should have been financed by the state transfer, the originally self-government competencies should have been financed from the local taxes. As the

financing of the public goods in the scope of the transferred competencies was not sufficiently financed, the municipalities were relying on the using of the other source (their own income base), with the use of their own tax incomes. We can unambiguously say that the situation got more complicated especially because of the time disagreement of the transfer of the competencies and the transfer of the finances to the self-government bodies what caused the problems among the main departments of the public administration.

Since passing the basic law that was adjusted the territorial self-government must pass another almost fifteen years till the bodies of the public power started to seriously deal with the issue of the financial decentralization in the field of public administration in practice.[1] In 2004 the new laws about the local taxes and fees were valid already and they should ensure the higher financial autonomy to the municipalities (that they required based on the underfinancing, but also according to European Charter of the Local Self-Government) with the approval of the government. This caused that at the beginning of 2005 people and firms paid for the land, houses, flats, offices or the production halls to some cities several times more than in the period before (the highest increase of the taxes compared to the year before was in one municipality as high as 2 353 %, see table 1). Also, the municipalities set 30-times higher tax to the entrepreneurs than to the citizens. The mostly introduced reasons are that the flat owners and the owners of the family houses create the biggest group of the voters. It is said that this was the reason why the self-governments were more considerate of citizens and the entrepreneurs. In any case, any limitation change we consider to be an intervention that impedes and presents the non-acceptable restriction for the self-governments (right at the beginning of running the new tax system).

The newly appraised adjustment should minimize mainly the extreme increase of the rate mainly in those municipalities whose localization in the social-economic space does not make any rational assumption for such behavior. There was no analysis realized which of the entrepreneurial field was effected by the behavior of the municipalities and/or if they were even effected. The higher real estate tax can decimate only those entrepreneurs that do not use their land and buildings, and they just wait for the appropriate time to sell them or those entrepreneurs whoa are the agricultural subjects in the urban space.

It is interesting to see how the removal of the limitations inspired some of the local assemblies in the rates increases that were firmly fixed until then. Some representatives of the entrepreneurial sector claim that they got into the real economic troubles because of such set down taxes. Such claims

that are also supported by the Ministry of finances should be also supported by the deeper analysis of the reasons but also by the numbers of such subjects to make it objective. However such analysis was not realized till now.

**Table 1 The total yield from the real estate tax in the selected medialised municipalities (in thousands Sk)**

	<i>2004</i>	<i>2005</i>	<i>Increase (%)</i>
<i>Pečeňady</i>	2 085	49 070	2 353
<i>Nededza</i>	137	2 525	1 843
<i>Kalná nad Hronom</i>	6 120	95 600	1 562
<i>Nový Tekov</i>	2 030	27 060	1 333
<i>Veľké Kostolany</i>	2 390	29 250	1 224
<i>Jaslovské Bohunice</i>	9 000	73 140	813
<i>Košice</i>	244 315	450 000	184
<i>Bratislava</i>	556 100	1 122 996	202

Source: MF SR

Probably the most problematic discrepancy is between self-government and the nuclear power station in the municipality Jaslovské Bohunice. The municipality created two tax zones, one for the municipality and the other for the nuclear power plant (table 2), that we introduce in comparison with the capital city Bratislava. We can state that the so-called „zoneness“ in Jaslovské Bohunice seems to be excessive, overblown as the new tax system solves also this one unique problem that directly deals with just two municipalities nuclear facility tax, what lead to possible double taxation (what the reform should be impeding). The amendment of the law does not allow to state different zones for different parts of the cadastral territory even though it is possible to understand the effort of the municipalities to build the sufficient income base for their own development. The anticipated increased yield of the real estate tax should have been the domain of especially the big cities, where the recent tax according to the market values of the real estates is lower than in the small cities or in the country.

**Table 2 Comparison of the rates of the real estate tax (Sk per m<sup>2</sup>)**

	<i>Bratislava</i>		<i>Jaslovské Bohunice</i>	
	<i>centre</i>	<i>other</i>	<i>municipality</i>	<i>Nuclear power plant</i>
<i>Flats and family houses</i>	9	10	1	-
<i>Recreational building and cottages</i>	27	30	4	-
<i>Industrial constructions</i>	81	90	30	500
<i>Constructions for other entrepreneurial activity</i>	112	161	50	500

*Source: Generally binding municipal regulations*

The taxes and fees were set down by the municipalities by themselves for the first time. The realized principles of the fiscal decentralization had the following signs:

- The facultative setting of the tax and the collection of the local taxes by the self-government were introduced,
- the authority and independence of the municipalities was strengthened,
- the rates of the local taxes did not have the set down maximum limit and thus it were the municipalities who made the decisions about the top sum,
- the municipalities can collect not only the taxes but also other payments of the similar character as the local taxes,
- the importance of the generally binding municipal regulations is being stressed and it should be determining in the application of the local taxes in practice. [1]

Currently, the municipalities may impose the following 8 local taxes: real estate tax, dog tax, tax on the use of public space, accommodation tax, vending machine tax, non-gainful (entertaining) slot-machine tax, tax on the entry into and parking of a motor vehicle in a historical part of the city, nuclear facility tax. The regional administration can impose the tax on a motor vehicle. The great media bubble about the local taxes has been already solved by the Financial resort that prepared the draft of the law amendment, although according to the municipalities representatives it was not as dramatic so that the upper limit of the local taxes rate had to be set down. It is necessary to solve just some extremes that are financially insignificant although as to the percents we deal with high numbers. One of the principles of the tax reform says that “tax principles must be realized without regards to the interests, intentions and goals of the different partial interest groups”. It depends only on the point of view what we will understand under the term partial interest group: municipalities or entrepreneurs.

Despite of the unjustified tax rate increase totally, the municipalities did not not increase the real estate taxes unbearably. Local taxes form the share of the expenses of the business subjects (according to the survey of The Business Alliance of Slovakia) only by one per cent. Nowadays, the new law amendment can come in force, and according to it the maximum limit of the real estate tax rate can reach not more than 20-multiple of the lowest year rate.

#### **4. Conclusion**

Even the short effect of the conclusions of the fiscal decentralization and the consequent reform of the local taxes points to the fact that the financing of the municipalities was underdimensioned and thus it leads to an increase of income base of the local taxes, however the financing of the shifted competences from the state administration is being financed insufficiently.

The protest wave of the economic subjects and the citizens against the increase of the own income base of the municipalities does not correspond to the wave of the requirements for higher and higher provision of the local goods and better meeting of the local needs that must be ensured by the municipalities.

From the macroeconomic point of view the realized tax reform is bringing positive effects for the business environment and the self-government space. The selective tax policy that was applied up to that time was based on the advantaging of the certain branches or the types of the business subjects was substituted by the plane tax policy that will create the generally appropriate conditions for entrepreneurship and investments (e.g. by the depreciation policy, longer period of amortization of the tax losses, etc.). The current state of the fiscal decentralization is substantially more transparent, activisating and more modern. It creates the sufficient basis for the own income basis of the municipalities' budgets, thus it is not very appropriate to interfere into the non-stabilized system of the local budgets immediately after the first year of their operation. The found disproportions that evoke the undesirable tax competition could have been solved by the impact of the mechanisms of the public or private markets.

# MEASURE OF CORPORATE GOVERNANCE IN BANKING: A PERSPECTIVE OF FINANCIAL RATIO ANALYSIS

**Esin Okay Örelrer**  
Istanbul Commerce University  
Faculty of Commercial Sciences  
Istanbul  
Turkey  
e-mail: eokay@iticu.edu.tr

## **Abstract**

*The international financial aspect is to establish a reregulation process to prevent potential crises and risks from the financial markets. So the potential target for the settlements is the banking organizations which are very likely to create crises and shocks. Banking International Settlements leading this way is trying to improve corporate governance practices in banking systems around the world and increase the efficiency and transparency of the financial system. Therefore, banks are working to meet the new guidelines with corporate governance initiatives that are so special and important for them. The purpose of this paper is to analyze Turkish Banks' performance which is reflected on their financial statements to provide evidence on the level of corporate governance in the banking sector. There are some financial ratios which are attained to interpret the level of corporate governance in banking (Gürbüz, Erginçan; 2004). The study consists of comparing the results of Turkish banks' ratios before corporate governance principles were implemented with the results of ratios after the implementation. It is carried by a comparative analysis of the total system's financial ratios with the foreign banks' ratios in Turkey. The financial analysis with the comparative analysis highlights the need and the importance to improve the corporate governance in the banking system in Turkey.*

**Keywords:** corporate governance, banking, financial ratio analysis; performance

## 1. Introduction

In the wake of the recent corporate scandals, corporate governance practices have received heightened attention. Shareholders, creditors, regulators, and academics are examining the decision-making process in corporations and other organizations and are proposing changes in governance structures to enhance accountability and efficiency.<sup>1</sup> Corporate governance may be identified as a performance evaluation system which requires restructuring of firms and organizations with risk culture and management, transparency, responsibility and inferiority. It suggests that the firms should be high performers and competitive and provide their stakeholders with highest possible income.

Corporate governance looks at the institutional and policy framework for corporations from their very beginnings, in entrepreneurship, through their governance structures, company law, privatisation, to market exit and insolvency.<sup>2</sup>

There has been a great deal of attention given recently to the issue of corporate governance in various national and international fora. In particular, the OECD has issued a set of corporate governance standards and guidelines to help governments "in their efforts to evaluate and improve the legal, institutional and regulatory framework for corporate governance in their countries, and to provide guidance and suggestions for stock exchanges, investors, corporations, and other parties that have a role in the process of developing good corporate governance."<sup>3</sup>

Recent research suggests corporations that have better corporate governance signal better performance. It has been stated that major contributions of corporate governance to the company include enhancing performance (Boubakri, Cosset and Guedhami, 2003) and preventing fraud (Lee, Yeh, Ko, 2002). According to the research of Black, Jang and Kan (2002), companies with better corporate governance have better performance than companies with poor corporate governance. Although the subject of corporate governance in developing economies has recently received a lot of attention in the literature (Oman, 2001; Goswami, 2001; Lin, 2001; Malherbe and Segal, 2001), the corporate governance of banks in developing economies has been almost ignored by researchers (Capiro and Levine,

<sup>3</sup> OECD, Principles of Corporate Governance, 2004, [www.oecd.org/tr](http://www.oecd.org/tr)

2002). Even in developed economies, the corporate governance of banks has only recently been discussed in the literature (Foerster and Huen, 2004; Macey and O'Hara, 2001). However, recent events, such as the Enron scandal and other corporate governance failures, have put corporate governance on the front.

Because of its unique nature, banking firm, whether in the developed or developing world, requires that a broad view of corporate governance, which encapsulates both shareholders and depositors, be adopted for banks.<sup>4</sup> Banking system is a critical component of any economy. Banks provide financing for commercial enterprises, basic financial services to a broad segment of the population and access to payments systems. In addition, some banks are expected to make credit and liquidity available in difficult market conditions. The importance of banks to national economies is underscored by the fact that banking is virtually a regulated industry and that banks have access to government safety nets. It is of crucial importance therefore that banks have to have strong corporate governance.<sup>5</sup> Sound corporate governance is an essential element of a strong risk-management process. Bankers and bank directors have specific responsibilities to manage the risks at their financial institutions and effectively oversee the systems of internal controls.<sup>6</sup>

Jensen and Meckling (1976) argue that board structure, ownership structure, and compensation structure are determined by one another as well as by a range of variables, such as risk, real and financial assets, cash flow, firm size, and regulation. They suggest that these variables also influence a firm's conduct and performance.<sup>7</sup>

In the case of local banks in Italy, Ferri, Masciandaro and Massori highlight three different forms of corporate governance testing the performance of them.<sup>8</sup> Another study of corporate governance and

performance was put to test using data of banks from Argentina in the 1990s including all types of bank ownership.<sup>9</sup>

This paper discusses the importance of corporate governance of banking institutions. This is an important issue given the essential role banks play in the financial systems of developing economies merely and the widespread banking reforms that these economies have implemented. Following the global crisis, banks all over the world had to go into critical change. Turkey, after two consecutive crises, still tries to reshape its financial system. Therefore, corporate governance principles were issued in the country. The analysis in this paper points that the Turkish Banking System showed progress through the implementation of corporate governance principles but still there is a need for further deliberate applications.

Accordingly, the paper is organized as follows: Section 2 gives information about corporate governance in banking. Section 3 and 4 are related with the Turkish banking sector and the corporate governance settlements. Section 5 provides the data and the methodology in detail. Section 6 discusses the results of the analysis, and Section 7 is devoted to the conclusions of the research.

## 2. Corporate Governance In Banking

Banking supervision cannot function as well if sound corporate governance is not in place and, consequently, banking supervisors have a strong interest in ensuring that there is effective corporate governance at every banking organization. Supervisory experience underscores the necessity of having the appropriate levels of accountability and checks and balances within each bank. Put plainly, sound corporate governance makes the work of supervisors infinitely easier. Sound corporate governance can contribute to a collaborative working relationship between bank management and bank supervisors.<sup>10</sup>

Recent sound practice papers issued by the Basel Committee underscore the need for banks to set strategies for their operations and establish accountability for executing these strategies. In addition, transparency of information related to existing conditions, decisions and

<sup>9</sup> Allen Berger; George Clarke; Robert Cull; Leora Klapper; Gregory Udell, "Corporate Governance and Bank Performance: A Joint Analysis of the Static, Selection and Dynamic Effects of Domestic, Foreign and State Ownership", **World Bank Policy Research Working Paper**, No: 3632, 2005, p. 1.

<sup>10</sup> BCBS, p. 4.

actions is integrally related to accountability in that it gives market participants sufficient information with which to judge the management of a bank. This guidance refers to a management structure composed of a board of directors and senior management. The Committee recognizes that there are significant differences in the legislative and regulatory frameworks across countries as regards the functions of the board of directors and senior management. In some cases, it is known as a supervisory board. This means that the board has no executive functions. In other countries, by contrast, the board has a broader competence in that it lays down the general framework for the management of the bank.<sup>11</sup>

Basel Committee declared two accords (Basel I and II) to maintain requirement for the banking system all over the world. Basel II is a complex new standard that intends to promote safety and soundness in the financial system, align regulatory capital requirements more closely with underlying risks, provide incentives for institutions to pursue more sophisticated and effective risk management, and demonstrate robust governance, processes, and controls to shareholders and institutions. The final version of the accord was published in 4Q03, with parallel testing with the new and old accords (Basel I) from YE05 through 2006, and the new accord being in place by 2007 (though this date could slip further). Users must not only address Basel II independently, but also coordinate efforts to achieve its compliance with related parallel compliance efforts to both leverage efforts and support the development of more efficient enterprise wide governance programs.<sup>12</sup>

The corporate governance of banks especially in developing economies is important for several reasons. First, banks have an overwhelmingly dominant position in developing-economy financial systems, and are extremely important engines of economic growth (King and Levine 1993; Levine 1997). Second, as financial markets are usually underdeveloped, banks in developing economies are typically the most important source of finance for the majority of firms, Third, as well as providing a generally accepted means of payment, banks in developing countries are usually the main depository for the economy's savings. Fourth, many developing economies have recently liberalized their banking systems through privatization/disinvestments and reducing the role of economic

---

<sup>11</sup> *ibid*

<sup>12</sup> John Van Decker; Stan Lepeak, "Incorporating Basel II Requirements Into an IT Corporate Governance Framework: Part 2 The Services Dimension", April 28, 2004, pp. 1-2.

regulation. Consequently, managers of banks in these economies have obtained greater freedom in how they run their banks.<sup>13</sup>

The focus on corporate governance is particularly acute in financial services and, most of all, in the banking sector. The banking sector is already highly sensitized to public scrutiny and has learned to its cost the risk of attracting adverse publicity through failings in governance and stakeholder relationships. Banking is clearly a very special sub-set of corporate governance with much of its management obligations enshrined in law or regulatory codes.<sup>14</sup>

These factors put governance in banks as a considerably more complex issue than in other sectors. Banks will attempt to comply with the same codes of board governance as other companies but, in addition, factors like risk management, capital adequacy and funding, internal control and compliance all have an impact on their matrix of governance.

The board of directors is ultimately responsible for the operations and financial soundness of the bank. The board of directors must receive on timely basis sufficient information to judge the performance of management. An effective number of board members should be capable of exercising judgment, independent of the views of management, large shareholders or governments. Qualified external directors can also become significant sources of management expertise in times of corporate stress. The board of directors should periodically assess its own performance, determine where weaknesses exist and, where possible, take appropriate corrective actions.<sup>15</sup>

Corporate governance for a developing economy has an added dimension. After all, since the late 1980s/early 1990s, the financial sector of a number of developing countries has seen a wave of liberalization and deregulation. Greater deregulation in markets and in banks operations requires better governance as more responsibility rests with the Board and the management.<sup>16</sup> Good corporate governance can help to ensure that the organization is fully prepared to manage potential threats, and to maximize the opportunities to be gained from business risk.<sup>17</sup>

### 3. Turkish Banking Sector

The Turkish economy has been in a continuing progress after the economic program that was launched in 2001. In parallel with the aim of reinforcing the market mechanism, important steps for strengthening the regulatory and supervisory institutions have been taken. The stable growth environment had positive effect on the banking system. To ensure financial stability serious structural reforms have been introduced in the banking system. Thus, the structure of the banking system has become healthier. An independent agency was formed for increasing the effectiveness of banking supervision and control (the Banking Regulation and Supervision Agency-BRSA). The Banking Act and other banking regulations have been considerably harmonized with international best practices.

In the field of banking supervision serious steps have been taken toward the transition from rule-based approach to risk-based approach. Due to this, market discipline has started to have a greater importance in ensuring financial stability. With the aim of providing the public and market participants with the information necessary to make meaningful assessments of banks, the implementations on accounting standards, reporting and public disclosure have been strengthened.<sup>18</sup>

Source: The Banks Association of Turkey (TBAT)

<sup>18</sup> The Banks Association of Turkey (TBAT) (2005), Financial Sector and Banking System in Turkey- March 2005, p. 9, [www.tbb.org.tr/english/TBBBrosur10032005englishi.pdf](http://www.tbb.org.tr/english/TBBBrosur10032005englishi.pdf)

In order to strengthen the capital structure of private banking system a special auditing process as a part of "banking restructuring program" was implemented. Assets of the banks were analyzed in detail, non-performing assets were determined, and necessary provisions were set aside for bad loans. Within the context of the restructuring program the balance sheet structure of state-owned banks was strengthened, and special importance has been attached to the increasing of the efficiency in these banks.

Shareholders' equity of the banking system has strengthened and free shareholders' equity has increased. Exchange rate risk has been considerably reduced. An improvement has been observed in the rates of return on assets and return on shareholders' equity. The practice of full insurance guarantee introduced to the saving deposits in 1994 and even to all liabilities of the commercial banks in 2001, was terminated in the second half of 2004. The insurance coverage over the saving deposits has been limited to 50 thousand YTL since July 2004. With the aim of full compliance with the EU Directives legislative work to amend the Banking Act continues. The amendments are mainly concentrated on improving risk-oriented supervision, strengthening the independent structure of the BRSA, and increasing the effectiveness of supervision in the banking system.<sup>19</sup>

#### **4. Corporate Governance In The Turkish Banking Sector**

In Turkey, Corporate Governance Principles are first issued by Capital Market Board. These Principles were issued to be implemented primarily by the listed companies in ISE. In the draft of new code on banking industry corporate governance principles are required for the financial institutions. Because corporate governance is a new concept for the Turkish companies and the compliance with the Principles is not compulsory, in order to understand the level of corporate governance, a survey among listed companies has been conducted. Although the main purpose of the survey is to understand the position of the companies in corporate governance context, there are other side effects of the survey such as increasing the awareness of corporate governance among listed companies and encouraging them.

The evidence indicates that the companies are eager to work on corporate governance and the number of companies having policies about social responsibility is growing. However, there many firms in Turkey both of the private and public sector that have to adopt corporate governance

---

<sup>19</sup> *ibid*, p. 10.

principles. At the same time, Turkey's firm structure made up of family and group holding points to a lack of corporate governance to a great extent.<sup>20</sup>

## **5. Data and Methodology**

The methodology used in this paper is comparing the selected banks' financial ratios. For the purpose of comparative analysis of Turkish Banking Sector's performance, listed banks on the TBAT were selected. These selected banks were compared with the foreign banks in Turkey that fully apply the corporate governance principles. These pair-matched samples are used so that meaningful comparative analysis of performance may be made.

For those selected banks, the performance ratios are calculated from the set of data on TBAT's miscellaneous yearly reports concerning the last five years (2000-2004). The performance ratios are summarized for each year of the past five years in the form of the simple average ratio. These summarized data are presented with the attached tables. Several financial ratios indicate the results of banks' performance. The ratios for this study include those of capital adequacy, assets quality, profitability, liquidity, debt management.

\* Fully apply corporate governance principles and have a different management style beyond Turkish Banks

## 6. Results of Comparative Analysis

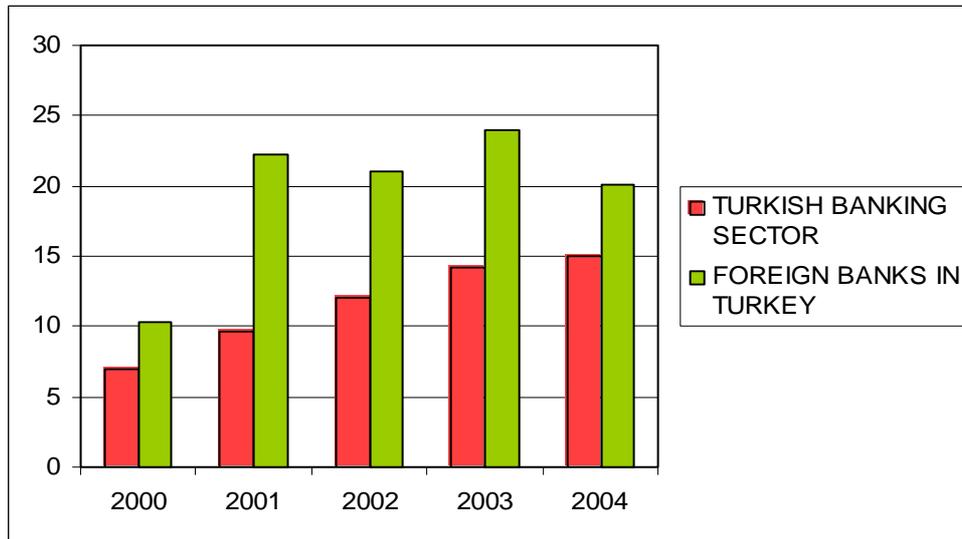

The capital adequacy ratio of Turkish banking sector lays small compared with the foreign banks' and it increases year by year as the corporate governance principles' implementation. The capital adequacy of foreign banks' showed a volatile trend but still higher than the sector's. Risk weighted assets of the sector reached and overtook the foreign banks' in 2004. That's one of the major exceptional results for the sector. At the same time, shareholders equity increases in the sector but remains low compared with the foreign banks'.

**Figure 1: Shareholders Equity / Risk Weighted Assets**

*Source: Author's calculation (from TBAT's data)*

**Figure 2: Shareholders' Equity / Total Assets**

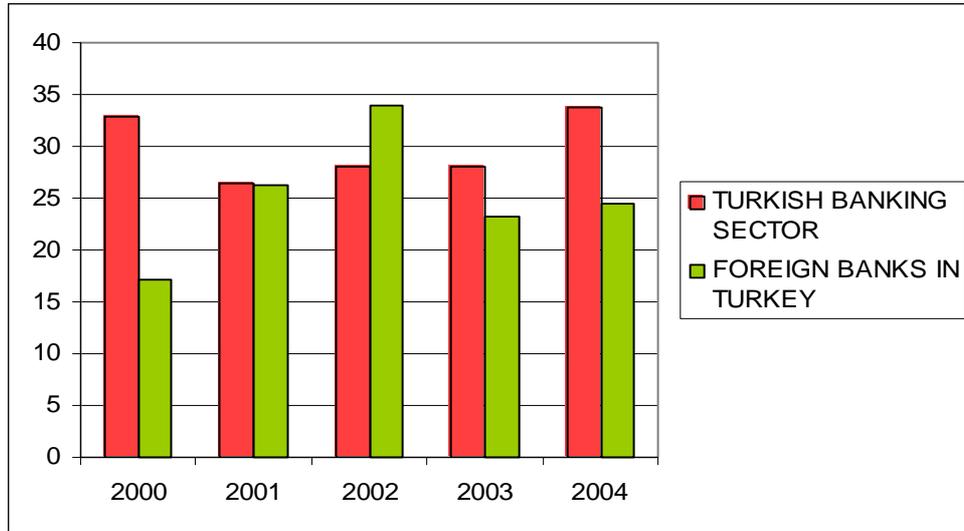

*Source: Author's calculation (from TBAT's data)*

According to assets quality, both the sector and the foreign banks had a volatile trend. The sector's loans grew bigger than foreign banks' thus the loans under follow-up flew high but slowed down in 2003 then catching the foreign banks' in 2004. That considerable change in the attitude towards the loans under follow-up is another important deviation from the result of the rest of the analysis. Just like the change in the risk weighted assets, the

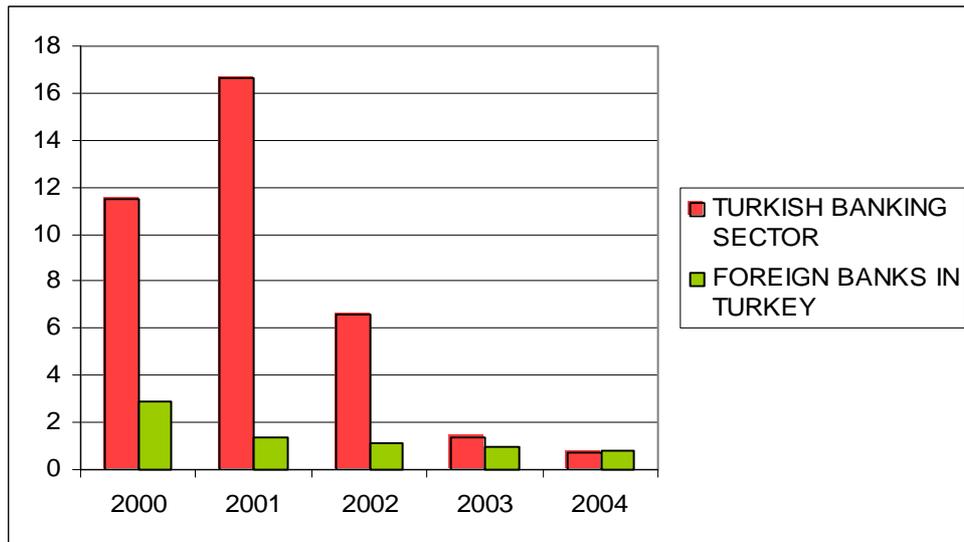

decrease in the loans under follow-up came through the settlement of risk management implementations that exist in corporate governance.

**Figure 3: Total Loans / Total Assets**

Source: Author's calculation (from TBAT's data)

**Figure 4: Loans Under Follow-up (net) / Total Loans**

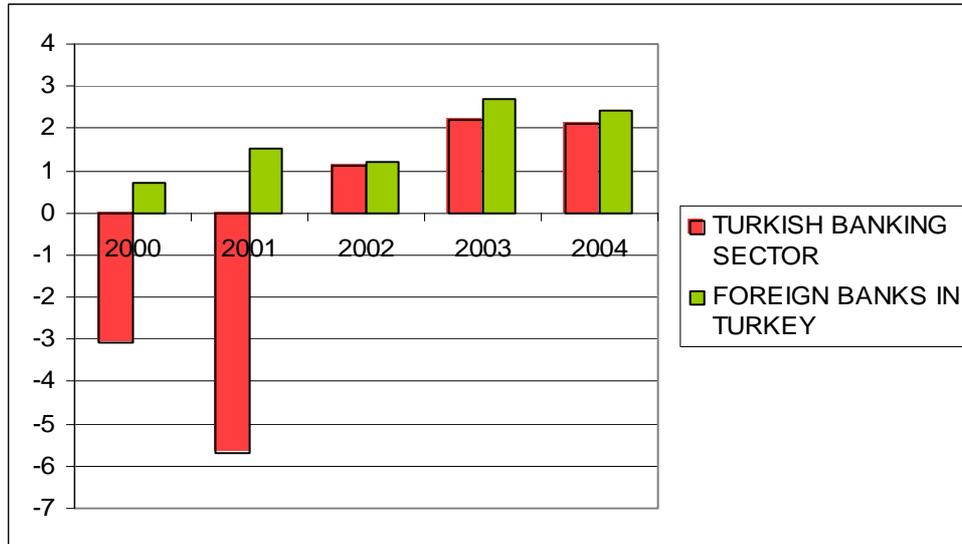

Source: Author's calculation (from TBAT's data)

Profitability of the sector showed considerable positive change especially in the return on equity. After 2001 a big jump started overtaking

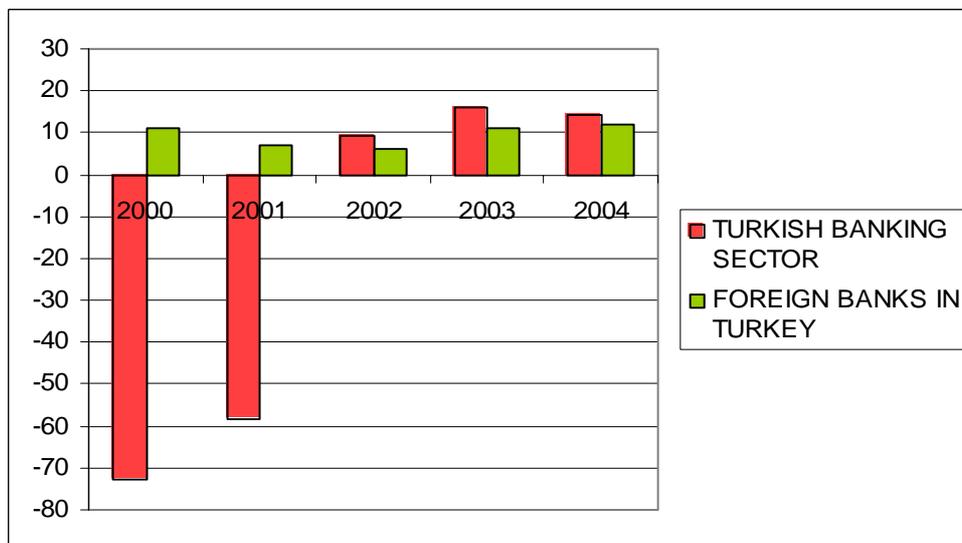

foreign banks' return on equity. On the other hand, rate of return on assets went slow reaching foreign banks' in 2003 and overtaking in 2004.

**Figure 5: Return on Assets**

*Source: Author's calculation (from TBAT's data)*

**Figure 6: Return on Equity**

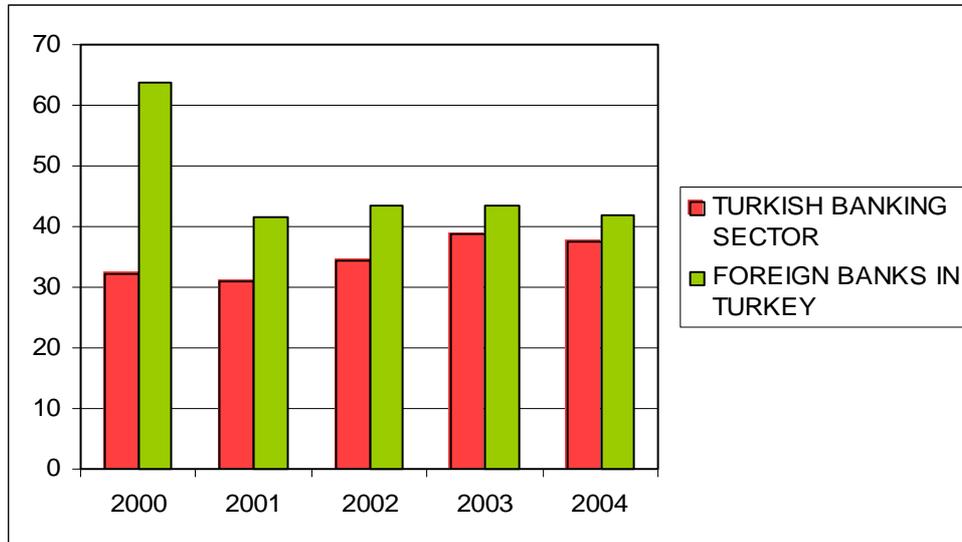

*Source: Author's calculation (from TBAT's data)*

Liquidity of the sector is strengthened and increased year by year. As for the ratio of liquid assets to total assets, sector remained lower than the

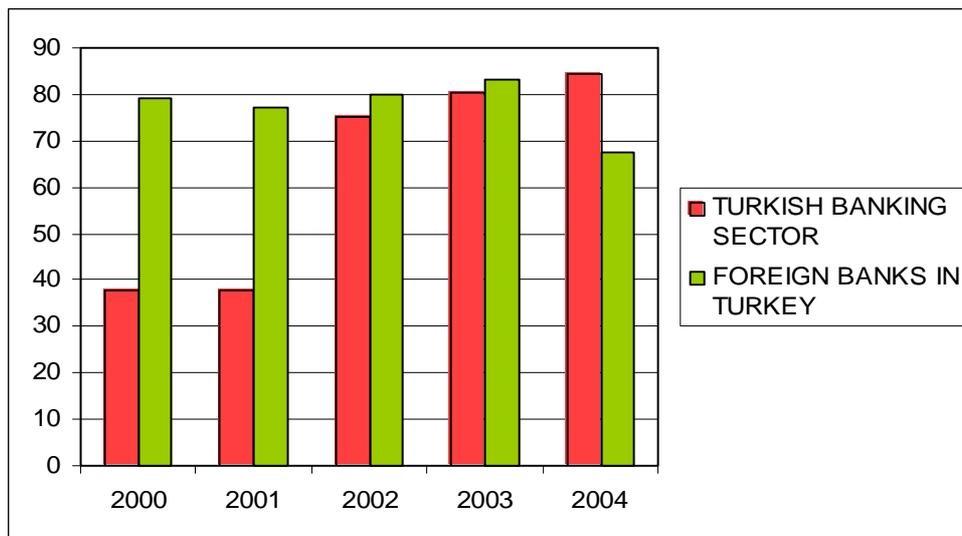

foreign banks at the end of 2004. But the ratio of liquid assets to short term liabilities showed a considerable change and went far than the foreign banks' in 2004.

**Figure 7: Liquid Assets / Total Assets**

*Source: Author's calculation (from TBAT's data)*

**Figure 8: Liquid Assets / Short-term Liabilities**

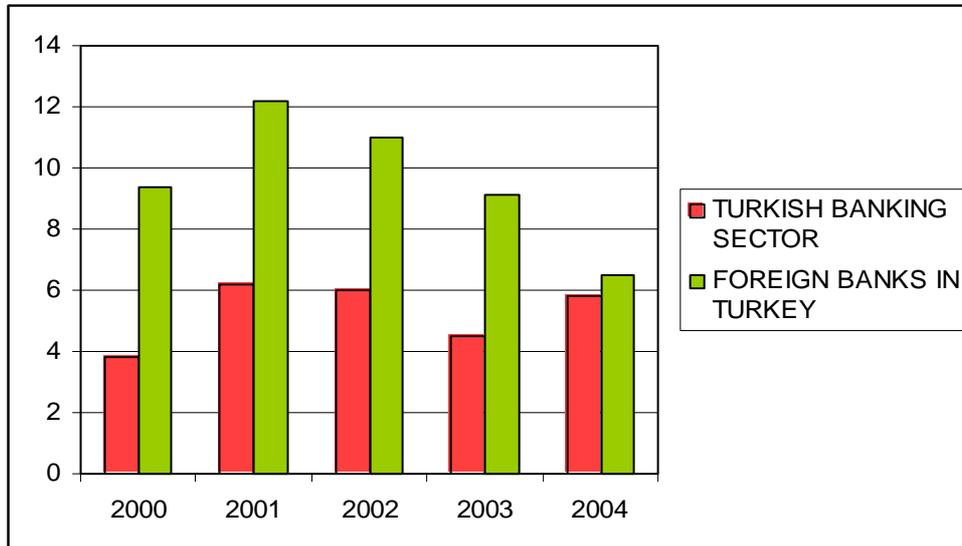

*Source: Author's calculation (from TBAT's data)*

As for the debt management, both the sector and the foreign banks showed a volatile trend in ratios. The ratio of net interest income to total

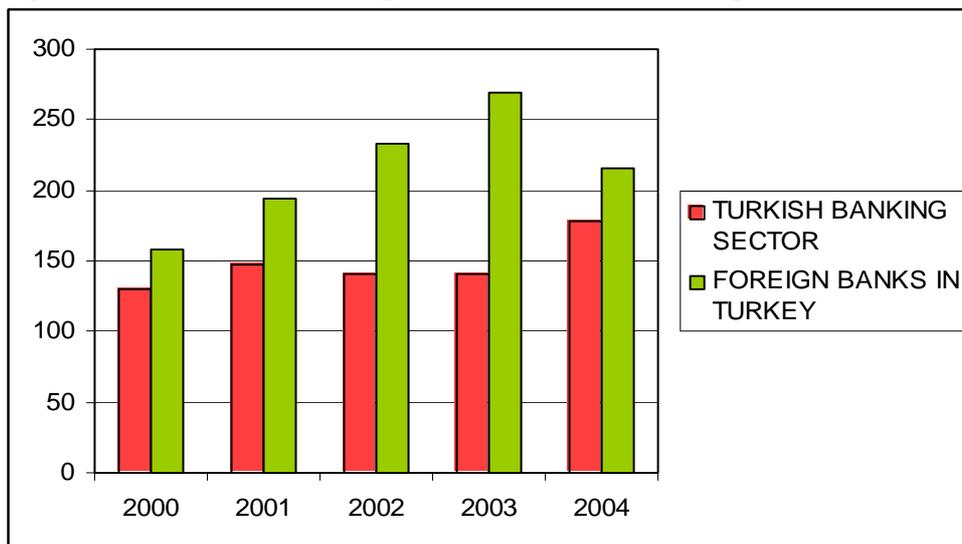

assets of the sector remained lower than the foreign banks'. The foreign banks' ratio slowed down whereas the sector's nearing a little closer in 2004 just like in the case of total interest income to total interest expenses.

**Figure 9: Net Interest Income / Total Assets**

*Source: Author's calculation (from TBAT's data)*

**Figure 10: Total Interest Expenses / Total Interest Expenses**

*Source: Author's calculation (from TBAT's data)*

The results totally show that foreign banks' management and performance in Turkey is much more adequate for the generally accepted corporate governance principles that had been set by OECD and especially BIS. Till 2004, generally ratios of the foreign banks went more adequate when compared with the sector's ratios. At the end of 2004, some of the ratios of the foreign banks started to fall below the sector's (shareholders' equity to total risk weighted assets; loans under follow up to total loans; return on equity, liquid assets to short-term liabilities) but others remained higher or more adequate.

It can be said that the Turkish banking sector showed a considerable change and reached to the level of foreign banks. The fact behind that change is the implementation of corporate governance in the sector and mainly the related issue of risk management. The ratios of the sector before the settlements were far beyond the foreign banks in Turkey. But after corporate governance principles, there happened a dramatic change in the financial management of banking system in Turkey. The sector reached a much more considerable level in ratios that reflect corporate governance. That shows the importance of corporate governance in banking as well as the need in the Turkish Banking System. But at the same time, it should be noted that the results still point to the need to attain stronger and sound corporate governance in the Turkish Banking Sector.

## **7. Conclusion**

The empirical evidence presented above constitutes the level of corporate governance in the Turkish banking sector. In addition to casting serious doubts on some conventional notions on the background of Turkish banks and confirming some of my suspicions in various performance ratios, this paper also proposes extra evidence about the need for corporate governance that sector has and the importance of corporate governance overall for banking.

Of the four ratios tested, the sector performed better than the foreign banks in Turkey. This means Turkish banking sector showed considerable change and upgrading the level of corporate governance. Although policies are designed to strengthen the corporate governance of Turkish banks, the rest of the performance test results compared with the foreign banks operating in Turkey, point to the need in enhancing the efforts to progress stronger corporate governance level in the banking sector. Moreover, there is a need for the management of banks to be granted autonomy and be gradually introduced further corporate governance practices. Banking sector in Turkey is required to publish comprehensive financial and risk-related disclosures.

Corporate governance for Turkey, is the major transition issue as of EU, especially for the banking sector in the long-run.

In short, governance of banks is crucial for growth and development of a country's economy. At the same time, banks are subject to financial risks, highly leveraged as failure can lead to large output costs. Corporate governance affects banks' performance, valuation, and cost of capital, risk taking and the risks of financial crises.

## **Abstract**

*Transformation of the banking sector to a stable and efficient banking system which should be able to support the economic growth has been one of the most important problems by the transition to a market economy. In foreground was the question of inaccessible loans and the settlement of this question was the main assumption for the transformation and for the economic growth. The burden of inaccessible loans have namely blocked the restructuralisation not only with its existence, but above all with it's volume. Beside the need to build of new institutions for the move of inaccessible bank claims apeared the question of their valuation. This contribution is intended to theoretical aspectes of solving the problem of inaccessible assets in banks and also to concrete solution of the situation in this area in the banks in Slovakia and in the Czech Republic.*

**Key words:** *banking sector, reclassification of banks, inaccessible claims, non- standing financial assets, risk loans, transformation institutions, valuation of claims, methods of valuation of claims, non-valuation assets*

## **1. Banking Sector in the Slovak and Czech Republic**

Demonopolization of banks in Czech-Slovak Federal Republic was accompanied through their strong undercapitalization, the capital appropriation has moved on the level 1,72 %. The disadvantage was also a very small number of qualified employees, lack of experience with managing of commercial banks, surroundings, absence of laws and other criterions in the area the central bank and the commercial banks. Banks were not equipped with modern technologies; branch -office net and know-how were absent. Despite that relatively a lot of banks came into being with home and foreign participation whereupon a lot of small banks have been founded mainly in the Czech Republic. New founded commercial banks have taken over a part of inaccessible loans from the Czech-Slovak National Bank, loans granted enterprises, loans for cooperative flat construction, how also loans for some big projects, for example power stations, water power stations and similar. Low experiences and political influences and insufficient legislature have contributed to the development of a other big parcel of not sufficient guaranteed loans and before long a lot of them was graded to the risk- or problem level.

The solution of the problem loans is dated from the Federal Czech-Slovak Republic when there were accepted measures for solving of the payment inability. The federal government placed at disposal 11 billion Czechoslovak crowns reclassification of potential viable enterprises and 4 billions Czechoslovak crowns for the capital strengthening of banks. Absence of experience with such projects has showed by us in a non system admission to solving of the payment inability. After dividing of the CSFR, the governments of the Czech and Slovak Republic have taken different steps to solve the situation in the banking sector. Both governments solved the state through consolidating institutions - moving of none financial standing assets to this institutions and at the same time through increasing of ground capital in this again healthy banks. The intention of both governments was also to sell the healthy banks to foreign investors.

### ***1.1 Solution of problems in the Slovak banking sector after 1993***

After dividing of the federation there have been the following main problems in the Slovak banking sector:

- prevailing state ownership in banks
- low capital adequacy
- quality of the credit portfolio- high stake of inaccessible credits
- lack of long term funds.

This state has had a negative impact not only on the liquidity of the banking sector, price policy and savings, but also on the whole economy of Slovakia, therefore in 1999 decline also in Slovakia to solution of unfavorable situation in the banking sector.

Resolution of the Government of SR No. 90/1999 and connecting resolution No. 908/1999 led to work out the procedure of restoring to health of banks under the name „Proposal of the program of reclassification of banks and reclassification of the private enterprise sector“. The objective was to displace a part of risky claims in such a way, that each bank will reach a part of max. 35 % of inaccessible claims and at the same time to increase the capital of banks and to reach a capital adequacy of 8 % according to the Basel criterions. On the basis of this documents, the reclassification was divided in two stages. The first stage of reclassification started in December 1999 and the second in June 2000.

**Table 2: Classified credits in Slovak banks in 2000**

<i>Year</i>	VUB, Ltd.	IRB, Ltd.	SlSp, Ltd.
2000	9707,3	174,7	1858,4

*Source: Consolidating Bank, Ltd.*

In the first stage of the recovery process have been joined the three biggest Slovak banks: General Credit Bank (VUB), Slovak Saving Bank (SlSp), and Investment and development bank (IRB). Entirely there have been displaced in the first stage credits in value about 82.2 billion Slovak crowns and in the second stage 34.2 billion Slovak crowns.

### ***1.2 Solution of problems in the Czech banking sector after 1993***

The Czech banking system at its beginning had to occupy itself with a lot of financial liabilities, which occurred in none economic surroundings of central planed economy. To that have been added problems with temporary founding of new small banks, which have been strong undercapitalized, they didn't have an experienced management and operated in an unstable microeconomic environment. That all was the consequence for a strong increase of bad assets, especially credits, which was not ordinary paid back. The situation, which came into being, the government of the CR solved through a declaration of the consolidation program I., on which basis the credits for long terminated reserves, have been transformed to the consolidating bank. Because there began to appear problems of small, new founded banks, the government declared to their solution the consolidation program II and in the frame of it have been applied the following measures: there was initiated a forced management, finished the activity or the banks have been soled and at the same time increased the ground capital. From the entire 18 small banks have been in the frame of this program solved 15 and the amount of the raised funds was 33 billion Czech crowns. In 1997 began the stabilizing program which basis was the purchase of non-financial standing claims. To this program entered 6 banks from which 3 have been later excluded, 3 of them have changed the ownership and the program was prematurely finished.

By the end of the 90th the state began to solve the problems in the big banks, they received a lot financial help and this banks have been consequently sold to strategic investors.

## 2. Admittances to the settlement of inaccessible credits

Searching of possibilities to settle the inaccessible credits have brought three admittances:

**Decentralized admittance**, when the state enter into the banks with capital and cover the loses from non-financial standing assets. The following step can be the privatization of such acquired stake. After it the banks are solving their non-financial standing assets in their own direction. This procedure has been used by the privatization of the banks in Poland. Certain modification is granting of state guarantee for non-financial standing assets. In the CR was the state guarantee partially used by privatization of the Czech saving bank and the Commercial bank, there have been issued guarantees to the new owners for risky assets.

**Centralized admittance**, by which non-financial standing assets purchase central institutions (AMC-Asset Management Company) and after it they manage this assets with the objective to reach a maximal yield or to reclassification them. The owner of these institutions can be the state, or a private person. We distinguish two types of these central institutions (AMC)

- restructuring institutions (Corporate Restructuring Vehicles), the objective of which is the restructuralization of banks and key enterprises
- rapid asset disposition vehicles , which objective is quickly sale of non-financial standing assets. This type of institutions doesn't pursue any reclassification of debtors.

The third way is the **combination** of the two a.m. admittances. Reclassified problematic credits, granted to big important enterprises will be moved to central institution and the rest of such credits remain to stay in commercial banks.

### **3. Reclassification instruments of non-financial standing bank assets**

Transformation institutions structure the received non-financial standing assets according to determined criterions ( for example according the debtors, the branches, regions, the financial situation of the debtor or according to the expected development of enterprising) in the portfolio and as follows they start the reclassification. The transformation institution has to decide which instrument it will use for the reclassification by consideration of the law- and tax aspects.

Emphasised is also the transparency of the reclassification process. By reclassification of non-financial standing assets in different countries will be used some of possible instruments, which are:

- capitalization of debts
- balancing, except the court balancing
- sells of portfolio assets, which can be realized:
  - . through individual sell
  - . through sell of fortune stakes
  - . auction through internet
- competitions
- securitization
- selling of guarantees

## **4. Transformation institutions in the Czech and Slovak Republic**

### ***4.1 Transformation institutions in the Slovak Republic***

The need to solve the problematic credits has activated the founding of the Consolidating bank a state institution in 1990. This bank took over form the big commercial banks credits on value about 110 billion Czechoslovak crowns. As counter-value the banks received from the state 50 billion Czechoslovak crowns in government loans 12 billion Czechoslovak crowns for increasing of the own capital stock and 38 billion Czechoslovak crowns for the remission of credits for long term reserves. The consolidating bank has one-sided and formal changed the one year character of credits to a

long term credit with the assumption of repayment of this credits until 2000. The enterprises confirmed the regime of repayment decided through the Consolidating bank. The enterprises stopped to distinguish the separate types of credits with which of the one side has been solved the problem of credits from the view of banks, on the other side for the enterprises it was a load and for the state it meant a loading of the state debt and the public finance.

Reclassification of the Slovak banking sector was solved in August 1999 when the government of Slovak Republic issued the reclassification program for the chosen banks and of business sector which connected to the resolution of government No. 90/1999. To secure the transparence of the privatization process the government cooperated with foreign counseling firms. Project was prepared in cooperation with the European commission, the World Bank through the program PHARE. The objective of the project was, to create a mechanism which could secure to dismantle the whole loss from the whole process on the owners of debt enterprises (loss of fortune), creditors (partial satisfaction of claims) including banks (using of reserves and correcting items) and state (through the cover of the rest of uncovered loss). As an important step is to consider the legislative measures as the law about bankruptcy and settlement, laws about banks, tax laws and the actualization of the commercial and the civil code.

Partition of the federation meant also division of the Consolidating bank on two subjects. Consolidating bank as a state institution, founded in 01.01.1993 through the Ministry of Finance, took over nearly 2000 clients with credits about 30,4 billion Slovak crowns. The main objective was the liquidation or arrangement of claims and obligations connected with credits for long terminated reserves.

Admittance to the founding of the Consolidating bank in Slovakia was considerable different to the CR where the Consolidating bank received from the FNP (Fund of National Property) CR 15 billion Czech crowns. Separate solved the FNP the liquidation of the debts by state properties through what it helped to speed up the process of reclassification in CR. The Slovak Consolidating bank has fulfilled an important task in reclassification of banks and enterprises.

The Slovak Consolidating bank was practical founded without a basic capital stock. In the course of the first two years of existing the bank has been entrusted a capital stock about 2,357 billion Slovak crowns. But that was not sufficient in view of the volume of credits which the bank took over. The capital adequacy of the bank was by end of 1994 deep under 8 %. <sup>2</sup> Volume of funds used for consolidation of the three biggest banks has been estimated

---

<sup>2</sup> Kovalčík, J.:Konsolidačná banka – pokus o centralizovaný prístup. In: TREND, 8. 11. 1995, s. 5A

on 105 billion Slovak crowns that is approximately 12 % of GDP.

*Source: Consolidating Bank, Ltd.*

The Consolidating bank was managed through the bank law and therefore it was not possible to make activities aside the frame of law ( for example selling of claims) and also the bank was not able to maintain the conditions of cautious undertaking of banks. With the resolution No. 908 of the Slovak government from 21.10.1999 therefore was founded a specialized finance institution the Slovak consolidated stock company (SKO) with stock capital about 1 billion Slovak crowns. It was a bank institution without bank license. The bank have arisen as stock company with following stakes: Ministry of finance-24 % , VUB, SSB, IDB and Consolidating bank each 19 %. The objective of the founding of the SKO was in a possible short time and effective realize the reclassification program of the government. The activities of the SKO are stated in the project of the agency for work with moved claims. For the SKO has been stated the conception of non banking institution. The mission of the SKO was to clear the classified claims, moved from the reclassified banks. An important task of the SKO was to create a secondary market with problematic claims and help to build a standard and transparent market in cooperation with IMF, World Bank, EU, foreign consolidated and consulting organizations.

The main objective of the company was a fast settlement of classified claims which has been moved to it's portfolio in the frame of the before privatizing reclassification in the past from the state owned banks, General Credit Bank VUB, Slovak Saving Bank SLSP and the Investment and Development Bank IRB.

After this stage, the SKO began its concrete activity with collecting of claims on the basis of mandate agreements with the banks in the first stage and after this stage the claims have been managed internal by SKO. By securing of return ability of claims the SKO used in the valued period non-court and also court forms of collecting. The company SKO has in the process of collecting of claims used the standard internal management and also part of claims has been collected through mandate agreements with reclassified banks, mandators, lawyer- or commercial offices. The intention of the administration of claims on the strength of mandate agreements and agreements about collecting of moved claims was to avoid

formation of damages and at the same time to save the continuity of the collecting process. Claims against subjects in CR and Russia have been transferred to chosen mandators. Collecting of most complicated juridical cases of claims the SKO has solved through lawyer- and commercial agencies. In area of court collecting of claims the SKO used all viable legal instruments, mainly proposals to issue of payment orders, to declare of crashes and to execute bailiftings. On the base of agreement between the SKO and the Fond of national property the company received assets from the Consolidating bank in value of 33,13 billion Slovak crowns The SKO registered to 31.12.2004 in it's portfolio claims from reclassified banks about 49,23 Bi Slovak crowns In comparison with the state at 31.12.2003 the nominal value of the portfolio dropped over 57,23 billion Slovak crowns First and for most the drop was initiated through the progress of claims in the frame of the VVK project about the value 42 billion Slovak crowns and realization of the project VVK 2004 on the nominal value 12,6 Billion Slovak crowns On decreasing of the portfolio in 2004 have participated except the named projects also individual moves of claims (0,156 billion Slovak crowns) and also reclassification of some debtors (0,842 billion Slovak crowns). In harmony with the accepted strategy of solving the claims of farm- and food firms have been realized the cession of claims from enterprises to the Slovak guaranty and development bank SZRB).

Reverse the increasing of the nominal value of the claims in portfolio of the SKO at the end of 2004 have activated a take over of claims from tax authorities in entire value about 24,6 Billion Slovak crowns SKO maintained to the 31.12.2004 in management claims in an entire sum about 73,93 Billion The value of the property represented to the 31.12.2004 a value about 22,949 Billion Slovak crowns Creating of correcting items to the entire amount, which have been created from costs have influenced a negative result in 2004. On the other side, there has been created space for reaching of positive economics in the society in the following years. In the past the society reached negative results in economy as consequence of undervalued loss contained in managed claims. Insufficient volume of created correcting items was the consequence, the bigger volume of claims was moved to third subjects, and the bigger was the loss. In 2005 the SKO await a positive result. Individual attention the SKO granted the solution of opened questions with Slovak saving bank and General credit bank in connection with transfer of classified claims in frame of the reclassification of the banking sector. The result was the closing of conclusion protocols with both named banks. The company SKO finished the solution of the guaranty question of the Fond of national property in connection to the part of managed portfolio with the closing of an agreement about extinction of the guarantee. An important reality was in 2004 the implementation of a new management information

system which makes it possible to follow in details the process of bankruptcy proceedings, distains, voluntary auctions, court disputes or liquidations in real time.<sup>3</sup>

In legislature area on the basis of negative experiences in connection with the interpretation and application problems of the current valid law about bankruptcy proceeding by management and by collecting of claims prepared the SKO a proposal for the parliament to change the law about bankruptcy and settlement No. 328/1991. This proposal has been accepted by the Slovak parliament and is valid since 01.01.2005.

In the period of its existence, the Slovak consolidated bank has solely managed and collected claims. At the present the institution is with its new professional management and personal equipment full prepared to manage further problematic claims from public finance sector.

<sup>3</sup> *Consolidating Bank, a.s.*

#### ***4.2. Transformation institutions in the Czech Republic***

Measures for relieving of the unfavorable situation in the banking sector solved the Czech government and the Central bank with measures which can be divided in three arrears:

- legislature and regulating measures (strengthening of competencies of the bank supervision and Commission for Securities, insolvency legislature and new bank laws)
- help the depositors, stricken through bankruptcy of banks
- direct help to banks or it's new owners.

By renovation of the banking sector in the CR there has been chosen a decentralized model, on which basis the Czech saving bank and Commercial bank received state guarantees for covering of risky assets.

By reclassification of the whole banking sector and also state enterprises has been chosen a centralized admittation by which the central state institution has bought non credible assets and was real reclassification institution. The task of these institutions was to remove the credits from the bank balances as result of the economy policy of the last regime and enable the banks and firms to do their business without burden from the past. Their next task was the taking over of non credible assets from the Czech banks and consequently to realize them. The reclassification institutions in CR fulfilled also an another task, they helped small banks which came to existence troubles and have been stabilized through the stabilizing programs I and II.

The Czech consolidating agency (CKA) is the legal successor of the Consolidating bank, Prague. Till 2000 this bank has made financing in development projects in the areas infrastructure and ecology. In 2001 the bank vanished and was replaced through the Czech consolidating agency (CKA). CKA was founded on the basis of a special law No. 239/2001. This agency is a non banking finance institution which doesn't receive deposits and doesn't offer credits. The main task of the agency is to solve the problematic assets active, transparently and quickly with the objective to make a maximal yield for the state. Through the law the agency will vanish on 31.12.2011 without liquidation. The main influence in the agency has the supervision council, named through the parliament. Management of the agency is named by the government. Main activity of the agency is the management and realization of assets, reclassification of enterprises chosen by the government and solving of the managed assets through the court. If the clients properly made their payments, there are no difficulties by the liquidation of the assets. Not repaid credits will be solved by transfer of claims to third subjects, realization of the pawned law or sale by auction. In

the frame of solving the debts through the court there will be used the possibility of bankruptcy, liquidations and submitting of suits. In subsidiaries will be realized the block sale of credit claims. In companies, which are able to survive and to fulfill their obligations the CKA applies the strategy of reclassification eventually the strategy of installment-repayment. In case of enterprises, appointed through the government with the interest to sell them to a strategic investor, the CKA looks up a partner. The agency bought gradually non credible assets about 400 billion Czech crowns except the selling of the claims from the commercial banks, the CKA took over also claims from health insurances about 4 billion Czech crowns. The big increase of the balance sum has been compensated with an active solution of claims.

The main objective of CKA is to reach a max return ability of claims in shortest time with min. of costs. The processes have to be transparent and standard according to the actual segmentation in the surroundings of the new information system and each debtor have to be solved in harmony with in advance agreed strategy. KONOPO a limited company has been founded through the Commercial bank and all classified credits have the bank transferred to this company. Today the only owner of this company is the CKA. Subject of enterprising is purchase and sell of credit claims, management of claims, collecting of claims and real estate activity. In 2002 were purchased from the Commercial bank incredible claims for 60 Billion Czech crowns for reclassification takes KONOPO individual sale of claims and block sale. Entire have been sold claims for 4,12 billion Czech crowns. PRISKO stock company was founded in 1992 on the basis of the project SKODA with the objective to separate some claims out of the new privatized company. The CKA is here the only property owner. Revitalizing agency was founded in 1999 as special division for solving of some big and complex cases. From 2001 the company is inactive and in liquidation. Sanakon was founded by the Consolidated bank in 2000. The company offers administrative-technical services which support the business activities of banks.

Czech financial (C F) was founded by Czech central bank from 2000 a 100 % subsidiary of the KOB. CF is active in management of assets which took over in frame of programs for increasing of stability of the banking sector and consolidation of smaller banks, management of property stakes with effective using of property and shareholder rights. The main activity is especially the management of assets (credit claims, CPO, property stakes) which the company took over as contribution to strengthening the banking sector. The stabilizing program will be financed through the CKA and the Fund of national property on the basis of the resolution of the government No. 539/1996 and the agreement closed between the KOB and FNP on 04.02.1997.

Transformation institutions realize the reclassification through using of a lot of instruments from which the most used are the individual sales, blocked sales of incredible assets, capitalization of debts, sale of property stakes, bankruptcy and liquidation, realization of reinsurance. The condition for the correct using of the a.m. instruments is the right valuation of credit claims.

## 5. Valuation of credit claims

Value determination of credit claims has an impact to the economy, banks and state and at the same time important information from the view of the investor. For each of the named subjects has the credit claim an another economic value. Behind the claim we have to see a concrete enterprise, therefore the price is stated on the basis of ideas of the contract partners about the value and the price at the same time implicated the ideas about the structure of credit claims. The price of the credit claim is always created under assumption, that there exist an offer and demand. These markets are different from the markets on which people sell usual commodities. Each offered credit claim has it's own individuality and specifications. The individuality of each credit claim is leading to the assertion, that for claims markets not exist and each sale of portfolio is an individual case, which is not possible to compare with an another case. Therefore it can not exist an objective value and it is the task of the expert by creating the value of the claim to consider the specifications of the concrete seller and buyer. Each so created value is rather a subjective value in that sense that there is expressed a certain value in connection between the buyer and seller. Concrete claim has for different investors often different values. The optimum case would be, if there could be stated a real price which would correspond to estimates of the buyer and seller.

The valuation of credit claims have to assume from the principle of maximal use. By valuation of claims states the seller and potential new investors their objective of valuation and on that ground their state their own

strategy.

The valuation of the credit portfolio has to fulfill the following criteria:<sup>4</sup>

- creating the value of the claim in that way, that the assumed yield will be reached
- analyse the impact of risks in connection with the credit claim to the value of credit claim portfolio
- find the proper strategy for the solution of the credit claims.

The choice of the proper method of valuation the credit claim require a correct classification of claims and consider the real expectations regarding the behavior of the debtor. On this ground is possible to choose the following strategies:

- capitalization of claims and the following sale of claims or reclassification of the company and the transfer of the claim to the standard claims and it's gradual repayment. This strategy is possible to choose, if the debtor is cooperating and there is the assumption that the claim will be repaid.
- Strategy of involuntary auction or distraint of the property or bankruptcy in case that the debtor has property viable for sale,
- Sale of the claim on the basis of collected property of the debtor to a third subject.

The credit claims will be valued with the objective to drop the volume of loss and endangered assets and to reach a maximal yield with minimal costs of their management. The valuation of the claim follows before the decision about sale or keep the claim in the own portfolio. The importance of the evaluation of the credit claim is given through specific factors of their solving in the conditions of the economy in Slovak and Czech republic and mainly out of following reasons:

- Credit claims are mainly from risky debtors, who over long periods don't pay back the credits, not submit documents and information to the bank according to the credit agreement and don't communicate with the bank.
- The claims are not enough secured through possible instruments
- the market of credit claims is not enough developed
- In Slovak and Czech Republic not exist a uniform method for valuation of credit claims, which would respect the

---

<sup>4</sup> Zmeškal, Z.: Finanční modely. Ostrava: VŠB-TU, Ekonomická fakulta, 2002. ISBN 80-284-0182-5

characteristics of big volumes of not repaid credits.

- The possibility that the credit claim will be repaid through the real debtor by means of a third person and legalized the obligation against the bank.

The valuation of the credit claims will be realized as follows:

- A. Establishing the nominal value of the claim incl. interest, costs and so on. In the same time is necessary on the basis of documents to state the credibility of the debtor and to judge if the value of the claim is zero.
- B. Judge the reinsurance of the credit claims and their sorting according to the manner of settlement
- C. Establishing a discount interest rate as addition of non risk yield and the risky surcharge.

By valuation of incredible assets there will be used a lot of methods in dependence from judging the situation on the basis of many points of view. There will be used four proceeds as follows:

- yield methods, by which the value of the claim will be stated as current value of future finance flows
- comparative methods, where for the statement of the value is to compare the given asset with the assets with similar qualities
- substantiating methods- the value of the given asset is stated on the basis of market valuation of the assets and the whole property
- optional method, if some consider the valuation of conditional claims, which can be asserted in some special cases.

Valuation of the portfolio of credit claims will be worked out on the basis of debtor analysis on the basis of bookkeeping statements - balance, statement profits and losses, cash flow and of public accessible information (business Journal, Annual reports of given firms and so on)

Objective of the valuation of claims is the determination of the value to a certain day. The value of the claims will be therefore stated from the valuable components which can be presented and quantified to the given day. The subject of valuation is always the unpaid value of the incredible asset to the given time where upon there will be considered also the expected development after the term of valuation. On the basis of given information and chosen strategy there will be judged the convenience of separate valuation methods, the most suitable will be chosen and on its basis will be stated the real value of the incredible asset.

System of valuation of incredible assets consists of following independent methods:<sup>5</sup>

- creation of value on the basis of payment ability of the debtor
- creation of value of the incredible asset through bankruptcy simulation
- creation of the claim value on the basis of value determination of pledging instruments
- credibility method
- comparison method
- combination of the named methods

### **Creation of value on the basis of payment ability of the debtor**

By using of this method there can be expected, that the debtor is willing to cooperate with the bank, the bank will get all information about his entrepreneur activity and the debtor will continue in his activity. This procedure takes into consideration the cash flow which will be used for the settlement of the given claim. The base for the analysis are historical dates for the last two years and the finance calendar for the period of repayment of expected installments. The quality of valuation will depend from the quality of submitted documents from debtor. The claims are valued on the basis of current value for future installments.

### **Creation of the claim value through bankruptcy simulation**

Statement of value of the claim on the basis of this method use the expected amount of received funds from the bankruptcy process which will be simulated. If a bankruptcy is not real, there have to be the valued the parts of property of the debtor separately for their sale and for their valuation have to be used the valuations in the case of bankruptcy. Starting point for the determination of bankruptcy value is the balance for the last period in the whole extension. The height of finance flows is stated through the asset volume. First there will be settled the claims from the bankruptcy virtue which occurred after declaration of the bankruptcy. All creditors have to be satisfied according to the statute of the bankruptcy.

<sup>5</sup> Křístek,L.:Metody oceňování pohledávek. In: Bankovníctví č. 10, 2001, s. 12

## **Creation of the claim value on the basis of value determination of pledging instruments**

On the basis of differentiation if there is material or immaterial property there will be used the cost (material) method or the yield and the comparison method. The cost method belongs to the oldest methods for creation of the market value of the enterprise. The objective of this method is how many funds are necessary for the renovation of the enterprise. Important is mainly the advantage value of separate parts of the property. This method will be used for example in the case of creating of the price of real estate property, for the valuation of the stake in finance companies and as complement statement by valuation of yields. The yield method is created on the time value of funds and relative risk of investments. The bases for the calculation are the annual earnings before taxation and will be used in business with real estates.

### **Credibility method**

By this method the claims will be valued with a point valuation from 1 to 5. The coefficients of valuation have to be converted with weights of importance of each criterion. By creation for the value of credit claims have to be used all information from the debtor. More information from the debtor makes the method better. It's so a subjective method.

### **Comparison method**

This method compares the buildings and ground with similar real estates on the market in the same period. The comparison will be executed on the place of real estates with the following valuation of offer and demand on the real estate market and with consideration of all criterions of real estates. This method can be used only limited and that mainly by valuation of plots and production halls.

### **Valuation of claims in case if there are not to disposal economical statements and the claims are not secured**

In case that it is not possible to use any of the named methods then will be used an independent valuation of the claim. The main factor of the quality of the valuation is the volume of accessible information. In the case that the debtor doesn't communicate with the bank there will be used all reachable information about the property of the debtor with the objective at least to reach a partly settlement of the claim.

## Conclusion

The solution of the problematic of inaccessible credits is a interdisciplinary problem. On the one side there are economic questions as valuation of inaccessible claims and determination of the settlement with inaccessible claims. On the other side there are legal questions- institutional covering of the credit moving, creation of laws and regulations. At the present is that also a political problem mainly from the view of creating of consolidating institutions and also of accepting of unpopular measures with the consequence of finance burdens for the state and the population.

The commercial banks have to eliminate the increase of new inaccessible credits what means the banks have to improve the system of risk management and consequent follow the problematic claims. The central banks have to increase the regulation and supervision in this area.

## **Abstract**

*Warrants are considered structured investments; in their classic form, they are also known as plain vanilla warrants. The function of warrants can be derived from their name: Warrants securitize the right, but not the obligation, to buy or sell a predefined amount of a good at a predefined date. The good upon which the warrant is based is called the underlying. Shares and share indices serve as underlyings; so do branches and regions, interest rates, currencies or raw materials. The right to buy the underlying is called a call or a buy option; the right to sell is called a put or a sell option.*

**Keywords:** *underlying assets, theta, omega, vega, rho, delta, index, sector baskets, leverage*

## **1. Introduction**

Over the last few years, there is hardly a single financial instrument that has whetted investor appetites as much as the warrant. Warrants can be used to make substantial gains, yet they can also lead to considerable losses. Anyone wishing to invest in warrants needs to know exactly how they work and what risks they typically entail. Losses have all too often been the result of a lack of experience in dealing with these products. Only those who know what factors can influence the price of warrants and, above all, how these factors influence them, can trade successfully in these instruments in the long run.

## **2. The warrant**

### ***2.1 Option contract at a petrol station***

The best way of explaining the origins and workings of warrants is to take an example from everyday life. Let us assume that you have just bought your dream set of wheels – a top-of-the range sports car with a powerful engine. Your initial enthusiasm is decidedly short-lived, however, when you arrive at the petrol station to fill-up your new car only to discover that a litre of premium petrol is going to set you back a whole euro. Suddenly remembering what has been written in the press over the past few weeks about rising crude oil prices in Rotterdam as well as the petrol tax, you are forced to reckon with the price for a litre of premium petrol hitting €1.50 or perhaps even €2 within the next two years. Your heart well and truly sinks as you realise that your dream car, depending on how fast it is driven, consumes between 15 and 20 litres per 100 kilometres.

You then have a flash of inspiration and enter into the following agreement with the owner of the petrol station. You acquire the right to buy 5,000 litres of premium petrol at €1 per litre over the next two years. This means you have purchased 5,000 petrol options, each entitling you to buy a litre of petrol under the agreed conditions. The rest of the deal with the owner of the petrol station works as follows. You pay an immediate €0.10 per litre for the agreed volume. The right to buy 5,000 litres of premium petrol at €1 per litre at any time within the next 24 months therefore costs you €500. You also agree with the other party to this agreement that you may sell your options, in part or in whole, to another car-owner at any time. At the end of the day, the petrol station owner is not really concerned who he sells the 5,000 litres to.

## ***2.2 Limited risk – no further obligations***

If the price of petrol were to rise to unexpectedly high levels over the agreed two years, you would be in a position to make a huge profit by buying 5,000 litres of premium petrol at well below the market price. If the price rose to €2 per litre, you could also consider selling your options, which, initially bought for €500, would then be worth €5,000. This would be a great deal all-round, and what is more, if the price of petrol were to fall, your risk would be limited to the sum needed to purchase the options. If the price per litre dropped to €0.80, for example, you would not be obliged to buy the 5,000 litres for €1. In this instance, the options would be worth nothing and expire worthless if the price of a litre of petrol remained below €1 for the term of the option contract. Let us now assume that during the agreed period of two years, the price of premium petrol for your dream car were to fall dramatically to rest at €0.70. In this instance, you would not make use of your right to buy 5,000 litres of petrol at €1 and would let the options expire. You would then have to assume the total loss of the sum paid for the options, i.e., €500. This loss would have been limited had you sold the options after a few months. If the petrol price were to shoot up to €2, you would have the following choice. Either you could continue to fill your sports car with petrol costing a mere €1 per litre or you could sell your options and make a large profit. Do not forget that as the buyer, you simply have rights, whereas the pump attendant, as the seller, has rights and obligations.

## ***2.3 Market value of the options***

Three months later, during a routine trip to your local petrol station, you notice that a litre of petrol now costs €1.20. The value of your options has therefore risen and, contrary to the other car drivers you meet at the pumps, you are happy at how things have turned out. Of course, all attention turns to you when they realise that you only have to pay €1 per litre. You tell them about the deal with the petrol station and a number of the higher-price payers then offer to buy some of your options. Something along the lines of a market then materialises. As most people fear that petrol prices are going to increase further, you could sell your options immediately for €0.30 per litre. The prevailing market value of each option, which you purchased for €0.10, is therefore €0.30.

## ***2.4 Maturity of the options***

The higher the petrol price per litre rises above €1.10 – i.e., above your profit threshold – the more your options are worth and the more profit you will make. Given that you may exercise your options at any time and actually receive delivery of the petrol, and that there are parties interested in

buying your options from you, you are free to choose between purchasing the 5,000 litres of petrol over the two years at a significant discount to the prevailing market price or selling your options at the prevailing market price. The price the other car drivers are willing to pay will, of course, be higher the more expensive a tank of petrol becomes. If the price of petrol were to rise to €1.20, you would save €0.20 by exercising your options. However, the “market value”, i.e., what others would be prepared to pay for these options, is €0.30. There is a good reason for this, namely that three months ago you entered into an agreement with a two-year term, i.e., the options are still valid for another 21 months. During this period of time, the price of petrol could rise to unexpectedly high levels. It therefore follows that the right to buy petrol at €1 per litre for another 21 months is worth more than the right to do this only for another two days, for example.

Another feature of your petrol options is that you and the pump attendant have agreed to physical delivery. This means that upon exercising the options, you actually receive physical delivery of the underlying, in this instance, the premium petrol.

## ***2.5 Future expectations***

Enjoying your role as a warrant owner, you take your pride and joy for a spin one morning and need to refuel again. On the display board at the petrol station you notice that the price of premium petrol has gone up overnight from €1.10 to €1.30. This price rise is due to the Organisation of Petrol Exporting Countries (OPEC) making a surprise decision to reduce crude oil production, thereby sending prices on the crude oil market in Rotterdam through the roof and causing oil companies to react as they always do in these circumstances, i.e., by hiking petrol prices. Groups of drivers can be seen standing around the pumps embroiled in heated discussions. An air of panic abounds as everyone fears that petrol prices will continue to rise even higher.

Now well known among local car drivers, you step onto the forecourt and become immediately surrounded by a group of them wanting to buy your options for 60, even 70, cents per litre. A particularly worried driver offers to buy 2,000 options for as much as €0.80. A few days later and the situation is different. Premium petrol has indeed risen to €1.35 a litre, yet no one expects prices to rise any further. The government has announced that, if necessary, it will lower petrol tax in order to keep prices stable. When you ask car drivers what they would be willing to pay for your options, the highest bid you receive is €0.50. It therefore goes without saying that expectations of future price trends for the underlying affect the value of an option. Hopefully, at the height of the panic, you will have accepted the highest bid and sold some of

your options, leaving your angst-ridden buyers to curse the planned petrol tax cuts and bemoan their unlucky investment decision.

## ***2.6 Playing the stock exchange***

Since acquiring your petrol options, you have developed a keener interest in petrol price trends and their influences. One day, you read an interesting newspaper article about Deutsche Automobil AG. The carmaker is about to bring out an attractive, high-performance car that only consumes 2 litres per 100 kilometres. The model looks set to be a roaring success – especially given the further rise in petrol prices over the past weeks.

In view of your positive experience of petrol options, you decide to try your luck with warrants traded on the stock exchange. The problem here is that there are a whole host of warrants available on Deutsche Automobil AG shares. All you have to do now is choose the right one. With the carmakers' shares currently trading at €43, you follow a hunch that they will significantly appreciate in value and therefore opt for a call warrant. However, before you part with your cash, you want to know which warrants are lucrative. This involves looking at various key data on the risk/return profile of these financial instruments. These indicators can give you an idea of not only how much more expensive a warrant on Deutsche Automobil AG shares is than buying the shares directly but also how much the price of your warrant can fluctuate over time. These decisive details are outlined in the following sections. Departing from our petrol station scenario, we would now like to introduce you to the intriguing world of warrant trading on the stock exchange.

## **3. The basics**

### ***3.1 The right warrant for the right investor. The choice is wide and the indicators varied.***

It is a well-known fact that investors can make a lot of money with warrants, yet can also suffer considerable losses. Before you venture into this market, you should familiarise yourself with the basics. Warrants are categorised as derivative financial instruments. This means that every warrant is linked to an underlying financial asset. The underlying asset performance is reflected in the price of the warrant according to a given ratio. It is generally only worth buying a warrant if you think the price of the underlying asset is going to move considerably. On the German exchanges, warrants are issued on a variety of underlying assets, such as German and international equities, German and international equity baskets, German and international bonds, bond and share indices, as well as commodities, such as oil or

precious metals. Index warrants, followed by equity warrants, comprise the largest segments with the highest trading volumes. Warrants on European and US equities, in particular, can be found in large supply. Those who want to speculate on the price movements of blue chips listed on say the DAX, the Dow Jones EuroSTOXX 50SM or the Dow Jones Industrial AverageSM, will not be disappointed with a lack of choice. In fact, the maturities as well as strike prices of these instruments are so varied that investors are likely to find exactly what they are looking for.

The direction in which investors expect the price to move will determine whether they buy a call or a put warrant. This is because the owner of a warrant has the right to either buy or sell the underlying (also referred to as the underlying asset) at a certain price (strike price) from or to the issuer within a specified period of time (maturity) according to a certain ratio (exercise ratio) on the capital market, or else receive an equivalent monetary amount (further explanations below). Investors therefore have to decide whether to purchase call warrants (calls) or put warrants (puts). Calls are bought when the price of the underlying is expected to rise, while puts are opted for when the price is expected to fall. The right to sell this underlying at a specified price therefore becomes more valuable the lower its price.

Those in possession of an option have the following three choices: they can either let it expire, sell it or exercise it. Should you decide in favour of exercising your option, you must not forget that there is an important difference between American and European options, namely that you may exercise the former at any time prior to expiration and the latter only on the expiration date. With otherwise identical indicators, European options often sell for less than their American counterparts as the right to exercise at any time presents an unquestionable advantage.

Many warrants are settled nowadays by means of cash settlement rather than physical delivery. Cash settlement was first introduced because physical delivery was not possible for certain warrants, e.g. index warrants – you cannot physically deliver the DAX. Now, however, with the streamlining of settlement procedures, even warrants where physical delivery is possible have a cash settlement feature.

### ***3.2 The value of a warrant***

Warrants can have various features in order to accommodate investors' expectations. Below are a number of terms used for these features. The price of a warrant is comprised of the intrinsic value and the time value. The latter is the difference between the warrant price and its intrinsic value. The time value is the consideration payable for the "lifetime" of the option. The longer the time to maturity of the option, the more valuable it is. This is

based on the belief that a change in price of the underlying will lead to an increase in the differential amount achieved up to the expiration date. As the time to maturity of an option decreases, its time value will thus decay at an accelerating rate, ultimately towards zero. The price of the warrant upon expiration will be no more than its intrinsic value. A warrant always has an intrinsic value – also known as parity – if it can be exercised at a profit. This is determined by whether the spot price of the underlying is above or below the strike price. In this instance, a difference is made between options that are in the money, at the money or out of the money.

In the case of out-of-the-money warrants, i.e., with no intrinsic value, the price simply equals the time value. If the option remains out of the money until maturity, the time value will shrink to zero and the option will expire worthless. Out-of-the-money warrants are ultimately a far riskier purchase than warrants with intrinsic value. Warrants that are extremely out of the money and soon due to expire are therefore highly speculative as they carry the highest risk of total loss. These warrants will only yield a profit if the price of the underlying makes a swift and sharp move in the desired direction. The probability of this happening has to be assessed in each individual case.

### ***3.3 The effects of price fluctuations***

Price fluctuations are one of the major factors influencing warrant pricing and should therefore be monitored constantly. One of the key premises of modern option pricing theory is that an option will be more valuable the greater the range of price fluctuations or volatility. The reason for this is that the probability of the warrant appreciating in intrinsic value increases the more intensely the price of the underlying fluctuates. As it is possible to make an exact calculation of historical volatility, this is an important indicator for assessing expected volatility and implied volatility, which are both priced into options. Past fluctuations can only ever serve as a guide, however, as the rate of volatility can change very rapidly. All traders have experienced this at some point or another. For example, a surprise profit warning that strips 30 percent off an otherwise conservative or even dull stock has a major impact on the price of calls and puts it underlies.

The nature of these events is that they come as a surprise. All warrant traders look at the historical volatility of options traded at a particular time on the market and draw their own conclusions as to their implied volatility. The latter has a considerable impact on option pricing. Conclusions on the interdependency between the price of a warrant and that of its underlying – expressed in dynamic indicators – can therefore only be applied as long as the market view of implied volatility stays the same.

Buying warrants just before a sharp rise in volatility can prove very lucrative. Let us assume, for example, that you acquire a put on an automotive stock just before the company releases a surprise profit warning. Previously classed as a relative non-mover, the stock then sheds 25 percent overnight. As the owner of that put, you stand to gain not only from the expected fall in the price of the underlying but also from a sharp rise in volatility.

### ***3.4 VDAX – the volatility index***

Following the same reasoning, you can also suffer significant losses by buying warrants on financial assets that are extraordinarily volatile. Let us now assume that the price of a share climbs from €100 to €200. You now decide to buy because you expect this strong rally to persist. Instead, the share price remains at the same level for weeks. Although the underlying has not fallen in price, calls on this stock will lose value due to the return to a lower level of volatility. In the worst case scenario, the share price could rise slightly while the calls continue to lose value because of the lower implied volatility. This scenario, of course, is also affected by the loss of time value.

As the level of volatility during bear markets tends to rise faster than in bull markets, the above also applies, and perhaps even to a greater extent, to markets following a crash. The reason for this is that downside trends are often faster and more furious than upside trends. The recognised volatility index VDAX measures the implicit volatility of options trading at the money and due to expire in 45 days. This index is predominantly influenced by the level of volatility expected by market participants.

The volatility of the underlying tends to vary greatly. The implied volatility of the DAX® is therefore always a lot lower than the implied volatility of its individual constituents; one share price goes up, one goes down, ultimately having a balancing effect on the overall volatility of the index.

## **4. Expensive or not?**

### ***4.1 From the wide range of warrants on offer, you now have to select the most suitable and least expensive***

What happens if ...? Indicators are important, especially given the fast pace of option trading. You not only have to know what they are, you also have to be able to interpret them. Static indicators facilitate a qualitative price assessment of similar warrants at a given point in time. These indicators should only be used to compare warrants with similar features.

One of the most important indicators when valuing options is the premium. The major advantage of this indicator is that it can be easily calculated, thus providing a quick overview of which warrants are worth investing in. When buying options, the aim is to invest a small amount and then make a proportionally larger gain from any price movements of the underlying. The premium shows (in the case of calls) how much more it would cost to acquire the underlying by exercising the option rather than buying it directly.

Ultimately, however, an option is more valuable the longer its time to maturity and so this indicator, which fails to take this time aspect into account, does not say much at all. A more sensible way of comparing warrants would therefore be to calculate the premium per time unit, usually per year of time to maturity.

But even this annual premium does not quite hit the mark, the reason being that it is not seen in relation to the warrant. It is obvious, for example, that a premium of €1 has to be treated completely differently according to whether the warrant costs €5, €10 or €100. The best way to compare warrants using this indicator is therefore to calculate the percentage premium. This premium shows how much more (in percent) it would cost to acquire the underlying by exercising the option rather than buying it directly, thereby serving as a useful criterion for comparing options.

Asserting that an option is cheaper the lower the premium would nevertheless be too simple. A comparison of warrants is only worthwhile if they have similar maturities and intrinsic values. Generally speaking, warrants with a high intrinsic value have low premiums and warrants with a low or no intrinsic value will only have a premium. A comparison based on the percentage premium serves two main functions. First, it provides investors with a quick and clear overview of which warrants are suitable. Secondly, if they have decided on a particular underlying, it enables them to compare the premiums of warrants with similar maturities and strike prices and then opt for the least expensive.

#### ***4.2 Leverage***

Arguably the most widely known options indicator is leverage, which shows the extent to which a warrant moves in line with its underlying. Current or simple leverage can be calculated by dividing the price of the underlying by the price of the option. If this ratio deviates from 1.0 or the underlying assets are denominated in a foreign currency (foreign equities), these factors are also priced into the warrants.

Simple leverage is based on the assumption that price movements in the currency units of both the underlying and the option will be equivalent. This assumption, however, does not hold any weight. Let us take the example of a warrant granting the right to buy a share that is trading at €100. The strike price is say €200, and the option is set to expire in two months. The warrant costs €1, producing a simple leverage ratio of  $100 \div 1 = 100$ . According to this ratio, a 10 percent rise in the price of the share to €110 would lead to a 1,000 percent rise in the price of the warrant to €11. In practice, however, this would never happen as the share price would still be a long way off the strike price of €200. If the share fails to move “into the money” within the space of two months, i.e., rises above €200, the option will expire worthless. This ratio is therefore only ever applicable to options with a high intrinsic value and not at all for those without any. It is for this reason that elasticity – also referred to as the omega – is mainly used nowadays.

Another key indicator is the break-even point, which shows the price level of the underlying at which the owner of the warrant will make a profit. Taking the example of a warrant costing €1, a strike price of €200 and an exercise ratio of 100:1, the share price would have to exceed €300 in order for the investor to make a profit.

## **5. Dynamic indicators**

### ***5.1 Alongside static indicators, dynamic indicators also provide key information on warrants.***

Dynamic indicators reflect changes in the price of an option relative to changes in the price, maturity or volatility of the underlying. As opposed to their static counterparts, they allow investors to make a forecast of the future price movements of warrants from a specific point in time and are generally determined using option valuation models. They are only valid for a short period of time and must be recalculated every time any key influential factor changes.

### ***5.2 Delta***

One of these indicators is the delta, which belongs to the family of modern valuation indicators otherwise known as the “Greeks” because they are named after letters of the Greek alphabet. In modern option pricing theory, this indicator represents the sensitivity of the price of a warrant to the price movements of the underlying. The delta is calculated exactly using option valuation models derived from financial theory. The delta of a call warrant may lie between 0 and 1, and for a put warrant between –1 and 0. A

delta of 0.70 means that, at an exercise ratio of 1:10, a €1 rise/fall in the price of the underlying would lead to a €0.07 rise/fall in the price of the warrant. It can also be used as a rough guide to whether the option will have intrinsic value upon maturity and therefore not expire worthless. The probability that the above warrant will not expire worthless is therefore 70 percent. In mathematical terms, the delta is the first derivative of the warrant price with respect to the price of the underlying.

### **5.3 Omega**

Elasticity, which shows the percentage change in the price of the warrant relative to the percentage change in the price of the underlying, has also been represented by a Greek letter, namely omega. It is obtained by multiplying the delta by the leverage ratio. The omega serves as a useful indicator yet, due to the fact that the delta changes with time, can only provide investors with a snapshot view.

Over the past decades, dynamic indicators have been used to develop a series of option price valuation models. Along with the binomial model, the fair value model, devised by the American mathematicians Fisher Black and Myron Scholes, has drawn particular attention. Using the Black-Scholes Model, which was named after its originators and later further developed, it is possible to calculate the “fair value” of an option. This value refers to the theoretically justified value at which there is an equal probability of making a profit or a loss. Unfortunately, valuation models such as these are founded upon basic assumptions that do not often hold true in real options markets. These assumptions include a constant interest rate, which is the same for credit and debit interest, and no constraints on short selling. Despite its flaws, however, the Black-Scholes Model has opened up a new perspective on the valuation of options. As a detailed discussion of this model is beyond the scope of this brochure, we have included a list of recommended literature in the appendix that addresses this subject in great detail.

### **5.4 Theta**

We have already mentioned that the price of an option is comprised of its intrinsic and its time value, and that the closer the expiration date, the faster the time value erodes. The theta measures the loss of time value per unit of time, e.g. per day or week, assuming that the price of the underlying, along with all other parameters, remain the same until expiration. This indicator is usually shown as a percentage. A weekly theta of 1.5 percent means that, providing the underlying price moves sideways, i.e., the intrinsic value remains constant, the option will lose 1.5 percent of its value every week. The theta is very much dependent on whether the option is in the

money, at the money or out of the money. A warrant with a high intrinsic value will have the lowest theta. At-the-money options will experience the fastest loss of time value as they move towards their expiration date. Generally speaking, the time value of a warrant will erode the most during the last three months until maturity.

Investors must be constantly aware of this loss of value, which is solely attributable to the decreasing time to maturity. The closer a warrant gets to its expiration date, the greater the price movement in the direction predicted by the investor must be in order both to offset the ever growing loss of value and ultimately generate a profit. In mathematical terms, the theta is the derivative of the warrant price with respect to time.

### ***5.5 Gamma***

Another key indicator is the gamma, which defines the sensitivity of the delta to changes in the price of the underlying. The higher the gamma, the greater the reaction of the delta to such price movements. A gamma of 0.02 means that if the price of the underlying rises or falls by €1, the delta will change by 0.02 units. Options trading at the money have the highest gammas. Furthermore, the gamma is higher the shorter the time to maturity of the option. Mathematically speaking, the gamma is the first derivative of the delta with respect to the price of the underlying and therefore the second derivative of the price trend of the option in relation to the price movements of the underlying.

### ***5.6 Vega***

The vega shows the influence of fluctuations in volatility of the underlying on the price of the warrant. You will remember that volatility is the range of fluctuations in the price of the underlying within a given period of time. Along with the price of the underlying, the vega is the most important factor that can influence the value of an option. This indicator measures the degree to which the price of the warrant moves when the implied volatility rises or falls by one percent. A vega of 0.25 means that if the volatility of the underlying changes by one percent, the value of the option will rise or fall by 0.25 currency units, adjusted for the exercise ratio. As is the case with the gamma, options trading at the money have the highest vegas. In contrast to the gamma, however, the vega is higher the longer the time to maturity of the option. From a mathematical perspective, the vega is the first derivative of the warrant price with respect to volatility.

## **5.7 Rho**

The rho is the indicator used to measure the influence of interest rate changes on the value of options. When pricing options, the forward rather than the spot price is used. The forward price is comprised of the spot price plus a factor known as the costs of carry. This factor can be defined as the total costs of financing the underlying until the agreed expiration date of the option. These costs are affected mainly by the interest rate level. A rho of 0.50 means that the option price – adjusted for the exercise ratio – will change by €0.50 if the domestic interest rate rises or falls by one percentage point. When trading in currency options, the foreign interest rate must also be factored in. Euro/US dollar warrants, for example, have two rho indicators – one for the euro interest rate and one for the dollar rate. As extreme short-term interest rate fluctuations are very rare, however, the rho can often be disregarded for most other options. In mathematical terms, the rho is the derivative of the warrant price with respect to the interest rate.

## **6. Types of warrants**

### ***6.1 Underlying assets come in all shapes and sizes***

Warrants can be acquired on various types of underlying and investors can use these derivatives to speculate on indices, equities, baskets, currencies, interest rates and commodities.

### ***6.2 Index warrants***

Index warrants are based on the performance of share or bond indices. In the case of bond indices, the German REX bond index plays a key role. The most popular underlying in this market segment, however, is the DAX, i.e., the German share index containing the top 30 German stocks. Warrants on the American S&P 500, the Nasdaq 100, the Euro STOXXSM as well as the Japanese Nikkei 225 indices also attract investor interest, as do a small number of warrants based on other major foreign indices, such as the Austrian ATX, the UK's FTSE 100, France's CAC-40 or the China/Hong Kongbased Hang Seng.

### ***6.3 Equity warrants***

The lion's share of these warrants is based on single stocks. Calls and puts can be acquired on national and international equities with various strike prices and maturities, although liquid stocks are always a favourite.

#### ***6.4 Basket warrants***

Warrants on sector indices, such as the sub-indices of the DAX or the Dow Jones Euro STOXXSM, also have their appeal. These warrants show parallels to index warrants in that they offer investors the opportunity to speculate on the performance of a sector as a whole. Their underlying consists of an equity basket. This basket is, of course, not put together at random; the stocks all have a common denominator in that they may all belong to the same sector or originate from the same country, or both. A suitable example would be a German automotive basket containing BMW, DaimlerChrysler, VW and perhaps even Porsche stocks. Basket warrants therefore give investors the chance to speculate on sector trends or the performance of a particular equity market rather than on single stocks. Investors who forecast a flourishing automotive industry and yet are unsure which stocks are going to fare best can buy a basket warrant and benefit from upside across the whole sector. The same applies to the downside, as basket warrants also come in the put variety.

#### ***6.5 Currency warrants***

A further market segment consists of currency warrants. These derivatives enable investors to speculate on the performance of the euro in relation to foreign currencies. The US dollar is by far the most important currency in this segment, although warrants do exist on the Swiss franc, the Swedish krona, the British pound, the Japanese yen and the Canadian and Australian dollars. In addition, warrants can be bought for exchange rate changes between two foreign currencies, such as the US dollar and the Japanese yen. It goes without saying that there are also a large number of puts on offer that can be used to speculate on the weakness of a particular currency or to hedge against currency losses. This can prove vital if you own foreign stocks or are owed a sum of money in a foreign currency. Note: you would buy a euro/US dollar call if you predicted that the euro was going to strengthen against the US-dollar and a euro/US dollar put for the reverse scenario.

#### ***6.6 Warrants for global markets***

The smallest segment of the options market consists of commodity warrants. The most popular and virtually exclusive underlying assets are gold and silver, measured in troy ounces (31.1035 grams). Investors who predict that the price of gold will shoot up quickly can achieve a far higher return on commodity warrants than gold coins or mine stocks. Warrants with bonds as their underlying are known as bond warrants. These derivatives can be used to speculate on the downside or upside potential of fixed-income securities

and thus also on a change in the general level of interest rates on the capital markets. The German term Zinsoptionsschein (interest warrant), however, is a little misleading as when you buy an equity call, you predict that the share prices are going to rise, whereas when you buy a bond call, you believe that the price of bonds is going to rise and are therefore speculating on a fall and not a rise in interest rates. As bonds are more sensitive to interest rate changes the longer their time to maturity, bond warrant buyers must not only consider the maturity of the warrant but also that of the underlying. This problem does not exist for equity warrants, whose underlying assets do not have a limited lifespan. The principal underlying assets of bond warrants traded in Germany are Bunds and US Treasury Bonds.

## **7. Conclusion**

Warrants are placed by issuers, i.e., banks, financial services providers, savings and loans and financial institutions. The purchase of an option creates a debt obligation between the investor and issuer, similar to the situation with bonds. Warrants have a limited, predetermined maturity, usually between six months and two years. The majority of warrants traded on the market forgo the delivery or acceptance of the underlying at the end of the maturity in lieu of a cash settlement. When the warrant can be exercised at any point during the entire maturity period, it is known as the American variation; if this is possible only at the end of the maturation period, then it is known as the European variation.

## **Abstract**

*European structural funds are important resources for the development within the countries of European Union. The EU funds are serving main goals that are oriented to the general economic develop at local, regional and national level. The major priority of the European Structural Funds and of the political cohesion promoted the UE is applying a balanced development and its purpose is decreasing the differences between various areas. The second priority has as purpose to revitalize all the areas with deficient structure (industrial, rural, urban). The activity of the European Structural Funds is based on 4 principals: focusing on the priorities; the implementation steps which is the result of several years lasting programs; the partnership which implies a close collaboration between Commission and the corresponding authorities at the national, regional and local level, in every member state from the preparing steep to the rules implementation; the subsidiary which means that it is up to the management authorities named by member States, to select the project which will get the finance and to supervise their implementation. Romania institutions are hardly working in order to prioritize the direction of strategic development. The process is very complex one and will assure the proper use of the funds after the well and long expected integration in EU.*

**Keywords:** *structural funds, strategic development, EU integration process*

## 1. Introduction

The Structural Funds are 4 financial instruments at countries disposal addressed to specific sectors that have been considered relevant for the social and economic development of European Union. They are: European Regional Development Fund(EDRF)- mainly finances infrastructure, job-creating investments, local development so measures, Small and Medium Enterprises development; European Social Fund(ESF) – is oriented to co-finance training and capacity building measures and systems fostering recruitment and employment; Financial Instrument for Fisheries Guidance(FIFG) – it includes measures financing the modernization of fishing industry especially in region where this sector is affected by recession; European Agricultural Guidance and Guarantee Fund(EAGGF) – the guidance section of this Fund finances rural development measures.

## 2. The European Social Fund and the Cohesion Fund

### 2.1. *The European Social Fund*

**The European Social Fund (ESF)** contributes to the economic and social cohesion objective set in article 158 of the EC Treaty, by supporting policies and priorities aimed to achieve progress towards full employment, improve quality and productivity at work, and promote social inclusion and cohesion, in line with the guidelines and recommendations under the European Employment Strategy (EES).

In order to achieve this objective, the ESF needs to address three major challenges: addressing the considerable employment disparities, social inequalities, skills gaps and labour shortages in an enlarged Union; an increasing pace of economic and social restructuring due to globalization and the development of the knowledge-based economy; and demographic changes, which have resulted in shrinking and ageing workforce.

#### *The mission on the European Social Found*

The ESF shall strengthen economic and social cohesion by supporting Member States' policies aiming to achieve full employment, improve quality and productivity at work and promote social inclusion and the reduction of regional employment disparities. In particular, the ESF shall support action in line with the guidelines and recommendations adopted under the European Employment Strategy.

In carrying out the tasks referred to in paragraph 1, the ESF shall support the priorities of the Community as regards the need to reinforce social cohesion, strengthen competitiveness and promote environmentally

sound economic growth. In particular, it shall take into account the objectives of the Community in the fields of social inclusion, education and training and equality between women and men.

*Scope of assistance*

1. Within the framework of the convergence and the regional competitiveness and employment objectives, the ESF shall support action under the following priorities:

- a) increasing adaptability of workers and enterprises, in particular by promoting:
  - increased investment in human resources by enterprises, especially SMEs, and workers, through the development and implementation of lifelong learning systems and strategies which ensure improved access to training of low skilled and older workers, transparency of qualifications and competences, dissemination of ICT and management skills and the promotion of entrepreneurship and innovation;
  - the anticipation and positive management of economic change, notably through the design and dissemination of innovative and more productive forms of work organization, including better health and safety, the identification of future occupational and skills requirements, and the development of specific employment, training and support services to workers in the context of company and sector restructuring.
- b) enhancing access to employment of job seekers and inactive people, preventing unemployment, prolonging working lives and increasing participation in the labour market of women and migrants, in particular by promoting:
  - the modernization and strengthening of labour market institutions, in particular employment services;
  - the implementation of active and preventive measures ensuring early identification of needs and personalised support, job search and mobility, self-employment and business creation;
  - specific action to increase sustainable participation and progress of women in employment, to reduce gender-based segregation in the labour market including by addressing the roots of the gender pay gaps, and to reconcile work and private life including by facilitating access to childcare and care for dependent persons;
  - specific action to strengthen the social integration of migrants and increase their participation in employment, including guidance and language training and validation of competences acquired abroad.
- c) reinforcing social inclusion of people at a disadvantage and combating discrimination, in particular by promoting:
  - pathways to integration in employment for disadvantaged people, people experiencing social exclusion, early school leavers, minorities and people

with disabilities, through employability measures, including in the field of the social economy, accompanying actions and relevant social support and care services;

- diversity in the workplace and the combat against discrimination in accessing the labour market through awareness-raising and the involvement of local communities and enterprises.

d) mobilizing for reforms in the fields of employment and inclusion, in particular by promoting the development of partnerships and pacts through networking of relevant stakeholders at national, regional and local level.

2. Within the framework of the convergence objective the ESF shall also support action under the following priorities:

a) Expanding and improving investment in human capital, in particular by promoting:

- the implementation of reforms in education and training systems, especially with a view to raising their responsiveness to the needs of a knowledge-based society, improving the labour market relevance of initial education and training and continually updating of skills of teaching and other personnel;
- increased participation in education and training throughout the lifecycle, including through action to achieve a significant decline in early school leaving and increased access to initial vocational and tertiary education;
- the development of human potential in research and innovation, notably through post-graduate studies and training of researchers and related networking activities between universities, research centres and enterprises.

b) Strengthening institutional capacity and the efficiency of public administrations and public services at national, regional and local level to embrace reforms and good governance especially in the economic, employment, social, environmental and judicial fields, in particular by promoting:

- good policy and program design, monitoring and evaluation, through studies, statistics and expertise, support to interdepartmental coordination and dialogue between relevant public and private bodies;
- capacity building in the delivery of policies and programs, including with regard to the enforcement of legislation, especially through managerial and staff training and specific support to key services, inspectorates and socio-economic actors including social partners and relevant non-governmental organizations.

3. In implementing the objectives and priorities, the ESF shall support the promotion and mainstreaming of innovative activities as well as transnational and inter-regional cooperation in particular through sharing of

information, experiences, results and good practices, and through developing complementary approaches and coordinated or joint action.

4. In implementing the social inclusion priority, the financing by the ESF of actions within the scope of the Regulation (EC) may amount to a maximum of 10% of the priority axis concerned.

The Member States and managing authorities shall ensure that the action supported by the ESF is consistent with and underpins the implementation of the European Employment Strategy. In particular, they shall ensure that the action set out in the strategic frame of reference and in the operational programs promote the objectives, priorities and targets of the Strategy in each Member State and concentrate support in particular on the implementation of the employment recommendations made under Article 128 of the Treaty as well as of the relevant objectives of the Community in the field of social inclusion.

Within operational programs, resources shall be directed towards the most important needs and focus on those policy areas to which ESF support can bring about a significant effect in view of the attainment of the objectives of the program. To maximize the efficiency of ESF support, operational programs shall take particular account of the regions and localities facing most serious problems, including deprived urban and declining rural and fisheries dependent areas.

The relevant elements of the Member States' annual report referred to in Article 19 of regulation (EC), shall be integrated respectively in the corresponding national action plans for employment and national action plans for social inclusion.

The quantified objectives and indicators selected to monitor the implementation of the national strategic frame of reference, shall be those used in the implementation of the European Employment Strategy and in the context of the agreed objectives of the Community in the fields of social inclusion and education and training. The monitoring indicators of operational programs should be coherent with these quantified objectives.

Evaluations undertaken in relation to the action of the ESF shall also assess the contribution of the action supported by the ESF to the implementation of the European Employment Strategy and to the objectives of the Community in the fields of social inclusion and education and training in the Member State concerned.

The ESF shall promote good governance and partnership. Its support shall be designed and implemented at the appropriate territorial level, with particular attention to the regional and local level, according to the institutional arrangements specific to each Member State.

The Member States and the managing authority of each operational program shall ensure the involvement of the social partners and adequate

consultation of nongovernmental stakeholders, at the appropriate territorial level, in the programming, implementation and monitoring of ESF support.

The managing authorities of each operational program shall encourage adequate participation and access of social partners to the activities funded under Article 2 of this Regulation. Under the "Convergence" Objective, at least 2% of the ESF resources shall be allocated to capacity-building and activities jointly undertaken by the social partners, in particular as regards adaptability of workers and enterprises.

The managing authority of each operational program shall encourage adequate participation and access of non-governmental organizations to the funded activities, notably in the domain of social inclusion and equality between women and men. When responsibility for implementation is delegated, support in the framework of a program may be provided through global grants.

The Member States and the managing authorities shall ensure that operational programs include a description on how gender equality is promoted in the programming, implementation and monitoring including any specific indicators, and in the evaluation.

In the framework of each operational program, Member States and managing authorities shall pay particular attention to the promotion and mainstreaming of innovative activities. After consulting the Monitoring, the managing authority shall choose the themes for the funding of innovation and shall define the appropriate modalities of implementation. The Member States and managing authorities shall ensure that programming of transnational and inter-regional co-operation activities takes the form of a specific priority axis within an operational program or a specific operational program. The Member States shall ensure coherence and complementarity between the action of the Fund and actions supported through other Community trans-national programs, in particular in the field of education and training, through appropriate co-ordination mechanisms, to optimise the use of Community resources in support of education and life-long learning.

The Commission shall promote in particular exchanges of experiences, awareness raising activities, seminars, networking and peer reviews to identify and disseminate good practices and encourage mutual learning with the aim of enhancing the policy dimension and contribution of the ESF to the objectives of the Community in relation to employment and social inclusion. The annual and final implementation reports shall contain a synthesis of the implementation of:

- gender mainstreaming as well as of any gender specific action;
- action to strengthen social integration and employment of migrants;
- action to strengthen social integration and employment of minorities;

- innovative activities, including a justification of the themes selected for innovation, a presentation of their results and of their dissemination and mainstreaming;
- trans-national and inter-regional co-operation activities.

The ESF shall provide support towards public expenditure which takes the form of non-reimbursable individual or global grants, reimbursable grants, loan interest rebates and micro-credits and the purchase of goods and services through public tenders.

The following expenditure shall not be eligible for ESF support:

- (a) Reimbursable VAT;
- (b) Interests on debt;
- (c) Purchase of infrastructure, depreciable movables, real estate and land.

Notwithstanding national eligibility rules, the expenditure declared under the operational programs co-financed by the ESF can include:

- the allowances or salaries disbursed by a third party to the benefit of them participants in an operation and certified to the beneficiary, on condition that such disbursements constitute the national public co-financing to the operation, in conformity with national rules in force.
- the indirect costs of an operation fixed on a flat-rate basis, up to 20 % of the direct costs declared for this operation, according to the type of operation, the context in which it is implemented and its location.

The links between the Community financial instrument and the Union's policy framework need to be reinforced in the future programming period to better contribute to the employment objectives and targets of the Lisbon strategy. To this end, the ESF should support the policies of Member States which are closely in line with the guidelines and recommendations made under the European Employment Strategy and the agreed objectives of the Union in relation to social inclusion and education and training.

The draft ESF Regulation for 2007-2013 provides a focussed framework for ESF interventions throughout the Union. Under both the 'Convergence' and the 'Regional Competitiveness and Employment' objectives, the ESF will provide support with a view to anticipating and managing economic and social change. Its intervention will focus on four key areas for action endorsed by the European Council: increasing adaptability of workers and enterprises; enhancing access to employment, preventing unemployment, prolonging working lives and increasing participation in the labour market; reinforcing social inclusion by promoting the integration in work of disadvantaged people and combating discrimination; and promoting partnership for reform in the fields of employment and inclusion.

In the least prosperous regions and Member States, the Funds will concentrate on promoting structural adjustment, growth and job creation. To this end, under the Convergence objective, in addition to the above-

mentioned priorities, the ESF will also support action to expand and improve investment in human capital, in particular by improving education and training systems, and action aimed at developing institutional capacity and the efficiency of public administrations, at national, regional and local level.

Furthermore, the proposal gives a greater emphasis to the Union's commitment towards the elimination of inequalities between women and men: specific actions addressed to women are combined with a robust gender mainstreaming approach, to increase participation and progress of women in employment.

Equally, the promotion of innovative activities and trans-national co-operation will be fully integrated in the scope of the ESF, and mainstreamed within the national and regional operational programs. Under both the 'Convergence' and the 'Regional Competitiveness and Employment' objectives, the ESF will give priority to funding trans-national cooperation, including exchanges of experiences and best practices across the Union and joint actions, ensuring where appropriate, coherence and complementarity with other trans-national Community programs.

Finally, the proposal attaches a particular importance to the promotion of good governance. The involvement of the social partners is of particular importance in the programming and implementation of the Fund priorities and operations. To this end, under the new Convergence objective, social partners will be encouraged to actively participate in capacity building actions and to undertake joint activities in the policy areas where they play a decisive role.

## **2.2. *The Cohesion Fund***

**The Cohesion Fund** is enshrined in article 161, paragraph 2, of the treaty, with the objective of contributing financially to interventions in the field of the environment and the trans-European networks. Regulation (EC) No 1164/94 established the Cohesion Fund, and, for the first time, provided a framework for its implementation. This regulation was subsequently complemented by Regulations (EC) No 1264/99 and (EC) No 1265/99. Following the Union's enlargement on May 1st 2004, the Cohesion Fund applies to the 10 new Member States until the end of 2006, as well as to the three Member States eligible at the end of the 2000-2006 period (Greece, Portugal and Spain).

Creation and purpose of the Cohesion Fund:

- A Cohesion Fund (hereinafter: the Fund) is hereby set up for the purpose of strengthening the economic, social and territorial cohesion of the Community in the interests of promoting sustainable development.

- The Fund shall contribute to the financing of programs, which support the objectives set out in the Treaty.
- The Fund is governed by the provisions of Regulation (EC) and by the provisions of this Regulation

Regulation (EC) lays down the general provisions for the functioning of the structural funds and the Cohesion Fund for the programming period 2007-2013. It envisages that the Cohesion Fund contributes to the convergence of less developed Member States and regions through financial participation in the operational programs of this convergence objective.

Under the reform of the implementation system of cohesion policy, Cohesion Fund interventions are integrated into the multi-annual programming of the structural funds, including major projects. The reform was announced in the third cohesion report, which was adopted by the Commission in February 2004. While maintaining the fundamental principles which underlie the value of the policy (multi-annual programming, partnership, evaluation, shared management), this reform provides a balance between an increased strategic component, and a simplification of the implementation system. Simplification notably occurs through the reduction in the number of funds, simplified programming, a clarification of the roles of the Commission and the Member States in terms of financial management and control, and by adapting the implementation modalities to reflect the intensity of the community contribution.

In the field of trans-European transport networks, actions financed by the Cohesion Fund must follow the guidelines for these networks, which were adopted by the Council in revised decision (EC) 1692/96. In the environmental field, the Cohesion Fund contributes to achieving the Union's policy objectives envisaged under article 174 of the treaty.

An extension of the domains of intervention is justified by the accession of new Member States on May 1 2004, all of which are eligible to the Cohesion Fund, and which face new and important financing needs. Thus the Cohesion Fund can also finance actions in support of sustainable development, where these have a clear environmental dimension, such as energy efficiency or renewable energy. Beyond the trans-European transport networks, this also allows for financing of rail, navigable maritime and river waterways, multi-modal transport actions and their inter-operability, road and air traffic management, clean urban transport, and communal transport. This extension of the domain of interventions is in accordance with the corresponding provisions in the treaty, and is in line with the priorities decided by the European Council in Lisbon (March 2000) and Gothenburg (June 2001).

The aim of this regulation is to specify the tasks of the Cohesion Fund, and its specific application, in particular regarding the conditionality of assistance and the fields of intervention of the Fund.

Member States benefiting from the Cohesion Fund must conform to the conditions set out in the treaty regarding convergence programs and those regarding excessive deficits for the Member States participating in economic and monetary union. Assistance under the Cohesion Fund is conditional upon the satisfaction of these conditions. If the Council decides, on the basis of a Commission proposal, that an excessive deficit exists and that the Member State concerned has not taken effective action, the payment will be suspended, effective from January 1 of the following year. The suspension ceases, when the Council decides, on the same basis, that the Member State concerned has taken the measures necessary to allow a return to a situation that is in accordance with the Treaty and with the Council decisions.

### **3. Impact of European Structural Funds for the future development of Romania**

For Romania the regulations for the implementation of structural funds are:

- The Regulation of the Commission (CE) No. 438/2001 from 2<sup>nd</sup> of March 2001 which establishes detailed rules for the implementation of the Regulation of the Council (CE) No. 1260/1999 concerning the administration and check systems within the framework of the Structural Funds [Official Journal L63 from 03.03.2001].
- The Regulation of the Commission (CE) No. 448/2001 from 2<sup>nd</sup> of March 2001 which establishes detailed rules for the implementation of the Regulation of the Council (CE) No. 1260/1999 concerning the procedure for the realization of the financial corrections for the assistance within the framework of the Structural Funds [Official Journal L64 from 03.06.2001].
- Regulation (CE) No. 1059/2003 of the European Parliament from 26th of May 2003 concerning the establishment of a common classification of the Territorial Units for Statistics (NUTS) [Official Journal L154 from 06.21.2003]

The Operational National Program (ONP) 2007-2013 in Romania based on:

- National Strategy for the Regional Development and Sectorial Strategies of PND 2007-2013 (at national level)
- Regional Documents for Programming and Implementation (DRPI, at regional level)

The structures of the ONP are:

- Analysis of the existing situation and strategy

- Priorities and Measures
- Coherence and concordance of the strategy
- Financial programming
- Implementation

For Romania as arias of stipulated interventions are:

- Development of the regional and local infrastructure: transport infrastructure, environment infrastructure, power infrastructure, social infrastructure, urban rehabilitation
- Business support: the support of the micro-enterprises and SMEs development (start-ups), business infrastructure development (industrial, technological, scientific parks, etc.), consulting and formation for SMEs
- Tourism support : tourism infrastructure, tourist services improvement, tourist marketing development
- Rural development support: diversification of the economic activities in rural environment, development of the rural infrastructure
- Support of the research, development, innovation and information society: support of the technological transfer to SMEs, development of the innovation capacity of the SMEs, development of the communication between the university environment and SMEs

Financial package proposal for Romania for 2007- 2013 is:

- Agriculture
  - Market measures – 732 millions euro
  - Direct payment – 881 millions euro
  - Rural development – 2 424 millions euro
- Structural and cohesion funds – 5 973
- Internal politics - 765,8 millions euro
- Administrative expenses - 242,2
- Total of engagements: about 11 millions euro
- Total of payments: about 6,3 millions euro

At European level for the cohesion found is allocated a sum of 344 billions euro, representing about 0,41% comunitary GIR. For Romania between 2007 and 2009 will be allocated about 6 billions euro, and for the same period 2010 and 2013 are anticipated maxim 4% from the Romanian GIP on a year.

Should be considered that the structural and cohesion founds:

- Are co-financed from the national budget
- The sums allocated in the year n should be sped gradually till n+2
- The sums afferent to the structural founds are financed from the EU budget until maxim 75% from the project's value
- The sums afferent to the cohesion founds are financed from the EU budget until 85% from the project's value

For 2007-2013 Romania proposes as eligibility on those two objectives as follows:

- ❑ Convergence objective: Romania will be eligible with the whole territory (eight development regions NUTS II) for the cohesion politics 2007-2013:
  - Regional GIP per capita under 75% from community GIP average;
  - FC (GIR under 90% from community GIR average);
- ❑ European Territorial Cooperation Objective:
  - Trans-frontier cooperation (regions NUTS III longway the external and internal frontier)
  - Trans-national cooperation
  - Inter-regional cooperation

#### **4. Conclusion**

Development Fund, the European Social Fund and the Cohesion Fund, establishes the framework for the action of the Structural Funds and the Cohesion Fund. It fixes, in particular, the objectives, the principles and the rules concerning partnership, programming, evaluation and management. It is therefore necessary to specify the mission of the Cohesion Fund in relation to this new framework and to the purpose assigned to it in the Treaty and to repeal, for the sake of clarity, Council Regulation (EC) No 1164/94 of 16 May 1994 establishing the Cohesion Fund.

Trans-European network projects financed from the Cohesion Fund must fit the guidelines for these networks adopted by the Council and the European Parliament. The Community may, through the Cohesion Fund, contribute to action in pursuit of the Community's environmental policy objectives specified in Article 174 of the Treaty. Under Article 175 of the Treaty and without prejudice to the principle that the polluter should pay, the Council can decide, in the case of measures on the basis of paragraph 1 of that Article which are deemed to involve disproportionate costs for the public authorities of a Member State, that the measure is to be aided from the Cohesion Fund.

Granting of assistance from the Cohesion Fund must take due account of the priorities of the enlarged Union, in particular those set by the Göteborg European Council on the environment in the interests of sustainable development. Regulation (EC) provides that eligibility of expenditure is to be established at national level, with certain exceptions, for which it is necessary to lay down specific provisions. The exceptions concerning the Cohesion Fund should therefore be laid down.

Conditionality provisions in the granting of financial assistance will continue to apply in conjunction with the fulfilment of the conditions of economic convergence as set out in article 104 of the Treaty and the need for

sound government finances. In this respect, Member States participating in the Economic and Monetary Union are to implement stability programs and non participating Member States convergence programs.

Romania institutions are hardly working in order to prioritize the direction of strategic development. The process is very complex one and will assure the proper use of the funds after the well and long expected integration in EU.
